(BW) gain, blood pressure, laboratory data, and amount of phosphate binders. Phosphate binders included calcium carbonate, sevelamer hydrochloride, and lanthanum carbonate. Moreover, univariate and multivariate analysis were used. Bicarbonate 30 mEq/L was the dialysate used for all patients.

Results: The mean age was 66.4 years old and HD vintage was 130 months. The mean amount of calcium carbonate was 1.62g, sevelamer hydrochloride was 1.19g, and lanthanum carbonate was 0.41g. Patients who showed a predialysis bicarbonate level of ≤22 mEq/L were 22.3%. Univariate analysis showed that predialysis bicarbonate levels significantly correlated with age (β= 0.249), inversely with HD vintage (β = -0.26), BW gain (β = -0.408), potassium (β = -0.174), phosphate (β = -0.247), intact parathyroid hormone (β = -0.257), nPCR (β = -0.227), calcium carbonate (β = -0.177), sevelamer hydrochloride (β = -0.436), and lanthanum carbonate (β = -0.243). Multivariate analysis showed that HD vintage (β = -0.174), BW gain (β = -0.310), and sevelamer hydrochloride (β = -0.306) were dependent factors for metabolic acidosis. Subgroup analysis without sevelamer hydrochloride treatment indicated that HD vintage (β = -0.261) and BW gain (β = -0.399) were independent factors.

Conclusions: In this study population, HD vintage, BW gain, and sevelamer hydrochloride treatment seemed to be associated with predialysis bicarbonate levels.

PUB380

The Effect of Diet on Deposition of Skin Advanced Glycosylation End Products Assessed by Skin Autofluorescence in Chronic Haemodialysis Patients Arkom Nongnuch,[1,2] Andrew Davenport.[2] *[1]Renal Unit, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand; [2]UCL Centre for Nephrology, UCL Medical School, London, United Kingdom.*

Background: The major cause of death in chronic dialysis population is cardiovascular disease (CVD), owing to traditional and nontraditional risk factors. Amongst the nontraditional risk factors, Advanced Glycosylation End Products (AGEs), a group of heterogeneous compounds derived from the non-enzymatic reaction called Maillard reaction. are renally excreted, thus both serum AGEs and AGEs deposited in tissues are increased in dialysis patients. Previous studies have shown that tissue AGEs had greater association with CVD than serum AGEs. Currently, tissue AGEs deposition can be measured by using skin autofluorescent technique (SAF), reliable and convenient measurement.

Methods: We measure SAF AGEs using DiagnOptics, Groningen, Netherland on non fistular arm in multiethnic chronic haemodialysis population.

Results: The mean age of 332 patients was 65.2 ± 15.1 years, 64% male, 42% diabetes, 66% Caucasian,21% Afro-Caribean, 13% Asian, with a dialysis vintage 38.5 months (1-413), 37% smoker, 8.1% vegetarian, 57% prescribed calcium carbonate, and 15% prescribed lanthanum. In multivariate analysis, woman, Caucasian ethnicity, older age, longer dialysis vintage, diadetes, prescribed calcium carbonate and lanthanum was associated with higher tissue AGEs whereas vegetarian has lower tissue AGEs.

Table 3. Multiple regression analysis of factors associated with SAF of dialysis cohort (R^2 = 0.334, adjusted R^2 = 0.309).

Variable	B (95% CI)	P value
Race C/A/Af	-0.52 (-0.64 to -0.39)	<0.001
Age	0.014 (0.008 to 0.02)	<0.001
Male gender	-0.22 (-0.4 to –0.04)	0.019
Log dialysis vintage	0.30 (0.14 to 0.46)	<0.001
Diabetes	0.23 (0.05 to 0.42)	0.013
Vegetarian	-0.39 (-0.7 to -0.07)	0.019
Calcium carbonate prescription	0.311 (0.12 to 0.5)	0.001
Lanthanum carbonate prescription	0.38 (0.12 to 0.64)	0.005

Conclusions: Caucasoid ethnicity, older age, female gender, longer dialysis vintage, diabetes status, and both prescription of calcium and lanthanum based phosphate binders were associated with increasing skin AGEs deposition. On the other hand, patients eating vegetarian, low AGEs diets had lower tissue AGEs accumulation, and further interventional studies are required to determine whether dietary intervention can modify tissue AGE deposition and CVD risk.

PUB381

A Decade of Tight Infection Control in Hemodialysis, Did It Make a Difference? Jafar Al-Said, Aimee Pagaduan, Soni Murdeshwar. *Nephrology and Internal Medicine, Bahrain Specialist Hospital.*

Background: Hemodialysis related bacteremia and hemodialysis access infection are the major causes of morbidity and the second cause of mortality in ESRD population. The aim of this study was to determine the outcome, over 10 years, of tight infection control in preventing Hemodialysis related Bacteremia and vascular access infection.

Methods: This study is a retrospective longitudinal analysis for the outcome of the hemodialysis infection protocol srtictly implemented over 120 months from January 2004. All Hemodialysis sessions were included. Patients' demographics and the types of vascular access were collected from the electronic data. The following outcomes variables were calculated: Hemodialysis induced bacteremic infection per 100 patient months, admission rates for Hemodialysis related bacteremia per 1000 patient years, admission for vascular access infection, hemodialysis bacteremic infection per patient, monthly blood infection rates, and infection rate per hemodialysis session.

Results: Total Patients were 138. Total Hemodialysis sessions were 9383. Mean age was 57.6 years (SE 1.3). Male gender were 55%. Types of vascular access were; 56.3% cuffed tunneled catheters, 19.5% AV fistula, 18.2 AV grafts and 5.8% were vascath. Total Hemodialysis related bacteremia occurred in 9 patients. Hemodialysis related blood stream infection per 100 patient month was 0.01. Admission for hemodialysis related bacteremia per 1000 patient year was 0.55. Admission for vascular access infection over 120 months was Zero. Hemodialysis bacteremic infection per patient was 0.06. Hemodialysis bacteremic infection per month was 0.075. Infection rate per HD session was 0.00096.

Conclusions: The tight infection control protocol followed was able to reduce Hemodialysis Bacteremia and eliminate Vascular Access infection. We would like to share our infection control protocol, that we followed for the last decade, to participate in reducing hemodialysis related bacteremia and vascular access infection.

PUB382

Improving Care for Hemodialysis Patients: Rationale and Design of a Patient-Centered Medical Home Model for Patients with End-Stage Renal Disease Anna C. Porter, Michael J. Fischer, Jose A.L. Arruda, Michael L. Berbaum, Sheila R. Castillo, Rani Gallardo, Marian L. Fitzgibbon, James P. Lash, Lisa Sharp, Denise M. Hynes. *Univ of IL at Chicago.*

Background: More than 500,000 patients with end-stage renal disease (ESRD) in the United States depend on chronic hemodialysis (HD) for their renal replacement therapy. Despite receiving this treatment, chronic HD patients incur a disproportionately high burden of morbidity, mortality, resource utilization, and poor quality of life (QOL). Enhanced coordination of care through a patient-centered medical home model has been used to improve outcomes in other complex chronic illnesses, but has not been studied in chronic HD patients.

Methods: The Patient-Centered Medical Home Model for Patients with Kidney Disease (PCMH-KD) will implement a comprehensive multidisciplinary care team within the dialysis unit to improve coordination of primary care for chronic HD patients. The PCMH-KD will expand the existing care team of the dialysis unit (comprised of a nephrologist, dialysis nurse, dialysis technician, social worker, and dietitian) to include a general internist, pharmacist, and health promoter, all of whom will see the patient during dialysis treatments and separately as needed. An approximately 300-patient cohort at the University of Illinois independent freestanding dialysis unit and one freestanding for-profit dialysis unit will be recruited for study participation.

Results: The effect of the PCMH-KD model on the following outcomes will be examined: i)patient- and caregiver- reported outcomes such as QOL and care satisfaction; ii)clinical outcomes such as blood pressure and dietary management; iii)healthcare use such as ER use, hospitalizations; and iv)staff perceptions of care.

Conclusions: Patients with ESRD on HD suffer from a significant burden of hospitalizations, mortality, and poor QOL. Improvement of care coordination with a PCMH-KD provides an opportunity to potentially reduce this burden.

PUB383

Which Reality behind the New Dialyser Fx Cordiax? Matching Study and Comparative Efficacy of Molecules Removal Sebastien Deleuze, Jean Pierre Rivory, Isabelle Selcer, Francois Maurice, Catherine Rouanet. *Nephrology, Nephrocare Castelnau le Lez, Castelnau le Lez, France.*

Background: It seems that the removal of middle molecules solute using the recently developed high flux dialysis membranes in haemodialysis (HD) is close to the results obtained by on line pre (Pre) and post dilution (Post) haemodiafiltration. The subject of this study is to compare the removal of urea, beta 2 microglobulin (β 2 m), and myoglobin (myo) by the new dialyser in these 3 technics.

Methods: We realized an observational study on 200 patients after matching patients by duration of dialysis. Extraction of β 2 m and myo was evaluated by the reduction ratios (RR) using a kinetic model.The dialyser's area was prescribed depending on the body area of the patient (Fx cordiax 800 or 1000 for Post and Pre, Fx cordiax 80,100,120 or Bk for HD).

Results: We matched 35 patients in HD (7 Bk, 28 Fx Cordiax), 35 patients in Post (Fx cordiax 800, 1000), and 35 patients in Pre(Fx cordiax 800, 1000). The mean of volume substitution is 20,09 l in Post, and 45,63 l in Pre. **Comparison HD versus post:** Two groups are similar in duration of dialysis (p=0, 96), blood flow, and volume of treatments. There is no difference between HD and post in predialysis level of β 2 m, myo and Albumin (alb). Post is better than HD group for RR of myo(70, 56% +/- 8, 99 versus 38% +/-9,92; p< 0,0001) and RR of β 2 m (79,8%+/- 8,56 versus 64,3%+/- 14,9; p<0,001), Urea extraction (76,91 % +/- 6,45 versus 73 % +/- 7,26; p= 0,025) and Kt/v e (1,48 +/- 0,32 versus 1,32 +/- 0,3, p=0,021). **Comparison PRE versus POST:** Two groups are similar in duration of treatment (p= 0,51), blood flow, and volume of treatments.There is no difference between Post and Pre in the pre dialysis level of β 2 m, myo, and alb. Post is better than Pre group for RR myo (70, 09% +/- 8, 19 versus 47,55 % +/-11,05; p< 0,0001), RR β 2 m (79,37%+/- 9,67 versus 74,77%+/- 12,01; p<0,039).There is no difference between the 2 groups in urea extraction and Kt/v e.

Conclusions: Our study showed that treatment using Post with FX Cordiax (800 or 1000) remains the best treatment for removing molecules of any size, and in particular for those higher than 17kDa (despite the fact that we used a less than 23 l substitution volume).

PUB384

Validity of Registry Data: Agreement between Comorbidities in ANZDATA Compared to Administrative Data in Australia Sradha S. Kotwal,[1] Angela C. Webster,[2,3] Alan Cass,[1,4] Martin P. Gallagher.[1,5] *[1]The George Institute for Global Health, The Univ of Sydney, Sydney, Australia; [2]Sydney School of Public Health, The Univ of Sydney, Sydney, Australia; [3]Centre for Transplant and Research, Westmead Hospital, Westmead, Australia; [4]Menzies School of Health Research, Charles Darwin Univ, Darwin, Australia; [5]Concord Clinical School, Univ of Sydney, Sydney, Australia.*

Background: Coding quality of administrative data has been considered poor for comorbidity recording. Co-morbidities recorded by ANZDATA are considered reliable, but audit of registries is time consuming. To assess agreement of comorbidity recording between the ANZDATA Registry and the New South Wales (NSW) Admitted Patient Data Collection (APDC).

Methods: ANZDATA identified all incident patients in NSW receiving dialysis or transplant between 01/07/2000 and 31/07/2010. Patients were then linked to APDC (records up to 55 medical conditions impacting upon an admission). We calculated agreement between the two datasets for diabetes, cardiovascular disease (CVD), chronic lung disease (CLD) and peripheral vascular disease (PVD) and agreement beyond chance using the kappa statistic (κ). A kappa of >0.75 indicates excellent agreement, 0.40-0.75 fair to good agreement and <0.40 poor agreement.

Results: ANZDATA identified 11,036 patents, 531 did not match within APDC or had missing data, leaving 10,505 patients with 2,384,218 hospitalisations including 2,282,850 dialysis or daystay admissions. ANZDATA recorded diabetes in 3199 (30.5%) while APDC recorded diabetes in 3086 (29.4%; κ = 0.81) patients. CVD was recorded in 3756 (35.8%) patients in ANZDATA and in 3253 patients in APDC (31.0%; κ=0.46). CLD was recorded in 1564 (14.9%) patients in ANZDATA and in 674 patients in APDC (6.4%; κ=0.28). ANZDATA recorded PVD in 2500 (23.8%) patients while APDC recorded PVD in 548 patients (5.22%; κ=0.09).

Conclusions: Excellent agreement exists between ANZDATA and APDC for the recording of diabetes, good agreement for cardiovascular disease but poor agreement exists for the other co-morbidities tested. These findings have implications for future health care funding models and the ability to use administrative data in clinical risk adjustment tools.

PUB385

Association between Bacterial Colonization in Tunneled Cuffed Catheter and Residual Renal Function and Mortality in Incident Hemodialysis Patents Jangwon Lee, Sang Heon Song, Ihm Soo Kwak, Soo Bong Lee, Dong Won Lee, Eun Young Seong, Byeong Yun Yang, Il Young Kim. *Dept of Internal Medicine, Pusan National Univ School of Medicine, Busan, Republic of Korea.*

Background: Hemodialysis (HD) patients have compromised immunity that permits bacterial colonization. There are 3 main passages through bacteria can enter the body, that are gut mucosal break, dialysis water, and dialysis access. Influences of the former two on the clinical outcomes of HD patients have long been studied, but there are few reports about the bacterial colonization of tunneled cuffed dual lumen catheter (TCC), mainly used incident HD access.

Methods: Retrospectively we found the clinical data of 155 patients who received TCC removal from Jan. 2005 to Dec. 2012. In Dec. 2013 we collect follow-up data by phone calls which were urine output (UO) at that time and time to anuria or death from HD initiation. Not only the relationship between biochemical, clinical parameters and TCC colonization, but also the survival of kidney and patients according to TCC colonization were assessed.

Results: Of the 155 patients, 33 (21.3%) had bacterial colonization in TCC. Eighty six were followed up by phone calls and 21 of them (24%) were ones in the colonization group(C- group). The rate of decrease in UO was significantly more rapid in the C-group (68.1 ± 75.2 versus 32.9 ± 42.6 mL/month, p=0.012) and the time to anuria was also shorter in the C-group (19.3 ± 18.9 versus 48.6 ± 46.1 months, p=0.011).

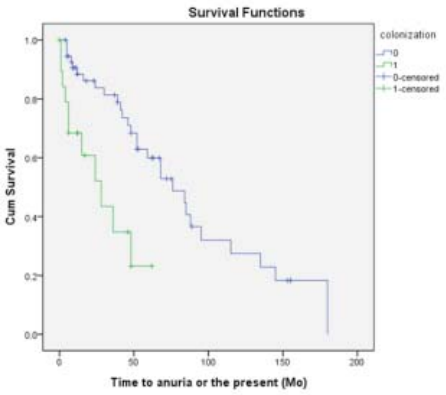

Figure 1. Kaplan-Meier curve showing anuria free survival in incident hemodialysis patients with bacterial colonization of tunneled cuffed dual lumen catheter compared with those without bacterial colonization.

In kidney survival analysis, patients in the C-group had significantly worse estimated anuria-free survival (log rank p=0.001).

Conclusions: Bacterial colonization in TCC was associated with more rapid decrease rate in UO and worse anuria-free survival.

The Establishment of Endtoxin and Bacteria Free Pure Dialysate in South East Asian Developing Countries Tomotaka Naramura,[1,2] Kenichi Kokubo,[1,3] Shunichiro Urabe,[1,3] Moe Kojima,[1,4] Natsumi Abe,[1,5] Emi Kimura,[1,5] Rika Yamanaka,[1,5] Hirokazu Matsubara,[1] Haruki Wakai,[1,5] Sovandy Chan,[6] Sabo Ojano,[6] Fumitaka Nakajima,[1,7] Toru Hyodo.[1] *[1]NGO Ubiquitous Blood Purification International, Yokohama, Japan; [2]Dept of Medical Engineering, Faculty of Health Sciences, Junshin Gakuen Univ, Fukuoka, Japan; [3]School of Allied Sciences, Kitasato Univ, Saamihara, Japan; [4]Clinical Engineering, Tokai Univ Oiso Hospital, Oiso, Japan; [5]Reiseikai Shinagawa Garden Clinic, Tokyo, Japan; [6]Blood Purification Center, Sen Sok International Univ, Phnom Penh, Cambodia; [7]Moriguchi Keijinkai Hospital, Moriguchi, Japan.*

Background: We have reported that dialysis patients and facilities number has been increasing in South East Asian developing countries, but the condition of dialysate was poor [Nephron Extra 2014;4:64-69]. So only low flux dialyzers have been used in dialysis in these countries. In this study, we show the simple method to keep dialysate clean and present that the dialysate purification has been established at 5 dialysis facilities in Myanmar and Cambodia.

Methods: The dialysate survey pertained to the endotoxin(ET) level and bacterial count in tap water, reverse osmosis (RO) system water, dialysate. And we set up ET retentive filters just before dialyzers and continued the dialysate survey for 5 or 6 months in 5 facilities in Myanmar (4) and Cambodia (1).

Results: The ET and bacteria in dialysate were not observed between just after setting up and 5 or 6 months after setting.

			Hosp. A	Hosp. B	Hosp. C	Hosp. D	Hosp. E
At 0 month	Tap Water	ET (EU/mL)	7.09	11.26	18.11	8.94	9.34
		Bacteria (cfu/mL)	48	>300	>300	>300	210
	RO Water	ET (EU/mL)	0.21	0.26	0.71	0.42	0.12
		Bacteria (cfu/mL)	>300	>300	>300	>300	180
Before ETRF setting	Dialysate	ET (EU/mL)	1.40	0.28	0.82	0.37	0.65
		Bacteria (cfu/mL)	>300	>300	>300	>300	>300
Just after ETRF setting	Dialysate	ET (EU/mL)	N.D.	N.D.	N.D.	N.D.	N.D.
		Bacteria (cfu/mL)	N.D.	N.D.	N.D.	N.D.	N.D.
5 or 6 months after ETRF setting	Dialysate	ET (EU/mL)	N.D.	N.D.	N.D.	N.D.	N.D.
		Bacteria (cfu/mL)	N.D.	N.D.	N.D.	N.D.	N.D.

Conclusions: The high-flux dialyzers have been started in Cambodia by this know-how to keep dialysate clean. But more efforts to clean RO water line should be needed.

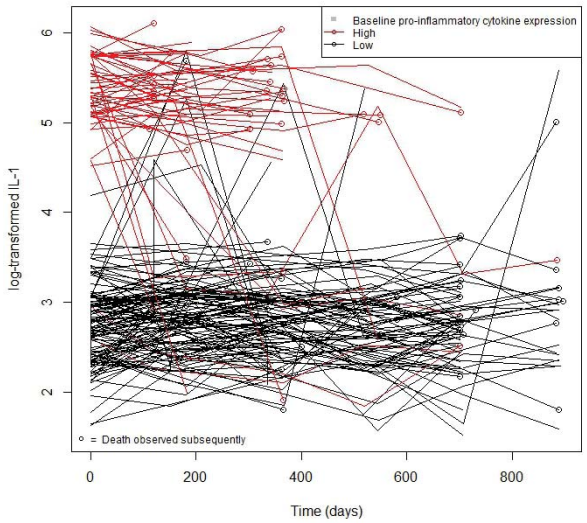
Cytokine Variability in Hemodialysis Patients over Longitudinal Follow-Up

Paul L. Kimmel,[1] Kenneth J. Wilkins,[2] Dawei Xie,[3] J. Richard Landis.[3] *[1]Div of Kidney, Urologic and Hematologic Diseases, NIDDK, NIH; [2]Biostatistics Program, NIDDK, NIH; [3]Dept of Biostatistics and Epidemiology, Univ of Pennsylvania Perelman School of Medicine.*

Background: High baseline levels of circulating pro-inflammatory cytokines have been linked to mortality in several prospective studies of hemodialysis (HD) ESRD patients. Whether cytokine levels in such patients are stable over time is unknown.

Methods: We previously studied interleukin (IL)-1, IL-6 and IL-2 (an anti-inflammatory T-cell mediator) levels in 234 HD patients (75 incident, 159 prevalent), followed for a mean of 3.3 (3.1, 3.3 respectively) years with a mean of 3.9 assessments at 3 centers in Washington, DC. Cytokine levels were skewed, ranging over 6 natural logs. Scatter plots revealed high and low groups for all three cytokines at baseline. This grouping was assessed for each cytokine to have >90% accuracy by established methods (K-means cluster, quadratic discriminant and principal components analyses).

Results: Of the 157 in the low IL-1 group, only 5% exhibited post-baseline values greater than 4 log (54.6 pg/mL). Of the 77 in the high IL-1 group, only 13% similarly exhibited values under 4 log (Figure; no differential misclassification, McNemar's $\chi 2$ p=0.8). A majority's levels remain roughly constant over follow-up, such that 84% of variability (95%CI: 80-87%) is explained by individual mean levels. Similar findings were noted for IL-2 and IL-6.



Conclusions: Cytokine levels exhibit limited variability over time in the majority of HD patients studied. Longitudinal cytokine levels can be characterized as "high" or "low" according to baseline measurements with only modest misclassification rates. Such characterization might be useful in HD patients in designing clinical trials with stratification to enhance event rates. Further study will assess if longitudinal trajectories add prognostic precision.

PUB388

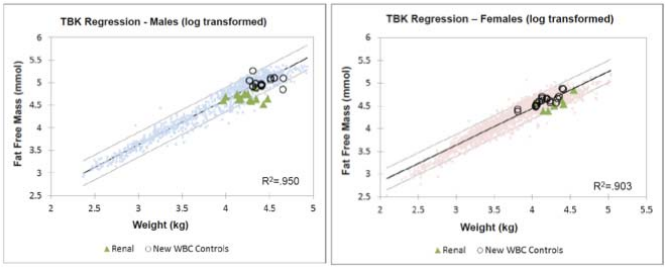
Muscle Wasting in the Emergent Dialysis Population

Biruh Workeneh, Roman Shypailo, William E. Mitch. *Baylor College of Medicine, Houston, TX.*

Background: The care of patients receiving emergent dialysis is a growing public health concern (incident rate estimated to be >6,000/year), and the magnitude of muscle wasting that occurs in this population is not known. The emergent dialysis population is comprised of primarily undocumented individuals who have high rates of employment and productivity, even among ESRD patients, and muscle wasting can affect all aspects of their lives including their socioeconomic status.

Methods: We used a case-control design to determine differences in lean body mass, using total body potassium (K^{40} counter), in emergent dialysis patients and healthy normal subjects. We controlled for 4 variables including age, sex, height and weight and studied 22 subjects matched with controls.

Results: We found that TBK is 18% lower suggesting significant muscle wasting has occurred in the emergent dialysis subjects versus controls (p=.001). Additional analysis found that muscle wasting was more profound among male compared to female subjects (see figure).



Conclusions: We conclude that among other consequences, muscle wasting is a significant concern in the growing emergent dialysis population. This should inform any efforts to rehabilitate these patients and develop uniform policies regarding the management of this vulnerable population.

PUB389

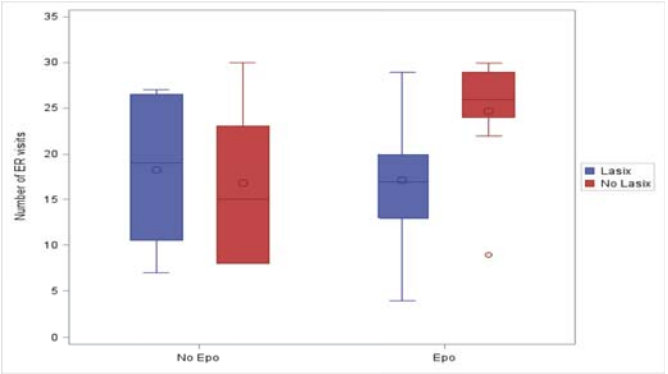
Diuretic Management in Emergent Dialysis Patients

Salman Ahmed, Charles G. Minard, Danielle Guffey, Biruh Workeneh. *Baylor College of Medicine, Houston, TX.*

Background: There are nearly 11 million undocumented immigrants residing in the U.S. and the incidence of ESRD is estimated to be >6,000 /yr. There is no uniform policy regarding the management of these patients, the majority of whom utilize the ER for their dialysis related care. Severe HTN, volume overload and hyperkalemia are commonplace among the emergent dialysis population, and the benefit of diuretic use in this population has never been evaluated.

Methods: We sought to answer whether furosemide use is associated with decreased ER utilization. We reviewed charts of 93 patients at Ben Taub County Hospital in Houston, TX during a 3 month period. We abstracted prescription data, number of ER visits HD sessions and peak potassium values.

Results: The furosemide group had 3.1 (SE=1.8) fewer ER visits compared with the non-furosemide group (p=0.10). We found no significant relationship between furosemide TDD and peak serum K levels. In a multiple regression model, furosemide treated subjects had significantly fewer ER visits after adjusting for EPO and sevelamer use (p=0.007). Among subjects using EPO, patients on furosemide had 7.7 (95% CI: 1.9,13.6) fewer ER visits comparatively (p=0.04) compared with those not on furosemide.



Conclusions: Although our analysis revealed no *independent* association between furosemide dosage and number of ER visits, there was nevertheless a strong trend. We speculate a larger sample size controlling for residual renal function would reveal a significant independent effect of furosemide. The reason for decreased ER utilization among patients on EPO *and* furosemide is unclear, but might be explained by less symptomatology because of EPO. The care of the emergent dialysis population is becoming an increasing public health concern and hospitals systems that cannot offer maintenance dialysis to these patients should explore best practices and consider diuretics as a possible strategy.

PUB390

Survival on Haemodialysis in Elderly Patients at a Single Center Australian Private Hospital Gavin Lee, Andrew M. Bofinger, Karen Ann Herzig, Rhianna G. Miles. *Nephrology, Greenslopes Private Hospital, Brisbane, Queensland, Australia.*

Background: Increasing numbers of elderly patients with end-stage renal failure are initiated on haemodialysis. This population tends to have more comorbidities and a shorter life expectancy than younger patients on haemodialysis. Our aim was to assess the survival on haemodialysis of patients aged 80 or over at time of dialysis initiation in an Australian private hospital.

Methods: We retrospectively reviewed the records of patients over the age of 80 who were initiated on haemodialysis in a single centre over a 12 year period. Patients were excluded if their duration of haemodialysis was less than 1 month. Data was also collected on cause of renal failure, comorbidities and serum creatinine at time of dialysis initiation.

Results: 82 patients aged 80 or over were commenced on haemodialysis between 1999 and 2010 at Greenslopes Private Hospital in Brisbane, Australia. 52 were aged 80-85 years, 24 were aged 85-90 years and 6 were aged greater than 90 years. The median estimated glomerular filtration rate (eGFR) at commencement of dialysis was 9mL/min/1.73m^2. Median survival on haemodialysis (with 25th and 75th percentiles) was 29.8 (13.0-44.4) months for the whole group, 30.3 (13.9-41.0) months for the 80-85 years group, 26.27 (9.0-43.4) months for the 85-90 years group and 39.28 (19.9-50.5) months for the >90 years group. This is in comparison to the Australian and New Zealand Dialysis and Transplant Registry (ANZDATA) national dialysis survival data of 35.6 (15.6-63.2) months in the 75-85 years age group and 24.4 (8.8-47.6) months in the >85 years age group.

Conclusions: The median survival on dialysis at this centre is comparable to the national data, with particularly extended survival in the patients aged over 90 at time of initiation. Elderly patients can have a reasonable life expectancy on haemodialysis if well selected. Age is not necessarily a contraindication to haemodialysis.

PUB391

Polyoma Viral Replication on Plasma in End - Stage Renal Disease Patients Waiting for Renal Transplantation Mediha Boran,[1] Ertay Boran,[2] Mertay Boran,[3] Hasan Kilic,[4] Ebru Gok Oguz,[5] Derya Yurdakul,[4] Pinar Parlak.[4] *[1]Dept of Nephrology, Hemodialysis and Transplantation, Turkiye Higher Education Hospital, Ankara, Turkey; [2]Dept of Anesthesiology and Reanimation, Duzce Univ School of Medicine, Duzce, Turkey; [3]Dept of Thoracic Surgery, Duzce Univ School of Medicine, Duzce, Turkey; [4]Dept of Microbiology, Turkiye Higher Education Hospital, Ankara, Turkey; [5]Nephrology Dept, Ankara Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey.*

Background: Progression of BK virus (BKV) infection to BKV-associated nephropathy remains an undesirable because of early graft dysfunction and graft loss in renal transplant recipients. In generally, BKV infection or reactivation has not been searched in pre-transplant hemodialysis (HD) patients.

Methods: In this study, the prevalence of BKV infection on plasma was investigated in 100 HD patients from different hemodialysis units, who were in waiting list as future candidates for renal transplantation and in 25 age- and sex- matched healthy controls. Because these HD patients were without diuresis, only the prevalence of BKV infection on plasma was analysed by quantitative real-time polymerase chain reaction.

Results: A total of 100 HD patients, 41 female (41%) and 59 male (59%), median age 44.7 years (range 23-67), median dialysis age 66.29 months (range 24-132 months) and 25 healthy controls, 10 female(40%) and 15 male (60%), median age 42.84 yrs (range 33-57) were included in the study. BKV replication on plasma of these HD patients and control individuals, was not detected.

Conclusions: We thought that BKV infection in renal transplant recipients maybe due to donor origin and we recommend pre-transplant routine screening for polyoma virus infection in dialysis patients and their living or disease donor at transplantation centres.

PUB392

Influence of Type D Personality on Health Related Quality of Life and Physical Activity in Patients on Dialysis Christopher Susanto,[1] Constantijn Konings.[2] *[1]Dialysis Centre Deurne, Elkerliek Hospital, Helmond, Netherlands; [2]Dialysis Centre Eindhoven, Catharina Hospital, Eindhoven, Netherlands.*

Background: Type D personality, which is defined by both negative affectivity (NA) and social inhibition (SI), has been identified as an independent predictor of health-related quality of life (HRQOL) in patients with cardiovascular disease. An interesting hypothesis is if this relation also exists in patients on dialysis. Besides this, CVD shares several other risk factors with CKD such as lack of physical activity. Aim of this study was to explore the prevalence of type D personality and was to show its influence on HRQOL and physical activity in patients on dialysis.

Methods: 63 patients, who had received maintenance hemodialysis for more than 3 months at outpatient Dialysis Centre Deurne, the Netherlands completed the Dutch version of the DS14 and the kidney disease quality of life instrument (KDQOL-SF™). Physical activity is defined as an accumulation of at least 30 minutes of moderate-intensity physical activity on most—and preferably all—days of the week.

Results: 41 patients were men (65%)and 21 patients were women (35%). The prevalence of type D personality in patients on dialysis was 48% which was indicated by a score≥ 10 on both NA and SI subscales of the DS14. The mean score of the NA and SI scale for all participants with type D personality was 14.7 (SD=3.9) and 14.3 (SD=2.8) respectively. The mean score of NA and SI scale for all participants with non type D personality was 4.7 (SD=5.2) and 9.7 (SD=3.7) respectively. 62% (n=21) of patients with type D personality had lack of physical activity compare with 38% (n=13) of patients with non type D personality (p=0.02). HRQOL in patients with type D personality was lower compared with non type D: 57.5 (SD=11.4) and 65.9 (SD=11.2) respectively (p=0.005).

Conclusions: Type D personality influenced HRQOL and physical activity in patients on dialysis. Future research should address appropriate interventions in order to improve HRQOL and physical activity in patients on dialysis.

PUB393

Emergency Department (ED) and Hospital Admissions in All of New England and New York: A Comparative Study of Fellow (FL) versus Non-Fellow (NF) Managed Hemodialysis Units (HDU) George N. Coritsidis,[1] Marie France R. DeLeon,[1] Jasjit Singh,[1] Aleef M. Rahman,[1] Carol Lyden,[2] Jaya Bhargava,[2] Payam Shakouri.[1] *[1]Nephrology, Icahn School of Medicine at Mount Sinai/EHC, Elmhurst, NY; [2]IPRO.*

Background: Most HDU staff is primarily technicians and nurses supervised by nephrologists. ED visit and hospitalization rates of dialysis patients are important measures of care in end stage renal disease (ESRD) patients. Previously when reviewing New York state data, we found that FL-managed HDU had significantly higher African American patients but without any outcome differences. We were interested to see what impact an academic fellowship program has on outcomes in HDU throughout New England and New York.

Methods: We retrospectively reviewed the de-identified records of all of Networks 1 and 2 (the 7 states) for 2010 regarding demographics, ED visits and hospitalization rates. FL managed HDU were compared to non-fellow managed HDU. Data was corrected for the number of patients per HDU.

Results: There were a total of 46 FL and 342 NF managed HDU. FL-HDU was concentrated in urban settings near their academic medical centers. FL managed HDU had a significantly higher minority (African American and Hispanic) population, but younger with lower diabetes prevalence. History of hypertension, rate of arterio-venous fistula, grafts and catheter were similar in both groups. ED visit/pt, percent admissions from ED and total hospital admissions were similar in both FL and NF managed HDU.

	FL: 7456 Pts	NF: 45335 Pts	P value
Age	59.46	64.11	<0.01
Hispanic %	14.90	12.11	<0.05
African American %	42.29	31.92	<0.01
Minorities %	57.19	44.03	<0.05
DM %	36.10	41.11	<0.05
Catheter > 30 days %	11.66	11.01	ns
ED visits/pt	1.35	1.35	ns
% Hospitalized from ED	43.20	44.10	ns
Total hospitalizations/pt	0.96	0.99	ns

Conclusions: Fellow managed units were comparatively younger with fewer diabetics but a higher minority and urban population. Despite being associated with lower socio-economic status and compliance issues, FL managed HDU had similar outcomes as to hospitalizations and ED visits.

PUB394

Formation of Patient Social Networks in a New Urban Hemodialysis Clinic Avrum Gillespie,[1] Athanasia Polychronopoulou,[2] Sarah Bauerle Bass,[3] Judith R. Greener,[3] Teri Browne,[4] Zoran Obradovic.[2] *[1]Temple Univ School of Medicine; [2]Biomedical Informatics, Temple Univ; [3]Public Health, Temple Univ; [4]Univ of South Carolina College of Social Work.*

Background: Social networks are important in chronic diseases, yet hemodialysis (HD) patient social networks are poorly understood. Building on work that showed the influence of social networks in established clinics, this study characterizes the formation of social networks in a new urban clinic.

Methods: Eighty seven percent of the patients (26/30) admitted to 3 shifts at a new clinic in Philadelphia were enrolled. Exclusion criteria were: in the clinic less than a month and unable to speak English or Spanish at/or above 6th grade level. Patients were surveyed on admission and every 3 months in English (85%) or Spanish (15%). Mean enrollment was 14 months (6-22). Data was analyzed using either an independent t-test or Fischer's exact test.

Results: The mean age was 57.4 (24-80). Patients identified themselves as black (42%), Hispanic (39%), or white (19%). Almost half (47%) had been on HD for less than 6 months. Thirty nine percent of patients identified other patients as part of their social network within 6-9 months of admission. Patients identified the HD staff (58%) and their nephrologist (81%) as part of their social network, usually within a month. Eighty percent of the patients who identified other patients in their network were on the first shift (p=0.04) which had a more consistent seating arrangement (p=0.0001). Spanish speaking patients identified other patients and their doctor but not HD staff as part of their network (p=0.022).

Conclusions: Over a third of HD patients form patient networks within 6 months, most were on the shift with most stable seating. Half of patients identify the staff and 80% their nephrologist in their network usually within 1 month of admission, however, networks continue to form over time. Spanish speaking patients appear not to form networks with staff. Further research is underway to understand the effects of the newly formed hemodialysis patient social networks on adherence outcomes, and transplantation.

PUB395

Prevalence of Hepatitis C and B in Hemodialysis Patients in United Arab Emirates over Two Decades (One Center Experience) Yousef Boobes, Bassam O. Bernieh, Mohamed Raafat Al Hakim, Ahmed Ahmed Ahmed, Qutaiba Hussain Daoud, Ahmed Chaaban, Hanan Eljack, Mohamed E.O. Ahmed, Imran Khan. *Nephrology/ Medicine, Tawam Hospital, Al Ain, Abu Dhabi, United Arab Emirates.*

Background: Viral hepatitis is a challenging clinical problem in hemodialysis patients of the developing countries in general, and in the Middle East in particular. In order to monitor the size and the trend of this problem, we are reporting the prevalence of hepatitis C and B in our hemodialysis unit for the last 20 years.

Methods: our hemodialysis unit started to function in 1987, with less than ten patients. Since 1993 hepatitis screening is done regularly every three months for all patients. Our laboratory is using the well validated serology kits, and the most updated technics including the PCR. In this study we are reporting the screening results of the years 1993, 2002, and 2014.

Results: in 1993, total number of hemodialysis patients was 25, none of them had HBs Ag (zero prevalence), while ten (40%) patients had anti HCV positive. Action taken was complete isolation of HCV positive patients, in addition to maintaining high adherence to the universal precautions. In 2002, total number of hemodialysis patients was 60, HBs Ag was positive in 1 (1.6%) patient. Eleven patients (18.3%) were anti HCV positive. In March 2014, the total number of hemodialysis patients was 270, six (2.2%) patients had HBs Ag positive, and 26 (9.6%) patients had anti HCV positive. During this 20 years we did not have any single case of seroconversion.

Conclusions: During two decades: 1- the number of hemodialysis patients increased by 11 folds 2-Hepatitis B prevalence remained low and stable all over the time 3- the prevalence of HCV decreased significantly by 4 folds 4- No seroconversion happened during 20 years 5- the exact contribution of isolation policy in addition to the implementation of universal precausions in achieving these excellent results needs further researches.

PUB396

Outcome of ESRD Patients after the Initiation of Emergency Hemodialysis at an Academic Medical Center of a Developing Country Syed Rizwan Bokhari,[1] Hafiz I. Ahmad,[1] Syed A. Khalid,[1] Arif Asif.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: In developing countries, chronic kidney disease (CKD) patients fail to seek medical attention earlier on and often present to tertiary care hospitals with uremic complications and requiring emergent hemodialysis. Majority of these patients become aware of their CKD during such presentations. The dialysis centers at tertiary care hospitals are overwhelmed with long wait lists. After discharge vast numbers of these patients are unable to receive optimum dialysis treatment and follow up care. We set out to investigate the long-term outcomes of these patients.

Methods: 123 consecutive advanced CKD5 patients admitted for uremic complications over period of 4 months were included in this prospective study. Patients were interviewed according to a standardized questionnaire and were followed via telephone calls monthly for three months, at 6 months and then at 1 year after the initiation of dialysis. Eighteen patients died during the hospital stay due to co-morbid conditions. Thirteen patients at the end of first 3 months and another 8 patients at 6 months were lost to follow up.

Results: 92 patients completed the three-month follow-up, of which 54(58%) were males (mean age of 38±5 years). Forty five (49%) patients were alive at the end of 3 months and only 4 (9%) were getting optimum dialysis. At 6 months of follow-up 22(26%) were alive and at 1 year follow up only 11 (13%) patients were alive. Of the surviving 11 patients, one received renal transplantation, another one initiated CAPD and the remaining 9 patients were maintained on twice-weekly hemodialysis.

Conclusions: Only a small number (<15%) of ESRD patients who initiated hemodialysis on an emergent basis were alive at the end of 1 year and those who had survived were receiving suboptimal treatment. These disturbing outcomes call for a multifaceted comprehensive planning with appropriate funding required to improve the early detection, long-term care and provision of regular and chronic renal replacement therapy.

PUB397

Analysis of Rate, Cause and Cost of Hospitalization of Maintenance Hemodialysis Patients: A Single Center Study Yuan Luo, Hong Ye. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Chronic kidney disease (CKD) has become one of leading public health problems nowadays. It was reported recently that the prevalence of CKD is up to 10.8% in China. Most of the CKD patients will inevitably progress to end stage renal disease (ESRD) and need renal replacement therapy, such as hemodialysis. The hospitalization rate of dialysis patients is increasing which will consequently bring heavy economic burden to society. The aim of this study was to analysis the rate, cause and cost of hospitalization of maintenance hemodialysis patients in our dialysis center.

Methods: Patients underwent maintenance hemodialysis in the blood purification center of our hospital were enrolled in this study. The frequency and period of hospitalization, as well as the cause and cost of each hospitalization of these patients from January 2011 to December 2013 were collected and analyzed.

Results: The annual dialysis frequency in our center is more than 900 times. From 2011 to 2013, 252, 285 and 368 patients were enrolled each year. More than 60% were male and most of them were at their age of 50-69 years. Half of these patients had their dialysis ages more than 60 months. Among them, the rates of hospitalization were 464.29, 596.49 and 635.87 per 1000 patients, respectively. Patients who were over eighty-year-old or had dialysis ages of 0-12 months had the highest hospitalization rates. The top three causes of hospitalization were infection, cardio- and cerebro-vascular diseases and vascular access dysfunction. Infection caused 25% of hospitalization, among which 70% were respiratory infection. The hospitalization periods were relevant to the causes. About 35% of the total hospitalization costs were used to treat infectious diseases.

Conclusions: The annual hospitalization rate of maintenance hemodialysis patients in our center has being increased since 2011. Over eighty-year-old and one-year dialysis age patients had higher hospitalization rates. Infection was the most popular cause of hospitalization in our dialysis center, which was also the major cost. This study might help improving clinical care of maintenance hemodialysis patients and reducing medical expenditure.

PUB398

Introspective Examination of Quality of Life in Haemodialysis Patients Daniel J.W. Jones,[1] Laurie T. Butler,[1] John P. Harris,[1] Emma C. Vaux.[2] *[1]School of Psychology and Clinical Language Sciences, Univ of Reading, Reading, United Kingdom; [2]Renal, Royal Berkshire Foundation Trust, Reading, United Kingdom.*

Background: Haemodialysis (HD) is an all-encompassing treatment affecting patients' psychological/emotional well-being, as well as their physical state. This is reflected in the high prevalence of depression amongst patients. Moreover, the rate of depression is found to increase after more than a year living with HD, suggesting that it is more likely to be associated with the treatment process rather than ESRD itself. At present,the literature is limited in its attempt to examine the HD patient experience holistically, from a patient perspective, especially in terms of mental and emotional aspects of living with ESRD and HD.

Methods: We interviewed 20 patients receiving HD three times per week for 3-5 hours per treatment (all had been receiving HD >90days, with Kt/V >1.4). Semi-structured interviews were conducted at the bedside during a patient's HD. A topic guide consisting of 12 open-ended questions was used to direct the discussion: topics included mood, memory and pre/post-dialysis well-being. Elaboration was encouraged to allow patients to express their own personal concerns. Interviews were recorded and transcribed verbatim. Thematic analysis was conducted using ATLAS.ti software.

Results: Four distinct themes emerged from the data, reflecting common stressors associated with HD: fluctuations in mental/physical well-being across the dialysis cycle, restrictions due to treatment schedule, impact of the disease/treatment on relationships and overall emotional reactions to treatment. Findings suggest that identifying and addressing such areas will contribute to better patient welfare and improved quality of life.

Conclusions: This study is the first to provide a detailed understanding of HD patients' personal experiences, which can, in part, help guide treating clinicians and healthcare managers on the negative psychological/physical consequences of HD. The data suggests that a holistic approach is necessary to provide the optimal care for all aspects of patients' lives. Future guidelines need to take this into account to enhance patients' overall quality of life and improve current patient mortality rates.

PUB399

Haptoglobin 1-1 Genotype Is Associated with Lower Depression Rate in Hemodialysis Patients Zaher Armaly,[1] Kamal Hassan,[2] Amir Abd Elkadir,[1] Adel Rafik Jabbour,[1] Rawi Ramadan,[3] Bishara Shafik Bisharat.[1] *[1]Nephrology, The Nazareth Hospital-EMMS, Nazareth, Israel; [2]Nephrology, Western Galilee Hospital, Nahariya, Israel; [3]Nephrology, Rambam Health Campus, Haifa, Israel.*

Background: Depression is a common psychological disorder in hemodialysis (HD) patients. HD modality drastically and negatively affects life expectancy and quality of life at both the physical and psychological levels. This is largely attributed to stressors, including medication effects, dietary constraints, fear of death, and dependency upon treatment. Haptoglobin (Hp) genotype (Hp 1-1, 1-2, or 2-2) is associated with risk for cardiovascular

diseases, but its relationship with depression, a growing concern in HD, has not been studied yet. Therefore, the present study examines whether Hp genotype influences the prevalence of depression among the Arab population undergoing HD in Nazareth, Israel.

Methods: The study that included 54 patients in the HD unit with a mean age of 61.9 ± 14.1 years who had undergone HD and 26 relative healthy control subjects with a mean age of 59.3 ± 7.3 years. Beck's Depression Inventory and Hamilton Depression Scale assessments were administered. Blood analysis for Hp genotype was performed. Diagnosis was made using the Diagnostic and Statistical Manual of Mental Disorders scale to correlate depression with Hp genotype.

Results: The prevalence of depression was 35.2% in HD patients. 17% of HD patients were Hp 1-1, 28% Hp 2-1, and 55% Hp 2-2. Hp 1-1 genotype was more prevalent in non-depressed HD patients as compared with depressed HD subjects (23% versus 11%). Similarly, Hp 2-2 genotype was observed in 60.0% of non-depressed HD as compared with 42% in depressed HD patients. In contrast, most of the depressed HD patients were Hp 2-1 carriers as compared with non-depressant HD subjects (47% versus 17%).

Conclusions: Depression is highly prevalent in Arab patients undergoing HD in Nazareth area. Hp Arab patients who carry Hp 2-1 genotype may be at risk to develop depression during HD treatment. In contrast, Hp 1-1 HD patients have a lower prevalence of depression. The mechanisms underlying this phenomenon remain to be explored.

PUB400

Hazard Perception during Driving in Renal Patients Daniel J.W. Jones,[1] Laurie T. Butler,[1] John P. Harris,[1] Emma C. Vaux.[2] *[1]School of Psychology and Clinical Language Sciences, Univ of Reading, Reading, United Kingdom; [2]Renal, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom.*

Background: Lab based studies have found ESRD patients to be impaired in areas of attention, psychomotor speed and executive functioning. However, exactly how such impairments affect patients outside of the lab is still unknown. An area that seems likely to demonstrate the kind of impairments observed in the lab is driving a car; a cognitively demanding task that requires several cognitive processes working in harmony. Areas such as attention, motor control and psychomotor speed are essential for driving, and have all been shown to be impaired independently in the lab. This being said, driving as a whole has not been examined with the same level of scrutiny. Currently, the effects of ESRD on driving ability are simply unknown, and consequently no guidelines are in place.

Methods: We examined one aspect of driving: hazard perception. 24 ESRD patients (Kt/V>1.4) and 24 age, sex and education-matched controls completed the Official UK DSA Hazard Perception task. It involves viewing a series of driving video clips (driver's perspective) on a video monitor. Each clip contains a hazard the participant should respond to within a set response window by clicking the mouse; scores range from five, for responding immediately, to zero, for responding outside of the response window or not at all.

Results: Conventional hazard perception scores did not differ between groups, possibly due to the learning gradient associated with the test. Results analysed in terms of detection rate (hits versus misses) found patients to be significantly worse than controls.

Conclusions: Findings suggest ESRD patients may be processing the hazards in a qualitatively different way to controls and that their hazard perception may be impaired. Due to the complexities of the task we are unable to conclude which cognitive aspects may be contributing to the impairment. Nevertheless, this study does highlight the possibility that patients may be impaired when driving, and are potentially putting themselves, and others, inunnecessary danger. Studies such as this highlight the need for further examination to establish standardised driving guidelines for this population.

PUB401

Efficacy of Early Examination of Adequacy of Dialysis Compare with Regular Examination in Korean CAPD Patient Joong Kyung Kim, Jin Ho Lee, Seong Han Yun, Joon Seok Oh, Seong Min Kim, Yong Hun Sin. *Div of Nephrology, Dept of Internal Medicine, BongSeng Hospital, Busan, Korea.*

Background: Examination of adequacy of dialysis(especially, weekly KT/V) is important for initiation and maintaining of continuous ambulatory peritoneal dialysis(CAPD). Generally, because of inaccuracy of the test that was performed immediately after catheter insertion surgery, most of the test was performed 3 months after operation. But, if accuracy of early test was high, it could increase the compliance of patients and reduce costs.

Methods: From June 6, 2007 to October 13, 2013, 100 patients was enrolled in single center of Korea. We retrospectively compared the weekly KT/V at early test and follow up test(mean 16.2days and 516.4days after initiation of CAPD). p value under 0.05 were considered statistically significant.

Results: Female patients were more than male (62 versus 38) and mean age was 53.73 years old. Early test was significantly correlated with regular follow up test in every CAPD patients(2.96 ± 0.95 versus 2.75 ± 0.76, p<0.05). Especially early test and follow up test has statistical significance in DM patients(3.04 ± 0.62 versus 2.59 ± 0.69, p<0.05). But there was no statistical significance in non DM patients(2.89 ± 1.11 versus 2.88 ± 0.8, p = 0.35).

Sex(male/female)	38/62
Age(years)	53.73
Diabetes/non diabetes	36/64
Early weekly KT/V(all patients, 13.8 days after surgery)	2.96 ± 0.95
Follow up KT/V(all patients, 515.9 days after surgery)	2.75 ± 0.76
Early weekly KT/V(DM patients, 19.5 days after surgery)	3.04 ± 0.62
Follow up KT/V(DM patients, 477 days after surgery)	2.59 ± 0.69
Early weekly KT/V(DM patients, 13.8 days after surgery)	2.89 ± 1.11
Follow up KT/V(DM patients, 515.9 days after surgery)	2.88 ± 0.8

Table 1. Characteristics of the Patients(n=100)

Conclusions: Early examination of weekly KT/V in CAPD patients is effective and increase the compliance of patients and reduce costs.

PUB402

Predictors of Life Quality on Dialysis: A Cross-Sectional Study in a Northeastern Brazil Center Douglas Rafanelle Moura de Santana Motta, Kleyton Andrade Bastos. *Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.*

Background: Discuss quality of life has gained increasing importance in a scenario of increasing prevalence of patients on dialysis worldwide. The objective of the study is assessing quality of life in dialysis patients, seeking to identify demographic, social, clinical and laboratory predictors.

Methods: This is a cross-sectional study. 356 patients were selected from the largest dialysis center in Aracaju, city located in northeast of Brazil. Socio- demographic and laboratory data were obtained from medical records and supplemented directly with patients at the time of interview. Questionnaires to assess quality of life (KDQOL- SF), depression and anxiety (HADS), sleep disorders (Epworth and Pittsburgh) and sexual dysfunction (FSFI and IIEF) were used.

Results: 273 patients completed the study, 215 on hemodialysis (78.8%) and 58 on peritoneal dyalisis (21.2%). The average age was 50.9 years with a male predominance (61.9 %). Most of the population has low levels of education and economic status. When comparing the 2 main components of KDQOL, we see a worse involvement of the SF -36 (median 61.0) compared to the KDCS (median 69.8). There was no significant difference between dialysis methods, hemodialysis and peritoneal dialysis. In a multivariate multiple regression analysis, we found as independent predictors the presence of anxiety and depression for 2 subscales of KDQOL- SF (KDCS: adjusted R 0.49 $p < 0.001$ and SF-36: adjusted R 0.53 $p < 0.001$). Also in the SF -36, we observed as predictors age and the presence of erectile dysfunction.

Conclusions: No significant difference was found in quality of life between hemodialysis and peritoneal dialysis. The main predictors of life quality were the presence of anxiety disorder and depression. New strategies to approach these two pathologies are necessary.

PUB403

Prevalence of Anti HBc and Occult HBV Infection in Hemodialysis Patients Bassam O. Bernieh,[1] Ahmed Ahmed Ahmed,[1] Waheed Uz Zaman Tariq,[2] Yousef Boobes,[1] Mohamed Raafat Al Hakim,[1] Qutaiba Hussain Daoud.[1] *[1]Nephrology / Medicine, Tawam Hospital in Affiliation with Johns Hopkins Medicine, Al Ain, Abu Dhabi, United Arab Emirates; [2]Laboratory Medicine, Tawam Hospital in Affiliation with Johns Hopkins Medicine, Al Ain, Abu Dhabi, United Arab Emirates.*

Background: The prevalence of HBV infection is low (2.2%) among our hemodialysis (HD) patients. On the other hand we observed out of proportion high prevalence of anti HBc positivity among these patients. This led us to investigate further and look for the presence of occult HBV infection, and to compare the prevalence of anti HBc positive in (HD) with its prevalence in healthy subjects.

Methods: Hepatitis serologyis mandatory for all (HD) patients. In addition to the adherence to the stander precautions measures, we are adopting an isolation policy for both HBV and HCV infected patients. In January 2014, we did HBV DNA PCR for all (HD) patients with HBs Ag negative and anti HBc positive, for possible occult HBV. In addition we did random HBV DNA for other (HD) group. We compared the prevalence of HBs Ag, anti HBc positive, and anti HCV positve in our (HD) patients, with healthy people using the results of blood donors of the month of January 2014.

Results: Total number of (HD) patients screened was 270, total number of control healthy group (blood donors) was 1422 subjects. HBs Ag positive was found in six (2.2%) HD patients, and 3 (0.2%) of the control (p=0.000). 66 (25%) of HD, had HBs Ag negative with anti HBc positive Compared to 35 (2.5%) of the control (P=0.000). HBV DNA detected in one (1.5%) of the (HD) anti HBc positive, compared to zero in the control, and other (HD) groups. Anti HCV positive found in 26 (9.6%) of the (HD), and 2 (0.14%) in the control (p= 0.000). 9 (35%) of the anti HCV positive had anti HBc positive, none of them had HBV DNA detected.

Conclusions: 1- Anti HBc is highly prevalent in our HD patients 2- occult HBV infection detected in one patient with anti HBc positive 3- anti HCV positve is associated

with higher anti HBc positivity 4- the highly significant prevalence of anti HBc in (HD) group compared to healthy group raises the possibility of causal relationship between HBV exposure and CKD which requires further investigations.

PUB404

Multidimensional Frailty in Older Veterans with Advanced Chronic Kidney Disease Katharine L. Cheung,[1] Nicky M. Quinlan,[2] Vj Periyakoil,[2,5] Manjula Kurella Tamura.[3,4] *[1]Nephrology, Univ of Vermont College of Medicine, Burlington, VT; [2]Palliative Care and Hospice Medicine, Stanford Univ School of Medicine, Palo Alto, CA; [3]Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [4]Geriatric Research and Education Clinical Center, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA; [5]General Medicine Disciplines, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.*

Background: Frailty is common in patients with chronic kidney disease (CKD) and is correlated with poor outcomes. While the concept of frailty is used to describe physical characteristics (weakness, low activity, weight loss, slow walking speed and exhaustion), the emotional, psychosocial and cognitive effects of frailty are unknown.

Methods: Nineteen older adults with CKD with eGFR <20ml/min/1.73m^2, were enrolled between February and June 2013 at a large academic VA Hospital and followed for one year. Patients completed the following tests: SF-36, Mini-Cog, Clock-in-the-box test (CIB), Palliative Grief and Depression Scale (PGDS), Flourishing Scale, Barthel Index for ADL, Lawton IADL scale and Short physical performance battery (SPPB).

Results: Participants were male, age 75.4±6.5 years with low eGFR (12.8±3.1ml/min/1.73m^2) not yet on dialysis, were independent and primarily living at home (16/19). They demonstrated impaired physical functioning (SPPB score 7.8±2.2/12, range 5-12), memory (3 word recall 1.8±1.2, range 0-3) and executive function (CIB score 5.2±2.4/10, range 0-8). The PGDS subscores for depression, restorative oriented grief and loss oriented grief were 1.1 ± 2.4/10, 4±1.1/5, and 1.6±1.8/5, respectively. The flourishing score was 46.1±6.5/56, range 32-56. At one year, eight started dialysis (1 PD, 7 HD), ten were hospitalized, and four died (three withdrew from dialysis and one patient did not start dialysis.)

Conclusions: Older veterans with advanced CKD were found to be frail, had cognitive and functional impairment. Our subjects had intense preparatory grief about their loss of kidney function. More work is needed to better characterize multimorbidity in older adults with CKD as such data may improve informed decision-making and prognostication.

PUB405

Designing a Positive Discussion Environment Where Dialysis Patient and Supporters Support Each Other Atsuhiko Kiyota,[1] Ryoko Hanada.[2] *[1]Dialysis Unit, Kiyota Clinic, Matsubara City, Osaka Pref., Japan; [2]Dept of Psychology, Tokyo Woman's Christian Univ, Suginami-ku, Tokyo, Japan.*

Background: In order to reduce psychosocial burden caused by chronic diseases such as renal failure, we built a program to promote positive discussion that enables supporting of each other in the daily lives by a community consisting of three parties, patients, their family and the medical staff (physician, nurse etc.) serving them. We have assigned a "psychological counselor" as the key person that ties the three parties in an organic way in our research.

Methods: Objects are 11 cases. We have decided to develop a method where the psychological counselor listens to the patient's discussion during a dialysis treatment and analyzes the problematic patterns and avoid them to have more positive discussions.

Results: Following are the problematic patterns that were identified. 1. Organic symptoms and negative "feelings" (such as not wanting to undergo dialysis) were mixed, making it difficult for the staff to understand their complaints and to address them. 2. When the patient expresses his/her "feeling", they were unable to verbalize them well making the staff to misunderstand them as monster patient. By having the psychological counselor explaining that such problematic patterns exist, the community consisting of patient-family-medical staff was able to promote positive discussion among each other and as the result, the psychosocial burden caused by the disease was reduced.

Conclusions: Through this research, we tried to understand the patients' "feelings" in an empathic way with the support of the psychological counselor. With this, the patients felt that their existence was respected and as the result, they would re-identified "their uniqueness" enabling the positive and good communication environment among patient-family-medical staff.

PUB406

Renal Ultrasound and Other Procedural Experience of U.S. Adult Nephrology Fellows Mala Sachdeva, Daniel W. Ross, Hitesh H. Shah. *Medicine, Div of Nephrology; North Shore-LIJ Health System, Great Neck, NY.*

Background: Procedures are a key component to nephrology fellowship training. Current renal ultrasound (R-US) and other procedural experience of U.S. adult nephrology fellows is not known. In addition, it is uncertain if nephrology fellows undergo formal training in R-US during fellowship. To gain a greater insight into nephrology fellows' experience regarding R-US and other nephrology procedures, we conducted this study.

Methods: An anonymous online survey was electronically mailed to U.S. adult nephrology fellows through nephrology training program directors and coordinators in May 2014.

Results: So far, 125 nephrology fellows have responded to the survey (14% response rate). Half of the respondents were first-year fellows. 41% were graduating fellows. 34% of the respondents were U.S. medical graduates. 6% of the respondents had formal R-US training during residency. 83% of the respondent's fellowship program did not offer formal clinical training in R-US during fellowship. Only 34% had formal didactic R-US experience during fellowship. 64% of the respondents described their ability to identify normal anatomy on R-US as either fair or poor. Over three-fourths (78%) of the respondents described their ability to identify pathological findings on R-US as either poor or fair. Majority (96%) of the respondents felt that fellowship programs should offer a formal training in R-US. Nearly one-fifth plan to undergo R-US training outside their fellowship programs. None except one respondent had placed peritoneal dialysis catheters during fellowship training. While 28% of the respondents had placed <5 temporary femoral hemodialysis (HD) catheters, another 30% had placed none. In addition, 30% fellows had not placed a temporary internal jugular HD catheter. R-US guided native or transplant kidney biopsies were more commonly performed than either CT guided or blind technique kidney biopsies.

Conclusions: Most fellowship programs did not offer formal clinical training in R-US, although fellows believe this should be an important part of their curriculum. Measures to enhance R-US and other procedural experience of nephrology fellows should be considered by the training community.

PUB407

Development of a Telenephrology Chronic Kidney Disease Education Class Lucile Parker Gregg,[2] Raimund H. Pichler,[1,2] Bessie A. Young.[1,2] *[1]Medicine/Div of Nephrology, Veterans Affairs Puget Sound Health Care System, Seattle, WA; [2]Medicine, Univ of Washington, Seattle, WA.*

Background: CKD education has been shown to improve outcomes for patients approaching the need for renal replacement thereapy (RRT). Barriers to education of rural patients include lack of awareness of kidney disease and lack of nephrologist in rural areas prior to the need for RRT. In response to that need, we developed a telemedicine CKD education class for Veterans in the rural Pacific Northwest. In order to determine barriers to participating, we developed a patient survey that will be used in both pre and post assessment of patients asked to participate in the class.

Methods: As part of a quality improvement project, we developed a survey to determine barriers to participation in a telenephrology CKD education class. CKD classes were designed to inform patients about dialysis modalities and transplant options prior to the need for dialysis. A literature search was performed to determine barriers to CKD education and summarized. Questions were developed and refined based on the literature and reviewed by the authors for content and completeness.

Results: A one page questionnaire was developed. Needs assessment questions included: How many miles do you live from the VA; Do you have access to a computer; Do you use MyHealtheVe (secure messaging)t if necessary; What are your barriers to participation in a class:, would you be willing to attend class telecast from a regional VA center; Would you be willing to attended class by telecast from your personal computer at home. Surveys will be piloted with patients who participate both on-site and distance CKD education classes. Patients will be queried as to the ease of participation and surveys will be sent using either mail or Veterans Affairs secure email, MyHealtheVet.

Conclusions: Telenephrology is potentially a novel way to educate rural Veterans about CKD and RRT. A pilot study will be conducted to determine feasibility of either at home or off site education via telemedicine modality. Results will be used to further refine the CKD-distance education class, which could be a model for long-distance CKD education across the country.

Extracellular Matrix Regulates Polycystin Localization and Function in *Caenorhabditis elegans* Deanna M. De Vore, Maureen M. Barr. *Cell and Developmental Biology, Rutgers Univ, Piscataway, NJ.*

Background: PKD2 encodes a transient receptor potential polycystin (TRPP) channel receptor protein found in primary cilia of mammalian cells and sensory cilia of *C. elegans* neurons. In humans, PKD2 mutations result in Autosomal Dominant Polycystic Kidney Disease (ADPKD). Given the ancient and evolutionarily conserved role for polycystin-2 in cilia, we are using *C. elegans* as a model to identify new genes required for ciliary receptor localization. We recently found that extracellular matrix components are important for *C. elegans* PKD2 localization and function. ECM formation, secretion, and integrity have been shown to be a primary factor in ADPKD (Mangos 2010). Transmembrane and ECM proteins such as cadherins and galectins act in cilium retraction and elongation also play a role in cell-to-cell junction signaling via the ECM which is important since ADPKD is a ciliopathy (Seeger 2012, Rondanino 2011). *mec-1*, *mec-5*, and *mec-9* encode ECM components that play a role in mechanosensation and degenerin/epithelial sodium channel (DEG/ENaCs) localization (Du 1996, Emtage 2004). mec-1 and mec-9 contain multiple EGF and Kunitz domains; mec-5 is a collagen (Du1996, Emtage 2004). I hypothesize that these ECM proteins interact physically and physiologically with the polycystins and affect their localization and/or function.

Methods: I have tested this by constructing markers to visualize EMC protein location and proximity to LOV-1(PC1) and PKD-2(PC2) in C. elegans males to show direct or indirect interaction of polycystins and ECM proteins. Male mating assays are also being performed to determine the effect of ECM on *C. elegans'* polycystin protein activity.

Results: *mec-1, mec-5* and *mec-9* regulate PKD-2::GFP localization and polycystin-regulated male mating behaviors.

Conclusions: These studies, which link polycystins localization and activity with ECM proteins in *C. elegans,* will shed light on how sensory receptors like PKD-2 are targeted to cilia and may advance the understanding and treatment of ADPKD.

Simvastatin Suppresses Synthesis of Fibronectin in Fibroblasts via WNT10A Expression Akihiro Kuma,[1] Hiromichi Ueno,[1] Yoko Fujimoto,[1] Nana Ishimatsu,[1] Tetsu Miyamoto,[1] Kenichiro Bando,[2] Ryota Serino,[2] Masahito Tamura.[2] *[1]Second Dept of Internal Medicine, Univ of Occupational and Environmental Health, Kitakyushu, Japan; [2]Kidney Center, Univ Hospital of Occupational and Environmental Health, Kitakyushu, Japan.*

Background: In vivo studies have shown that statins suppress kidney fibrosis, which if left untreated can lead to renal failure. We previously reported that WNT10A expression in the kidney tissue of acute interstitial nephritis patients is related to a lower estimated glomerular filtration rate and fibrosis. Here, we investigated the effects of the simvastatin against WNT10A-expressing fibroblasts.

Methods: COS1 cells (kidney fibroblasts from the African green monkey) were transfected with a WNT10A expression plasmid (COS1-10A). Western blot analysis confirmed the expression of extracellular matrix components and apoptosis-related proteins, and cells were counted by trypan blue staining. Cell cycle was comfirmed by flowcytometry.

Results: COS1-10A enhanced the expression of fibronectin about 3- to 5-fold compared with controls, but did not alter the expression of type I or type III collagen. In contrast to normal medium, supernatant from COS1-10A cells induced fibronectin expression in the controls, and WNT10A overexpression promoted cell growth. Conversely, simvastatin suppressed cell growth in COS1-10A cells ($p<0.005$). Western blot analysis revealed that simvastatin induced apoptosis of the controls and that COS1-10A cells expressed cleaved caspase-3 and poly ADP ribose polymerase. And, the population of sub-G1 in COS1-10A cells treated with simvastatin was 25%, but one of sub-G1 in COS1-10A cells without simvastatin was 7%. Furthermore, simvastatin also suppressed WNT10A-dependent expression of fibronectin.

Conclusions: As WNT10A enhanced the synthesis of fibronectin in COS1 cells, WNT10A expression in kidney tissue may promote kidney fibrosis. Conversely, simvastatin suppressed both fibronectin expression and cell growth. Although simvastatin did not show specific WNT10A expression in COS1 cells, it might have the ability to prevent kidney fibrosis.

PUB410

miR-146a Attenuates TGF-β_1 Induced Epithelial-Mesenchymal Transition in Renal Tubular Cells by Targeting smad4 Yoshiyuki Morishita, Shigeaki Muto, Daisuke Nagata. *Div of Nephrology, Dept of Internal Medicine, Jichi Medical Univ, Shimotsuke city, Tochugi, Japan.*

Background: The epithelial-mesenchymal transition (EMT) of renal epithelial cells plays pivotal roles in the development of renal fibrosis. microRNA (miR) has been recognized to interact with multiple mRNAs which are involved in the EMT process and as a potential target for the therapy of renal fibrosis; however, not all members of miR in EMT of renal epithelial cells have been identified. In the present study, we identified miR-146a attenuates TGFβ_1-induced EMT in renal tubular cells by targeting smad4.

Methods: The cultured HK-2 cells (human renal proximal tubular cells) were induced EMT by stimulating with 1ng/ ml TGF-β_1 for 24 hours. In some cases, miR-146a mimic or control oligo transfected HK-2 cells by lipofection were stimulated with 1ng/ ml TGF-β_1. Then, the changes of epithelial cell markers (E-cadherin and occludin) and mesenchymal cell markers (fibronectin-1 and vimentin) were investigated by qRT-PCR and/or western blotting analysis. The morphological change of cells was evaluated by phase contrast microscopy. Furthermore, the cell invasion ability was evaluated by wound healing assay.

Results: The epithelial cell markers were significantly decreased and mesenchymal cell markers were increased in HK-2 cells by TGF-β_1 stimulation. The morphology was changed from a cobblestone-like monolayer to spindle-shaped fibroblast-like, and the invasion ability was significantly increased in HK-2 cells by TGF-β_1 stimulation. Overexpression of miR-146a significantly attenuated these changes of cell phenotypic markers, morphology and invasion ability induced by TGF-β_1 stimulation whereas control oligo transfection did not show these effects. In addition, asmad4 expression was increased during EMT process induced by TGF-β_1 stimulation, and it was significantly inhibited by overexpression of miR-146a in HK-2 cells.

Conclusions: miR-146a attenuates TGFβ_1-induced EMT in renal tubular cells by targeting smad4. It may be a potential good therapeutic target of renal fibrosis.

PUB411

Reversal of Epithelial to Mesenchymal Transition following Relief of Unilateral Ureteral Obstruction in the Rat Nan Shen. *Dept of Nephrology, The First Affiliated Hospital of Dalian Medical Univ, Dalian, Liaoning, China.*

Background: Renal fibrosis begins with renal tubular epithelial mesenchymal transition (EMT); the progression thereafter depends upon a number of fibrotic factors. Mesenchymal–epithelial transition (MET) is the reverse process of EMT.

Methods: Unilateral ureteral obstruction (UUO) is a well-described model of EMT. We used an improved reversible unilateral ureteral obstruction (RUUO) model to investigate whether a progressive renal injury model of EMT could be reversed to MET after relief of UUO in rats. Rats were subjected to UUO or sham operation and the obstruction was removed five days later. Rats developed EMT after reversal of 4, 8 and 12 weeks of ureteral obstruction as assessed by the expressions of fibrotic factors in this post-obstructive model.

Results: We found a significant decrease in the kidney weight and renal cortical thickness in the UUO group compared with the sham groups. This rise in the RUUO group was significantly reduced. In addition, UUO rats exhibited pronounced inflammatory and intrinsic proliferative cellular responses, and ultimately fibrosis. By comparison, RUUO mice had more controlled and measured extrinsic and intrinsic responses to EMT with a return to MET within several weeks after release of ureteral obstruction.

Conclusions: Our findings provide a model that allows investigation of the fibrotic factors during reversal of EMT that contribute to the development of fibrosis.

Automated Quantification in 2 Renal Interstitial Fibrosis Models with Sirius Red and Polarization Contrast Microscopy Jonathan Street, Ana C. Souza, Alejandro Alvarez-Prats, Taro Horino, Xuzhen Hu, Peter S.T. Yuen, Robert A. Star. *NIDDK, Bethesda, MD.*

Background: Kidney interstitial fibrosis is the final common pathway in chronic renal diseases. Improved methods for precisely quantifying the anatomic location of fibrosis are needed. Kidney fibrosis is commonly assessed by histology. The Masson trichrome stain is widely used, with semi-quantitative scores assigned by trained operators. Each operator may select and score fields differently, leading to subjective scoring. We have developed an objective technique combining Sirius Red staining, polarization contrast microscopy, and automated image segmentation and analysis.

Methods: Entire kidney cross-sections stained with Sirius Red were imaged using polarization contrast microscopy. Automated image segmentation identified the interstitial and perivascular regions and quantified the interstitial fibrosis. We compared the newly developed method with scoring of adjacent Masson trichrome stained sections in two kidney fibrosis models in CD-1 mice: 1) folic acid (FA, 250 mg/kg), and 2) unilateral ureteral obstruction (UUO).

Results: Repeated analysis of the same FA sections by the same operator ($r=0.99$) or by different operators ($r=0.98$) was highly consistent for Sirius Red, while Masson trichrome performed less consistently ($r=0.61$ and $r=0.72$ respectively). Both techniques performed equally well when comparing sections from left and right kidneys. Targeting interstitial fibrosis (via perivascular exclusion) improved Sirius Red reproducibility and agreement with Masson trichrome from $r=0.32$ to $r=0.41$ in the FA model. Agreement was similar in the UUO model ($r=0.49$). The greater specificity of Sirius Red, for collagen type I and III fibrils, may partly explain the differences between these techniques.

Conclusions: Combining whole section imaging and automated image segmentation and analysis with Sirius Red/polarization contrast is a rapid, reproducible, and precise technique that complements Masson trichrome. It also prevents biased selection of fields, as interstitial fibrosis is measured on the entire kidney cross-section. This new tool should enhance the search for novel therapeutics and non-invasive biomarkers for interstitial fibrosis.

Establishment of a Novel Method for Longitudinal GFR Measurement in the Conscious 5/6 Nephrectomized Rat Damian C. Matera, Paul Harrison, Kathleen A. Lincoln, Hongxing Chen, Susan Goldrick, Kristina Gueneva-Boucheva, Nicholas F. Brown, Hu Sheng Qian, Carine Boustany, Glenn A. Reinhart. *Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: The subtotal nephrectomy (5/6 Nx) rat model exhibits many features of chronic kidney disease (CKD) including hypertension, decline in renal function, glomerulosclerosis (GS) and tubulo-interstitial fibrosis (TIF). We thus sought to characterize this model as a tool for screening novel CKD therapies. Furthermore, we sought to develop a method for assessing true glomerular filtration rate (GFR) over time in the conscious state.

Methods: Rats underwent a 5/6 Nx surgery (removal of the right kidney + occlusion of 2/3 of the renal arteries of the left kidney) and were implanted with telemetry transmitters for continuous recording of mean arterial pressure (MAP). 4 weeks post 5/6 Nx, rats received one of 3 doses of losartan (10, 30, 100 mg/kg in drinking water) or vehicle. 8 weeks post surgery, a subset of rats was implanted with subcutaneous mini-pumps linked to an IV jugular catheter to continuously deliver FITC-Inulin thereby allowing for longitudinal measurement of renal function in the conscious free-moving rat. In order to validate this method, inulin clearance was also measured in the anesthetized 5/6 Nx rats at the end of the study using the conventional method.

Results: Compared to sham operated, rats that underwent 5/6 Nx surgery demonstrated significant reductions in survival (50%), CrCl (55%), and GFR (both conscious and terminal) (94 and 73% respectively). At both 8 and 12 weeks post 5/6 Nx, GS and TIF were significantly increased in 5/6 Nx rats compared to sham. Losartan treatment resulted in significant improvement in survival ($p<0.01$), and reductions in MAP (≤26%), GS (46.9%), and TIF (53.6%). GFR measurement by the novel method yielded similar results to that generated in the anesthetized 5/6 Nx by the traditional method ($r^2=0.82$).

Conclusions: We have characterized over time the functional decline in GFR in conscious 5/6 Nx rats using a novel methodology of inulin clearance assessment. Our data highlight the utility of the 5/6 Nx rat as a model to investigate novel CKD therapies.

PUB414

A Novel Role of CCN3 in Renal Diseases Tarunkumar H. Madne,[1] Iain Macphee,[2] Mysore K. Phanish,[1] Mark E. Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]St George's Univ of London, London, United Kingdom.*

Background: CCN3 (NOV) is a matricellular protein from the same family as the pro-fibrotic connective tissue growth factor CTGF (CCN2). CCN3 has been shown to have roles in: endothelial cell adhesion and migration; osteoblast differentiation; progression of cancer; and the possible regulation of renal fibrosis. In the last of these it is proposed that CCN3 may directly oppose the actions of CTGF, although the precise mechanism for this is undefined. We have previously demonstrated that TGFβ1 activates Smad 1/5/8 in human podocytes in a manner that was inhibited by the presence of CCN3. Here we investigate whether CCN3 can modulate extracellular matrix (ECM) production by human podocytes in culture.

Methods: Experiments were conducted on conditionally immortalised human podocytes incubated with TGFβ1 (2.5ng/mL) and CCN3 (360ng/mL). Real time PCR was performed to look for gene expression of Fibronectin, collagen IV and collagen I. Immuno fluorescence microscopy (IF) was performed to look for collagen IV protein expression.

Results: CCN3 in similar pattern as TGFβ1 induced the fibronectin, Collagen IV and Collagen I gene expression in human podocytes. But co-incubation of CCN3 with TGFβ1 did not modify any of above outcomes. Both TGFβ1 and CCN3 induced a similar pattern of perinuclear localisation of collagen IV as demonstrated by IF.

Conclusions: Our results suggest that CCN3 can inhibit the TGFβ1 induced Smad1/5/8 phosphorylation. CCN3 also can induce the ECM proteins gene expression: Fibronectin, Collagen IV and Collagen I. CCN3 induced collagen IV expression has been proposed in melanocytes but we believe this is the first report of it in podocytes. Thus our results suggest that CCN3 could play a key role in regulation of fibrosis. Further studies involving CCN3 are required to define its role in renal fibrosis.

PUB415

Changes in Expression Profile of microRNAs and Target Genes in the Development of Peritoneal Fibrosis in a Model of Progression Chronic Kidney Disease Teresa Renata Romero,[1] Carmen Josefina Mora,[1] Marcela Avila,[1] Carmen María del Prado,[1] Virgilia Soto,[2] Ramon Paniagua-Sierra.[1] *[1]Unidad de Investigacion Medica en Enfermedades Nefrologicas, IMSS, Mexico; [2]Dept de Patologia, Instituto Nacional de Cardiologia., Mexico.*

Background: Fibrosis is a problem of peritoneal dialysis (PD), the first involves a network of proteins whose translation is regulated by molecular factors such as microRNAs (miRNAs), which is unknown in the progression of Chronic Kidney Disease (CKD).The aim was analyze fibrosis development in parietal peritoneum, the expression of miRNAs, mRNAs of protein targets genes related to fibrosis in progression of CKD in a rat model.

Methods: Six experimental groups were developed; control group and CKD group (Nx 5/6) in 4, 8 and 10 progression weeks, seven miRNAs expression and its possible target mRNA in parietal peritoneum were analyzed by qT-PCR with Taq-Man probes.

Results: Quantification of serum creatinine and albumin confirmed the functionality of the IRC model. Analysis by ANOVA showed that the histological results of CKD group in 4 (72.52 px, $p \leq 0.01$), 8 (130.68 px, $p \leq 0.01$) 10 weeks (161.56 px, $p \leq 0.01$) by staining Trichrome Masson confirmed presence of progressive fibrosis in the IRC. A pattern of differential expression of seven miRNAs mir195_1, mir409-3p_1, mir376a_1, mir26a_1, mir206_1, mir29b-1_1* and mir30b_1, respect to time progression of CKD was observed. Direct correlation was found between COL4A5 mRNAs ($r = -.777$, $p \leq 0.01$), CTHRC1 ($r = -.647$, $p \leq 0.05$), Faim ($r = -.619$, $p \leq 0.05$) and TGFß ($r = -.796$, $p \leq 0.01$) in presence of fibrosis.

Conclusions: Our results suggest that fibrosis may result from the combined effects of multiple miRNAs, mRNAs and progression time in parietal peritoneum able to uremia and proceeding of any renal replacement therapy in CKD.

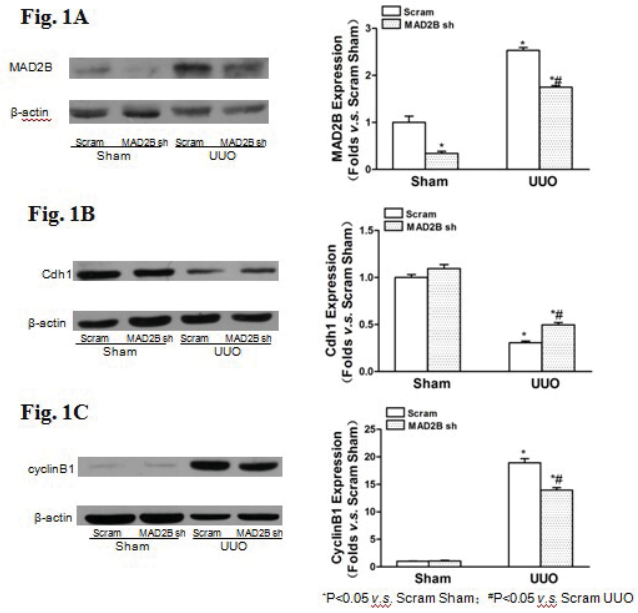
PUB416

MAD2B, a Novel Participant of Renal Tubulointerstitial Fibrosis in a Mouse Unilateral Ureteral Obstruction Model Hui Tang, Di Fan, Hua Su, Chun Zhang. *Dept of Nephrology, Union Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, Wuhan, Hubei Province, China.*

Background: MAD2B was known as an APC/C inhibitor which plays a critical role in maintaining mitotic fidelity. Our previous study has detected expression of MAD2B in both human renal tissue and renal cell lines, but it's particular role in renal disease remains unexplored. In this study, we aimed to explore the potential role of MAD2B in the pathogenesis of renal tubulointerstitial fibrosis in a mouse model of UUO.

Methods: Twenty C57 mice were randomly divided into four groups (n=5): sham, UUO-1d, UUO-3d, UUO-7d. Expressions of MAD2B, APC/C complex regulatory molecules Cdh1, as well as its substrates cyclinB1, skp2 and snon in each group were detected by Western blot and immunohistochemistry. Afterwards, in order to stably knockdown MAD2B, we developed shRNA Lentiviral directed against MAD2B and injected it into the renal cortex two days before UUO operation. Renal tissues were collected at 7-day after surgery. The expressions of APC/C regulatory molecules and substrates were detected by Western blot. Immunohistochemistry was performed to evaluate the expressions of a-SMA and FN.

Results: Comparing with sham groups, expressions of MAD2B were significantly upregulated in the UUO-7d group. Meanwhile, the obstructed kidney showed accumulation of cyclinB1 and skp2 but reduced Cdh1 and snon expressions. MAD2B deficiency attenuated the upregulation of cyclinB1 and increased the expression of Cdh1 in UUO groups, which was companyed with less severe renal interstitial fibrosis, reduced expression of α-SMA, less deposition of FN, compared to the UUO WT mice.



Conclusions: MAD2B participated in the development of renal interstitial fibrosis in UUO model through changing the expressions of Cdh1 and cyclinB1. Blockade of MAD2B pathway may be a novel approach for the prevention of renal interstitial fibrosis.

Calciphylaxis from Uremic and Nonuremic Etiologies Waqas Jehangir, Mohammed Amzad Hossain, Qiang Nai, Tarek Aly. *Internal Medicine, Raritan Bay Medical Center, Perth Amboy, NJ.*

Introduction: Calciphylaxis is a life-threatening syndrome of small vessel calcification and skin.

Case Description: A 55y/o male presented with dry gangrene to left ring finger and glans penis associated with pain and dysuria. PMH includes sarcoidosis, HTN, DM, CAD, IgA nephropathy and interstitial nephritis, nephrotic syndrome, ESRD, ILD, RF positive arthritis, hyperuricemia and anemia. Patient was taking prednisone for sarcoidosis. On physical exam, BP 180/87 with dry gangrene of left ring finger; black eschar to the tip of left middle finger and glans penis. Labs showed Ph 6.4, Ca 12.6, hep C antibody 2.5, RF 75, C3: 62, C4: 42, PTH 175, beta-2 microglobulin 6.3, d-dimer 1.03. CT showed diffuse sarcoidosis. Mediastinal lymph node biopsy revealed noncaseating granulomas. Xray showed extensive vascular calcification of medium and small blood vessels in hands, feet and penis.

Kidney biopsy showed diabetic nephropathy, IgA nephropathy and AIN. ECHO showed LV diastolic dysfunction. Upper extremities arterial Doppler showed bilateral peripheral arterial occlusive disease including small vessel disease in both hands. Carotid Doppler showed small amount of calcification to bilateral carotid bulbs. Amputation of left ring finger was performed. A suprapubic tube was placed.

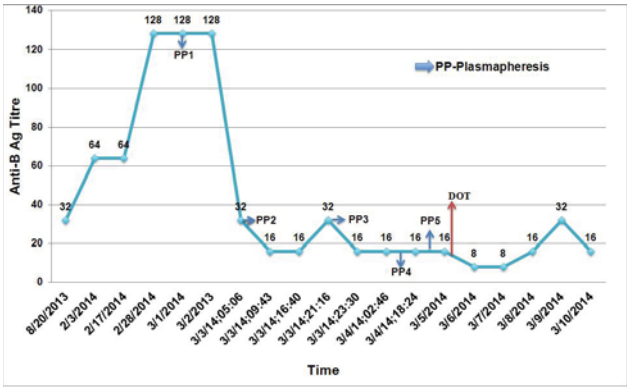
Discussion: Etiology of calciphylaxis remains elusive and may involve multiple co-morbid factors. We report a unique case where ESRD and multiple non-uremic conditions including sarcoidosis, cryoglobulinemia and DM may directly or indirectly contribute to the pathogenesis of calciphylaxis. Given the high mortality rate and increasing prevalence, emphasis should be on prevention, early diagnosis of vascular calcification and prophylaxis of secondary infection. Reduction of calcium phosphate product, avoiding prednisone usage, optimized glycemic control and effective wound care to prevent infection would enhance quality of life and prolong the life span.

PUB418

NxStage® System One™ Allows for Rapid, Cost-Effective Plasmapheresis for ABO Incompatible Kidney Transplantation Siddiq Anwar, Mohammed Abuzar Khan, Ravkiran Kaur Khurana, Ana Paula Rossi, Timothy A. Horwedel, Daniel C. Brennan. *Renal Div, Washington Univ School of Medicine, St Louis, MO.*

Introduction: ABO incompatible kidney transplantation (KT) requires removal of anti-A or B antibodies using expensive and time intensive selective adsorption columns or plasmapheresis. NxStage® System One™ is membrane-based technology that has been recently approved by the FDA for Therapeutic Plasma Exchange (TPE) and Plasmapheresis (PP). This allows for 4.0 liters of plasma exchange per hour with a low extracorporeal blood volume (110 ml), with a drop-in cartridge design for easy and quick set up plus a design feature which has 9 connections, which allows for concurrent set up of all the replacement fluid.

Case Description: 73yr female underwent a preemptive living related KT, blood group B into O from her son. 4 weeks prior to KT she received rituximab 200mg plus commenced on mycophenolic acid. Anti-B titers were 1:128 five days before planned surgery. PP was commenced using NxStage® System One™ aiming for a 1.5 plasma volume per exchange (4 liters). She received a total of 5 treatments with mean treatment duration of 95 minutes per treatment. Short treatment duration and easy tolerability allowed us to do 4 treatments in 2 days to deal with the rebound phenomenon associated with IgG which is predominantly extravascular. Anti-B titers went from 1:128 to 1:16 allowing for KT to proceed safely and on-schedule.



Discussion: Advantages of NxStage® System One™ for TPE and PP include ease of use and setup, ability to hang all the replacement fluid at once,and ability to run blood flows of 200mls/min with a large dialyzer cartridge 0.5m^2 that allows for 4L/hour of apheresis or exchange. These allow for shorter duration of hospitalization plus lower hospital and nursing costs. As demonstrated in our case, this technology is safe and effective at reducing ABO isoagglutinin titers rapidly.

PUB419

Catastrophic Lactic Acidosis with Post Embolization Syndrome after Trans Arterial Hepatic Embolization Ashwin Reddy Ganta. *Dept of Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Chemoembolization is being increasingly used in the treatment of Hepatic metastasis, for palliative and definitive treatment purposes. Acute Kidney injury (AKI) is being increasingly recognized as a complication of this procedure.

Case Description: A 67 y/o WF was transferred to the ICU after undergoing hepatic artery embolization (HAE). A few weeks ago, she was diagnosed with Carcinoid tumor with liver mets. Her PMH was significant for CAD, DM, CKD-II with baseline Scr of 1.3. Given her extensive hepatic involvement and recurrent abdominal pain, she underwent HAE. CT abdomen with contrast was done and HAE was successful with after adequate IVF. A few hours later, she c/o RUQ abdominal pain and she was initiated on PCA morphine. After a few hours, she became increasingly somnolent and oliguric. She was transferred to the ICU and labs showed elevated AST, ALT (3 x), K of 6.0 and a Scr 3.0. IVF and anti-hyperkalemia measures were started. Her Scr continued to worsen with worsening AGMA, lactate 6.2, AST and ALT in the 2000's and CPK 25000. She became hypotensive and was initiated on pressors. She developed fulminant hepatic failure with anuric AKI and was started on CRRT (CVVHDF). Her uric acid and phosphate levels were normal. She was continued on CRRT for the next 36 hrs and she died within 48 hours of her HAE.

Discussion: Discussion: HAE is being increasingly used for the management of Liver metastasis. Embolization can be done using Chemotherapy (TACE Transarterial Chemo Embolization) or using embospheres. AKI occurs in approximately 9% of patients after HAE and is most commonly secondary to Contrast induced Nephropathy(CI) in the setting of volume depletion from severevomiting that occurs in 90% of patients and is termed as post-Embolization syndrome. AKI can also occur form TLS. In our patient, AKI was of rapid onset and we hypothesise that the HAE precipitated massive tissue necrosis with release of inflammatory mediators which precipitated MOF. Ours is the only case reported in literature to our knowledge, with rapid such rapid onset AKI post-HAE and given the increasing use of HAE, nephrologists need to be aware of this catastrophic complication.

PUB420

Trapped in a Relationship: An Unexpected Case of Encapsulating Peritoneal Sclerosis Yaakov Y. Liss,[1,3] Jaime Uribarri.[2] *[1]Nephrology, Hospital of the Univ of Pennsylvania, Philadelphia, PA; [2]Nephrology, Mount Sinai Hospital, NY, NY; [3]Medicine, Mount Sinai Hospital, NY, NY.*

Introduction: Encapsulating peritoneal sclerosis (EPS) is an uncommon, devastating complication of peritoneal dialysis (PD), with an incidence of 0.5 - 4.4% and a mortality as high as 50%. Diagnosis is based on clinical features of bowel obstruction and radiographic or histopathologic findings of bowel encapsulation. This is a case of EPS occurring in a patient with no known risk factors for this uncommon condition.

Case Description: A 72 year old woman on PD for 3 years presented to the hospital with intractable nausea and vomiting of 3 months duration. She reported vomiting minutes after eating and a recent 20 pound weight loss. She had been hospitalized twice during the last 3 months for similar issues. Physical examination was significant for dry mucous membranes only. Prior workup was unremarkable and included esophagram, barium swallow, and EGD. Upon admission, the patient had a CT abdomen which demonstrated peritoneal thickening, loculated ascites, small bowel fecalization, sigmoid colon collapse, and moderate right hydroureter, consistent with a presumptive diagnosis of EPS. The patient was started on prednisolone and was switched from PD to hemodialysis (HD). Over the course of hospitalization, the patient's symptoms improved, and the patient was discharged home able to tolerate oral intake. She is currently doing well on HD.

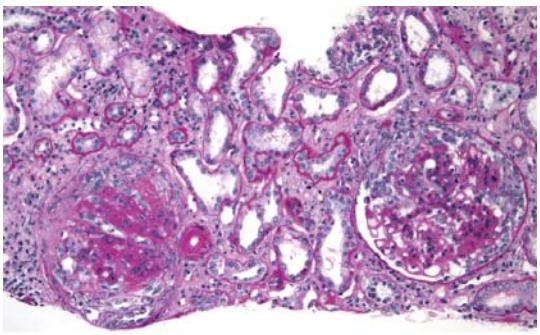
Discussion: This is a case of EPS occurring in a patient with no known risk factors for this condition. Risk factors for developing EPS include duration on PD, prior episodes of peritonitis, and use of high glucose containing PD solutions. For patients on PD for less than 3 years, the incidence of EPS is less than 1%. The patient described above was on PD for 2 years 11 months at diagnosis, had no prior episodes of peritonitis, and had minimal past use of high glucose containing PD solutions. Her lack of known risk factors for EPS undoubtedly contributed to a delay in diagnosis. This case highlights the need to determine additional risk factors for the development of EPS to allow for optimal prevention and early diagnosis.

PUB421

Recurrence of Lupus Nephritis in Transplanted Kidney Ardavan Mashhadian, Amir Abdi Pour. *Nephrology, Loma Linda Univ Medical Center, Loma Linda, CA.*

Introduction: The incidence of graft loss due to recurrent lupus nephritis (RLN) is extremely low, being less than 2-4% in most studies. Whereas the majority of patients with ESRD caused by lupus have had diffuse proliferative (class III or IV) disease, mesangial proliferative (Class II) disease is the most commonly described lesion after transplantation.

Case Description: 37 year-old African American male with lupus nephritis status post diseased donor allograft at age 20 was admitted for fever, weakness, and acute renal failure. He stated being compliant with immunosuppressive medications. Urinalysis showed numerous muddy brown casts suggestive of acute tubular necrosis. Serologic studies, including dsDNA antibody and complement levels were normal. Viral studies were negative. Doppler ultrasound was unremarkable. Renal biopsy was showed combined diffuse and membranous lupus nephritis with approximately 40% crescents, consistent with recurrent lupus (class IV + V) nephritis.



Despite pulse methylprednisolone and increased dose of immunosuppressive medications kidney function continued to worsen. He was discharged home on hemodialysis, and on follow up he continued to be hemodialysis dependent.

Discussion: Lupus nephritis patients who receive kidney transplant rarely develop clinically significant RLN. The excellent long-term outcome has been largely attributed to the use of chronic immunosuppressive therapy. The clinical consequences of RLN on allograft survival have ranged from no effect to a significant increase in the risk for graft loss and patient mortality. RLN significantly increases the risk for graft failure. However, it contributes far less than rejection to incidence of allograft loss. As such, diagnosis of lupus nephritis should not keep patients with advanced kidney disease from seeking a kidney transplant. In addition, successful transplantation has been reported after graft loss due to recurrence.

PUB422

"Pseudodiabetic" Glomerulosclerosis Cátia V.T. Cunha, Ana Marta Gomes, Daniela Lopes, Sónia Sousa, Susana Pereira, Joao Carlos Fernandes. *Nefrologia, Centro Hospitalar de Vila-Nova de Gaia, Vila-Nova de Gaia, Portugal.*

Introduction: The histological pattern of nodular glomerulosclerosis is typical of diabetic nephropathy (DN), but it is not exclusive of this entity.

Case Description: A 45-year-old man was studied at nephrology clinic to evaluate microscopic hematuria and proteinuria (protein-creatinine ratio of 2,44). He had a medical history of hypertension diagnosed 5 years early, dyslipidemia, active smoking (22 packs-year), an estimated alcohol consumption of 60 to 70 g per day and a body mass index of 27. The patient was taking an angiotensin II receptor antagonist and a statin. There was no history of diabetes. Laboratory values included a normal serum creatinine; high total cholesterol; mild elevation of gama glutamiltransferase; normal transaminases and alkaline phosphatase; normal serum glucose and glycosylated hemoglobin; and a normal hemogram. All serologies and immunology study were at normal range. No abnormalities were found on renal ultrasound. Renal biopsy was performed. The findings were a nodular glomerulosclerosis pattern and arteriolar hyalinosis. Congo red staining was negative. Immunofluorescence revealed 2+ intensity granular segmental focal capillary and tubular basement membrane positivity for C3. The podocyte foot processes were focally effaced on electron microscopy. There was also a mesangial and capillary membrane sclerosis. Rare subendothelial were found on mesangio-capilar transition. A diagnosis of idiopathic nodular glomerulosclerosis was established, probably in association with smoking and hypertension.

Discussion: The histological pattern of nodular glomerulosclerosis can be found in other situations besides DN, namely amyloidosis, thrombotic microangiopathy, chronic membranoproliferative glomerulonephritis, heavy chain deposition disease and fibrillary/immunotactoid glomerulopathy. The diagnosis of idiopathic nodular glomerulosclerosis is made by exclusion of the previous. It is a distinct clinicopathologic entity that should be considered in patient with active smoking, especially if there is concomitant hypertension. Some authors actually suggest the designation of "smoking-related nodular glomerulosclerosis" to this "pseudodiabetic" glomerulopathy.

PUB423

Acute Acetaminophen Toxicity Associated with Acute Kidney Injury without Hepatic Failure Sherif Y. Isshak, Bahar Bastani. *[1]Nephrology, Saint Louis Univ, St Louis, MO.*

Introduction: Acetaminophen toxicity commonly causes isolated acute hepatotoxicity,less commonly acute hepatotoxicity with acute kidney injury(AKI).The present case was unique in that AKI developed without hepatic failure.

Case Description: 63 year old Caucasian man committed suicide by taking 40 grams Acetaminophen, next day Acetaminophen level was 630 mg/dl. On admission, a baseline serum creatinine (Scr)1mg/dl, had increased to 1.9 mg/dl, FeNa was 2.7%,urinalysis showed multiple granular casts, ABG: PH 6.78,pCo2 76mmhg,pO2 173 mmhg, Hco3 10 mmol/l and 92% O2 saturation. Other labs: AST 142 u/l, ALT 150u/l, T.Bili 1mg/dl, lactic acid 11.3 mmol/l, phosphorus 10.1mmol/l, and blood glucose 277mg/dl with no ketones in urine. After mechanical ventilation and one session of Hemodialysis, ABG improved:PH 7.42,pCo2 40 mmhg,p02 100 mmhg,Hco3 25 mmol/l, and O2 saturation 95.5%.Next day patient was extubated, Acetaminophen level progressively improved to 341,130 and 3 mcg/ml;lactic acid 1.2 mmol/l and phosphorus 3.7 mg/dl .His Scr peaked at 4.3 mg/dl on the 5th day and declined to 2.5mg/dl by day 8 when he was transferred out of ICU.

Discussion: Patient developed AKI with mixed metabolic and acute respiratory acidosis with minimal liver damage. Patient never developed encephalopathy, Jaundice or coagulopathy.He had acidemia on admission, due to anion gap metabolic acidosis secondary to lactic acidosis and AKI, and acute respiratory acidosis. Patient was taking Metformin, which might have contributed to his Lactic acidosis.Hyperphosphatemia is thought to be due outward Transcellular shift and inhibited cellular glycolysis secondary to lactic acidosis. Hemodialysis is as an effective treatment for acute acetaminophen toxicity, however seldom used, because of the effectiveness of N-acetyl cysteine. The patient developed AKI despite receiving both N-acetyl cystiene and one session of hemodialysis.Our patient is the 37th case reported with the same presentation.It is Suggested that renal injury occurs when glutathione in tubular cells is overwhelmed with highly reactive metabolites inciting cellular damage, or reduction of PGE2 causing reduced renal blood flow.

PUB424

Chronic Granulomatous Interstitial Nephritis Recurring after Successful Glucocorticoid Therapy Namita Singh, Patricia L. Cantlin. *Div of Nephrology and Transplantation, Maine Medical Center, Portland, ME.*

Introduction: Granulomatous interstitial nephritis (GIN) is a rare histologic diagnosis that is present in 0.5 to 0.9% of native renal biopsies. GIN has been associated with medications, infections, sarcoidosis, crystal deposits, paraproteinemia, Wegener's granulomatosis and is also seen in an idiopathic form. We present a patient with chronic idiopathic GIN diagnosed by native renal biopsies 8 years apart.

Case Description: A 70 year-old woman presented with complaints of fatigue, poor oral intake, nausea and generalized weakness for one month. She had a history of hypertension, hyperlipidemia, chronic kidney disease stage 2, and of biopsy-proven acute interstitial nephritis with granulomata 8 years previous in the setting of exposure to nitrofurantoin. She had reported taking Naprosyn sodium consistently over at least one month period. Blood work was notable for peripheral eosinophilia and a serum creatinine of 10.4 mg/dL. Urine sediment revealed clumping white blood cells, 5-10 per high power field. Creatine kinase, complements, ANCA, hepatitis profile, serum protein electrophoresis and free light chains were within normal limits. A renal biopsy was performed which showed acute tubulointerstitial nephritis with poorly defined mixed necrotizing and non- necrotizing granulomata. Additional work up including renal tissue staining for mycobacteria and fungi, serum calcium, angiotensin converting enzyme and vitamin D 1,25-hydroxy levels, tuberculin skin test, and a chest x-ray, was all normal. The patient was started on prednisone 80 mg orally daily. Serum creatinine has trended down to 2.3 mg/dL, two months into therapy. Of note, the patient was treated with steroids 8 years ago and serum creatinine improved from 12 mg/dL to 1.1 mg/dL. We suspect that the patient had two episodes of acute interstitial nephritis caused by different agents, with a background of idiopathic chronic GIN.

Discussion: GIN is a rare finding; however, it should be considered in all patients with unexplained acute or chronic renal insufficiency and sterile pyuria. It can persist or recur after successful treatment with steroids.

PUB425

Acute Rejection after Prednisone Dose Reduction in a Failed Renal Transplant 4 Years after Return to Dialysis Ben Broome,[1] Anthony J. Langone,[1] David Shaffer,[2] Giovanna A. Giannico,[3] Rachel B. Fissell.[1] *[1]Div of Nephrology, Vanderbilt Univ, Nashville, TN; [2]Div of Kidney and Pancreas Transplantation, Vanderbilt Univ, Nashville, TN; [3]Dept of Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN.*

Introduction: The optimal level of maintenance immunosuppression in patients with a failed renal transplant is not known. We present a case of acute rejection in a graft that had failed 3 years previously, after decrease of prednisone.

Case Description: A 47yo woman with ESRD secondary to FSGS, received a deceased donor kidney transplant on the left side in 1999, and a subsequent 1 antigen mismatched living related donor transplant on the right side in 2009. She had biopsy proven collapsing glomerulopathy indicative of secondary injury 2 months after the second transplant, and returned to dialysis 4 months later. She was maintained on peritoneal dialysis and prednisone 5mg po each day. After 3 years the patient's nephrologist reduced the prednisone dose to 5mg QOD because of concerns about side effects. One month after the prednisone decrease, the patient presented with gross hematuria and right-sided tenderness at the site of the most recent graft. The prednisone taper was maintained at that time. Review of her medical record showed the presence of persistent microscopic hematuria since the second transplant. The patient underwent cystoscopy and ureteroscopy which revealed bleeding from the right transplant ureter as well as adjacent to the upper pole calyx. Because of symptomatic pain, tenderness and hematuria a right transplant nephrectomy was performed. Pathology showed changes suspicious for acute/active ABMR, chronic/active ABMR and numerous calcium oxalate crystals, in a background of near-global scarring. The hematuria resolved, and postoperative course was uneventful.

Discussion: This patient had ABMR after a slight decrease in maintenance prednisone, in a graft that had failed several years prior. Additional research may be needed to develop consensus recommendations for immunosuppression management and indications for graft removal in the growing population of patients with non-functioning renal transplants.

PUB426

Immunotactoid Glomerulopathy with Membranous Pattern in Patient with Rheumatoid Arthritis and Monoclonal Gammopathy Ghayyath Sultan,[1] Gaurav Agarwal,[1] Brent Wagner,[3] Sherry L. Werner.[2] *[1]Dept of Nephrology, Univ of Texas, San Antonio, TX; [2]Dept of Pathology, Univ of Texas, San Antonio, TX; [3]Dept of Nephrology, South Texas Veterans Health Care System, San Antonio, TX.*

Introduction: Immunotactoid Glomerulopathy (IMTG) is a rare cause of glomerular renal disease and frequently leads to end stage renal disease within few years. The optimal treatment still uncertain although steroids and other immunospressive agents have been tried with variable success.

Case Description: Proteinuria and microscopic hematuria occurred in a 69 year old man with history of rheumatoid arthritis receiving infliximab and sulfasalazine. Past medical history was significant for ground glass changes of the lungs (by computed tomography imaging), hypertension and monoclonal gammopathy of undetermined significance. Serum chemistries were non–contributory. Urine sediment was notable for one dysmorphic red blood cell and no casts. A 24 hour urine collection revealed 600 mg of protein. His

serologic evaluation for proteinuria was negative for hepatitis B panel, hepatitis C, human immunodeficiency virus, rapid plasma reagin, cryoglobulins, anti–nuclear antibody, double–stranded DNA antibody and anti–neutrophil cytoplasmic antibody. Complement C3 and C4 were normal. His serum protein electrophoresis showed an increased beta and gamma fractions with a possible monoclonal spike in the beta region. Immunofixation electrophoresis showed monoclonal bands in IgA/kappa and free kappa chains. Kidney biopsy showed morphologic changes consistent with immunotactoid glomerulonephritis with a membranous pattern.

Discussion: Most cases of ITGN are reported as idiopathic but screening for occult malignancy, paraproteinemia and automimmune diseases should be always considered once the diagnosis is established, as the treatment of the underlying disease will have great impact on the renal prognosis.

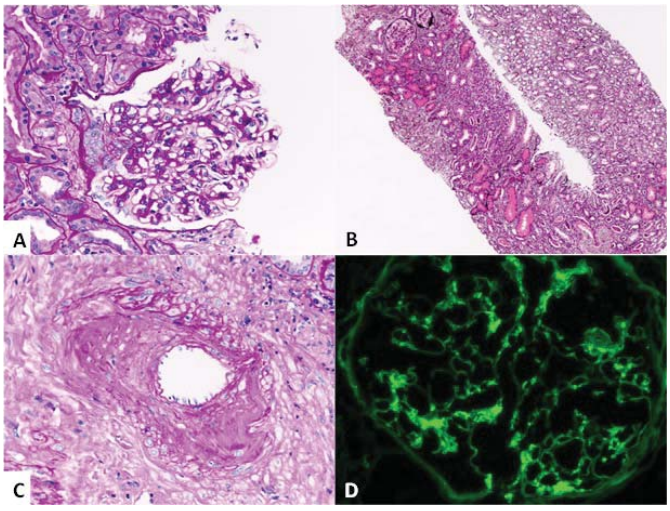
PUB427

Levamisole Induced ANCA Associated Glomerulonephritis

Eduardo J. Zouain, Mansi Mehta, Isha Gupta, Dipal R. Patel, Ira S. Meisels, Steven D. Smith. *Dept of Nephrology, Mt. Sinai St. Luke's Hospital Icahn School of Medicine at Mt. Sinai, New York, NY.*

Introduction: 69% of the cocaine in the U.S. may be contaminated with Levamisole. Levamisole has been associated with cutaneous vasculitis and agranulocytosis, while renal involvement has rarely been described.

Case Description: 56 year old female referred for acute kidney injury, diffuse rash and anemia. History of hypertension, depression and cocaine use. The rash was pruritic and maculopapular involving her face, upper chest, back, and the extensor surfaces of the forearms with a necrotic lesion on the helix of her right ear. There was associated weight loss, weakness, fatigue, and diffuse joint pain. No daily medications were being taken. Laboratories revealed AKI (serum creatinine 5mg/dl), anemia, elevated ESR (130mm/hr) and CRP (8.4mg/dl); positive ANA (1:160), decreased C3 (69mg/dl), normal C4; positive ds-DNA, strongly positive MPO Ab (greater than 8AI), positive Histone Ab, and positive urine toxicology for cocaine. The patient was negative for PR-3 Ab, GBM Ab, RF, SCL-70, LAC, anticardiolipins, anti-Smith Ab, Hep B Ag, Hep C Ab, and HIV Ab.



Renal biopsy: (A) MPO-ANCA associated focal necrotizing and crescentic glomerulonephritis (B) moderate tubular atrophy and interstitial fibrosis (C) moderate to severe arterio and arteriolosclerosis (D) immunofluorescence with granular global mesangial positivity for IgG, C3, kappa, and lambda - a greater degree of immune complex deposition than is usually seen in pauci-immune ANCA-associated glomerulonephritis.

Discussion: Our patient is one of only two biopsy proven Levamisole induced ANCA glomerulonephritis cases in the literature. The patient was treated with high dose steroids, and although had an initial improvement in renal function remains with significant chronic kidney disease.

PUB428

Nephrotic Syndrome in a Patient with Autossomal Polycystic Kidney Disease

Natacha Rodrigues, Alice Santana, António Gomes da Costa. *Dept of Nephrology, CHLN, Portugal.*

Introduction: The kidney biopsy represents an important tool for the approach of a nephrotic syndrome. When this procedure is contraindicated, the nephrologist faces diagnostic and therapeutic challenges. The authors present a case report of a patient with a nephrotic syndrome who was diagnosed with Autossomal Polycystic Kidney Disease (APKD) and several renal cysts.

Case Description: A 31 years old caucasian female with family history of APKD presented with prostration, edema of the inferior limbs and foamy urine. No history of infections, cutaneous lesions, joint pains or drug intake. Blood test results showed a creatinine of 0,7mg/dl and an albumin of 2,8 mg/dl. On urine test results she had proteinuria of 7340mg/24h, with erythrocytes and leucocytes. She was put on antiproteinuric measures. Investigation proceeded: C3 of 22mg/dl, C4 of 2mg/dl, CH50 of 5mg/dl, she was positive for ANA, with a DNAse of 920mg/dl and negative for ANCAs, TASO, e RA. She was negative for HIV, HCV, HBV and had normal electrophoresis. No Bence-Jones proteinuria was detected. Renal ultrasound showed two kidneys with 12,5 and 13 cm with good parenchymal-sinusal and corticomedullary differentiation, three centimetric cortical cysts on each kidney, parapielic cyst of 2 cm on the left kidney and microcysts on both kidneys. A 7mm cyst was visible on the right lobe of the liver. From the ultrasound imaging and laboratorial findings, the most probable diagnose was a lupic nephritis on a patient with APRD. There were no safety conditions for a percutaneous renal biopsy. The patient refused a laparoscopic renal biopsy. She was put on Prednisolone 0,5mg/kg/day and Micofenolate 2gr/day. After three months DNAse was not detectable, C3, C4 e Ch50 were normal, albumin was 3,9 mg/dl and proteinuria of 223 mg/24h.

Discussion: APKD is associated with several renal manifestations as microalbuminuria, hematuria, isosthenuria. Still, when nephrotic syndrome superimposes it is mandatory to exclude other causes. Unfortunately, renal cysts are often an obstacle to renal biopsy making impossible the confirmation and staging of many causes. It is the nephrologist's responsibility to handle the approach and therapeutics.

PUB429

Hemodialysis Characteristics for Treatment of Hypermagnesemia

Tushar Chopra, Rafia I. Chaudhry, Gerald Schulman. *Div of Nephrology and Hypertension, Dept of Medicine, Vanderbilt Univ School of Medicine, Nashville, TN.*

Introduction: Magnesium sulfate infusion is commonly used to treat eclampsia.

Case Description: A 22-year-old African American female presented at 28 weeks gestation with eclampsia, HELLP syndrome, seizures, and hypertensive urgency. Initial blood pressure was 200/130 mm Hg, after which she had a seizure. She received intravenous (IV) magensium sulphate (6 gm loading dose followed by maintenance doses at 2 gm/hour), and underwent an emergent cesarean section. The patient then developed progressive somnolence, hyporeflexia, and anuria. Her serial labs revealed hypermagnesemia (8 mg/dl), profound hypocalcemia (ionized calcium 1.77 mmol/L), acute kidney injury (creatinine 2.8mg/dl), and hyperkalemia (8.7 meq/L). IV calcium gluconate was administered to antagonize the effects of elevated magnesium (hypermagnesemia induces hypocalcemia by binding to Ca-SR on parathyroid gland and in the renal tubules). Emergent hemodialysis was performed, which reduced the serum magnesium level by 3.6 mg/dl. The patient was dialyzed for 5 hours using a high calcium (3 meq/L) and normal magnesium (1.8 mg/dL) dialysate concentration, across high flux membrane, with high blood flows.

Discussion: Therapeutic serum magnesium concentration recommended for the treatment of eclamptic seizures is 4.8-8.4mg/dL. In patients with normal renal function, the induced hypermagnesemia resolves with renal clearance. However individuals with a GFR< 30ml/min are at risk of persistent hypermagnesemia, and it's fatal neurological and cardiovascular complications including ventricular arrythmias and sudden cardiac death. Hence obstetric patients with impaired renal function, who are treated with large parentral doses of magnesium are at increased risk of accidental overdose. Hemodialysis is efficient in rapid removal of magnesium, and can achieve a magnesium clearance of 100 ml/min, due to the small size and large, ionized fraction (70%) of magnesium in the serum. There is no need to lower dialysate magnesium concentration (average 1.8 mg/ dL), as low magnesium hemodialysis sessions are not well tolerated due to increased intradialytic hypotension and leg cramping.

PUB430

Dense Deposit Disease: A Case Study

Andrew R. Sacks, Jennifer A. Fillaus, Troy J. Plumb. *Nephrology, Univ of Nebraska Medical Center, Omaha, NE.*

Introduction: Dense deposit disease (DDD) is a rare form of glomerulonephritis, affecting 1 to 3 in one million people, typically children and young adults. Historically considered a type of MPGN (type II), it is now recognized as a pathologically distinct and one of the so-called C3 glomerulopathies. Progression to ESRD is common despite treatment, and recurrence after transplant is nearly universal.We discuss a case of DDD and its management.

Case Description: A 21 year old female with no past medical history presented to the ED after several days of worsening dyspnea, edema, and cough. Further review was negative, and her only medication was a rare NSAID. Physical exam was significant for blood pressure of 219/145, tachycardia, tachypnea, chest rales, and moderate leg edema. Labs showed elevated creatinine, low serum albumin, and high ESR. Urine studies showed red blood cell casts and profound proteinuria. Serologic workup for glomerular disease was negative. Kidney biopsy showed presence of C3 with electron dense subendothelial deposits and chronic change. She became dialysis dependent and began treatment within days of presentation. Several months later, she received a transplant from a living donor with excellent graft function and no sign of recurrence.

Discussion: DDD is a rare condition mediated by C3 and the alternative complement system. C3 activation is left unchecked by a stabilized C3 convertase, which results from C3 nephritic factor, reduced complement factor H activity, or both.This leads to deposition of C3 and terminal complement components within the capillary membrane.Patients present with varying degrees of proteinuria and hematuria. Serum C3 is often depressed. C3NeF and factor H deficiency may be present. Incidence and degree of hypertension and reduced kidney function are variable. Biopsy with electron microscopy is required for diagnosis. With no randomized trials, there is no clear best treatment. Options include plasma infusion or exchange, rituximab, and eculizumab. RPGN may warrant additional immune suppression. Proteinuria, hypertension, and hyperlipidemia should always be treated. Transplant is an option. Recurrence can be up to 100 percent, but this leads to graft loss in less than 30 percent of patients.

PUB431

Contrast-Induced Nephropathy in Enlarged Kidneys: Utility of Renal Ultrasound in Diagnosis of Multiple Myeloma Ekamol Tantisattamo, W. Charles O'Neill. *Renal Div, Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.*

Introduction: Broad range of renal manifestations makes multiple myeloma (MM) sometimes difficult to be diagnosed. However, classic presentations of MM could be a clue to further workup even in unsuspected cases. Renal ultrasound (RUS) is commonly used to diagnose an obstruction as a cause of acute kidney injury (AKI); however, kidney size is also one of the most important pieces of information to narrow differential diagnosis of underlying renal diseases.

Case Description: A 69 year-old woman presented with NSTEMI and underwent PCI. Two days later, she was discharged but had not been feeling well. Ten days after discharged, she came to follow-up and was found to have elevated serum creatinine (SCr) of 19 mg/dL from baseline SCr of 1.1 mg/dL. BUN was 119 mg/dL. Urinalysis showed protein 50 mg/dL, 26 RBC/hpf. RUS revealed enlarged echogenic kidneys with the right and left kidney length of 14 and 11.9 cm, respectively(figure 1). Further workup revealed urine protein/Cr ratio of 2.98 and urine albumin/Cr of 0.09 g/g of Cr, respectively. She was uremic; therefore, intermittent hemodialysis (HD) was initiated. κ and λ free light chain were 38.1 and 39,124 mg/L, respectively. Urine immunofixation demonstrates a free λ light chain paraprotein. Bone marrow biopsy revealed 40-50% plasma cells. She was diagnosed with MM. Chemotherapy was started as an outpatient. Her renal function had been improved and HD was discontinued 1 month later with stable SCr of 2.3 mg/dL.

Discussion: MM is one of the risk factors of CIN. CIN and enlarged kidneys could be an initial manifestation of MM and quantified proteinuria should be tested for possible paraproteinemic renal disease. Our case underscores the utility of RUS in measuring a kidney length as a clue to diagnose underlying renal diseases causing enlarged kidney such MM.

figure1: *Longitudinal scan of right kidney showing an enlarged right kidney with 14 cm in length and increased cortical echogenicity.*

PUB432

Light Chain Deposition Disease: The Importance of Early Diagnosis Paul Bradley Brasher,[2] Arif Asif.[1] *[1]Nephrology, Albany Medical College, Albany, NY; [2]Internal Medicine, Albany Medical Center, Albany, NY.*

Introduction: In this report, we present two unique cases of light chain deposition disease (LCDD) and the challenges facing diagnosis and treatment.

Case Description: *Case#1* is a 37-year-old female with a previous diagnosis of pulmonary hypertension and cryptogenic organizing pneumonia was on increasing dosages of steroids without improvement of her exertional dyspnea. She presented in moderate respiratory distress with significant lower extremity edema. Initial laboratory studies revealed a hemoglobin of 8.7 g/dL and a BUN/Cr of 108/3.2 mg/dL. Later she was found to have an elevated serum kappa light chain level of 5360 mg/L. Renal biopsy was consistent with LCDD. A right heart catheterization suggested a restrictive cardiomyopathy and endomyocardial biopsy revealed deposition disease, interstitial widening and negative amyloid. Bone marrow biopsy was consistent with lymphoplasmacytic lymphoma as the source of her kappa light chain deposition. She required hemodialysis for ESRD and was treated with bortezomib, rituximab and bendamustine with a resultant decrease in her serum light chains and a recent echocardiogram with no functional abnormalities. *Case#2* is a 31-year-old female with no prior history who presented with anasarca and hypertension after a one-year history of progressive numbness and tingling in her hands. She was found to have a BUN/Cr of 56/4.8 mg/dL. A renal biopsy demonstrated light chain deposition. Bone marrow biopsy revealed cyclin D1 kappa restricted plasma cells. The patient progressed to ESRD requiring hemodialysis. Treatment was initiated with bortezomib. She is currently undergoing evaluation for autologous stem cell transplantation (ASCT).

Discussion: There is no standard treatment for patients with LCDD. Treatment with high-dose chemotherapy with or without ASCT may result in disease stabilization and/or improvement in end organ damage. These two cases highlight the difficulties in diagnosing LCDD early in its course, demonstrate the importance of renal biopsy and the challenges of treatment thereafter. Each of these patients was symptomatic for greater than a year yet a diagnosis was only made as the patients were approaching renal failure.

PUB433

Acute Renal Infarction Secondary to Membranous Glomerulopathy Frederick Elises Ogbac, Cherisse Ann P. Panlilio, Kristine Tan Gapuz, Alicia Baldonado. *St. Luke's Medical Center-Quezon City, Philippines.*

Introduction: Acute flank pain is a common complaint of patients in the emergency department (ED). A frequently misdiagnosed differential for acute flank pain is acute renal infarction. It has an estimated incidence of 0.007% and clinically diagnosed in 0.014% of patients. We present a case of a young female diagnosed to have membranous glomerulopathy with acute renal infarction presented as sudden onset flank pain.

Case Description: A 19-year-old female diagnosed with membranous glomerulopathy presented in the ED with an acute onset, severe, right sided, flank pain associated with nausea and vomiting. No fever, dysuria, hematuria, or history of trauma. There was no family history of connective tissue disease or vascular diseases. Her BP was 110/70mmHg, heart rate of 82bpm with regular rhythm and afebrile. Pertinent examination showed non-tender abdomen, positive for shifting dullness, fluid wave, right sided costovertebral angle tenderness and grade 1 pitting bipedal edema. Initial diagnostics showed leukocytosis with neutrophilic predominance, serum creatinine of 0.77mg/dL, and proteinuria of >600mg/dL. Abdominal ultrasound showed normal sized kidneys with isoechoic right kidney raising the possibility of non-specific parenchymal disease and ascites. Contrast-enhanced CT-Scan of the abdomen was requested revealing areas of non-enhancement in the upper to middle portions of the right kidney which may relate to areas of ischemia and/or infarction, likely due to thrombosis involving the more distal portion of the right renal artery and massive ascites. Result was confirmed by CT-Angiography of the kidneys showing right renal artery thrombosis. Evaluations for the cause of renal artery thrombosis were done and were negative. Anti-coagulation therapy was initiated using LMWH and maintained on warfarin.

Discussion: A high index of clinical suspicion is needed to diagnose acute renal infarction because of its non-specific symptoms. Early diagnosis and prompt initiation of anti-coagulation therapy is important to avoid irreversible kidney damage. Acute renal infarction should be considered as a cause of acute onset flank pain in patients with risk factors and normal initial screening test.

PUB434

Ceftriaxone Induced Acute Encephalopathy in a Peritoneal Dialysis (PD) Patient Sami Safadi, Michael A. Mao, John J. Dillon. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Introduction: Encephalopathy is a rare side effect of 3rd and 4th generation cephalosporins. Renal failure and preexisting neurological disease are notable risk factors. Recognition is important as discontinuation of the offending agent usually resolves symptoms. We present a case of acute encephalopathy in a patient with ESRD on PD who received IV ceftriaxone for peritonitis. This case raises awareness of the potential severe neurologic effects of cephalosporins, which are recommended by international guidelines as first-line antimicrobial therapy for spontaneous bacterial peritonitis.

Case Description: A 37 y/o female with ESRD due to lupus nephritis, on PD presented with fever and watery diarrhea. Medications included mycophenolate mofetil and prednisone. Her PD catheter exit site was clean. Initial lab workup showed no leukopenia/leukocytosis. The patient initially received IP ceftazidime(125 mg/L) for yersinia enterocolitica peritonitis. Two days later, she was admitted for possible sepsis, and switched to IV ceftriaxone(2 grams/day). PD was continued. After 3 days of IV ceftriaxone, she developed agitation and visual hallucinations. Her exam was non-focal. An EEG showed background moderate diffuse nonspecific slowing without seizure activity. An MRI showed cerebral volume loss but no focal findings to account for the symptoms. Since these symptoms occurred a few hours after ceftriaxone infusion, it was switched to ciprofloxacin with complete symptom resolution after 36 hours.

Discussion: Neurotoxicity has been reported in both 3rd and 4th generation cephalosporins, though more frequently with cefepime. Possible mechanisms are inhibition of GABA release leading to neurological excitation and endotoxin release from dead bacteria leading to cytokine generation. Dialysis patients are vulnerable due to altered drug pharmacokinetics, and dosing changes. In conclusion, encephalopathy is a rare but severe side effect of cephalosporins. Renal failure is a risk factor. Timely diagnosis can be delayed due to the broad differential diagnoses of encephalopathy in dialysis patients. However, recognition is important as cessation of the medication typically leads to resolution of symptoms, decreased morbidity and costs.

PUB435

Immediate-Peritoneal Dialysis Post-Kidney Transplantation: An Approach to Avoid Catheter-Related Vascular Complications Ekamol Tantisattamo. *Renal Div, Emory Univ School of Medicine, Atlanta, GA.*

Introduction: Delayed graft function (DGF) post-kidney transplantation may require dialysis and peritoneal dialysis (PD) is an option for PD patient. However, concerning for intraabdominal complications may lead to hesitation in performing PD. We report a case of a PD patient who developed DGF. Hemodialysis (HD) was planned despite PD catheter was still in place. Common carotid artery was accidentally punctured and dilated requiring insertion with a large-bored non-tunnel hemodialysis catheter to stop bleeding. The catheter was emergently surgical removed.

Case Description: A 50 year-old man with history of ESRD on PD was admitted for deceased donor kidney transplantation (DDRT). The preoperative induction immunosuppressive medications included basilliximab, methylprednisone, and belatacept. The operation was uneventful. Cold and warm ischemic times were 18 hours 41 minutes and 0.5 hours, respectively. Eighteen hours after operation, he developed DGF with

serum creatinine (SCr) of 10 mg/dL from preoperative SCr of 11 mg/dL. Urine output was 25-30 ml/hour. Serum K was 5.6 mmol/L. Tacrolimus trough level was 21 ng/mL. HD was planned via the right IJ vein despite PD catheter was not removed during DDRT. Unfortunately, the right common carotid artery was accidentally punctured and dilated. Due to rapidly bleeding from the dilated artery even direct pressure, the 14-Fr dialysis catheter was inserted. Emergent catheter removal and common carotid artery repair were performed in the operating room. His vital signs had been stable and neurological signs were intact. Postoperatively, he required HD once via the left femoral dialysis catheter and DGF was improved. He was discharged on postoperative day6 with SCr of 4.2 mg/dL and Hb of 8 mg/dL.

Discussion: Given extraperitonial approach during DDRT, PD is a feasible option for dialysis. The possible complications of immediate-PD post-kidney transplant including peritoneal leak, infectious complications such as peritonitis could be avoided by individualized PD prescription. This approach may prevent unnecessary invasive procedure with potential fatal complications such vascular HD catheter placement-related complications.

PUB436

Acute Tacrolimus Nephrotoxicity in Graft-versus-Host Disease Patient: Overdose and Interaction

Ekamol Tantisattamo, Harold A. Franch. *Renal Div, Emory Univ, Atlanta, GA.*

Introduction: Drug-drug interactions lead to calcineurin inhibitor (CNI) dosing much lower than expected by medical personnel creating potential for medical errors.

Case Description: A 60-year-old woman with history of diffuse large B-cell lymphoma status post allogeneic bone marrow transplantation, GVHD on tacrolimus 0.5 mg oral 3 times a week and boosted-voriconazole 200 mg twice a day, was admitted for an elective colectomy for colonic adenocarcinoma. The operation went well and pain was controlled with morphine PCA. However, she received tacrolimus 5 mg oral once post operative day 1. Twenty nine hours later she was unresponsive and did not respond to naloxone. Shortly, she awoke confused complaining of tinnitus, tingling, and tremors. She developed non-oliguric acute kidney injury with elevated serum creatinine of 2.02 mg/dL from the baseline of 1.10 mg/dL. Urine microscopy showed bland urinary sediment and FE_{Na} was 0.11%. Tacrolimus was held and the tacrolimus level was 18.5 ng/mL 31 hours after the dose. Renal function and neurological symptoms improved to baseline and tacrolimus level went down to therapeutic level (Figure1). The physician who wrote for the wrong dose of tacrolimus admitted that he was unfamiliar with extremely low doses of tacrolimus for drug-drug interactions.

Discussion: Even though tacrolimus absorption post-intestinal surgery may be decreased, our patient developed nephro- and neurotoxicity from a single 10 fold higher dose of tacrolimus, due to her concomitant voriconazole. Her small home tacrolimus dose contributed to the error. Carefully monitoring CNI level especially in perioperative period and with concomitant medications causing potential drug-drug interaction is crucial to achieve adequate dose and avoid CNI toxicity. In addition, automated flagging in the electronic medical record of large changes in CNI dosing could have prevented this outcome.

PUB437

Lacosamide Intoxication Induced Acute Kidney Injury in a Suicide Attempt by an 18 Year Old Woman

Vishal Bharat Parekh,[1] James L. Bailey.[2] *[1]Nephrology, Emory Univ, Atlanta, Georgia; [2]Nephrology, Emory Univ, Atlanta, GA.*

Introduction: Lacosamide (LCM) is approved by the U.S. Food and Drug Administration for the management of partial-seizures. LCM acts on sodium channels. Suicide risk and cardiac arrhythmias are reported with its use. Little is known about its kidney toxicity at higher doses.

Case Description: We report the clinical course of an 18-year-old woman with refractory partial-seizures, being treated with LCM, who overdosed herself with 12 g of LCM in a suicide attempt. Her course was complicated by coma, respiratory failure requiring mechanical ventilation, shock requiring IV pressors, and acute kidney injury (AKI) with anuria and severe acidemia managed initially with a session of hemodialysis (HD) then continuous renal replacement therapy (CRRT) for 60 h followed by a session of HD. On presentation, the pH, bicarbonate, lactic acid were 6.9, undetectable, 19.2 mmol/L, respectively which corrected to 7.44, 24 mg/dL and 7.05 mmol/L respectively. The serum BUN, Creatinine, potassium levels were 7 mg/dL, 1.09 mg/dL and 2.8 mmol/L respectively. Urine demonstrated 3-5 coarsely pigmented granular casts consistent with acute tubular necrosis (ATN). Complete clinical recovery occurred after several days of supportive care. The serum creatinine level on presentation was 1.09 mg/dL which peaked at 19 mg/dL before returning to 1.2 mg/dL in about 45 days post ingestion.

Discussion: This case highlights how LCM intoxication can result in AKI requiring CRRT and HD. After oral intake of LCM, it peaks in 1-4 h and has a 13 h elimination half-life. A recent study showed that severe renal impairment reduces total body clearance of LCM from 30% to 11% and that a 4 h HD session clears 50% of LCM. In our patient LCM intoxication may have induced cardiac dysfunction by its direct action on cardiac sodium channels, as a result, reduced cardiac output, leads to hypotension and ATN. Thus, patients initiated on LCM therapy should be alerted of the potential complication of AKI as a result of intoxication with LCM. The case also underscores how the clinical course of AKI after LCM intoxication and its management is still unclear and warrants further research.

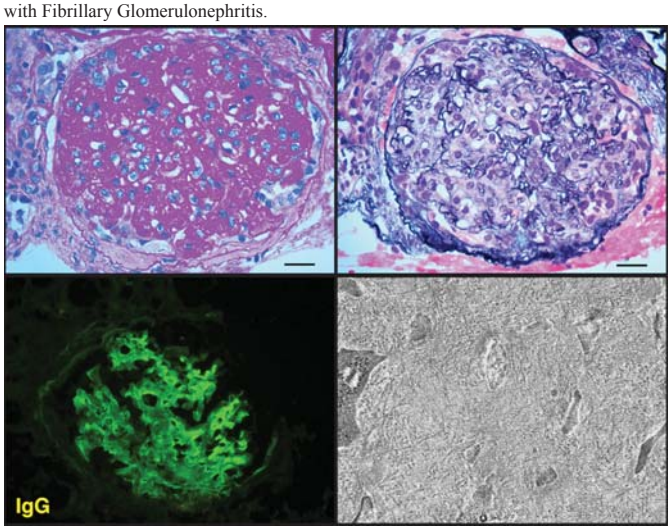
PUB438

An Unusual Renal Biopsy Finding in a Patient with Type 2 Diabetes Mellitus

Kerri A. McGreal, Elizabeth W. Dehmer, Timothy A. Fields. *Nephrology, Univ of Kansas Medical Center, Kansas City, KS.*

Introduction: Diabetes is the most common cause of ESRD in the United States, and many nephrology referrals are for patients who, without biopsy, are presumed to have diabetic nephropathy (DN). However, case series in the literature indicate that a significant number of diabetic patients who undergo renal biopsy have disease other than or in addition to DN. We present a case that highlights clinical features in diabetics that should prompt renal biopsy.

Case Description: A 55 year-old morbidly obese male with well controlled hypertension, type 2 diabetes mellitus of <10 years duration without retinopathy, and baseline CKD 3 was referred to nephrology clinic for worsening renal function. His renal function had been stable with a serum creatinine (SCr) of 1.9 g/dl that had worsened to 2.7 over the course of 4 months with an increase in urine protein/creatinine ratio (UP/C) from 1.8 to 4. Urinalysis showed 3+ protein without blood; urine microscopy was unremarkable. Serologic work up for glomerular disease was negative. Six months later his SCr was shown to be 3.67 with a UP/C of 8. Renal biopsy was performed, which revealed IgG-containing, non-congophilic, fibrillar deposits (15-25 nm in diameter) in mesangial areas, consistent with Fibrillary Glomerulonephritis.



Discussion: DN is an unfortunately common complication of type 2 diabetes. The prevalence of non-diabetic renal disease in diabetics is difficult to assess, since most patients with presumed DN are not biopsied. Clinical features in diabetics that should prompt renal biopsy to rule out non-diabetic disease include shorter duration of diabetes, absence of retinopathy, microscopic hematuria, abrupt onset of proteinuria, and active urine sediment. This case, with rapid progression of renal insufficiency and proteinuria, illustrates the utility of applying these criteria for selecting diabetic patients for biopsy.

PUB439

A Case of Plavix Induced Thrombotic Thrombocytopenic Purpura (TTP)

Aedan Olaso,[1] Anshul Kumar,[1] Vibha Agrawal,[2] Nelson P. Kopyt.[1] *[1]Medicine, Lehigh Valley Hospital, Allentown, PA; [2]Medicine, Metropolitan Hospital, New York, NY.*

Introduction: Ticlopidine has been associated with the development of TTP, estimated incidence 1: 1600 to 5000. Clopidogrel widely replaced it due to more favorable safety profile. Approved by FDA in early 1998, > 3 million people received the drug with few reported cases of induced TTP.

Case Description: Case: 82 year old male with CAD s/p CABG, Type 2 DM, HBP, CKD, baseline creatinine (Cr) of 1 presents to ER with SOB and CP. The diagnosis was

NSTEMI, treated (Tx) with ASA, atorvastatin, and Plavix 300mg load followed by 75mg daily. On day 7, hemoglobin dropped to 8.0, platelet (Plt) to 69 from 280 thou/mm^3 and Cr to 2.0 mg/dl. He became confused and required intubation. LDH was 521 U/l with haptoglobin level 126. HIT panel was negative. Peripheral smear demonstrated > 50% schistiocytes. Thinking of Plavix induced TTP, Plavix was substituted with Ticagrelor. ADAMTS13 was sent and daily plasmapheresis (Plex) initiated with cryo poor FFP. After 5th session Plt counts were 150 thou/mm3, Cr stabilized between 1.2 – 1.3 mg/dl and LDH improved to 188. With this improvement sessions were decreased to alternate day Tx. ADAMTS13 returned normal at 52%. Plex was then tapered to twice weekly for 1 week and then stopped. Plt counts stabilized at 190-220 thou/mm^3 and Cr improved to 1.0mg/dl. He was still intubated more alert and responding by head nodding.

Discussion: TTP is a life-threatening multisystem disease. Drugs associated are Quinine, Mitomycin C, Gemcitabine, Cisplatin, Tamoxifen, Bleomycin, Cytosine, Arabinoside, Daunomycin, Cyclosporine A, OCP, Penicillin, Rifampin and Ticlopidine. Historically, TTP in patients receiving clopidogrel have some interesting features. Firstly, TTP usually occurs within 2 weeks after the initiation of treatment. Secondly they require more plasmapheresis, sometimes >30, and have frequent relapses. Our patient was interesting as improvement was noted after 5th treatment and did not have any relapse, perhaps related to rapidity of diagnosis and onset of treatment. Early consideration of TTP with this presentation among patients receiving clopidogrel may impact outcomes.

PUB440

Hypertensive Emergency after AV Fistula Balloon Angioplasty in a Patient with Non-Obstructive Hypertrophic Cardiomyopathy Jose F. Lizcano Perez,[1] Ammar Almakkee,[1] Craig S. Courville,[2] Alfredo M. Peguero.[2] *[1]Nephrology, Univ of South Florida, FL; [2]JAHVA Medical Center, Tampa, FL.*

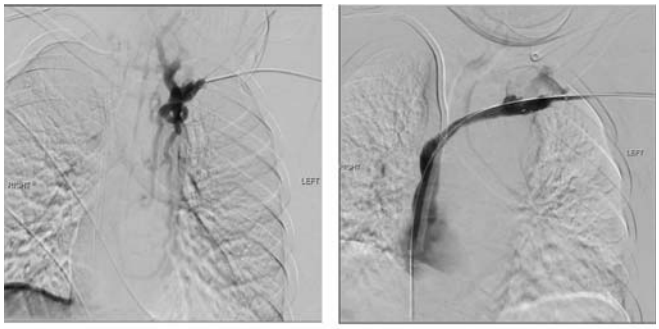
Introduction: 69 year-old patient with ESRD secondary to hypertensive nephrosclerosis and non-obstructive hypertrophic cardiomyopathy without valvulopathy and preserved LV function by echocardiography underwent balloon angioplasty of subclavian vein for stenosis. Followed successful intervention patient experienced severe pulmonary edema in association with arterial hypertension without evidence of cardiac arrhythmias or acute coronary event. On clinical examination he was found to be in acute respiratory distress with hypoxemia requiring supplemental oxygen by non-rebreather mask with FiO2 100%. BP 210/96, HR 112 (sinus tachycardia), and bibasilar wheezes with crackles on auscultation but no significant peripheral edema or any other clinical evidence of volume overload. Post procedure CXR significant for pulmonary edema. Patient's hypertensive emergency was treated medically with appropriate BP response and improvement of symptoms prior to initiation of dialysis. Patients with HCM usually have normal to supra-normal LV systolic function; however, they can experience diastolic dysfunction due to decreased ventricular compliance and impaired relaxation. Impaired relaxation in HCM results in a reduced rate and volume of filling during the rapid filling period of diastole, with a resultant compensatory increase in atrial systolic filling. Late in the evolution of diastolic dysfunction, a restrictive type of diastolic filling defect may become evident in which a high atrial pressure results in an increased rate and volume of filling during the rapid filling period with reduced filling during atrial systole. Our case illustrates the pathophysiological changes experienced by a patient with HCM having pulmonary edema secondary to hemodynamic changes post angioplasty which leads to rapid increased flow and venous return to the right heart in someone with decreased ventricular compliance and impaired relaxation who cannot maintain an adequate stroke volume despite having a good LV systolic function in the face of increased sympathetic response leading to an increase in afterload.

PUB441

Recannulation of Central Vein Stenosis—Maintain Lifeline Patent Jie Cui,[1,2] Zubin Irani.[2] *[1]Nephrology Dept, Massachusetts General Hospital, Boston, MA; [2]Interventional Radiology Dept, Massachusetts General Hospital, Boston, MA.*

Introduction: Central vein stenosis (CVS) is one of the most common complications for dialysis access. Failure to recannulate central veins is detrimental, and usually leads to loss of dialysis access in upper extremities. Successfully recannulate stenotic lesions can not only save patient's upper extremity for future access creations but sometimes can also salvage nonfunctional arteriovenous fistula (AVF).

Case Description: A 44-year-old women with a history of SLE induced end-stage renal disease (ESRD) was initiated on dialysis therapy 12 years ago. She was initially received peritoneal dialysis, which was failed due to frequent peritonitis. In 02/2013, hemodialysis was initiated via right tunneled internal jugular dialysis catheter and right brachiocephalic AVF was created in the meantime. One month later, fistulogram showed occluded right cephalic vein, which failed angioplasty. She then had a left brachiobasilic AVF creation in 04/2013. However, the left side fistula failed to mature, and patient remained catheter dependent. In 08/2013, patient developed facial swelling and was diagnosed with superior vena cava syndrome. Fistulogram showed occluded bilateral brachiocephalic veins, and left brachiocephalic vein was successfully recannulated. A drug-eluting stent was placed in the left brachiocephalic vein.



IA IB

Patient's left AVF was matured in 02/2014. Patient received hemodialysis through left AVF since then and fistulogram in 04/2014 showed widely patent AVF.

Discussion: Bilateral CVS is detrimental for ESRD patient, which leads to no access options in upper extremities. Great attention and best effort should be given to treat CVS. Successful recannulation of CVS can salvage dysfunctional AVF. Dialysis access strategy should be carefully planned prior to dialysis initiation, and catheter should be avoided if possible.

PUB442

Use of High-Flux Hemodialysis for Vancomycin-Induced Acute Kidney Injury (AKI): A Case Report Snigdha Reddy, Jerry Yee, Vivek Soi. *Div of Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Introduction: Vancomycin is commonly selected as therapy for presumed serious bacterial infections. Serum trough concentrations of 15–20 mcg/mL are recommended for treatment of pneumonia in adults. Vancomycin-associated nephrotoxicity (VAN) has occurred, despite adherence to these recommended levels. A standardized outpatient vancomycin dosing protocol may not apply to all patients. There is paucity of literature on the use of hemodialysis (HD) to treat VAN. We report a case of a patient treated by high-flux HD for VAN to prevent multiorgan failure.

Case Description: A 45 y.o. male with untreated AIDS and esophageal candidiasis was discharged on a 3-week course of vancomycin and ertapenem for necrotizing pneumonia. His outpatient vancomycin trough level was 141.6 mcg/mL and further evaluation revealed oliguric AKI with a SCr level of 5.71 mg/dL (repeat 154.9 mcg/mL) and eosinophilia 11%. Urinalysis revealed trace protein, and the sediment exam revealed 0–2 granular casts/LPF. Labs pre-discharge showed a SCr 0.54 mg/dL and vancomycin trough level of 18.9 mcg/mL. To avoid extrarenal toxicities (ototoxicity, agranulocytosis, etc) that may occur with high levels, hemodialysis (HD) was initiated for vancomycin clearance. An initial 5-h treatment was conducted with a 1.6 m^2, high-flux membrane and followed by 2 additional HD treatments using a 2.5 m^2, high-flux membrane (Rexeed 25S) to mitigate vancomycin "rebound". Notably, 71% of vancomycin was removed in 36 h, without any adverse effects. HD was discontinued when the vancomycin level was <50 mcg/mL and urine output exceeded 1 L/24-h. After conclusion of 3 HD sessions, the SCr was 1.29 mg/dL on hospital day 10. A kidney biopsy performed on the fourth hospital day demonstrated acute tubular necrosis and severe allergic interstitial nephritis. At follow-up, 4 months post-discharge, the SCr was 0.8 mg/dL.

Discussion: Frequent monitoring of vancomycin trough levels is recommended in patients treated with long-term regimens. Serial, high-flux HD should be considered in patients who are at risk for potentially irreversible vancomycin toxicity.

PUB443

Intraoperative Extracorporeal Membrane Oxygenation Rescue for Pulmonary Hemorrhage during Orthotopic Liver Transplantation Muhammad R. Syed, Gary S. Xiao, Stephen Guy, Talal A. Khan, Purna Bindu Nandigam, Dhaval Sureja, Shabnum Haleem, Amit A. Deshpande, Disha Narula, Karthik M. Ranganna, Gregory Malat, PharmD, Alden Michael Doyle. *Div of Nephrology, Drexel Univ College of Medicine, Philadelphia, PA.*

Introduction: Herein we report the first case of the use of intraoperative extracorporeal membrane oxygenation (ECMO) for a transplantation procedure. Data from the international extracorporeal life support organization (ELSO) reports nearly 51,000 patients have received extracorporeal life support (ECLS) through July 2012. Of these, 50% (>25,000) were for neonatal respiratory failure. Previously stable at about 100 cases a year for a decade, adult respiratory failure ECLS cases saw a dramatic increase in 2009 with the H1N1 influenza pandemic.

Case Description: A 54 year old white female with alcoholic cirrhosis underwent an orthotopic liver transplant procedure at our facility. Soon after the liver was reperfused, profuse bleeding started through the endotracheal tube. Despite multiple blood product transfusions and an intraoperative bronchoscopy, the bleeding continued. Blood gases revealed a PO2 of 48 mmHg and a PCO2 of 180 mmHg. The transplantation procedure could not proceed further so a quick decision was made in the OR to initiate high flow ECMO through the existing venovenous bypass circuit to reverse the severe hypoxemia. After initiating ECMO, the congestion around the liver reduced enough to allow for the biliary system anastomosis. Patient remained on ECMO for 7 days post-op until the pulmonary

hemorrhage was controlled with embolization of the bronchial arteries. Our patient made a remarkable recovery and is now doing well at home with excellent allograft function.

Discussion: Our case demonstrates that ECMO can be successfully employed emergently during a complicated transplantation procedure to overcome acute respiratory failure, especially when an existing venovenous bypass circuit is in place.

PUB444

Myositis Ossificans – A Case Report Bo Broberg,[1] Ewa Lewin,[1] James G. Heaf,[1] Henrik Groenborg,[2] Henrik Post Hansen.[1] *[1]Dept of Nephrology, Copenhagen Univ Hospital at Herlev, Copenhagen, Denmark; [2]Dept of Orthopedic Surgery, Univ Hospital Copenhagen at Herlev, Copenhagen, Denmark.*

Introduction: Extraskeletal calcifications (EC) are common manifestations of Chronic Kidney Disease - Mineral and Bone Disorder (CKD-MBD) in patients with advanced CKD. Myositis Ossificans is a rare example of EC with severe calcification related to muscle tissue, often due to trauma or surgery. The condition is often related to a high calcium-phosphate product.

Case Description: We present a 67-year old woman with ESRD, who had been on peritoneal dialysis for 6 years. She previously had severe hyperparathyroidism (HPT), treated with parathyroidectomy and later had a second relapse treated with alfacalcidol, calcium carbonate, and cinacalcet. Due to Budd-Chiari Syndrome the patient was treated with Warfarin. The patient had undergone a total hip arthroplasty in 2009. Over several months from 2012 she developed progressive, invalidating pain at the right gluteal region. Clinical examination and X-ray revealed a large solid tumor mass (20x15 cm) at the right gluteal region and the diagnosis of Myositis Ossificans was made. This was confirmed by MR/PET-CT and DEXA scan. A biopsy showed changes compatible with chondrocalcinosis and no signs of malignancy. Due to a high risk of recurrence of the tumor mass, surgical removal was not chosen. The patient was subjected to intensive treatment, focusing upon reducing the calcium and phosphate product. Alfacalcidol and calcium carbonate was discontinued and the patient was switched to intensive HD (4 hours 5 times per week), using ultralow calcium (Ca^{++} 1.00 mM) and low bicarbonate dialysate (25 mM). Treatment with cinacalcet was intensified. Initially an increase in blood levels of calcium and phosphate was observed and interpreted as a sign of mobilization from the tumor mass. The symptoms gradually diminished and clinical examination and radiographic investigation 3 months later showed significant reduction of the tumor mass.

Discussion: The present case demonstrates an impressive and rapid reversal of large extraskeletal calcification, induced by intensive treatment of CKD-MBD.

PUB445

A Rare Case of Hyperkalemia in a Patient with ESRD Amir Abdi Pour. *Internal Medicine/Nephrology, Loma Linda Univ Medical Center, Loma Linda, CA.*

Introduction: Hyperkalemia is common in ESRD patients it could be be fatal. It should not be observed in adequately dialyzed patients, especially post dialysis. We report a case of hyperkalemia in a patient with ESRD undergoing kidney transplant.

Case Description: A 55 year old female with ESRD due to hypertension was called in for deceased donor kidney transplant. She was dialyzed adequately prior to admission. Her exam was unremarkable. She was not on a beta blocker or NSAIDs. She was anuric. Her serum potassium (K) was 4.4 mg/dl on admission, which was drawn 6 hours after dialysis. An hour after induction of anesthesia with Recuronium, Propofol, versed, and fentanyl while on Sevoflurane for maintenance, the anesthesiologist noted a serum K of 6.7 mg/dl and pH of 7.53 on ABG. Stat basic metabolic panel showed blood sugar of 124 mg/dl and K of 6.8 mg/dl. She did not have any electrocardiogram changes. She was given calcium gluconate, insulin, and glucose. Her serum K gradually decreased to 4.4 mg/dl post surgery. She remained anuric during the operation. She was oliguric over the next day and was taken back to the operating room for exploration of possible arterial kinking. Her serum K was 4.5 mg/dl prior to the second operation. She was exposed to same anesthesia medications except that cisatracurium was used this time. Immediate post operative serum K was 6.4 mg/dl.No labs were drawn during the second operation. She was dialyzed for 2 hours. Her serum K postdialysis was 3.7 mg/dl.

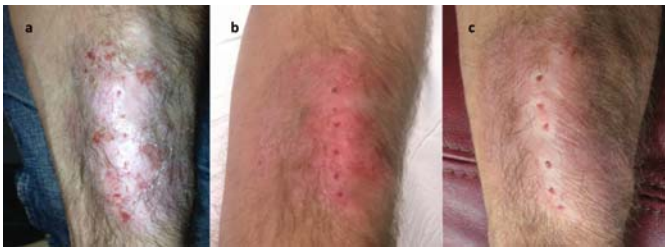
Discussion: Sevoflurane is a nonflammable volatile liquid and is administered via inhalation of the vaporized liquid. Sevoflurane is defluorinated via cytochrome p450 (CYP) 2E1 resulting in the production of hexafluoroisopropanol (HFIP) with release of inorganic fluoride (F) and carbon dioxide (1). Studies have shown that F^- increases intracellular Ca^{2+}, which is thought to trigger Ca^{2+}-dependent K^+ channels and produce a K^+ efflux. (2) We believe hyperkalemia was due to K shift form being exposed to sevoflurane. To the best of our knowledge, this has not been reported in the literature. References 1. medicines.org.uk 2. Fluoride-induced hyperkalemia: The role of Ca^{2+}-dependent K^+ channels Charles C. Cummings, MD, Michael E. McIvor, MD AJEM, January 1988.

PUB446

Dogs Are Not Always Our Best Friend Karlien Francois, Christopher T. Chan. *Div of Nephrology, Univ Health Network Toronto General Hospital, Toronto, ON, Canada.*

Introduction: We present a case of Staphylococcus pseudintermedius bacteremia highlighting the unique interaction of risk factors between environment and host in home hemodialysis.

Case Description: Mr. ME is a 49-year-old man with IgA nephropathy undergoing home nocturnal hemodialysis (HHD). During a regular clinic visit, we diagnosed severe allergic contact dermatitis at the level of his left radial cephalic arteriovenous fistula (AVF) [figure a]. We suspected chlorhexidine to be the allergen. Cleansing regimen was changed to water and soap wash and saline. Three months later, the skin lesions improved although dermatitis persisted [figure b]. A trial of topical 0.5% hydrocortisone cream was used and IV3000 dressing was switched to silk tape. Given the suspicion of skin superinfection, blood culture (BC) was drawn from the AVF site. One day later (D1), the gram stain of the BC showed gram positive cocci in clusters and BC from AVF site as well as from the other arm were repeated. Antibiotics were deferred given the patient was asymptomatic. On D4, both BC drawn from the AVF arm but not the peripheral grew coagulase-negative staphylococci and oral cefazolin was initiated. On D6, the results of both positive BC were corrected to Staphylococcus pseudintermedius. S. pseudintermedius isolates are not reliably susceptible to beta-lactam antibiotics. Intravenous Vancomycin was prescribed for a total of 5 doses. A favourable evolution of the skin lesions was noted when ending the Vancomycin treatment [figure c].



Discussion: Human colonization and bacteremia with S. pseudintermedius, a coagulase-positive staphylococcus occurring in domestic animals, is rare and has never been reported in patients treated with dialysis. Contact with dogs in the setting of an inflamed vascular access site resulted in the infection in our case. HHD programs need to have a continuous awareness for vascular access care and the interaction with environmental risks.

PUB447

Differentiating Cerebral Salt Wasting (CSW) from SIADH in Critically Ill Patients Muzzaffar Hussain, Jiuming Ye, Gregory Lee Braden, Benjamin J. Freda, Michael H. O'Shea, Jay Steingurb. *Dept of Medicine, Baystate Medical Center, Springfield, MA.*

Introduction: Differentiation of CSW from SIADH can be difficult and proper assessment of extracellular fluid volume (ECFV) status is key in differentiation. We studied a case of CSW characterized by continued elevation of Nt-proBNP levels and increased fractional excretion of urate(FEUrate) after correction of hyponatremia which differentiated CSW from SIADH.

Case Description: A 57 year old woman presented to the ICU with intractable seizures and respiratory failure. Brain MRI showed hyper-intensity lesions. Brain biopsy revealed lymphoma. She received intravenous dexamethasone and radiation therapy. 3 weeks later, she developed increased urine output > 3 liters/day. She was clinically volume depleted, marked by hypotension(SBP 88mmHg), tachycardia(HR 108),low CVP(<4mmHg). She had a serum sodium of 126 mEq/L, uric acid 1.3 mg/dL, a urine sodium of 190 mEq/L and urine osmolality of 508 mOsm/kg water. FEUrate was 33% (normal <12%); Nt Pro-BNP was 3618 pg/ml. Kidney, thyroid and endocrine tests were normal; echocardiogram was normal. The constellation of hypovolemia, marked natriuresis, hyponatremia and hypouricemia in the setting of cerebral lesions suggested CSW. With isotonic saline serum sodium increased to 133 mEq/L; urine osmolality was 120 mOsm/Kg water and urine sodium of 90 mEq/L. Though the serum sodium normalized at 72 hours, Nt-proBNP remained markedly elevated(6856pg/ml) and the patient continued to have significant renal salt wasting, low serum uric acid levels and increased FEUrate (29%). Serum ADH was undetectable at the time of diagnosis and at 72 hours. 1 week later, serum sodium remained normal but Nt-ProBNP and FEUrate were still significantly elevated.

Discussion: CSW can be differentiated from SIADH in critically ill patients by carefully assessing intravascular volume status and by monitoring for persistently high FEUrate and elevated levels of Nt-ProBNP after normalization of hyponatremia.

PUB448

A Unique Case of Falciparum Malaria-Induced Glomerulopathy Sumedha Dhar, Yashpal S. Kanwar, Eudora Eng. *Nephrology, Feinberg school of Medicine, Northwestern Univ, Chicago, IL.*

Introduction: Acute kidney injury in the setting of falciparum malaria occurs in 15-48% of non-immune cases with renal biopsy demonstrating acute tubular necrosis (ATN), tubulointerstitial nephritis and glomerular changes with mesangial proliferation and immune complex deposition. Falciparum-induced glomerulonephritis mainly occurs in children with autopsy studies reporting a rate of 18%. Falciparum glomerulopathy is usually mild (< 1 gm of proteinuria) and rarely causes nephrotic syndrome. The highest reported proteinuria is 15 gm in a single case study from 1967. We present an unusual case of falciparum-induced glomerulopathy with persistent nephrotic range proteinuria despite infection eradication.

After returning from Nigeria without antimalarial prophylaxis, a 29-year old African-American female presented with altered mental status, fever, and oliguria. Her serum creatinine was 1.2 mg/dl with urine granular casts and a spot urine protein: creatinine ratio of 83.5 gm. After prompt treatment with artesunate, parasitemia rappidly dropped from 20% to undetectable. Renal replacement therapy was initiated on day 1 for oliguric renal failure and she remained dialysis-dependent for a month. Following discontinuation of dialysis, her serum creatinine stabilized at 2.5 mg/dl with proteinuria of 25 gm. Renal biopsy was performed for the persistent proteinuria despite complete eradication of malaria

parasitemia, showed chronic tubulointerstitial disease, ATN, glomerular proliferation with thickening and splitting of the glomerular basement membrane and immunofluorescence with Ig M and C3 deposition. Even on angiotensin converting enzyme inhibition (ACE-I), she continues to have 7.2 gm proteinuria.

Discussion: Falciparum malaria-induced nephropathy has been shown to be reversible by 2-6 weeks after infection eradication with few case reports documenting persistent mild proteinuria. We add to the scant body of literature a case illustrating persistence of high grade proteinuria despite early, effective treatment and ACE-I. Our case highlights the importance of malaria prophylaxis when travelling to malaria-infested areas, especially in non-immune populations.

PUB449

A Case of Immune Complex-Mediated Necrotizing Glomerulonephritis due to Bartonella Infection Shan Shan Chen,[1] Ameet T. Karambelkar,[1] Sheldon Bastacky,[2] Roderick J. Tan.[1] *[1]Renal-Electrolyte Div, UPMC, Pittsburgh, PA; [2]Pathology, UPMC, Pittsburgh, PA.*

Introduction: Treatment of glomerulonephritis (GN) is challenging if the underlying etiology is unclear. Here we report a rare case of culture-negative, transesophageal echocardiogram (TEE)-negative Bartonella henselae infective endocarditis (IE) causing acute kidney injury (AKI) due to an immune complex-mediated necrotizing GN.

Case Description: A 20 year old caucasian male presented with weight loss for 2 months and was found to have AKI. Past medical history was significant for congenital heart disease with aortic and pulmonic valve replacements. He studied as a veterinary student. Physical examination was significant for a temperature of 38.4° C and a systolic murmur at the left upper sternal border. Serum creatinine was 3.1 mg/dl compared to a baseline of 1.1 mg/dl. Urinalysis showed microscopic hematuria with dysmorphic RBCs and mild proteinuria (870mg/gm creatinine). C3 and C4 were decreased at 77 and 12 mg/dl, respectively. Extensive serologic, hematologic and infectious work-up including blood cultures, TEE and white blood cell scan was negative. Renal biopsy showed a necrotizing and crescentic GN with mesangial and focal subendothelial immune complex-type deposits with immunofluorescence studies positive for IgM, IgA, fibrinogen and C3. As the patient continued to have deteriorating renal and cardiac function, cardiac catheterization with intracardiac echocardiography was performed and revealed vegetations on the pulmonic valve. This was treated with valve replacement and pathology revealed Bartonella infection. After antimicrobial treatment, the patient's creatinine improved to 1.4 mg/dl.

Discussion: GN associated with Bartonella IE is a rare condition and it can manifest as an immune complex-mediated necrotizing GN and rarely as an ANCA-positive pauci-immune necrotizing GN. As it is usually culture-negative, diagnosis is often delayed and in this case required invasive testing for definitive diagnosis. It should be considered in patients with risk factors in which the initial work-up for infection is unrevealing. A high index of suspicion is needed, as misdiagnosis may lead to suboptimal or inappropriate treatment.

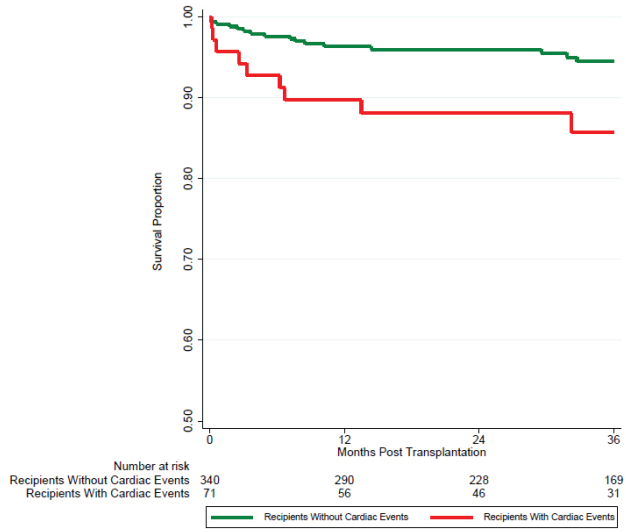
PUB450

Circulating Levels of Troponin of 0.5 ng/mL in the Immediate Post Transplantation Period: A Prognostic Biomarker of Mortality in the First 36 Months of Kidney Transplantation Guan Hua Xu, Darshana Dadhania, Thangamani Muthukumar, Manikkam Suthanthiran, John R. Lee. *Medicine, Weill Cornell Medical College, New York, NY.*

Introduction: Cardiovascular events are the leading cause of death in the first year of kidney transplantation. Early predictors for cardiac events as well as their outcomes on mortality have not been fully characterized.

Case Description: We performed a retrospective chart review of 411 renal allograft recipients who received their allografts from 2005 to 2010 at our center and who had a troponin evaluated within the first month of transplantation. We collected demographical characteristics and pre-transplant cardiac stress test evaluations and evaluated whether they were associated with development of cardiac events defined as a post-transplant circulating troponin level greater than 0.5 ng/mL. We also evaluated whether the cardiac events were associated with death using Kaplan Meier survival analysis.

71 of the 411 renal allograft recipients had a cardiac event (troponin greater than 0.5 ng/mL) within the first month of transplantation. Recipients with a cardiac event were more likely to be diabetic (55% versus 43%, P=0.09, Fisher's exact test) and older (61.5±11.3 versus 58.2±11.3, P=0.02, two sample t test). The most common cardiac stress test utilized among the recipients who developed a cardiac event was a nuclear perfusion test. 53% of the nuclear perfusion tests had no perfusion defects prior to the cardiac event. Recipients with a cardiac event during the first month of transplantation had inferior survival than those without a cardiac event (P=0.01, log rank test).



Discussion: Better pre-transplant screening tests are needed to identify recipients at risk for critical post-transplant cardiac events. Moreover, circulating troponin level of 0.5 may serve as a prognostic biomarker of mortality in the first 36 months following kidney transplantation.

PUB451

Renal Failure as an Isolated Presentation of Sarcoidosis Bhupesh Khadka, Thomas M. Kaneko, Clay A. Block. *Nephrology, Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Sarcoidosis is a multisystem disorder characterized by formation of non-caseating granulomas in organs, most commonly in lungs, but may also involve other organs including eyes, lymph nodes and kidneys. Renal failure as an isolated manifestation of sarcoidosis is uncommon. Here we present one such case.

Case Description: A 65 year old white male with no medical history who started having progressive dry mouth, anorexia, listlessness, insomnia and weight loss of 25 pounds over the last 4 months was referred to renal clinic. He had creatinine of 1.64 mg/dl and calcium of 9 mg/dl. His chest x-ray, serum/urine protein electrophoresis and renal ultrasound were normal. A week later his creatinine was down to 1.38 mg/dl. Proteinuria was absent and urine sediment bland. Anti-nuclear antibody and anti-ssA/ssB antibody were negative. After 10 weeks at scheduled follow up visit, creatinine had risen to 2.7 mg/dl and calcium to 15 mg/dl. He was hospitalized and treated with intravenous normal saline, calcitonin and a dose of zoledronic acid. Computed Tomography scan of the chest/abdomen/pelvis showed bilateral <5 mm solitary pulmonary nodules without lymphadenopathy and bilateral enlarged pelvic lymph nodes. Biopsy of a pelvic node revealed non-caseating granulomas. He had elevated angiotensin converting enzyme level and dihydroxy vitamin D. He was started on prednisone with slow taper. His symptoms resolved, calcium level normalized and renal function improved to normal.

Discussion: Renal involvement in patients with sarcoidosis is uncertain but may occur in up to 35-50% based on several small series, but renal failure as isolated presentation of sarcoidosis is very rare. Also, hypercalcemia may be present only in about 20% of these cases. Delay in diagnosis and treatment of renal sarcoidosis may lead to chronic calcium deposition and ESRD in some cases. We should consider sarcoidosis in the differential diagnosis of unexplained renal failure and be aware that calcium level may be normal in such patients.

PUB452

Case Report: An Unusual Cause of Hematuria in Lupus Patient Jonatas Dantas, Alcino Pires Gama, Cristiane B. Dias, Luis Yu, Lectícia Jorge, Viktoria Woronik. *Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Introduction: Lupus nephritis (LN) is the major cause of kidney injury in SLE patients and it demands prompt recognition and treatment. However, physicians must be prepared to recognize other causes of hematuria to avoid unnecessary immunosuppression (IS).

Case Description: A 43-year-old woman was referred to nephrologist due to "refractory hematuria". Six years ago received diagnoses of SLE and APS (with multiple episodes of venous thrombosis). IS and anticoagulation (AC) were started. Two years later, her rheumatologist diagnosed proliferative LN (based on increase serum creatinine plus hematuria and hypocomplementemia) and started prednisone plus mycophenolate mofetil. Kidney biopsy was not performed due to AC. After 6 months, both serum creatinine and complement levels normalized but hematuria persisted (despite INR levels always on therapeutic range). IS was not stopped nor reduced. Before nephrology consultation, she was previously investigated by an urologist, who performed an urinary tract ultrasound and cystoscopy (both unremarkable for hematuria causes). At presentation, except for persistent hematuria, there was no feature of lupus activity and the INR was on normal

range. Since the isolated hematuria did not seem to be due to glomerular or urologic disorders, we performed a Computed Angiotomography, then we identified the cause of persistent hematuria. The patient has an atrophic right kidney(probably secondary to renal artery thrombosis) and a vicarious left kidney into a venous hypertension regimen (due to multiple chronic thrombosis sites). Her left gonadal vein was remarkably thickened and in intimate contact with collecting system.

Discussion: Physicians who treat LN must be prepared to recognize other causes of hematuria and avoid unnecessary IS. Vascular disorders must always be remembered as a cause of isolated hematuria.

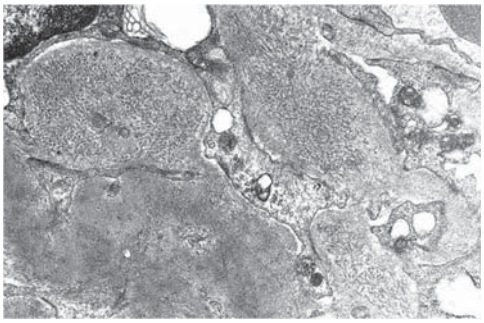
PUB453

Fibrillary Glomerulonephritis in a Morbidy Obese Patient Presenting with Nephrotic Range Proteinuria and Elevated Creatinine Gaurang P. Mavani, Jordan L. Rosenstock. *Div of Nephrology, Lenox Hill Hospital, New York, NY.*

Introduction: 43 year old morbidly obese white male presented with elevated serum creatinine and proteinuria. Kidney biopsy revealed fibrillary glomerulonephritis. This case supports the recommendation that kidney biopsy should be considered in morbidly obese patients presenting with nephrotic range proteinuria.

Case Description: 43 year old male with past history significant for morbid obesity, hypertension and hypothyroidism was referred to a nephrologist for CKD. Creatinine was 1.5 mg/dl in 2012 associated with proteinuria. In October 2013 creatinine increased to 1.95 mg/dl associated with persistent proteinuria. Home medications include amlodipine, synthyroid and simvastatin. Physical examination revealed morbid obesity with BMI 42, blood pressure 150/100 mmHg; pulse 70/min. Examination did not reveal edema. Hb 12.7 g/dL, BUN 27 mg/dL, creatinine 2.27 mg/dL, eGFR 34. Urine analysis revealed 4+ proteinuria, RBC 4-10. 24 hour urinary protein excretion was 8902 mg. Sonogram of the kidneys revealed normal size. Serum immunofixation and hepatitis panel was negative. CT guided kidney biopsy revealed mesangial proliferative and sclerosing glomerulonephritis with segmental membranoproliferative features. Electron microscopy revealed fibrillary glomerulonephritis.



He was started on losartan and is scheduled for follow up visit and may be treated with rituximab for his disease.

Discussion: This case is an example of an unexpected diagnosis in a patient whose kidney disorder was thought to be related to his morbid obesity. Kidney biopsy should be considered in morbidly obese patients who have features atypical for obesity related secondary FSGS such as high grade proteinuria.

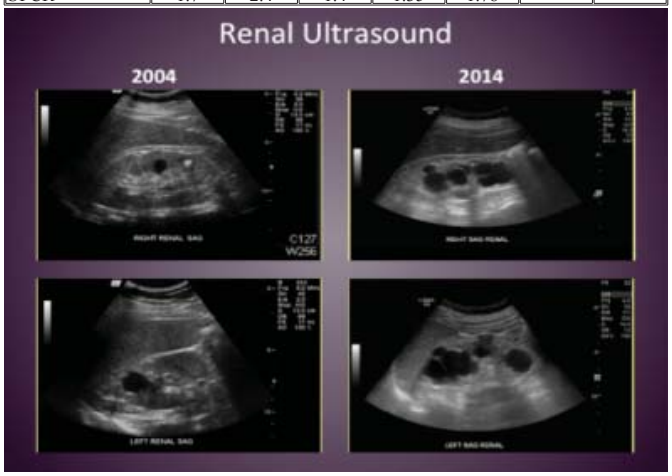
PUB454

Natural History of Renal Involvement of Fabry Disease in a Female Carrier Basma Omar Merhi, Reginald Y. Gohh. *Medicine, Brown Univ, Providence, RI.*

Introduction: Fabry disease(FD) is an X-linked genetic disease caused by mutation in GLA gene resulting in α-galactosidase A (GalA) deficiency, characterized by globotriaosylceramide accumulation in vessel walls and cortical and parapelvic renal cysts, progressing to end-stage renal disease(ESRD) in males and some females. We report a case of FD in a female carrier where normal GalA resulted in misdiagnosis and progression to ESRD.

Case Description: Case presentation: A 41-year old female presented in 1997 for 3-year history of subnephrotic proteinuria and creatinine(Cr) 0.8mg/dl. She had a normal renal ultrasound(US), negative ANA, C3/C4, lupus anticoagulant and hepatitis serologies. In 2000, ophthalmologic evaluation revealed corneal whorl-like opacities suspicious for FD, but normal GalA. She declined kidney biopsy and managed with lisinopril. In 2004, follow-up US showed thin lobulated renal cortices with cysts and stable Cr. She developed stroke-like symptoms in 2007 and atrial fibrillation in 2009. 2010,routine labs revealed Cr up to 1.8mg/dl. She was lost to follow-up until 2013, when she was referred for Cr 4.5mg/dL (Table 1). US showed cortical thinning and cystic parenchymal replacement(figure 1). Symptoms and exam are notable for leg pain, anhidrosis and angiokerotomas. Genetic testing demonstrated heterozygous mutation of Y207X variant of GLA gene, confirming FD. She got referred for enzyme replacement therapy (ERT).

Year	2000	2003	2007	2009	2010	2013	2014
Creatinine	0.9	1.2	1.2	1.79	1.83	4.5	5.36
UPCR	1.7	2.4	1.4	1.35	1.78		



Discussion: Unlike in males, α-GalA activity is not a reliable marker of FD in carrier females. Genetic testing represents a more reliable diagnostic assay. Despite having normal α-GalA level, the renal involvement in females can be as severe as in males progressing to ESRD. Early diagnosis and ERT may alter the natural history of kidney disease in affected patients.

PUB455

Case Report of a Patient with Crescentic Necrotizing Lupus Nephritis (LN) with Positive Anti-Neutrophil Cytoplasmic Antibody (ANCA) and False Positive Human Immunodeficiency Virus (HIV) Test Maybel M. Tan, Aiyu Zhao, Suchita J. Mehta, Mary C. Mallappallil, Moro O. Salifu. *Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction: Patients with systemic lupus erythematosus (SLE) may present with a variety of autoantibodies and some false positive results such as HIV. In addition, ANCA have also been detected in the serum of some patients with LN. We present an unusual case with both HIV and ANCA positive in newly diagnosed SLE. Verification of HIV was negative by repeat western blot testing. Positive myeloperoxidase (MPO) and proteinase-3 (PR-3) verified to positive ANCA.

Case Description: 50 year-old-woman with history of chronic sinusitis, hypertension, pancytopenia presented with intractable nausea, vomiting and weakness for 6 weeks. Physical exam was significant for mild lower extremities edema. She was found to have acute kidney injury with peak serum creatinine of 6.7mg/dl, low serum albumin, nephrotic range proteinuria and microscopic hematuria with no cast. HIV ELISA test was positive, however which was negative with western blot testing. She was also noted positive antinuclear antibodies, ANCA, MPO, PR-3 and Anti-Smith. A kidney biopsy showed grade IV-G LN with necrotizing crescents. Hemodialysis was initiated because of worsening of kidney function. Her condition was noted to be progressive despite steroids, cyclophosphamide, IV gammaglobulin and she developed spontaneous pulmonary hemorrhage resulting in death after an attempt at bronchoscopic embolization.

Discussion: ANCA can be seen in 37.3% of LN, predominantly perinuclear pattern (p-ANCA). The titers of ANCA were more in LN as compared to SLE without nephritis. LN cases with crescents had higher titer p-ANCA positivity with corresponding anti-MPO antibodies. A common problem in SLE is that nearly all the patients are ANA positive by indirect immuno-fluoresce (IIF) and this might vitiate the IIF readings for ANCA, therefore the ELISA test is used to detect the presence of specific antibodies to individual

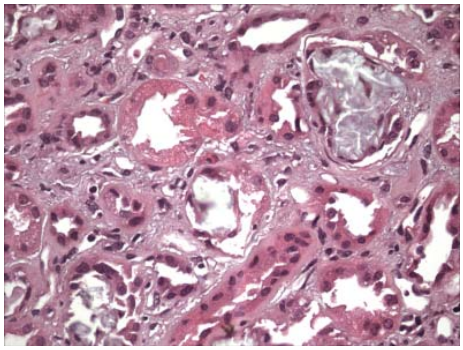
ANCA specificities. In this case HIV testing looking for antibodies to the p 24 gag protein of HIV-1 was a false positive due to the molecular mimicry to homologous host proteins.

PUB456

Acute Kidney Injury as a Complication of Total Gastrectomy: An Interesting Case of Oxalate Nephropathy Mamta Shah,[1] Rahul Mutneja,[1] Scott M. Benson.[2] *[1]Internal Medicine, Univ of Connecticut, Farmington, CT; [2]Nephrology, Hartford Hospital, Hartford, CT.*

Introduction: Roux-en-Y esophagojejunostomy is the preferred mode of reconstruction after total gastrectomy for gastric carcinoma. Oxalate nephropathy, although uncommon, has been seen as a complication of Roux-en-Y gastric bypass (RYGB). Prognosis is poor, and efforts towards prevention should be implemented early. In patients with acute renal functional deterioration and a history of RYGB, the differential diagnosis should include oxalate nephropathy, and renal biopsy should be considered.

Case Description: A 70 year-old male with newly diagnosed metastatic gastric adenocarcinoma underwent a total gastrectomy with Roux-en-Y esophagojejunostomy. Serum creatinine (Cr) at the time was at his baseline of 1.2 mg/dL. Four months later he was referred to nephrology for rapidly worsening renal function (Cr-4.8 mg/dL) with remarkable decline compared to 2 months prior (Cr-2.1 mg/dL). One month later he had kidney biopsy for worsening creatinine (Cr-8.1 mg/dL) and an otherwise negative work up. Biopsy revealed acute and chronic tubulointerstitial nephropathy with abundant calcium oxalate deposits consistent with oxalate nephropathy.



Hemodialysis was initiated.

Discussion: Oxalate nephropathy as a complication of RYGB procedure is thought likely from fat malabsorption with increased free fatty acid load in the intestine which binds calcium. This leads to increased free oxalate which is absorbed causing hyperoxaluria. Recurrent kidney stones and progressive medullary nephrocalcinosis lead to relatively rapid loss of kidney function, requiring dialysis or transplantation. Diagnosis is made by biopsy. It may be prevented by low-fat, low-oxalate diet along with calcium supplementation; but once the disease develops prognosis is rather poor with majority of patients eventually requiring permanent dialysis.

PUB457

Pericardial Effusion Contributing to Decrease Renal Function even without Tamponade Aiyu Zhao, Moro O. Salifu, Aung Kyaw S. Maung, Maybel M. Tan, Mary C. Mallappallil. *State Univ of New York at Downstate, Brooklyn, NY.*

Introduction: Pericardial effusion (PE) is usually not associated with hemodynamic compromise unless it leads to cardiac tamponade. Acute renal injury (AKI) resulting from PE is rare, with only six cases reported to date. We are reporting a patient with chronic kidney disease (CKD) who presented with AKI secondary to PE without cardiac tamponade and with improvement of kidney function after pericardial window placement.

Case Description: A 56 year woman with history of hypertension, diabetes, CKD 4 and hypothyroidism presented with shortness of breath (SOB) and bilateral leg swelling for 2 months. Physical exam was significant for mild lower extremities edema. There was no pericardial rub, pulsus paradoxus or jugular venous distension. Hemoglobin was 9 g/dl, serum creatinine was 4.5 mg/dL which was 2.2 mg/dl one year ago. Thyroid function tests were normal. Echocardiogram showed large PE with ejection fraction of 55%. Workup for AKI was unrevealing. Her symptoms were significantly improved after pericardial window with drainage of 1 liter serosanguineous fluid. Her Creatinine went down to 3.9 mg/dl. Patient refused initiation of dialysis. One week later, she presented again with SOB, repeat echocardiogram showed a moderate PE. This time, she refused further drainage. The amount of PE decreased with high dose diuretics; however, kidney function got worse and dialysis was initiated.

Discussion: Several mechanisms have been proposed to explain the pathophysiology of AKI caused by PE. Hemodynamic derangement lead to decreased renal blood flow and ultimately decreased GFR. PE decreases transmural pressure which is associated with multiple hormone changes, including decreased secretion of atrial natriuretic peptide and increased release of renin and arginine vasopressin. Increase of renal nerve activity may occur before hemodynamic collapse. PE with or without tamponade should be included in the differential diagnosis of AKI. Two-dimensional echocardiogram is the "gold standard" for diagnosis and remains the most common and sensitive method of detecting PE. When a CKD patient presents with unexplained AKI, echocardiogram should be obtained to rule out PE.

PUB458

Nephrotic Syndrome Associated with Renovascular Hypertension Worsening after Renal Angioplasty and Successfully Treated with Renin:Angiotensin System Inhibitors Yuri Kasagi, Tatemitsu Rai, Keita Kusaka, Soichiro Iimori, Shotaro Naito, Eisei Sohara, Tomokazu Okado, Sei Sasaki, Shinichi Uchida. *Dept pf Nephrology, Tokyo Medical and Dental Univ., Tokyo, Japan.*

Introduction: Nephrotic syndrome (NS) is not a common complication of renovascular hypertension (RVH). However, there are a few reports demonstrating simultaneously occurring RVH and NS in certain clinical settings, which have often been in cases of unilateral occlusion of the renal artery. Although the mechanism is not fully understood, it has been postulated that activation of the renin-angiotensin system(RAS) by unilateral renal artery occlusion may produce hyperfiltration injury to the contralateral kidney, leading to profound proteinuria. Here we report a patient presenting with NS and hypertension with severe bilateral renal artery stenosis / occlusion.

Case Description: A nineteen-year-old man consulted our hospital for evaluation of hypertension (200/135 mmHg). He also had concomitant NS with a proteinuria of 4.7g/day. He had multiple stenosis of major arteries and a diagnosis of aortitis syndrome was made. Total occlusion of the left renal artery and severe stenosis of the right renal artery were seen. RVH was considered as the cause of hypertension, and percutaneous transluminal renal angioplasty (PTRA) was performed to the stenotic right renal artery. Massive increase of proteinuria (40g/day) was seen immediately after the procedure. With the left renal artery still occluded, RAS-mediated hyperfiltration injury to the recanalized right kidney was speculated to be the cause of the acute exacerbation of NS. Intensive treatment aimed at blockade of the RAS system was initiated. Combination therapy by angiotensin-II-receptor blocker and direct renin inhibitor succeeded in controlling both hypertension and proteinuria satisfactorily.

Discussion: This is a unique report of NS complicating RVH. Paradoxical exacerbation of NS was seen after unilateral angioplasty whereas resolution of NS was achieved by intense blockade of the RAS system. This case illustrates the importance to understand the effects of RAS-mediated renal hemodynamics and hyperfiltration injury in the treatment of NS complicating RVH with renal artery stenosis.

PUB459

Membranoproliferative Glomerulonephritis following Cardiac Transplantation Phillip Madonia,[1] Agnes B. Fogo,[1,2] Anna Marie Burgner.[1] *[1]Nephrology, Vanderbilt Univ, Nashville, TN; [2]Pathology, Vanderbilt Univ, Nashville, TN.*

Introduction: Successful solid organ donations in the United States have been increasing since the 1980s with the advent of calcineurin inhibitors (CNI) like cyclosporine and tacrolimus. With this success comes the burden of increasing chronic kidney disease following transplantation due to CNI toxicity. Membranoproliferative glomerulonephritis (MPGN) following heart transplant has only been described in the post-infectious setting.

Case Description: A 44-year-old Caucasian woman with congenital heart defects of dextrocardia and single ventricle underwent an orthotopic heart transplant 11 years prior to presentation to nephrology clinic for evaluation of worsening renal function and nephrotic syndrome. Since transplant, she had been maintained on cyclosporine and mycophenolate, and her baseline creatinine was 1.4 mg/dL. Creatinine was increased to 2.3 mg/dL, with 15 grams/24 hours proteinuria, and albumin of 1.9 gm/dL. Complements were low. Rheumatoid factor, ds-DNA, ANA, hepatitis panel, cryoglobulins, HIV, SPEP, and UPEP were negative. She had no history of recent infection or rash. Renal biopsy had characteristic features of MPGN, with full-house staining of deposits. With no apparent infectious cause, she was treated with prednisone and lisinopril with stabilization in creatinine and decrease in proteinuria. She subsequently developed disseminated opportunistic infections. After minimizing her immunosuppression, her renal disease worsened and she was started on dialysis.

Discussion: Chronic kidney disease is common following cardiac transplantation. Traditional risk factors play a major role, but the incidence and progression of CKD is complicated by use of nephrotoxic agents like immunosuppressants, contrast dye, and antimicrobials, and an increase in unresolved AKI. GN following heart transplant is rare, much lower than the general population. The cause of this discrepancy is unknown but could be because transplant patients are maintained on immunosuppressants. This case illustrates that transplant patients are not completely protected from these diseases, and that de novo GN can be considered in the differential of renal dysfunction in these patients.

PUB460

A Case of Syphilitic Nephropathy Complicated by Nephrotic Syndrome and Acute Kidney Injury Presenting with Liver Dysfunction Kyoko Watanabe,[1] Akihiro Shimizu,[1] Kentaro Koike,[1] Nobuo Tsuboi,[1] Masahiro Suyama,[1] Keita Hirano,[2] Masato Ikeda,[1] Yoichi Miyazaki,[1] Takashi Yokoo.[1] *[1]Dept of Medicine,Div of Nephrology and Hypertension, The Jikei Univ Hospital Tokyo, Japan; [2]Div of Nephrology, Ashikaga Red Cross Hospital, Japan.*

Introduction: In Japan,syphilis is now rarely seen in routine clinical practice,and regarded as a disease of the past.Most common presentations of syphilitic nephropathy(SN) are isolated proteinuria and nephrotic syndrome(NS).To our knowledge,there have been only few reports of SN requiring dialysis.

Case Description: A 46-year-old male with no past medical history presented with acute dyspnea after drinking alcohol.Blood tests showed liver dysfunction with AST

150IU/l,ALP 2183IU/l and γGTP 602IU/l.Liver biopsy demonstrated granulomatous hepatitis.On day 6 of hospital admission, he developed gross proteinuria and AKI with a serum creatinine(sCr) level of 4.5mg/dl,and anuria.His renal function since admission had been normal until this day with no proteinuria.Nephrologists were consulted,and he was commenced on hemodialysis(HD).Renal biopsy was also performed during that time,which showed 10% glomerular sclerosis and 30% tubulointerstitial damage.In addition,there was endocapillary proliferation in some glomeruli,but this was an insignificant finding on light microscopy.On electron microscopy,there was a loss of podocyte foot processes with endothelial deposits.Morphological diagnosis was stage I membranous nephropathy. Syphilis was diagnosed on the basis of positive Treponema Pallidum andtibody and Rapid Plasma Reagin(RPR) with an RPR titer of 166.4 T.U.Taken together,the diagnosis of SN was confirmed.For treatment,oral benzylpenicillin was started with a good response.HD was then discontinued,and proteinuria ceased with recovery of his renal function to sCr 1.10 mg/dl.

Discussion: SN is a condition,which can be treated with penicillin.The condition can present in various ways.Hence,it is important to always bear in mind the possibility,and test for syphilis and other infections at an early stage in management of patients with AKI or NS.

PUB461

Case Series of Dialysis Patients Receiving Lanthanum Carbonate as Treatment for Calciphylaxis Quratulain Shabbir,[1] Narayana S. Murali,[2] Brad C. Astor,[3] Micah R. Chan.[4] *[1]Div of Nephrology, Dept of Medicine, Univ of Wisconsin, Madison, WI; [2]Div of Nephrology, Marshfield Clinic, Marshfield, WI; [3]Div of Nephrology, Dept of Medicine, Univ of Wisconsin, Madison, WI; [4]Div of Nephrology, Dept of Medicine, Univ of Wisconsin, Madison, WI.*

Introduction: There are limited effective treatment options for patients with calciphylaxis. There is anecdotal evidence that non-calcium based phosphorus binders may offer some benefit. Our goal was to determine if lanthanum carbonate would be of benefit as a non-calcium based phosphorus binder in a prospective study.

Case Description: We identified four dialysis patients who had biopsy proven diagnosis of calciphylaxis with phosphorus levels >4.5mg/dL. We wanted to determine if treatment with lanthanum would be helpful for inducing remission of calciphylaxis. Also we assessed if there was improvement in the quality of life assessed with a validated Dermatology Life Quality Index (DLQI) survey as a result of treatment of these lesions. As secondary outcome measures we assessed PTH levels, calcium and albumin levels. All the patients received lanthanum carbonate titrated to achieve phosphorus level 3.5-5.5mg/dL. We assessed them over 12 week period and obtained photograph of the skin lesions at the end of this period as well as DLQI responses at the end of this period.

All four patients were assessed at the end of 12 weeks with photographs that demonstrated remission in skin lesions. In addition there was a statistically significant improvement in the serum albumin. There was also significant improvement in DLQI score at end of this period with subjective improvement in symptoms and feelings (p=0.01), personal relationships (p=0.03) treatment effect (0.03) and overall score (p=0.02).

Discussion: Lanthanum carbonate as a non-calcium containing phosphorus binder appears to be efficacious in terms of improving the lesions of calciphylaxis and can be helpful in improving quality of life associated with the burden of these lesions along with some beneficial impact on serum albumin level.

PUB462

An Unexpected Cause of Hyponatremia in a Clinically Euvolemic Patient Sandipani Sandilya, Deep Sharma. *Nephrology, Montefiore Medical Center, Bronx, NY.*

Introduction: We typically evaluate hyponatremia by assessing a patient's volume status. Cardiac etiologies of hyponatremia are usually hypervolemic states with reduced effective arterial blood volume. We describe a case of a clinically euvolemic patient whose evaluation led to the diagnosis of a cardiac etiology of her hyponatremia.

Case Description: An 80 year old female with a history of hypertension, idiopathic pulmonary fibrosis, Sjogren's syndrome, esophageal dysmotility, Hashimoto's thyroiditis, 2:1 AV block with a dual chamber pacemaker inserted three weeks prior to admission was admitted with cough and asymptomatic hyponatremia (serum sodium 118 mEq/L). She had a serum Na+ of 135 mEq/L twenty days prior to admission. Three days prior, the serum Na+ was 128 mEq/L. Physical examination was significant for clear lungs and no lower extremity edema. Significant serum labs were: potassium 5.3 mEq/L, creatinine was 0.7 mg/dL, uric acid was 2.3 mg/dL, osmolality was 249 mOsm/kg. Morning cortisol and thyroid function were within normal limits. Other significant labs were: urine Na+ below 20 mEq/L, urine osmolality 737 mOsm/kg. The patient was clinically euvolemic and thought to have SIADH from pulmonary and thyroid disease, with a "tea and toast" diet contributing to hyponatremia. She was started on sodium chloride tablets with minimal improvement. Because the low urine Na and borderline hyperkalemia suggested a low flow state, we obtained an echocardiogram to evaluate her ejection fraction. The echo showed a large hemopericardium due to perforation by the right atrial pacemaker lead. The patient underwent pericardiocentesis and her serum sodium subsequently gradually improved to baseline (130-135 mEq/L).

Discussion: We present this as a case of a clinically euvolemic patient with potential causes of SIADH (pulmonary and thyroid disease) and a low solute diet. In this case, the low urine sodium led us to investigate for a cardiac etiology which revealed hemopericardium as the cause of hyponatremia.

PUB463

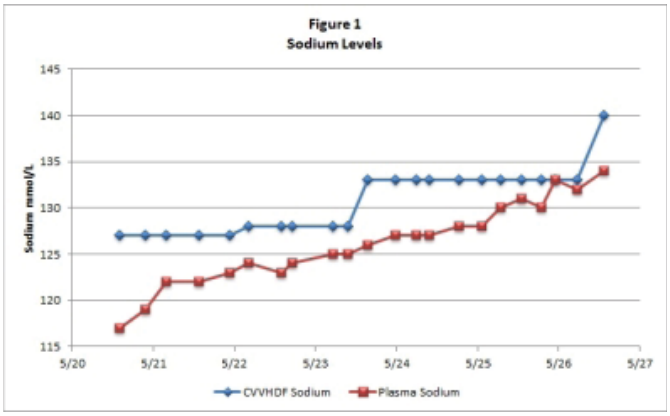
A Simple Solution for Hyponatremia in Patients Needing Renal Replacement Therapy Jiten Patel,[1,2] Julio C. Chirinos,[1,2] Susan Hedayati.[1,2] *[1]Nephrology, Univ of Texas Southwestern, Dallas, TX; [2]Nephrology, VA North Texas Healthcare System, Dallas, TX.*

Introduction: Hyponatremia in patients needing renal replacement therapy is challenging. This case illustrates a simple solution.

Case Description: A 55 year old male with hypertension, diabetes mellitus, heart failure, IgA nephropathy, and chronic kidney disease stage 3a was admitted for a right foot infection. He developed acute kidney injury, hyperkalemia, hyponatremia, and volume overload. Despite aggresive treatment his renal function worsened. We decided to start dialysis, but his serum sodium was 122meq/L. There was concern that potential large sodium shifts with conventional hemodialysis with a reduced dialysate sodium of 130meq/L or continuous venovenous hemodiafiltration (CVVHDF) with standard PrismaSol® (sodium of 140meq/L) may lead to central pontine myelinolysis. We chose CVVHDF and added 500mL of sterile water to each 5L bag of PrismaSol® to decrease the sodium concentration (Table 1). Lesser amounts of sterile water were serially added to PrismaSol® as the serum sodium slowly rose. The patient's sodium gradually improved without adverse events associated with over-correction of hyponatremia, and we were able to switch to standard PrismaSol® (Figure 1).

Table 1
Fluid Concentration

	PrismaSol® $4K^+/2.5Ca^{2+}$	Plus 500 mL Sterile Water	Plus 450 mL Sterile Water	Plus 250 mL Sterile Water
Na^+(meq/L)	140	127	128	133
Ca^{2+}(meq/L)	2.5	2.3	2.3	2.4
Mg^{2+}(meq/L)	1.5	1.4	1.4	1.4
Cl^-(meq/L)	113	103	104	108
HCO_3^-(meq/L)	32	29	29	30
Glucose(mg/dL)	100	91	92	95
Osmolarity (mOsm/L)	300	273	275	286



Discussion: Addition of sterile water to standardized dialysate to lower the sodium concentration has been previously described in hyponatremic patients with hepatorenal syndrome for intraoperative CVVHDF during liver transplantation. We demonstrate that this approach can also be safely used in hyponatremic patients with AKI in the ICU setting.

PUB464

Case of Transplant Renal Artery Stenosis Treated with Intervention Using Carbon Dioxide Angiography Joon-Seok Kim, Chung Hee Baek, Hyosang Kim, Su-Kil Park. *Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Seoul, Republic of Korea.*

Introduction: Transplant renal artery stenosis (TRAS) is a relatively common, treatable cause of graft dysfunction and refractory hypertension after transplantation. TRAS can also cause sodium retention and recurrent episodes of pulmonary edema (flash pulmonary edema). We are reporting a case of TRAS in elderly patient that was managed with endovascular intervention using carbon dioxide (CO2) as a contrast agent.

Case Description: A 78-year-old Korean man with a history of ESRD due to diabetic nephropathy received an expanded criteria donor allograft in 2006 and presented with a history of generalized edema. He had chronic allograft dysfunction after transplantation. One month ago, he suffered a traffic accident in the U.S.A. and entered a community hospital. Severe anasarca and worsening of graft function were developed during hospitalization. So, thrice-weekly hemodialysis was begun 3 weeks ago. He wanted to undergo treatment in homeland and transferred to our hospital. Physical examination revealed a generalized edema and crackles at the bases of both lungs. Chest radiogram showed a pulmonary edema and bilateral pleural effusions. Hemodialysis was continued and body weight was reduced about 13 %. During the hospital course, however, episodes of severe hypertension and bouts

of pulmonary edema were repeated. CO2 angiography was performed to rule out TRAS. Angiography revealed a tight stenosis at the anastomosis site, so balloon angioplasty was done. Following intervention, an angiogram showed improvement of stenosis and graft perfusion. Since then hemodialysis was stopped and graft function and clinical status were closely monitored. Notwithstanding some weight gain, pulmonary edema did not recur and serum BNP level was decreased markedly from 1376 pg/ml to 249 pg/ml. His graft function and urine output is maintained stably.

Discussion: TRAS should be considered as a cause of unexplained edema, flash pulmonary edema or graft dysfunction. If graft function is marginal and iodinated contrast material use is concerned, CO2 angiography may be used for both diagnosis and intervention of TRAS.

PUB465

Muckle Wells Syndrome - A Case Report Jhoomar R. Makhija, Hemant J. Mehta, Anup Chaudhari. *Nephrology, Lilavati Hospital and Research Center, Mumbai, India.*

Introduction: Muckle-Wells syndrome, a rare disorder, has been reported in many regions of the world, but its prevalence is unknown. It is characterized by periodic episodes of skin rash, fever, and joint pain. Progressive hearing loss and kidney damage also occur. It is uncommon in India, and this is probably first report of such case from India.

Case Description: 62 yrs old dentist, presented with loose motions for 1 month. He had hearing impairment since early childhood, and progressively increasing blackening of both legs for past several years.

(sclerodermoid lesions with hyperpigmentation and sclerosis).

He had normal S. Creatinine to begin with but 1 week back, it was 9mg/dl and 17mg/dl on admission. He was admitted with lethargy, loss of appetite, breathlessness and decreased urine output. He had high anion gap metabolic acidosis, hyponatremia, hyperkalemia and TLC of 32,000. He was initiated on dialysis. Audiogram showed bilateral sensory neural deafness. Ophthalmic examination did not show spherophakia, lenticonus or retinal changes. His skin biopsy and colonic biopsy showed evidence of amyloidosis. there was a family history of deafness in younger son who had developed meningitis leading to quadriparesis but cause of meningitis was unknown. Analysis of all coding exons with flanking intronic regions of MEFV gene by bidirectional sequencing showed compound heterozygote (including heterozygous missense variants c.443G>C/p.E148Q and c.605G>A/p.R202Q in exon2). Heterozygous mutations p.E148Q and p.R202Q are individually reported as pathological variants, consistent with the diagnosis of familial Mediterranean fever. This case has clinical features of Muckle Wells syndrome.

Discussion: Patient was started on colchicine without response. We were trying to get kineret (anakinra), recombinant, non-glycosylated synthetic form of human Interleukin-1ß receptor antagonist. But the patient succumbed to septicaemia.

PUB466

Oxalate Nephropathy: An Unexpected Cause of Acute Kidney Injury Shivani Shah, Derek M. Fine, Srinivas Ramakrishna Gottipati. *Nephrology, Johns Hopkins Univ, Baltimore, MD.*

Introduction: Oxalate nephropathy with Roux-en-Y gastric bypass is well-described, but it is rare in the current era. Nevertheless, the diagnosis should be considered in otherwise unexplained acute kidney injury.

Case Description: A 69 year old woman with a history of hypertension, Roux-en-Y gastric bypass in 2003, Crohn's disease, and a creatinine of 1.9 mg/dL two months prior to admission, presented to a hospital with pneumonia. Her creatinine was 3.56 mg/dL five days prior to admission and increased to 9 mg/dL on presentation. She was transferred to our institution the following day where she was afebrile, had a heart rate of 88 bpm, and blood pressure of 130/57 mm Hg. Her physical exam was notable for altered mental status, normal heart sounds, 1+ lower extremity edema, and asterixis. Her chemistry panel was significant for BUN 107 mg/dL, creatinine of 9.1 mg/dL, and phosphate level of 15 mg/dL. Urinalysis revealed 1+ protein and 13 RBC/hpf. Serologic testing was negative for C-ANCA, P-ANCA, SPEP, UPEP, HCV, and HBV antigens. Complement levels were normal. Renal ultrasound showed no obstruction. The patient became anuric and initiated dialysis. Her acute kidney injury was attributed to acute phosphate nephropathy, although no inciting etiology was discerned historically. A renal biopsy was performed which showed focally severe tubular injury with oxalate crystals in the setting of hypertensive nephrosclerosis. The patient ultimately had some improvement in renal function and was discharged off dialysis with a creatinine of 4.9 mg/dL.

Discussion: This patient appears to have had undiagnosed hyperoxaluria secondary to increased gastrointestinal absorption of oxalate in the setting of gastric bypass surgery and Crohn's disease. Though oxalate nephropathy with Roux-en-Y gastric bypass is well-described, it is unusual to occur so long after the procedure. Her concomitant Crohn's disease, chronic kidney disease, and acute illness likely exacerbated her hyperoxaluria to necessitate dialysis. In patients with acute kidney injury and a history of gastric bypass, the differential diagnosis should include oxalate nephropathy; kidney biopsy should be considered to determine the diagnosis.

PUB467

A Case of Mistaken Identity: 2, 8-Dihydroxyadenine Misdiagnosed as Uric Acid Nephrolithiasis Akinwande A. Akinfolarin, Julian L. Seifter. *Renal Div, Brigham and Womens Hospital, Boston, MA.*

Introduction: Adenine phosphoribosyl transferase (APRT) deficiency is a rare autosomal recessive disorder with a higher prevalence among Japanese. Normally adenine is converted to adenine monophosphate by APRT. Known gene mutations result in APRT deficiency in which adenine is alternatively oxidized to 2, 8-dihydroxyadenine (2, 8-DHA) by xanthine oxidase. 2, 8-DHA is an insoluble purine that may result in nephrolithiasis or in some cases renal failure. We present a patient with recurrent nephrolithiasis initially thought to be uric acid in origin.

Case Description: We consulted on a 44 year old Japanese-American woman with a history of hypertension and recurrent kidney stones for 20 years. The stones were radiolucent on abdominal X-ray but CT scan revealed numerous calculi of varying sizes. Colorimetric analysis previously revealed the stones to be 100% uric acid. She was placed on sodium citrate, achieving a urine pH of 6.5. However she continued to develop new stones. 24-hour urine collection showed a normal uric acid super saturation of 0.628. Stone analysis using infrared spectrophotometry revealed the stone was 2, 8-DHA and not uric acid. Maltese crosses, typical of 2, 8-DHA crystals were seen under polarized light microscopy. Red blood cell APRT activity was normal. Gene sequencing showed a mutation of methionine to threonine (Met136Thr) confirming type II APRT deficiency. Allopurinol, a xanthine oxidase inhibitor was initiated with a low purine diet and high fluid intake. Stones have not recurred and repeat CT imaging demonstrated disappearance of her previous calculi.

Discussion: Colorimetric stone analysis cannot distinguish adenine from uric acid and is not recommended. Infrared spectrophotometry or x-ray crystallography is preferred. Alkalinization of urine is not effective for 2, 8-DHA as it is for uric acid nephrolithiasis. Allopurinol decreases formation of 2, 8-DHA in favor of the soluble 8-hydroxyadenine. In this case, recognition of 2, 8-DHA and therapy with allopurinol prevented stone growth and may have led to dissolution of existing stones.

PUB468

Antiphospholipid Syndrome Nephropathy - From Migraine to the Kidney Ana Teresa Nunes,[1] Inês Castro Ferreira,[1] Eva Borka Mariz.[3] *[1]Nephrology, Centro Hospitalar de São João, Oporto, Portugal; [2]Internal Medicine, Centro Hospitalar de São João, Oporto, Portugal; [3]Rheumatology, Centro Hospitalar de São João, Oporto, Portugal.*

Introduction: Antiphospholipidic syndrome (APS) can affect any organ with a wide range of clinical features, requiring a high index of diagnosis suspicion. We describe a case of APS nephropathy preceded by frequent migraine and an episode of amaurosis fugax.

Case Description: A 21 years old woman without any medical/obstetric history started frequent migraines followed by an episode of amaurosis fugax. Brain MR showed bilateral ischemic lesions. Hypertension was detected along with renal impairment, proteinuria and intermittent hematuria. She presented a slightly increased activated partial thromboplastin time with no abnormalities in immunological evaluation. Kidney biopsy revealed segmental glomerulosclerosis, mesangial proliferation and arteriosclerosis with recanalized thrombosis. Immunofluorescence was negative for all sera but ultrastructural evaluation detected mesangial immune deposits. An antiphospholipid syndrome was suspected. Triple positivity for phospholipid antibodies (aPL) was detected and anticoagulation was started (INR 2-3) with a remarkable improvement of neurological complains. Currently she is at 3rd year of follow-up without any major thrombotic event or migraine recurrence. Renal function and proteinuria improved and hematuria resolved. Immune evaluation persists negative.

Discussion: APS is characterized by vascular thrombosis and/or pregnancy morbidity along with presence of aPL. The kidney is a major target organ with a broad spectrum of histological findings. Our patient started with mild neurological manifestations followed with an ischemic event and renal involvement. A secondary APS cannot be excluded since renal histology identified immune deposits beyond the thrombotic lesions. Anticoagulation is the main therapy for APS providing a dramatic improvement of clinical complaints as well preventing new events. This case highlights the complexity of the diagnosis. Non-criteria manifestations should alert the nephrologist to this entity so that morbidity and mortality can be tackled at the earliest.

PUB469

Elevated Creatinine, Tacrolimus Toxicity and Ketonuria in a Kidney Transplant Recipient following Dietary Preparation for Gastric Sleeve Bariatric Surgery Maybel M. Tan, Laurel W. Yap, Mariana S. Markell. *Renal Diseases, SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction: Following successful kidney transplantation, weight gain can result in morbid obesity. Very little has been written about post-transplant bariatric surgery, and there have been no reports of adverse effects of pre-op preparation, which can be very restrictive.

Case Description: A 44 year old woman with history of systemic lupus erythematosis, received a deceased donor kidney in 2010. Post-transplant, the patient gained 60 pounds, weighing 240 pounds (BMI 40). She was accepted for gastric sleeve procedure and was prescribed 1000 calorie, very low carbohydrate, liquid diet for two weeks pre-operation. At start of the diet, creatinine was 1.66 mg/dl, tacrolimus level 4.5 and urine analysis negative. Diet consisted of "Muscle Milk", chopped carrots, diet pudding and jello. She complained of diarrhea, but continued the diet. One week later, creatinine was 2.1 mg/dl. She was told to increase fluid intake. After two weeks, BUN was 42, creatinine 2.44 mg/dl, tacrolimus 11.9, glucose 110, bicarbonate 17, chloride 113, urine analysis small acetone, SSA 1+, specific gravity 1.030, CBC with WBC 11K, 4 Bands, and multiple abnormal RBC's. After overnight hydration, creatinine was 2.5 and a kidney biopsy was performed which revealed no lymphocytic infiltrate, no tubulitis or intimitis and minimal tubular vacuolization. She continued hydration and tacrolimus dose was decreased. One week later, the creatinine was 1.55, tacrolimus level was 4.1 and other laboratory studies normalized.

Discussion: This previously stable patient developed a rapid rise in creatinine and ketonuria coincident with a diet of "Muscle Milk", a protein supplement that contains creatine in unknown amounts; large quantities of ground carrots and artificially sweetened pudding. We believe that she developed ketosis secondary to carbohydrate restriction, and severe dehydration secondary to diarrhea caused by artificial sweeteners and high carrot intake. An interaction with tacrolimus from an ingredient in the "Muscle Milk" is also possible. It is unclear whether the presence of creatine in the supplement contributed to her rise in creatinine and dehydration.

PUB470

Previously Unreported GLA Gene Mutation as a Cause of Kidney Dysfunction and Classic Fabry Disease Phenotype A Case Report Ruth Ixel Rivas Bucio, Odette D. Avendano, Elvira González, Juvenal Torres Pastrana. *Nefrologia, Centro Medico Nacional 20 de Noviembre Issste, Mexico DF, Mexico.*

Introduction: Fabry Disease (FD) is an X-linked disease which affects glycosphingolipid metabolism due to a deficiency in the production of the lysosomal enzyme alpha-galactosidase A (α-gal A).

Case Description: Case presentation: A 30 year old male patient with only medical information was a 6 year history of medically controlled hypertension. He refers his first symptoms 5 years prior, with acroparesthesias, intermittent pain crises and foamy urine. 4 months before being admitted he had sudden hearing loss, increase in pain, intermittent episodes of dyspnea. He was admitted with lab serum creatinine 3.8 mg/dL, eGFR (MDRD) 19.7 mL/min and albuminuria 1.2 g/24 hr urine sample. α-gal A activity in dried blood spot revealed extremely low activity 0.1 μmol/L/hr. Diagnosis of Fabry Disease was confirmed with molecular analysis, which revealed a previously unreported mutation in exon 1 of the GLA gene (c.107T>Gp.L36W). Plasma lyso GL-3 levels were 31.7 ng/mL. Echocardiography established left ventricle diastolic dysfunction. Ophthalmology confirmed the presence of bilateral *cornea verticillata*. He began therapy was started on ACEI/ARB therapy. ERT was initiated with agalsidase beta on standard dose of 1 mg/kg every other week; so far, he has received 4 infusions. Since the initiation of ERT pain perception and pain crises have diminished.

Discussion: We report the finding of a previously unreported mutation in the GLA gene, presenting as classic Fabry disease. Enzyme replacement therapy seems to have stanched kidney disease progression.

PUB471

Air Embolism: Alarming but Clinically Insignificant and Common in Hemodialysis Jose F. Lizcano Perez,[1] Panagiotis Zervogiannis,[1] Craig S. Courville,[2] Alfredo M. Peguero,[2] Ammar Almakkee.[1] *[1]Nephrology, Univ of South Florida, FL; [2]JAHVA, Tampa, FL.*

In one day, an 81 year old male with ESRD and LVEF of 10-15 % had a thoracentesis, fistulagram with angioplasty of upper arm AV fistula, and immediately afterwards was started on hemodialysis. Five minutes after the initiation of hemodialysis treatment, his blood pressure decreased with dyspnea and mental changes. An evaluation for possible pulmonary embolism or pneumothorax revealed free air in the right ventricle. Discontinuation of dialysis and supportive care with 100% oxygen per non-rebreathing mask and placement in left lateral decubitus positionat 30 degrees trendelenburg was initiated. CT of the head did not reveal acute changes or air embolism. Serial troponins were negative. Intermittent episodes of non-sustained ventricular tachycardia with severe stunned myocardium on echocardiography prompted the use of amiodarone, pressors, inotropic agents and CVVHDF. Later evaluation of the initial chest CT showed right ventricular air embolism was a bystander as is seen in 20-43% of cases after contrast procedures. The most likely cause of the decompensation was the acute increase in the venous return after angioplasty and thrombectomy of the AV fistula, taxing the left ventricle's severely limited function. A complete investigation of the dialysis circuit and air trap mechanism ruled out hemodialysis procedure as source of air entry into blood vessels. Hemodialysis immediately after fistulogram is common in the hospital setting. Air in the right ventricle is also common after fistulagrams and the discrimination of its magnitude and location through CT scan and analysis of the circuit lines easily rules out air embolism. As hypotension and dyspnea are not rare events during dialysis, it is concluded that hypotension, dyspnea and air in the right ventricle may coexist without causality. Analgorithm for the diagnosis and treatment of clinically relevant pulmonary air embolism during hemodialysis was designed.

PUB472

A Case Report with Acute Renal Failure due to Plasmodium Falciparum Sook Hyeon Park, Jason Cobb. *Renal Divison, Emory Univ School of Medicine, Atlanta, GA.*

Introduction: Malaria has a significant health impact in some parts of the world, especially Asia and Africa. Many Americans are at risk of infection while traveling in endemic areas. In 2011, 1925 cases of malaria were reported to the Centers for Disease Control and Prevention and 16% of the patients had acute renal failure. Malaria associated renal disease is caused primarily by *P. falciparum* and *P. malariae.*

Case Description: A 49 year old white female with no significant past medical history presented with fever and generalized malaise. The patient went on a mission trip to Haiti from 6/9/2013 until 6/16/13. On 6/25/13, she developed fever, abdominal pain, dark urine. Seven days after the first symptoms developed, the patient presented to our academic medical center with positive malaria test at a local clinic. On admission day, her creatinine was 2.51mg/dL, BUN 34mg/dL, bicarbonate 19 mmol/L, sodium 128mmol/L, hemoglobin 10.1gm/dL, platelets 28000 10E3/mcL, elevated liver function tests and total bilirubin 2.5mg/dL. Peripheral blood smear showed 2.1 % *P. falciparum*. She was admitted to the ICU for close monitoring and started on Quinine and doxycycline. A urine microscopic exam showed innumerable muddy brown casts. Her cr peaked at 3.26mg/dL and started trending down with conservative treatment. On discharge date, her cr went down to 1.56mg/dL. She finished her malaria treatment during hospital stay and discharged home. The patient was seen at nephrology clinic 1 week and 4 months after discharge. Her creatinine has remained at 1.08mg/dL.

Discussion: Malaria incidence is approximately 1,500 travelers per year in the Unites States. Malaria related acute renal failure occurs 1% to 4.5% among native population of endemic areas. However, acute renal failure can occur up to 25-30% in non-immune European adults. *P. falciparum* is mainly associated with acute renal failure and patients infected with *P. malariae* can progress to chronic progressive glomerulopathy and nephrotic syndrome. It is important to recognize that malaria can be the cause of acute or chronic kidney disease in febrile patients who have returned from abroad.

PUB473

Acute Kidney Injury and Hypercalcemia due to Sarcoid-Lymphoma Syndrome Vanya Grover,[1] Adebayo Shakir Adewale,[1] Kristine H. Jang,[2] Tahmeena Ahmed,[3] Nand K. Wadhwa.[1] *[1]Nephrology, Stony Brook Medicine; [2]Medicine, Stony Brook Medicine; [3]Pathology, Stony Brook Medicine, Stony Brook, NY.*

Introduction: Sarcoidosis and lymphoma can occurs simultaneously or lymphoma mainly Hodgkin's lymphoma can precede sarcoidosis. We report a case with acute kidney injury and hypercalcemia due to sarcoidosis associated with incidental marginal zone lymphoma.

Case Description: An 81 year old man with hypertension, anemia, COPD, and coronary artery disease, presented with altered mental status, dragging of left foot and worsening lethargy. Physical examination revealed BP 157/70 mmHg, HR 76/minute, RR 20/minute. Neurological examination was normal. He had no palpable lymphadenopathy but had mild splenomegaly. Laboratory data showed WBC 6.2 k/mcL, hemoglobin 10.1 mg/dL, platelets 139 k/mcL, serum sodium 137 mEq/L, potassium 4.4 mEq/L, chloride 104 mEq/L, and bicarbonate 30 mEq/L, BUN 34 mg/dL, creatinine 2.4 mg/dL, calcium 13.3 mg/dL, angiotensin converting enzyme (ACE) 107 U/l and vitamin D 1,25 Dihydroxy 103 ng/ml. Bone marrow clot section showed non-caseating granulomas and a small lymphocytic infiltrate composed of clonal B cells consistent with immunophenotype of marginal zone

lymphoma by flow cytometry (which was seen on both blood and bone marrow). He was treated with IV hydration and prednisone. His serum calcium normalized to 9.8 mg/dl and creatinine decreased to 1.67 mg/dl over a period of one week. He was discharged home on tapering doses of prednisone. He did not receive treatment for marginal zone lymphoma. His serum calcium, ACE, vitamin D 1,25 Dihydroxy remained normal over a 2- year follow up period.

Discussion: Sarcoidosis and lymphoma can co-exist. Both can have common presenting features which pose a diagnostic challenge. Bone marrow granulomas may be seen in patients with lymphoma but are nonspecific and do not usually cause elevated ACE and hypercalcemia Our patient had acute kidney injury and hypercalcemia likely due to sarcoidosis as he responded to steroids and remained stable. He may have incidental marginal zone lymphoma or it may be sarcoid-lymphoma syndrome.

PUB474

Hanging Diagnosis of Acute Thrombocytopenia and Hemolytic Anemia in Sickle Cell Disease Patient with End Stage Renal Disease

Akshita Narra, Gaurav Alreja, Ruchir D. Trivedi. *Div of Nephrology, Univ of Connecticut, CT.*

Introduction: Microangiopathic hemolytic anemia and thrombocytopenia without other apparent etiology can be manifestations of thrombotic thrombocytopenic purpura (TTP), a potentially life threatening disorder. In a sickle cell disease (HbSS) patient with ESRD, malignant hypertension, systemic infections, bone marrow necrosis, or delayed transfusion reaction (DHTR) can mimic TTP creating a diagnostic dilemma.

Case Description: A 39 year-old female with HbSS disease and ESRD on peritoneal dialysis presented with acute onset bilateral hip and shoulder pain. Her only medication was folic acid. The patient was febrile, with mild scleral icterus and elevated BP(220/110mmHg) but with no evidence of papilledema. Lab data revealed hemoglobin(Hb) 8.6mg/dL, wbc 7.7×10^9/l, platelets 118,000/cm^2, reticulocyte count 4.6%, LDH 1495 IU/L, haptoglobin <15mg/dL, indirect bilirubin 2.5mg/dL, alkaline phosphatase 450 IU/L and negative direct and indirect coomb's test. Peripheral smear revealed 2+ schistocytes, 1+ sickle cells and no platelet clumping. Prothrombin time and fibrinogen were normal. There was no evidence of infection. In 72hrs, Hb dropped to 3.4mg/dL and platelet count to 14,000/cm^2 despite PRBC and platelet transfusions. Lab data was consistent with intravascular hemolysis with elevated LDH, indirect bilirubin, and low haptoglobin. Plasmapheresis (TPE) and systemic steroids were initiated for a presumptive diagnosis of TTP. After 7 consecutive sessions of TPE the platelet count improved to 76,000/cm^2 on day-10. A bone marrow aspiration biopsy in the interim revealed marrow necrosis. A repeat indirect coomb's test was positive. ADAMTS13 activity returned as normal (32%). Patient had significant clinical improvement with stabilization of Hb and platelet count.

Discussion: The renal manifestations, one of the pentad diagnostic features of TTP, are irrelevant in ESRD patients. In the acute setting when the diagnosis is uncertain, the high fatality of untreated TTP cases favors the urgent initiation of TPE while awaiting ADAMTS levels. Our patient initially had HbSS related bone marrow necrosis later complicated by DHTR that improved with steroids and TPE.

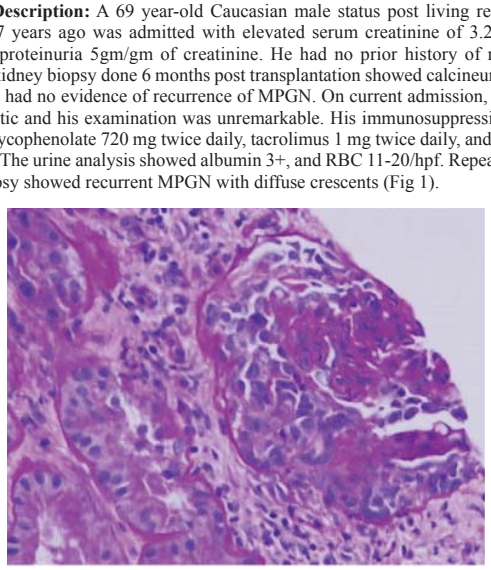
PUB475

Recurrent Membranoproliferative Glomerulonephritis Type Presenting as Crescentric Glomerulonephritis in Living Related Donor Renal Transplant Recipient

Sandeep M. Patil, Denisse E. Menendez, Neeraj Singh. *Div of Nephrology, Louisiana State Univ Health Sciences Center, Shreveport, LA.*

Introduction: Recurrent glomerulonephritis is a significant cause of allograft failure post-kidney transplantation. We present a patient with recurrent crescentic membranoproliferative glomerulonephritis type 1(MPGN-1) leading to rapid graft loss despite intensive treatment.

Case Description: A 69 year-old Caucasian male status post living related donor transplant 7 years ago was admitted with elevated serum creatinine of 3.2 mg/dl and increasing proteinuria 5gm/gm of creatinine. He had no prior history of rejection. A transplant kidney biopsy done 6 months post transplantation showed calcineurin inhibitor toxicity but had no evidence of recurrence of MPGN. On current admission, patient was asymptomatic and his examination was unremarkable. His immunosuppressive regimen included mycophenolate 720 mg twice daily, tacrolimus 1 mg twice daily, and prednisone 5 mg daily. The urine analysis showed albumin 3+, and RBC 11-20/hpf. Repeat transplant kidney biopsy showed recurrent MPGN with diffuse crescents (Fig 1).



Electron microscopy revealed large irregular electron dense mesangial deposits. Serum BK and CMV virus PCR, serum and urine protein electrophoresis, complements levels, hepatitis B and C serology, c-ANCA and P-ANCA were negative. The serum creatinine and proteinuria worsened despite treatment with oral cyclophosphamide, pulse steroids, plasmapheresis, rituximab, intravenous immunoglobulin and patient was initiated on hemodialysis 5 weeks after admission.

Discussion: Although, MPGN type -1 is a rare cause of ESRD, the disease recurs in a significant proportion of patients after kidney transplantation. Unlike the disease in native kidneys, recurrent MPGN may present with a cresentic form of glomerulonephritis with a rapid fulminant clinical course unresponsive to treatment.

PUB476

Hyponatremia, a Constant Clinical Challenge- Euvolemic Hyponatremia Secondary to Solute Loss

Ramya Vejella, Sarah Khan, Neeraj Singh, Zulqarnain Abro, Stacey Wells. *Nephrology, LSUHSC Shreveport, Shreveport, LA.*

Introduction: Poor solute intake has been reported to cause euvolemic hyponatremia typically in the setting of chronic alcoholism or malnutrition when patients present with low serum Na,low urine osmolality, and normal urine output. We present a patient who developed euvolemic hyponatremia secondary to solute loss from diarrhea while maintaining adequate free water intake.

Case Description: A 42 year old Hispanic female with a history of kidney transplant thirteen years ago was evaluated for diarrhea for 4 weeks. Her immunosuppression consisted of mycophenolate 720 mg oral twice daily, tacrolimus 2 mg oral twice daily, and prednisone 5 mg oral daily. Patient had her mycophenolate decreased and subsequently stopped 2 weeks prior to presentation due to continuous diarrhea. The stool studies ordered at that visit were unremarkable. She was advised to maintain adequate hydration. At her current visit, she was afebrile with BP of 128/68 mmHg, HR of 61/minute, RR of 18/min, weight 122.6 lbs, and BMI 21.7. Her weight had been unchanged over the past 6 months. She was euvolemic and non-orthostatic and rest of the examination was unremarkable. Laboratory data revealed: Serum Na-116mmol/l, K-4.0mmol/l, Cl-83mmol/l, CO2-24mmol/l, Glucose-80mg/dl, BUN-8mg/dl, Creatinine-0.9mg/dl, Calcium-8.2mmol/l, Albumin-2.5g/dl, Phosphorus-2.7mmol/dl, and Magnesium-1.2mmol/dl. Patient denied excessive water intake. Further work up revealed measured serum osmolality of 239, TSH- 0.208, Free T4- 1.4, random cortisol- 7.5, urine osmolarity- 62, Urine Na < 19, Urine K < 7.5, Urine Cl < 33 and 24 hour urine volume of 2000ml. SIADH which was initially suspected, was ruled out due to remarkably low urine osmolarity. Instead, a diagnosis of low solute hyponatremia was confirmed. Patient responded well to IV hydration with normal saline and to high salt diet with normalization of serum Na at a desired rate.

Discussion: Diarrhea is known to cause hypovolemic hyponatremia. However, if the adequate hydration is maintained despite chronic diarrhea, the patients may instead present with euvolemic hyponatremia. This presentation should be considered in the discussion of the causes of euvolemic hyponatremia.

PUB477

Severe Tubulo-Interstitial Nephritis (TIN) Accompanying Mesangio-Capillar Glomerulonephritis in Patient with Chronic Lymphocytic Leukemia (CLL)

Hanna Bartosik,[1] Krzysztof Letachowicz,[1] Magdalena Krajewska,[1] Agnieszka Halon,[2] Katarzyna Madziarska,[1] Waclaw Weyde,[1] Marian Klinger.[1] *[1]Dept of Nephrology and Transplantation Medicine, Wroclaw Medical Univ, Wroclaw, Poland; [2]Dept of Pathomorphology and Oncological Cytology, Wroclaw Medical Univ, Wroclaw, Poland.*

Introduction: Glomerulonephritis in B-chronic lymphocytic leukemia is rarely reported. The association between nephrotic syndrome and hematological malignancy should be revealed in the future.

Case Description: 62-year old female with diagnosed in 2010 chronic lymphocytic leukemia was admitted to Nephrology Department due to severe nephrotic syndrome [NS] (total serum protein level 4.4g/dl serum albumin level 1.8 g/dl) with significant renal insufficiency (serum creatinine level 4.0 mg/dl; eGRF 12ml/min/1.73m^2). Nephrotic syndrome occurred 4 months along with renal impairment (serum creatinine level 1.7 mg/dl). For 4 weeks the patient was treated with steroids (prednisone 20 mg per day) and 3 pulses of cyclophosphamide were administered (500 mg/m^2). This treatment was abandoned due to infectious complications. After admission to Nephrology Department pulses with methylprednisolone were introduced (40 mg per day) and intravenous diuretics were applied (160 mg of Furosemide per day). 3 weeks later kidney biopsy was done showing mesangio-capillar glomerulonephritis with severe TIN (III0). This intensive tubulo-interstitial nephritis differs our case from primary mesangio-capillar glomerulonephritis. Such a histological pattern, especially with concomitant TIN, is very rarely seen in a patient with chronic leukemia. Due to progressive renal impairment and exhaustive, non-responding to described treatment NS dialysis with ultrafiltration were started. After 2 weeks the patient was referred to Hematology Department in stable, good clinical shape in order to start chemotherapy (rituximab, cyclophosphamide).

Discussion: This atypical histological finding might be a feature of hematological malignancy-associated nephrotic syndrome.

PUB478

Methotrexate Induced Acute Symptomatic Hyponatremia Priyanka Govindan, Arjun V. Sharma. *Nephrology, Univ of Washington, Seattle, WA.*

Introduction: 61 year old female with a history of CNS lymphoma treated with intrathecal methotrexate infusion who developed acute symptomatic hyponatremia. This case demonstrates salt wasting as the mechanism of methotrexate induced hyponatremia.

Case Description: This is a 61 year old female with CNS lymphoma who underwent her 8th out of 10 intrathecal methotrexate infusions with hyperhydration with sodium bicarbonate and subsequently developed hyponatremia with altered mental status. She was initially treated with normal saline then 2% saline which caused her sodium to drop from 120 to 116. Lasix 40 mg was given and she was started on 3% saline. With this as well as discontinuation of her methotrexate, she corrected to a sodium of 128 mEq/L and ultimately sustained at 135 mEq/L. During this time her urine osmolality remained high. The serum sodium correction correlated with decreasing levels of methotrexate. Mental status subsequently improved and became normal in 24 hours.

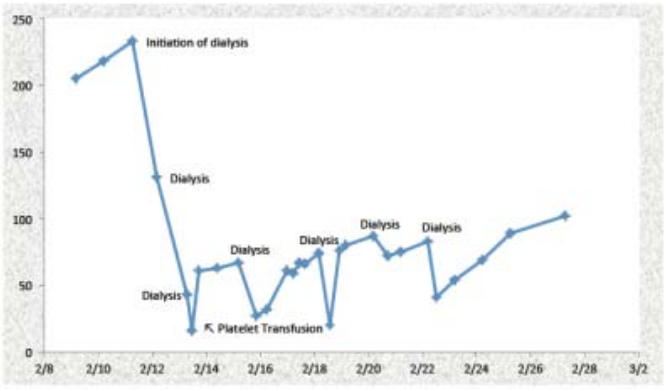
Discussion: The diagnosis of drug induced salt wasting was reached due to the fact that hyponatremia occurred as the patient received 600 mEq of sodium (as sodium bicarbonate) and urinated 600mEq of sodium with a net even fluid balance (rather than retaining free water as in SIADH) in spite of severe hyponatremia. There are three previously described cases of methotrexate induced salt wasting. This is the first instance of methotrexate induced salt wasting in the presence of SIADH as seen by the patient's continued high urine osmolality. This case is also unusual as the salt wasting occurred on her eighth dose of methotrexate rather than on her first.

PUB479

Dialysis Induced Thrombocytopenia Adil R. Ali, Biruh Workeneh. *Div of Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: Thrombocytopenia (TCP) associated with HD has been attributed to a number of causes including complement activation from membrane surface interaction, exposure to filter preservative, direct activation of cellular components and so on. Cuprophane and cellulosic membranes, which activate the complement system, are often implicated but these membranes are no longer in common use. In this case report, we described a patient who developed profound membrane-associated TCP after exposure to modern biocompatible polysulfone membranes.

Case Description: A 28 yo woman with progressive CKD secondary to lupus nephritis, antiphospholipid antibody syndrome (h/o pulmonary embolus) presented with uremic symptoms. She was initiated on HD with 3 sessions using a electron-beam sterilized Fresenius Optiflux 160. On the morning prior to initiation her plt count was 233 x10^3/uL; on the second day 131 x10^3/uL; and after the third fell to 12 x10^3/uL. She received no heparin with HD treatments, and evaluation for DIC, HIT and thrombotic microangiopathy were negative. TCP continued to occur after HD despite flushing the priming solution with 1 liter of saline prior to HD (see figure).



The dialyzer was switched to steam sterilized Gambro Revaclear, and her plt count again decreased from 87 x10^3/uL to to 41 x10^3/uL. She was subsequently transitioned to peritoneal dialysis, her plt count recovered and remained stable while on PD.

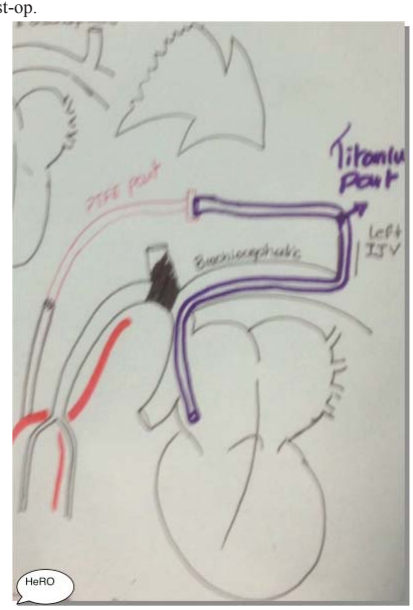
Discussion: This case report shows persistent TCP associated with hemodialysis with two different biocompatible membranes. There are reported cases of resolution of dialysis-induced TCP after switching dialyzers, but this patient's TCP did not improve. This report suggests studies to examine risk factors and pre-existing antibody or induced antibody that activate plt are sorely needed in order to able to predict occurrence of this potentially devastating complication.

PUB480

The Use of the HeRO Graft in Haemodialysis Patients with End Stage Vascular Access: A Case Series Frank J. O Brien, Mohamed Shantier, David Lappin. *Dept of Nephrology, Galway Univ Hospital, Galway, Ireland.*

Introduction: The Hemodialysis Reliable Outflow graft (HeRO) is a subcutaneous implant consisting of a silicone venous outflow component and an arterial PTFE component. It traverses central venous stenoses and allows for long-term vascular access in haemodialysis patients who have exhausted venous access sites. We describe the first three cases of HeRO graft use in Ireland.

Case Description: A 59 year old with hypertensive ESRD who commenced RRT via left brachiocephalic AVF. She developed left subclavian stenosis which failed multiple angioplasties. She underwent a HeRO procedure to relieve the proximal obstruction as well as restoring her AVF as source of vascular access. She was dialysed successfully via the HeRO day 1 post-op. A 71 year old with hypertensive ESRD who commenced HD via left brachio-cephalic fistula. Following its failure, a R AVF was created. She subsequently developed SVCO syndrome. She underwent a HeRO procedure to relieve the SVCO and provide permanent dialysis access. She was dialysed successfully via the HeRO day 1 post-op.



83 year old with ESRD secondary renovascular disease commenced haemodialysis via RIJ permcath 2007. Subsequently had R Brachiocephalic AVF created in 2008. Developed SVC obstruction secondary to R brachiocephalic vein stenosis. Required multiple angioplasties and had high venous pressures resulting in recurrent bleeding from AVF cannulation site. Underwent HeRO procedure to relieve this stenosis, and provide permanent access. He successfully dialysed 2 weeks post op.

Discussion: These cases highlight the potential benefit of the HeRO graft in patients with difficult vascular access. We also describe the use of the HeRO in restoring previously failing AVFs.

PUB481

Hypernatremia in a Patient with Paranoid Adipsia Laith Farah Al-Rabadi, Jean M. Francis. *Nephrology, Boston Univ Medical Center.*

Introduction: Hypernatremia is associated with high mortality. Antidiuretic hormone (ADH) secretion and thirst mechanism are tightly regulated within hypothalamus circuits to prevent hypernatremia. Adipsia is an extremely rare entity with fewer than 100 reported cases worldwide. However, more unreported cases are likely present. Psychogenic adipsia, a syndrome extremely opposite to the frequently reported psychogenic polydipsia associated with hyponatremia, is even rarer and represents a diagnosis of exclusion in a patient presenting with hypernatremic dehydration. It is marked by normal ADH activity, intact urinary concentrating ability with maximally concentrated urine. Herein, we describe a case of severe hypernatremia caused by paranoid adipsia.

Case Description: A 32 year old white male incarcerated patient with history of schizophrenia had paranoid thoughts of water carrying chemicals that may poison his body. He indulged in drinking his own urine and avoiding any sources of water despite his severe thirst. He was obtunded and confused on presentation. Sodium level reported as higher than 176 mmol/l as lab assay could not accurately measure such high levels, Cr 2.8 mg/dl, Glucose of 143 mg/dl. Serum osmolality of 414 mosm/kg and urine osmolality of 960 mosm/kg with urine Na less than 20 mmol/l. Isotonic fluid was chosen in the absence of definite Na to guide treatment. We asked the lab to dilute the sample to have a better estimate of Na level. Level was measured at 177 mmol/l after 12 hours of hydration with 0.9%NS. Urine osmolality of 382 mosm/kg and urine Na of 57mmol/l following resolution of hypernatremia revealed suppressed ADH and reflecting intact regulatory mechanisms. Psychiatric management of his disease helped resuming normal drinking habits.

Discussion: Hypodipsia–adipsia related hypernatremia can occur from psychiatric illness which may directly disturb thirst mechanism or induces psychiatric conflicts with

voluntary self-restriction of water intake. However, this does very rarely occur and exclusion of other disorders and structural diseases is mandatory as thirst mechanism is a very powerful sensation and very difficult to thwart. Reinstituting normal drinking behavior will be most beneficial in preventing further episodes of hypernatremia.

PUB482

Idiopathic Pulmonary Hemorrhage in a Peritoneal Dialysis Patient

Andrew M. South. *Div of Pediatric Nephrology, Stanford Univ, Palo Alto, CA.*

Introduction: Infants on peritoneal dialysis (PD) are at risk for complications. Tachypnea and tachycardia frequently occur but are non-specific. Rarely they are a precursor of pulmonary hemorrhage (PH). Idiopathic pulmonary hemorrhage (IPH) is rare but well described in infants and prompt recognition and management is vital.

Case Description: Two month-old term female with bilateral renal dysplasia, pulmonary hypoplasia and moderate pulmonary hypertension (pHTN) on PD. On the floor she had intermittent tachypnea and tachycardia. On day three she developed an oxygen requirement. There was no issue with PD or fluid status. Electrolytes were stable and a chest x-ray (CXR) and blood gas were normal. She received a fluid bolus with no improvement. She acutely decompensated and was intubated. Ventilation was difficult with gross blood on laryngoscopy and suctioning. Conventional mechanical ventilation required high settings. CXR showed diffuse consolidation, hematocrit dropped from 25 to 20 and she received packed red blood cells, platelets, fresh frozen plasma and desmopressin. There was no evidence of infection. Echocardiogram showed improved pHTN and coagulopathy workup and CT angiogram were negative. Five days later she had cardiorespiratory arrest with an acute drop in hematocrit due to PH associated with Klebsiella pneumonia requiring blood products. Bronchoscopy and cardiac catheterization three weeks later were negative. A rheumatologic workup of the patient and her mother was negative. She was transferred to the floor at age four months. PD was stable with no oxygen requirement. No etiology was found and she was diagnosed with IPH. Over the next year she had multiple cardiorespiratory arrests without PH and she eventually passed away during an arrest.

Discussion: Infections and congenital heart disease most commonly cause pediatric PH. Pediatric IPH rarely occurs but prompt diagnosis and treatment is essential. Infant IPH is defined as abrupt airway bleeding with diffuse pulmonary infiltrates leading to severe respiratory illness requiring mechanical ventilation. Our patient met these criteria, though she was not previously healthy and had neonatal medical problems.

PUB483

A Case of Spontaneous Subcapsular Renal Hematoma and Severe Thrombocytopenia in a Patient with Antiphospholipid Syndrome

Alexander Osei-Bonsu, Jabulani Sidile, Nand K. Wadhwa, Edward P. Nord, Patrick Gerard Lynch. *Nephrology, Stony Brook Univ Hospital, Stony Brook, NY.*

Introduction: Anti-Phosphosholipid syndrome (APS) is characterized by thrombotic events with antiphospholipid antibodies. However bleeding diathesis can occur. We report a case of spontaneous renal subcapsular hematoma with primary APS and severe thrombocytopenia.

Case Description: A 71 year old woman with deep vein thrombosis and pulmonary embolism on coumadin underwent aorto-femoral bypass and endarterectomy for an occlusive clot of the left common iliac artery. This was complicated by acute kidney injury, anemia and thrombocytopenia associated with a large right subcapsular renal hematoma requiring embolization of the right renal artery to achieve hemostasis. She was started on emergent hemodialysis. Physical examination revealed right CVA tenderness, and areas of ecchymosis. Laboratory data showed a WBC19.0 k/mcl, Hgb 9.1 g/dl, platelet 33k/mcl, BUN 83mg/dl, creatinine 7.58mg/dl, HIT Ab negative, C3 normal and C4 low. ADAMTS13 was 64% with positive lupus anticoagulants, anti-cardiolipin IgM antibodies were 14 mpl units and beta 2 glycoprotein-1 IgM antibodies were 27mpl units. Right kidney biopsy showed thrombotic microangiopathy. A diagnosis of catastrophic APS was made. She was treated with plasmaphersis for 7days; IVIG daily and methylprednisolone 1 g IV daily for 3 days followed by oral prednisone. Her platelets increased to 82 k/mcl. Heparin was restarted for anticoagulation. Her platelets again decreased to 25k /mcl. She received a second 3 day course of IVIG and 4 doses of Rituximab. Her kidney function did not recover and she remained on chronic hemodialysis. She was discharged home on coumadin and prednisone taper. Her Platelets were 268 k/mcl at 8 week outpatient follow up.

Discussion: Severe thrombocytopenia in APS appears to be an immune mediated process. Our case demonstrated resolution of thrombocytopenia with a combination therapy of plasmaphersis, IVIG and Rituximab. A subcapsular renal hematoma is rare in APS and was stabilized with an improvement in thrombocytopenia while receiving coumadin.

PUB484

An Unexpected Presentation: Minimal Change Disease in an Adult with Hepatitis C Virus-Related Cryoglobulinemia

Zhenda Zheng,[1] Cailian Cheng,[2] Chenggang Shi,[2] Xun Liu,[2] Tan-Qi Lou.[2] *[1]Dept of Cardiology, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Nephrology, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China.*

Introduction: The hepatitis C virus (HCV) infection is associated with several renal diseases including mixed essential cryoglobulinemia, membranoproliferative glomerulonephritis (MPGN) and less frequently membranous nephropathy and crescentic glomerulonephritis.

Case Description: A 43-year-old male was referred due to progressive edema in the lower limbs and nephrotic range proteinuria, His past medical history included being an intravenous drug abuser. Biochemistry test showed raised serum creatinine of 163μmol/l. He had nephrotic range proteinuria of 12g/day and a serum albumin of 19 g/l. Viral serology for hepatitis B and HIV was negative but confirmed evidence of HCV infection with genotype 3A and viral load of 659000 copies. Laboratory parameters showed presence of cryoglobulin.He had a renal biopsy and histology demonstrated features of minimal change disease. We commenced treatment with intravenous methylprednisolone 24 mg once daily for 10 days, followed by oral Medrol 24 mg Q.d. Concurrently, Mycophenolic acid 0.5g Bid was commenced. After a 2-week treatment, proteinuria had remitted, his renal function showed remarkable recovery with creatinine reduced to 81 μmol/l. The patient didn't receive antiviral therapy. At 4 months follow-up clinic, his renal function was normal with serum creatinine of 68 μmol/l, 24-h urinary protein had dropped to 0.12 g/day, serum albumin increased to 42 g/l and HCV RNA didn't increase and Alanine transaminase and aspartate aminotransferase were normal.

Discussion: This is the first case report that a patient who presented as nephrotic syndrome with renal pathology minimal change disease associated with hepatitis C virus-related cryoglobulinemia was treated successfully with steroid and Mycophenolic acid. Our case highlights an important treatment strategy and may be beneficial to nephrologists facing this clinical scenario. However, a randomized controlled trial is required to evaluate the efficacy of this treatment combination before it can be a standard treatment.

PUB485

Acute Kidney Injury in the Post Cardiac Surgery Setting Is Not Always Acute Tubular Necrosis

Haris Farooq Murad,[1] Hernan Rincon-Choles,[2] Fahad Saeed.[2] *[1]Internal Medicine, Cleveland Clinic, Cleveland, OH; [2]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Introduction: Post cardiac surgery acute kidney injury due to an overlap of thrombotic thrombocytopenia purpura and disseminated intravascular coagulation is rarely reported.

Case Description: We report a case of a 69 year old gentleman with coronary artery disease, cardiac surgery and solitary kidney who underwent aortic and mitral valve replacement surgery. His post-operative course was complicated by hypotension and creatinine peaked to around 2.4mg/dL but stabilized around 1.9 mg/dl. Eleven days after the surgery, his Creatinine again started rising (3.3 mg/dL) without any obvious insult. Platelets dropped to 72,000, he had peripheral schistocytosis, and hemoglobin was 8.8g/dL. Urine studies showed microscopic hematuria, 30mg/dL protein and muddy brown casts. ADAMTS 13 level was low (7) and ADAMTS 13 inhibitor was detectable (1.4). He was treated with a total of 11 sessions of plasma exchange (PLEX) resulting in improvement of anemia, thrombocytopenia and creatinine. ADAMTS 13 activity also improved to 44 and ADAMTS 13 inhibitor assay became negative. However, a few days later he relapsed with recurrent anemia and thrombocytopenia, along with a rise in Creatinine to 2.4 mg/dL. He was restarted on PLEX for an additional 14 sessions leading to improvement of hematological parameters and renal function. During the next week, he had episodes of hypotension resulting in anuric renal failure requiring renal replacement therapy. He continued to have thrombocytopenia with high LDH, low haptoglobin, normal prothrombin time, decreased fibrinogen, increased d-dimer and fibrinogen split products. This time ADAMTS13 level was normal. Bone marrow biopsy was unrevealing. He had treatment with broad spectrum antibiotics for presumed underlying infection and his thrombocytopenia eventually resolved 2 weeks later. However, he remained dialysis dependent.

Discussion: Our case highlights that TTP/DIC overlap is an important cause of AKI in the post cardiac surgery setting. Physicians should consider sending ADAMTS13 level and the inhibitor activity to entertain this diagnosis, which has high morbidity and mortality.

PUB486

Focal Segmental Glomerulosclerosis in a Patient with Mantle Cell Leukemia

Sumeet Hindocha, Seerapani Gopaluni. *Renal Unit, Churchill Hospital, Oxford, United Kingdom.*

Introduction: Focal segmental glomerulosclerosis (FSGS) can either be a primary disease or secondary to an underlying condition. FSGS is rarely reported in association with haematological malignancies.

Case Description: A 67 year old gentleman presented with a 1 month history of progressive lower limb swelling and shortness of breath. He was previously fit and well. He was severely nephrotic with marked peripheral oedema and nephrotic range proteinuria. Urinalysis showed 3+blood and 4+ protein. Investigations revealed high urea 27.8mmol/L, high creatinine 272 umol/L and decreased serum albumin. Haemoglobin was 13.7g/dL, WCC $8.19x10^9$/L. Immunoglobulins, complement, ANA and protein electrophoresis were all normal. He underwent a renal biopsy and the histology was consistent with early FSGS, showing segmental sclerosis, epithelial hypertrophy and hyperplasia, endocapillary foam cells and tip lesions, with positivity for IgM. He had good response to prednisolone 60mg OD. Within 6 weeks his creatinine had normalised and proteinuria improved. Ciclosporin was added following a 2nd relapse 9 months after finishing his first treatment. This was again initially met with good response. Further follow up showed a persistent, marked lymphocytosis and nephrotic syndrome began to relapse. Peripheral blood immunophenotyping revealed a significant increase in the number of CD19+ve B-cells. CT imaging showed no significant lymphadenopathy. Fluorescence In-situ Hybridization analysis was positive for t(11:14) consistent with mantle cell leukaemia. He was commenced on 3 cycles of R-CHOP chemotherapy, to which he responded well. His renal function normalised and proteinuria resolved. He remained in remission for more than one year.

Discussion: Although nephrotic syndrome rarely occurs in association with acute leukemia, they have often been described in chronic lymphocytic leukemia (CLL).

Membranoproliferative glomerulonephropathy and membranous glomerulonephropathy are the most common lesions observed in CLL. Nephrotic syndrome has been well documented among patients with lymphomas, in particular, Hodgkin's lymphoma. However FSGS remains a rare association with mantle cell leukemia.

PUB487

Pseudo Colonic Obstruction Induced Hypokalemia in End Stage Renal Disease Patient Ramya Vejella, Cherinet S. Adgeh, Deepa Gali. *Nephrology, LSUHSC Shreveport, Shreveport, LA.*

Introduction: Hyperkalemia is one of the most common complications we encounter in CKD and ESRD patients, since excretion of potassium is mainly renal. Here we present a rare case where an ESRD patient who was on long term dialysis who presented with chronic hypokalemia.

Case Description: This is a 69 year old male with history of ESRD requiring HD since October 2011 who had multiple admissions since April 2012 for severe watery diarrhea, abdominal distention. During the same time frame, patient was noted to have persistent hypokalemia(highest potassium level being 3.5 mmol/l) despite being on a high potassium bath prescription on his outpatient hemodialysis. The current admission, abdominal x-ray showed colonic distention up to 11 cm in diameter. Obstruction secondary to volvulus, which was initially suspected was ruled out after a colonoscopy. Subsequently, a diagnosis of pseudo-colonic obstruction secondary to Ogilvie Syndrome was made, which was confirmed by return of colonic peristaltic movement after administration of IV neostigmine. The patient was managed conservatively, continued on a high potassium hemodialysate bath as an outpatient and discharged on oral potassium supplements.

Discussion: Persistent hypokalemia in a setting of End Stage Renal Disease is not a common presentation. This is a rare presentation of an ESRD patient presenting with chronic hypokalemia secondary to colonic pseudo obstruction. The mechanism involved in this patient is most likely massive up regulation of colonic BK channels, which is known to happen rarely in ESRD patients.

PUB488

Polymyxin B in Septic Shock: Two Case Reports Luigi Vernaglione. *Nephrology and Dialysis Unit, "A. Perrino" Hospital, Brindisi, Italy.*

Introduction: Nephrologist are involved in the management of septic shock by performing hemoperfusion with Polymyxin B (HPB) which consists in 2 hours sessions repeated over 3 consecutive days. HBP is indicated in case of sepsis coming from post-surgical, intra-abdominal, triggers and plasma endotoxin levels (PEL) higher than 0.6 EAA™ units. We present 2 cases in which HBP has been performed in our unit.

Case Description: CASE #1: G.M., a 37 y.o. male admitted with fever (41 °C) resistent to paracetamol and steroids. He was hypotensive (73/40 mmHg) and oliguric (200 ml/day). Lab values: hb 9.3 g/dl, WBC 79.100/ml, neutrophils 90%, INR 2.92, ATIII 43%, s.sodium 127 mEq/l. Renal function was normal and blood cultures were positives for Bacteroides ureolyticus. He was prescribed vancomycin (1 g x 2/day) and meropenem (1g x 3/day) without effects. Due to PEL=0.77 EAA™ units HPB was prescribed. After 3 days diuresis rose to 3000 ml/day, PEL fell to 0.4 EAA™ units, body temperature was normalized, WBC became 20.000/ml. After 24 hours from the third HPB session AKI occurred (s. creatinine 4 mg/dl) coupled to hypernatremia (156 mEq/l) and hypotension. Infusion of steroids and vasopressors was started but 36 hours later the patient died.

CASE #2: V.M., a 55 y.o. female admitted with headache, hypertension, hypoesthesia and hypotonia to the left side of body. For the last 5 days she had been complaining for fever. The CT scan revealed subarachnoid bleeding due to aneurysm rupture. She undervent surgical intervention. After 1 month she experienced hypotension (80/60 mmHg), high PEL (1.02 EAA™ units) and blood culture positive for klebsiella pneumoniae. After tigecycline (1 g x 2/ day) and meropenem (1g x 3/day) without improvement she started HPB. After this treatment the clinical picture improved with remission of fever, normalization of blood pressure and lab values, even if PEL remained high (0.8 EAA™ units).

Discussion: In conclusion, HPB in sepsis lowers the PEL but this is not sufficient if the septic trigger remains. It is the right combination between timing of HPB intervention, surgical treatment and antibiotic therapy the key of clinical success that can be appreciated, also without a significant reduction of PEL, even in case of extra-abdominal trigger of sepsis.

PUB489

Dilemma of Diagnosing Partial Central Diabetes Insipidus and Partial Nephrogenic Diabetes Insipidus Mayurkumar Gohel, Evan Norfolk. *Nephrology, Geisinger Medical Center, Danville, PA.*

Introduction: Partial central diabetes insipidus and partial nephrogenic diabetes insipidus are very difficult to differentiate with each other. Clinical history, blood tests and response to desmopressin (dDAVP) are helpful to make accurate diagnosis.

Case Description: 60 years old male with significant history of schizophrenia on chronic lithium, mental retardation and autism admitted due to fever, cough and hypernatremia. As per his caregiver, he was having polyuria, polydipsia and nocturia since last 4 yrs. Chest x-ray was within normal limits. Water restriction test was without change in urine osmolality so we gave dDAVP 4 microgram intravenous and urine osmolality went up 307mOsmol/kg and urine output was drop to 10 ml in first hour and 60 ml in second hour. The diagnosis of partial central diabetes insipidus was made and started on dDAVP 0.2 mg oral twice a day. Serum cortisol, growth hormone, adrenocorticotrophic hormone and insulin like growth factor 1 were within normal range. Magnetic resonance imaging of brain showed 1.7 mm pituitary microademona. Over the next 2 days, requirement of D5W went down, urine osmolality was in 200s and urine output was 100-150 ml/hr. Then patient allow to have more water and then his urine osmolality went down <200 and urine output was increase so increase dDAVP dose to 0.4 mg orally twice a day however urine output remain high and urine osmolality remained low. So with history of chronic lithium use and was not responding to high dose oral dDAVP, patient was treated for nephrogenic diabetes insipidus with hydrochlorothiazide 25 mg orally daily and patient urine output decrease and serum sodium was remain stable. Antidiuretic hormone level came later which was normal.

In our case patient has partial response with intravenous dDAVP and pituitary microadenoma suggest he has some partial central diabetes insipidus, however he was not responded well with oral dDAVP. Patient was on chronic lithium use, normal antidiuretic hormone level and was not adequately responded with dDAVP are favoring diagnosis of partial nephrogenic diabetes insipidus.

Discussion: Clinical history and response to dDAVP are very important factors to make accurate diagnosis of diabetes insipidus.

PUB490

Flank Pain and Shortness of Breath: Think outside the Box Mohamed Hassanein, Shalini Barlapudi. *Capital Health - Regional Medical Center, Trenton, NJ.*

Introduction: It is well documented in the literature that venous thromboembolic events such as DVT, PE and RVT are highly associated with nephrotic syndrome. This risk is particularly high in patients with idiopathic membranous nephropathy.

Case Description: A 24 year old Hispanic man with no past medical history presented to the emergency room with 3 months of left sided flank and back pain. He also reported progressing left sided chest pain, aggravated by inspiration and associated with dry cough and shortness of breath. Vital signs were Temperature: 98.4 °F, HR: 78bpm, BP: 147/69 mmHg, RR: 16/min, and SO2: 98% on room air. Physical exam was unremarkable. Laboratory findings showed serum creatinine: 0.76mg/dl, BUN: 16mg/dl, electrolytes were within normal range, total protein 4.7g/dl, albumin 2.1g/dl and cholesterol 358 mg/dl. Urinalysis showed moderate occult blood, hyaline and granular cast, protein > 300mg/dl which was confirmed by a 24 hour urine protein of 11gm. Computed Tomography showed a left lower lobe pulmonary artery embolism, associated with a moderate to large left pleural effusion and thrombus in the left renal vein and associated IVC. Left thoracocentesis was performed for diagnostic and therapeutic purposes which yielded 800 ml of transudative fluid. Serological studies including antinuclear Ab, anti-GBM Ab, p-ANCA and c-ANCA titers, CRP, complement levels, hepatitis panel, HIV-1 RNA PCR and RPR screen were negative; hypercoagubility workup was negative as well. Renal biopsy showed stage 2 membranous nephropathy and focal acute tubular injury and interstitial edema associated with renal vein thrombosis. Therapeutic anticoagulation was initiated, the patient was started on lisinopril and atorvastatin as well as prednisone and cyclosporine.

Discussion: Pleuritic chest pain with shortness of breath or flank pain in a patient with findings of nephrotic range proteinuria may be an alarming symptom of underlying serious thromboembolic complications of nephrotic syndrome. Close attention should be paid to patients with albumin levels < 2.8 g/dl. It is well documented in the literature that the risk of VTE increases 5.8-fold when serum albumin level is < 2.2 g/dl.

PUB491

Renal Infarction Associated with Oral Contraceptives: Third Case Report in Literature Suchita J. Mehta, Maybel M. Tan, Moro O. Salifu, Mary C. Mallappallil. *Suny Downstate.*

Introduction: Renal infarct is an uncommon condition that is reported to have an incidence of as low as 0.007% to 1.6%. This could partly be attributed to non-specific clinical presentation that can be misleading resulting in a missed/delayed diagnosis. The common causes are atrial fibrillation causing thromboembolism, renal artery injury/dissection, hypercoagulable conditions and occasionally polyarteritis nodosa, cocaine. Here below, we report the third case of renal infarction associated with oral contraceptives, based on our review of the literature.

Case Description: 28 year-old woman non-smoker with no past medical history presented to the emergency room on 14th September 2013 for 2 days duration of worsening right-sided flank pain without any fever. She was menstruating at that time but denied hematuria or dysuria. She was on oral contraceptive pills since 2009. Her BP was 118/70, normal sinus rhythm 79/min, and normal renal function. Urinalysis showed trace proteinuria with 182 RBCs, 6 WBCs with trace leucocyte esterase. Lactate dehydrogenase (LDH) was elevated at 434 IU/L. On C.T. abdomen she had a focal wedge shaped right renal infarct. Extensive work up for hypercoagulable conditions including protein C, protein S, antithrombin deficiencies, lupus anticoagulant, anticardiolipin antibody, beta2 gylcoprotein, Factor V Leiden mutation; were all negative. Her contraceptives were discontinued and symptoms of flank pain resolved in a week.

Discussion: Renal infarction, a relatively uncommon condition can often be missed and thus possibly under-reported. Patients present with pain in 96.8% cases, 46% uncontrolled hypertension, 90% have increased LDH, 40% with abnormal renal function Mean age of presentation is 53 years. We report a patient who was diagnosed with renal infarct at a relatively young age and was noted to have only two of the common clinical presenting signs and more importantly the only possible etiology, after ruling out atrial fibrillation and hypercoagulable conditions, is likely oral contraceptives. Based on our literature review, this is only the third case of renal infarct associated with oral contraceptives without any other risk factors for thromboembolism or hypercoagulable conditions.

PUB492

Normotensive with Proteinuria During Pregnancy: Is This Preeclampsia? Purna Bindu Nandigam, Talal A. Khan, Muhammad Awais Arif, Akshay Sharma, Ziauddin Ahmed. *Div of Nephrology, Drexel Univ, Philadelphia, PA.*

Introduction: Preeclampsia is defined as new onset of hypertension (HTN) and either proteinuria or end organ dysfunction after 20 weeks (wks.) of gestation in a previously normotensive woman. In 2013, ACOG removed proteinuria as an essential component for diagnosing preeclampsia. In the United States, preeclampsia/eclampsia is one of 4 leading causes of maternal death. For this reason, most healthcare providers tend to make a diagnosis of preeclampsia based on both HTN and proteinuria being present. However over diagnosis can result in premature delivery. Here in we present a case of isolated proteinuria in a normotensive parturient.

Case Description: 41 years old south Asian G3P3 female presented at 28 wks. gestation for evaluation of proteinuria. She had no complaints and denied any headache, vision problems, or abdominal pain. Her blood pressure was 110/60 and physical examination was unremarkable except for 2+ lower extremity edema. UA showed 4+ proteinuria. Urine tests done at the 24th week showed micro albumin to creatinine ratio of 2713 mg, serum BUN of 7mg/dl and creatinine of 0.6 mg/dl. Her platelets, hepatic profile, ANA, and complements were all within normal limits. She had no known history of proteinuria or kidney disease. Preeclampsia was a strong differential diagnosis with discussion of the need for possible early delivery. Since the past medical history of proteinuria was unknown and the patient remained normotensive without any signs or symptoms of hypoperfusion, the decision was made to monitor the patient's BP and proteinuria every 2 wks. for any signs of disease progression. The patient's proteinuria fluctuated during subsequent visits but BP remained normal. The patient was induced at 38 wks. secondary to possible cholestasis, and delivered a full term baby without complications.

Discussion: Our case demonstrates that careful monitoring of a pregnant patient with normal BP and proteinuria especially diagnosed after 20 wks. can be managed to a term delivery. As per new ACOG guidelines new onset of HTN after 20 weeks of gestation is the most important factor in the diagnosis of preeclampsia. Isolated proteinuria should not be a trigger for encouraging early delivery.

PUB493

Case Report : Acute Kidney Injury and Hemolytic Anemia in Falciparum Malaria Anila P. Sankar,[1] Sudheer K. Sankar.[2] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Medicine/Nephrology, Memorial Hermann Southwest Hospital, Houston, TX.*

Introduction: Falciparum malaria (FM) is a mosquito vector borne disease caused by a parasite plasmodium malariae. Though not endemic to U.S., incidence of FM is our country is around 1500 per year mainly from travelers and immigrants. Common renal manifestation of acute FM are acute interstitial nephritis, and acute tubular necrosis from hemolysis. Post infectious glomerulonephritis and membranoproliferative glomerulonephritis are less common.

Case Description: 46 year old AAM with no past medical history but a recent travel to Africa presented to the ER with fevers and altered mental status. Physical examination: BP 93/44 mmHg, temperature 103.3, abdominal examination with splenomegaly, and no pedal edema. Hemoglobin was 7.7 gm/dl. Total bilirubin was 2.8. Creatinine was 3.1mg/dl, BUN 45 mg/dl, sodium 126,with albumin of 2.3. Urine analysis with specific gravity of 1.005,large blood, 1+protein, and RBCs. LDH was 351 with haptoglobin of 26.Peripheral smear showed plasmodium falciparum with parasitemia of 6 %. Serological workup was negative except for a new diagnosis of HIV. Ultrasonography showed splenomegaly and enlarged kidneys .Renal biopsy for FM glomerulonephritis shows widening of mesangial area, hypertrophy and hyperplasia of endothelial cells. EM with electron dense deposits in subendothelial and paramesangial areas. Patient was treated with aggressive volume resuscitation, quinine and supportive care with plans for exchange transfusion and renal replacement therapy. He subsequently became polyuric. As parasitemia improved renal function returned to baseline creatinine of 1.1.

Discussion: Early detection and aggressive treatment prevents worsening of renal function in FM from acute tubular necrosis and acute interstitial nephritis. Hyponatremia is observed in 6% of patients with FM secondary to increase in antidiuretic hormone. Acute kidney injury is common secondary to acute intravascular hemolysis or heavy parasitic infection. Patients diagnosed with FM with parasitemia greater than 10% have complications of renal failure requiring renal replacement therapy. Quinine still remains the treatment of choice.

PUB494

A Mysterious Case of Hypomagnesaemia Patricia Nasr, Marc M. Saad, Ninad D. Parekh, Rabih Nasr. *Internal Medicine, Staten Island Univ Hospital, Staten Island, NY.*

Introduction: Since there is no major hormone regulating serum magnesium level, the etiology of hypomagnesemia includes poor intake or gastrointestinal loss or renal magnesium wasting. Here we present an interesting case of hypomagnesemia.

Case Description: A 24 year old male presented for repeated episodes of acute muscle twitching and numbness. He has no significant past medical history and takes no medications. His vitals including blood pressure were within the normal range. Neurological exam was normal. Laboratory values showed low magnesium (1.3 mg/dL) with a fractional excretion of magnesium of 18.3%, and hypocalciuria with a urine calcium creatinine ratio of 0.03. He also had metabolic alkalosis with bicarbonate of 31, and potassium of 3.9 mmol/L. An AST was found to be 42 IU/L and ALT 67 IU/L and were persistently elevated with negative hepatitis B and C serology and no history of alcohol abuse. Renal ultrasound showed renal cysts. He was treated with IV magnesium and switched to oral magnesium oxide upon discharge.

Discussion: Causes of renal magnesium wasting include genetic renal tubular defects or drugs. Gitelman syndrome, characterized by renal magnesium wasting, metabolic alkalosis, hypokalemia and hypocalciuria, is caused by mutation of the SCL12A3 gene that encodes the sodium-chloride cotransporter (NCCT). However, our patient had normokalemia. Isolated dominant hypomagnesemia (IDH) with hypocalciuria occurs due to mutation of FXYD2 gene that encodes a gamma subunit of the DCT basolateral Na+/K+ ATPase. Hepatocyte nuclear factor 1β (HNF1β) is a well-known transcription factor that plays a role in the activation of FXYD2 gene and mutations in HNF1β is reported to cause renal magnesium wasting, renal cysts, elevated liver function tests. To the best of our knowledge, Gitelman syndrome does not present with normal serum potassium and HNF1-B mutation spectrum is not characterized by metabolic alkalosis and hypocalciuria. Our case is unique in that it represents a hybrid of two well-defined renal magnesium disorders. Our patient was referred for further genetic testing, which are pending at this time.

PUB495

Bilateral Renal Vein Thrombosis: A Rare, Life-Threatening and Reversible Cause of Acute Kidney Injury Dearbhla Kelly, Mark N. Canney, Brenda B. Griffin. *Dept of Renal Medicine, Cork Univ Hospital, Ireland.*

Introduction: Renal vein thrombosis (RVT) is a rare thrombotic entity outside of the context of nephrotic syndrome or malignancy. It may occur with hypercoagulable states, trauma, infection or with use of oral contraceptive pill. Its prevalence within the nephrotic syndrome ranges from 5-60%. It is particularly common with membranous nephropathy or in those with protein excretion >10g/day. It can be diagnosed by Doppler ultrasound, computed tomography (CT) or magnetic resonance imaging. The gold standard test is a selective renal venogram. Chronic RVT is often asymptomatic but acute RVT can present dramatically as outlined in this case.

Case Description: A 47 year old male presented with a 10 day history of abdominal pain, distension and diarrhoea. On examination, he had ascites and significant bilateral lower limb oedema. He had developed an oliguric acute kidney injury (AKI) with a rapidly rising creatinine from 163μmol/l. to 684μmol/l. He had microscopic haematuria without significant proteinuria. He had a persistent thrombocytosis (platelet levels of $1059X10^9$/L). A contrast-enhanced abdominal CT scan was performed. This revealed an extensive thrombus in his inferior vena cava with bilateral RVT and a right segmental pulmonary embolism. In addition, he had acute appendicitis. He was commenced on unfractionated heparin and intravenous antibiotics. He required intermittent haemodialysis for 2 months and then made an excellent renal recovery. The patient was subsequently diagnosed with a JAK2 positive myeloproliferative disorder and is now maintained on lifelong aspirin, warfarin and hydroxyurea.

Discussion: This gentleman illustrates classic symptoms of RVT including flank pain and haematuria. He had multiple risk factors including a previously undiagnosed thrombophilia and abdominal sepsis. Bilateral disease can cause a rapidly progressive AKI as in this case. Treatment of symptomatic RVT involves anti-coagulation with either unfractionated or low molecular weight heparin followed by warfarin. There is limited evidence for local thrombolytic therapy with or without thrombectomy. Early diagnosis and prompt management is key as untreated acute RVT has a mortality of greater than 50%.

PUB496

Henoch-Schonlein Purpua Presenting as a Paraneoplastic Syndrome with Pancreatic Cancer Smita Mahendrakar, Shiba Khorsandi, Suneet Verma, Arshia Abbasi, Nitin Behl, Reza Amerinasab, Michael Yudd. *Renal Section, Dept of Veterans Affairs NJ Healthcare System, East Orange, NJ.*

Introduction: Adult-onset Henoch –Schonlein Purpura (HSP) rarely has been described as a paraneoplastic syndrome with solid organ malignancies, and to our knowledge, this is the first description with pancreatic cancer.

Case Description: 54 year-old AA man was found to have purpura, microscopic hematuria and intermittent abdominal pain during an admission for alcohol rehab. No heroin or cocaine use. The rash involved legs, torso and arms. Serum creatinine was 1.2 mg/dl. Urinalysis: 3+ protein, 30 RBC/HPF, many were dysmorphic, and RBC casts. Urine protein/creatinine ratio was 5.3. Negative or normal: ANA, ANCA, anti-dsDNA, complement, hepatitis B, C, HIV, toxicology screen, serum and urine electrophoresis. A skin biopsy showed leukocytoclastic vasculitis. Renal biopsy light microscopy showed mild to moderate endocapillary proliferation and increased mesangial matrix, no crescents. EM : small mesangial and rare subendothelial deposits; IF: granular mesangial deposits of IgA (2+), C3 (2+), and IgM(1+)in all glomeruli. These findings of purpura, glomerulonephritis with predominant IgA deposits, and abdominal pain with negative serologies favored the HSP diagnosis. He was given steroids, improved, and was transferred for prolonged rehab. Seven months later, CT of abdomen showed a mass in the pancreatic tail. A month later, a repeat CT showed new liver lesions. Liver biopsy showed metastatic high grade carcinoma, consistent with pancreatic primary. In retrospect, the pancreatic mass was present on CT interventional images done at renal biopsy.

Discussion: HSP is a small vessel leukocytoclastic vasculitis with deposition of IgA which commonly involves the skin, kidney and GI tract. In adults, paraneoplastic HSP has infrequently been described in lung, prostate and renal carcinomas.This is the first case of HSP that is associated with pancreatic cancer. Unfortunately, the pancreatic cancer, although present at the time of the renal biopsy (see above), was diagnosed too late for our patient. It may be prudent to screen older patients presenting with HSP for occult malignancies.

PUB497

Minimal Change Disease in Adults: Challenges Posed; a Series of 3 Cases Roveena N. Goveas,[1,2] Inder Patel,[1,2] James H. Sondheimer.[1,2] *[1]Wayne State Univ School of Medicine, Detroit, MI; [2]Detroit Medical Center, Detroit, MI.*

Introduction: We present a series of 3 cases of minimal change disease referred to adult nephrology clinic and the challenges faced in their management.

Case Description: All 3 patients, previously healthy, presented with nephrotic range proteinuria, and renal biopsy demonstrated minimal change disease. All had normal renal function and no precipitating factors identified such as non -steroidal use, atopy or lymphoma. The first patient, 45 yr old African American (AA) male received prednisone for 16 weeks, but remained steroid dependent. Proteinuria persisted on low dose maintenance prednisone, and addition of MMF led to only a transient improvement. He is being started on cyclosporine which was previously declined. The second patient, a 40 year old AA female achieved complete remission with prednisone, then relapsed 4 months later. ACE inhibitor was added to low dose prednisone and patient is maintained in remission. The third patient, a 25 year old AA female was initiated on prednisone, but failed to achieve remission. She was offered but declined cyclosporine or cyclophosphamide; a trial of MMF achieved a partial remission. None of these 3 patients had complications related to nephrotic syndrome at 1 year of follow-up.

Discussion: These cases had in common; normal renal function at presentation, AA race, age group of 25-45, normotension at presentation and during treatment and absence of underlying disorders; however, each of these patients responded quite differently. The partial response and frequently relapsing proteinuria may raise the suspicion of a underlying focal segmental glomerulosclerosis, however, renal function remained normal for over 1 year of follow up. Adults presenting with minimal change disease may respond differently to therapy. None of these patients had repeat renal biopsy yet as its role in treatment failure is not well established. Unlike in children, our adult minimal change disease patients appear to follow a more chronic course. As minimal change disease is rare in adults compared to children, there are limited randomized and prospective clinical studies, making the treatment and prognosis assessment challenging.

PUB498

Boric Acid Poisoning in the Very Elderly: A Case Report Selena Longhi, Monica Limardo, Lucia Del Vecchio, Maria Carla Bigi, Donatella Casartelli, Mauro Maria Corti, Flavia Tentori, Giuseppe Pontoriero, Francesco Locatelli. *Nephrology and Dialysis, A. Manzoni Hospital, Lecco, Italy.*

Introduction: Boric acid is a weak acid, which is often used as an antiseptic, insecticide, fungicide and as eye wash in dilute solution. In nature it exists in the form of colorless crystal or as white powder. 90% of oral dose is excreted through kidneys. Letal acid boric poisoning is defined as ingestion of 15-20 g or serum concentration of 1000 µg/ml. The clinical manifestations are hypotension, fever, gastrointestinal, cutaneous, central nervous system symptoms and acute renal failure. There is no agreement on therapy following acid boric intoxication. Hemodialysis removes 60% of acid boric and it is combined with forced diuresis. Forced diuresis may be used alone; peritoneal dialysis is an option mainly in children.

Case Description: 95 year-old woman ingested 20 g of boric acid by mistake. On admission she had fever, vomit, diarrhea. Laboratory data showed: s-creatinine 1.79 mg/dl (basal s-creatinine 1.3 mg/dl), leukocytosis, anemia. Boric acid serum concentration was not available. Rehydration therapy and forced diuresis were decided given mild acute renal failure and comorbidities. After few hours severe hypotension, oliguria and increased s-creatinine level (2.52 mg/dl) occurred. Two hemodialysis sessions were performed followed by rehydration and high dose of diuretic therapy. Overall patient conditions improved showing stable blood pressure levels (130/70 mmHg) and diuresis recovery. After few days renal function was completely restored.

We described a theoretical lethal dose of acid boric poisoning with renal involvement in an elderly patient. Despite high dose, advanced age and comorbidity, the patient had a complete recovery of acute renal failure thanks to combined therapy (hemodialysis and forced diuresis). This case confirms the efficacy of hemodialysis in the treatment of acid boric poisoning and it suggests its early start.

PUB499

A Case of Nephrotic Syndrome due to Antiphospholipid Syndrome Nephropathy Miho Karube, Shinya Kaname, Kazuhito Fukuoka, Yoshinori Komagata, Yoshihiro Arimura. *First Dept of Internal Medicine, Kyorin Univ School of Medicine, Tokyo, Mitaka, Japan.*

Introduction: Although renal complications are common in patients with antiphospholipid syndrome (APS), nephrotic syndrome is rarely seen.

Case Description: [Case] A 71-year-old woman with a history of hypertension was referred to our hospital because of leg edema that had appeared six months before and the laboratory findings including elevated serum creatinine, nephrotic range proteinuria and pancytopenia. The anticardiolipin antibody titers were repeatedly positive, but serum cryoglobulin was negative. Renal biopsy revealed five global sclerosis among 9 glomeruli, while diffuse hypercellularity in the mesangium, double contour of the capillary walls, and foam cells were found in the rest of the glomeruli. Chronic lesions such as focal cortical atrophy and fibrous intimal hyperplasia of the arterioles were also observed. Immunofluorescence study revealed granular deposits of IgM in the mesangial areas. On the other hand, IgG, IgA, C1q, and C3 were all negative. Electron microscopy revealed mesangial interposition and subendothelial deposits with endothelial swelling and widening of subendothelial spaces all of which suggested thrombotic microangiopathy (TMA). During the course of disease, she presented with autoimmune hemolytic anemia and thrombocytopenia, but did not show findings suggesting SLE such as fever, oral aphtha, skin rash, arthritis, serositis, neurological sign, and antinuclear and anti-DNA antibodies. Based on the pathological findings and the presence of anti-phospholipid antibodies, we diagnosed her as APS nephropathy. She was treated with intravenous cyclophosphamide and steroid pulse therapy, and proteinuria decreased two months later.

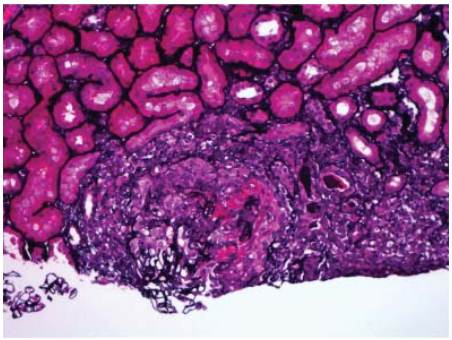
We report a rare case of APS nephropathy.presenting with nephrotic syndrome. We should consider the possibility of APS nephropathy when we see the patient with proteinuria and renal dysfunction showing chronic glomerular and vascular lesions with TMA but no immune deposits.

PUB500

Fortunate Enough to Pick Up Very Early - Double Positive ANCA and Anti-GBM Disease Girish Singhania, Jogiraju V. Tantravahi. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Double positive serologies for both ANCA and Anti-GBM antibodies is common in patients with either antibody. They usually present with severe disease and have a poor prognosis. We report a case of double positive for both ANCA and Anti-GBM antibodies picked up very early and got appropriate treatment in time.

Case Description: 71 y/o male with history of idiopathic pulmonary fibrosis was referred for microscopic hematuria and positive P-ANCA (ordered by pulmonologist due to worsening dyspnea). Exam was remarkable for minimal lung crackles. Labs showed normal sodium, potassium and bicarbonate. BUN was 17 mg/dL and S. creatinine was 1.1 mg/dL (Baseline 0.8-1.0). CT was negative for kidney mass. Urine showed 6 RBCs and proteinuria of 0.63 gm/gm of creatinine (negative in past). His SPEP, UPEP, hepatitis panel, ANA and complements were negative. To explain microscopic hematuria and positive P-ANCA, kidney biopsy was performed which showed necrotizing and crescentric glomerulonephritis (GN) with no immune complex deposition in EM consistent with pauci-immune GN.



Anti-GBM came back positive also. Treatment was started with cyclophosphamide and prednisone. In the last clinic followup, he was feeling better and his kidney function was stable.

Discussion: Pauci-immune GN correlates closely with ANCA disease due to circulating antibodies. There are cases of coexistence of Anti-GBM Antibodies and MPO-ANCAs in Crescentic GN. Although etiology is unknown, some believe that it is related to activation of matrix metalloproteinase-9 (MMP-9) by MPO and cleavage of goodpasture epitope by MMP-9. Studies have shown that histological characteristics in double-positive patients contain elements of MPO-ANCA disease (ie, granulomatous periglomerular inflammation) and renal survival in these patients is not better than that in anti-GBM-positive patients and is worse compared with patients with MPO-ANCAs only.

PUB501

An Atypical Case of Light Chain Deposition Disease Presenting as Acute Interstitial Nephritis Sadaf S. Khan,[1] Yashpal S. Kanwar,[2] Cybele Ghossein.[1] *[1]Div of Nephrology, Northwestern Univ Feinberg School of Medicine, Chicago, IL; [2]Dept of Pathology, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Introduction: Light chain deposition disease (LCDD) typically presents with asymptomatic proteinuria or nephrotic syndrome due to glomerular infiltration of monoclonal light chains. We report a rare case of LCCD in a patient who presented without proteinuria and tubulo-interstitial nephritis on renal biopsy.

Case Description: A 59 year old female was noted to have an elevated serum creatinine 2mg/dl on routine lab testing. Initial renal biopsy demonstrated acute tubulo-interstitial disease with granulomatous reaction. Serum protein electrophoresis (SPEP) and urine protein electrophoresis (UPEP) were initially negative. Prednisone was initiated for presumed allergic interstitial nephritis without improvement. Five months later, serum creatinine increased to 3.11 mg/dl and repeat SPEP and UPEP demonstrated monoclonal free kappa light chains. Repeat renal biopsy demonstrated chronic tubulo-interstitial disease, acute interstitial nephritis with granulomatous reaction, and 3+ linear kappa light chain deposition along the tubular basement membrane on immunofluorescence. Further diagnostic workup was consistent with a diagnosis of multiple myeloma.

Discussion: In conclusion, LCDD usually presents as a glomerular disease with nephrotic range proteinuria. A primary tubulo-interstitial pattern, however, can also be seen. A high index of suspicion and low threshold for renal biopsy is important to identify this group of patients.

PUB502

Successful Pregnancy in End Stage Renal Disease Secondary to Lupus Nephritis: A Case Report Nicole G. Reyes. *Internal Medicine-Section of Nephrology, Univ of the Philippines Manila-Philippine General Hospital, Manila, NCR, Philippines.*

Introduction: Chronic kidney disease (CKD) secondary to Lupus Nephritis in a pregnant patient have always been a challenge among nephrologists. There is paucity of clinical guidelines in the management of hemodialysis (HD) requiring pregnant patients, more so in patients with Systemic Lupus Erythematosus (SLE).

Case Description: We are presented with a 25-year old female with SLE, with baseline creatinine of 238 umol/L (2.69 mg/dL), 24-hour urine protein of 2.76g, maintained on Azathioprine, Prednisone, and Calcium Carbonate+Vitamin D, admitted due to decreasing urine output, swelling of lower extremities, and vomiting on her 27th week of gestation. On physical exam, blood pressure was 150/80, afebrile, with anasarca. Laboratory results showed hemoglobin 112 g/L, WBC 15.4 x10^3g/L, Platelet 232 x 10^3g/L, Creatinine of 670 umol/L, BUN 38.2 mmol/L, TCO2 15.7 mmol/L, 24-h urine protein 2.2g, normal C3, routine urinalysis showed pyuria, no hematuria and no cast, and urine culture showed >100,000 colonies of Hafnia alvei. She was given Piperacillin-tazobactam, Prednisone, Methyldopa, Hydroxychloroquine, Ferrous Sulfate, and Unfractionated Heparin. HD was initiated, targeting a BUN of <15 mmol/L, TCO2 of ~20mmol/L, and hemoglobin maintained at 100-110g/L; average HD was 20 hours per week. Ultrafiltration adjusted in accordance to the expected weight gain of the patient, blood pressure controlled to maintain a MAP of 106, and serial fetal monitoring performed. However, fetal distress was noted at the 28th week age of gestation and consensus was to deliver the baby the soonest time possible, hence, cesarian delivery was done delivering a baby boy with an APGAR score of 9,9 and weighed 850grams. On follow up, patient's creatinine was ranging between 200 and 300 umol/L (2.26-3.39 mg/dL), on maintenance HD 2x/week. The baby was discharged after a month of staying in the neonatal ICU.

Discussion: This case illustrates the potential benefit of intensified, tailored, early initiation of HD regimen in a pregnant patient, as well as BP control, aggressive infection containment, with the goal of carrying the fetus into term as much as possible.

PUB503

Steal Syndrome Causing Delayed Graft Function Shukri Abdullah, Warren L. Kupin.[1,2,3] *[1]Nephrology Dept, Univ of Miami Hospital, Miami, FL; [2]Transplant Nephrology, Jackson Memorial Hospital, Miami, FL.*

Introduction: The presence of AVG or AVF in lower extremities can lead to DGF of the transplanted kidney if placed on ipsilateral side. If untreated, Steel syndrome from lower extremity AV Graft or AVF can lead to DGF or even allograft loss. The importance is to increase awareness of the effect of lower extremities AV graft or fistula and make plan to prevent DGF. In this case even diagnosis was a challenging and took two months following transplant surgery while patient was on dialysis three times a week.

Case Description: 24 year old born with right ventricle dysplasia, had heart transplant at age 13. At age 20, she, being non adherent to medications, suffered rejection, cardiac arrest, had heart transplant again, was hypotensive before and during surgery so she developed acute kidney injury, needed hemodialysis permanently. At age 24, she received a living related kidney transplant from her sister but suffered DGF and started on hemodialysis again. Her kidney biopsy showed ATN, no rejection. After two months of being on hemodialysis, an extensive radiologic and vascular workup reveal steel syndrome of her right femoral AV graft from her transplanted kidney which was also placed on the right. (poor diastolic flow and pressure to allograft was detected). Her vasculature was exhausted following cardiac arrest.

Discussion: Steal syndrome: (the arterial flow is diverted to the low-resistance system of the AV graft rather than allograft) can lead to DGF, graft loss and hemodialysis following surgery. Options: Ligation of femoral AV grafts, contralateral placement of the allograft, performing a detailed preoperative workup, ultrasound, venography, pressure measurements, or conducting intraoperative ultrasonography can prevent it and regain allograft function. It is important to consider vascular access availability in case dialysis needed. Steal syndrome can represent a diagnostic challenge as in this case report.

PUB504

Profound Catheter Related MRSA Bacteremia Causing Cardiac Vegetations and Septic Emboli From the New Catheter in Just Three Days Lisa Aimee Hechanova, Seyed-Ali Sadjadi. *Jerry L Pettis VA Medical Center, Loma Linda, CA.*

Introduction: Hemodialysis catheter related bacteremia is an unfortunate but relatively common complication of hemodialysis in patients using either temporary or tunneled hemodialysis catheters, at a 10-fold higher rate than that of AVF or AVG. Unfortunately when there is no other functional access, catheters become a necessity. When a patient develops a catheter related infection, current IDSA guidelines recommend empiric antimicrobial therapy and immediate catheter removal if the infectious agent is Staphylococcus aureus, Pseudomonas, or Candida. They also recommend temporary catheter insertion at another anatomic site. Although these measures are usually adequate for management of a catheter related infection when initiated promptly, occasionally one can see further complications. Herein we present such a case.

Case Description: A 65-year-old male with longstanding hypertension, diabetes mellitus, and recent ESRD due to hypertension and diabetes, was admitted for a one day history of diarrhea. He was noted to have marked leukocytosis, as well as fever and chills. Blood cultures and stool studies were obtained. Two days later, blood cultures revealed MRSA (MIC for vancomycin of <0.5). IV vancomycin was initiated, and his right IJ tunneled hemodialysis catheter was immediately removed. Therapeutic vancomycin levels were achieved, and on hospital day 5, a new right IJ temporary hemodialysis catheter was inserted by IR for continuation of hemodialysis. TTE done on the same day did not show any obvious cardiac vegetations. Patient had persistent MRSA bacteremia, so on hospital day 8, patient underwent CT chest with contrast and TEE. CT chest revealed evidence of septic pulmonary emboli. TEE showed normal EF, patent foramen ovale, 0.5cm mitral valve vegetation, and a 0.5cm vegetation attached to the tip of the temporary hemodialysis catheter. The new hemodialysis catheter was immediately removed, blood cultures eventually cleared, and patient continued for a 6 week course of antibiotics for MRSA endocarditis.

Discussion: One must continually reevaluate for potential complications of MRSA bacteremia. In addition, prompt catheter removal and echocardiographic evaluation are also mandatory.

PUB505

A Case of Nephrotic Syndrome with Biopsy Evidence of Both IgA and Membranous Glomerulonephritis Gilsemar E.C. Boavida, Eduardo Jorge Duque de Sa Carneiro Filho, Lilian Cordeiro, Epitácio Rafael da Luz Neto, Lectícia Jorge, Leonardo Abreu Testagrossa, Roberto Zatz, Cristiane B. Dias, Viktoria Woronik. *Univ of São Paulo, Brazil.*

Introduction: We present an uncommon association between membranous glomerulonephritis and IgA nephropaty.

Case Description: A 45-year-old Caucasian woman sought medical attention due to edema of the lower limbs. She had been healthy until about one year earlier, when she noticed progressive leg swelling. Her past medical history was unremarkable. Urinalysis prior to admission showed proteinuria in excess of 1 g/L, without hematuria. She was treated with hydrochlorothiazide, 25 mg/day, referred to Nephrology and admitted for investigation. She was in good general condition. Blood pressure was 140/70 mmHg and BMI was 26 kg/m^2. Leg edema, 1+, was also noted. New tests showed: Hemoglobin 12 g/dL, BUN 10.3 mg/dL and Cr 0.62 mg/dL. Serologic tests for ANF and ANA were negative, whereas C3 (180 mg/dL) and C4 (37 mg/dL) were normal. Serum albumin was 3.5 g/dL, and total cholesterol was 266 mg/dL. Albumin/creatinine was 3.0. Ultrasonography showed kidneys with normal size and echogenicity. Renal biopsy revealed thickening of the glomerular basement membrane, with spikes seen in silver stained sections, and an occasional double contour. Diffuse mesangial expansion was also observed, along with slight focal endocapillary proliferation. Immunofluorescence showed diffuse mesangial deposition of IgA (2+), as well as diffuse and intense (3+) granular loop deposits of IgG and less intense deposits of IgM (1+), C1q (1+), C3 (1+) and lambda chains (1+). These findings prompted the diagnosis of IgA Nephropathy combined with Membranous Nephropathy. The patient was treated with enalapril and diuretics, with amelioration of proteinuria and preservation of renal function. She is presently being followed in an outpatient clinic.

Discussion: Combined IgA nephropathy and membranous GN is a rare condition, with relatively mild clinical manifestations, good prognosis, stable renal function and no specific therapeutic requirement. The mechanisms underlying this combination are unknown, although fortuitous association cannot be excluded.

PUB506

Vancomycin Nephrotoxicity: A Case Report of Biopsy Proven Vancomycin-Associated Acute Tubular Necrosis Coral Parikh,[1] Jacob Esquenazi,[3] James M. Pullman,[2] Deep Sharma.[1] *[1]Nephrology, Montefiore-Einstein Medical Center, Bronx, NY; [2]Pathology, Montefiore-Einstein Medical Center, Bronx, NY; [3]Medicine, Montefiore-Einstein Medical Center, Bronx, NY.*

Introduction: Vancomycin toxicity is commonly thought to be an acute interstitial nephritis. There are few reported cases of adult vancomycin-associated acute tubular necrosis (VAATN). The purpose of this report is to highlight the biopsy findings of a patient thought to have VAATN.

Case Description: The patient received vancomycin and ceftriaxone with no other known nephrotoxic agents for osteomyelitis/discitis on hospital day 1. Her baseline serum creatinine of 0.9 mg/dL rose to 4.5 mg/dL on day 9 of therapy. Peak vanco random level was 43.9 ug/mL. Renal biopsy revealed acute tubular necrosis with only mild interstitial inflammation. In addition, despite the lack of clinical findings suggestive of an intrarenal infection, the biopsy showed the extensive presence of neutrophils and dead cells in the tubular space resembling "pus casts".

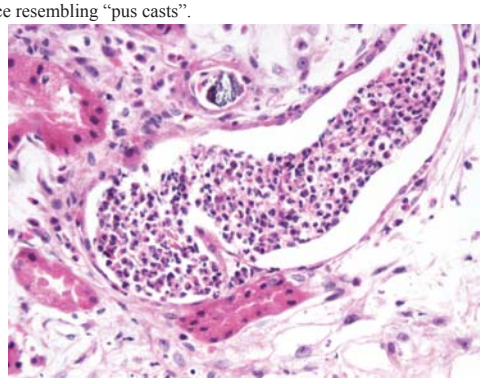

Figure 1 demonstrates renal tubule with neutrophils and surrounding interstitial edema.

Discussion: The presence of neutrophil casts may be a unique biopsy findings in VAATN.We present this case of adult VAATN as there is insufficient biopsy proven evidence of the pathological changes associated with vancomycin in kidney injury available to clinicians or pathologists.

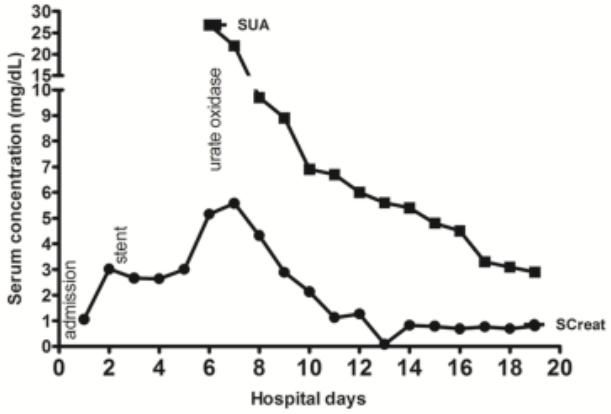
PUB507

Acute Uric Acid Nephropathy- Reversible If Recognized and Treated Early with Uric Acid Lowering Agents Hem P. Chataut, Imtiaz M. Ather, Taha Ayach, Yuvaraj Thangaraj, Keerti K. Bhanushali, A. Ahsan Ejaz. *Medicine, Div of Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Serum uric acid may have a role in acute kidney injury. We present a case to illustrate that crystal-independent mechanisms maybe involved in this phenomenon.

Case Description: We present a 67-year-old cardiac transplant recipient admitted with newly diagnosed lymphoma. Patient developed AKI and investigations revealed left hydronephrosis secondary to ureteral obstruction from retroperitoneal lymphadenopathy. Left ureteral stent placement did not result in improvement in renal function. Nephrology was consulted due to progressive worsening of AKI. Physical exam was unremarkable. Labs showed worsening SCreat of 5.6mg/dl. BUN 76 mg/dl, Na 134mEq/L, K 4.5mEq/L, Cl 108mEq/L, HCO3 23 mEq/L, Phos 5.8 mg/dL, calcium 8.8 mg/dl, UA: 100 RBC/hpf, WBC 7/hpf, trace protein and occasional calcium oxalate crystals. Serum uric acid (SUA) was found to be 26 mg/dL and the diagnosis of clinical tumor lysis syndrome (TLS) established. Patient received two doses of rasburicase (3 mg IV 12 hours apart), a recombinant urate oxidase and SUA normalized within 48 hours and was associated with prompt improvement in renal function.

Discussion: SUA causes renal vasoconstriction and has pro-inflammatory and anti-angiogenic properties. While crystal-dependent mechanisms of AKI are frequently observed in TLS, our case demonstrates the presence of crystal-independent mechanisms, which if recognized early and treated with uric acid lowering agents can lead to resolution of AKI and avoid need for renal replacement therapies.



PUB508

A Rare Cause of Renal AA Amyloidosis Bita Fakhri,[1] Lauren D. Stern.[1] *[1]Internal Medicine Residency Program, Boston Univ School of Medicine, Boston, MA; [2]Renal Section, Boston Univ School of Medicine, Boston, MA.*

Introduction: Serum Amyloid A (AA or secondary) amyloidosis is an unfortunate and rare complication of chronic inflammatory disease. This condition develops when proteolytic fragments of serum amyloid A (SAA), are deposited into tissue as amyloid fibrils and then lead to progressive deterioration in organ function. A number of conditions have been well known to be associated with secondary amyloidosis, but systemic sarcoidosis has rarely been mentioned in the literature in association with this condition. We present a case in which AA amyloidosis was found to be secondary to systemic sarcoidosis.

Case Description: A 64 year old African-American woman with past medical history significant for diabetes mellitus, hypertension, and systemic sarcoidosis was referred to nephrology clinic for evaluation of proteinuria. A kidney biopsy was performed and revealed AA amyloidosis as the etiology of her nephrotic syndrome. A workup was performed to identify the etiology of secondary amyloidosis due to its very rare association with sarcoidosis. After other common causes were ruled out, sarcoidosis was determined to be the cause of AA amyloidosis.

Discussion: A number of conditions are well known to be associated with secondary amyloidosis. These include chronic inflammatory conditions, malignancies, and chronic infections; as well as a number of cases which have no identifiable cause of secondary amyloidosis. The mainstay of treatment in AA amyloidosis is controlling the underlying disease, and thus reducing the production of serum Amyloid A protein. Antibiotics and colchicine are effective at treating and preventing infection related and familial Mediterranean fever-related AA amyloidosis, respectively. Recently, TNF-alpha blockers have emerged as effective agents in AA amyloidosis associated with some autoimmune disease. Eprodisate, a new agent, binds to the glycosaminoglycan binding site on amyloid fibrils, thus targeting amyloid fibril polymerization and tissue deposition. The results of a recent randomized trial showed that eprodisate may slow the decline of renal function in AA amyloidosis and confirmatory studies are underway.

PUB509

Acute Glomerular Disease Masked by Severe Rhabdomyolysis Juan M. Quevedo, Farhang Ebrahimi. *Medicine/Nephrology, Richmond Univ Medical Center, Staten Island, NY.*

Introduction: Severe rhabdomyolysis is a known cause of renal failure. We however present a case of underlying acute interstitial nephritis (AIN) and IgA nephropathy (IgAN) which could have been overlooked as concomitant causes of our patient's severe renal failure in the context of rhabdomyolysis had we not followed the leads of proteinuria, hematuria and the presence of active urine sediment.

Case Description: A 38 year old male with no past medical history was brought to the emergency room after he was found lying on the floor for 12 hours due to worsening leg swelling and muscle pain. The muscle pain started after shoveling snow for which he took ibuprofen. Physical exam revealed ill looking male, BP 145/83 mmHg, nauseas, localized epigastric tenderness and bilateral leg swelling. Laboratory findings were significant for BUN 166 mg/dL; creatinine 17.3 mg/dL; Potassium: 6.6 mmol/L, CO2: 8 mmol/L; Lipase 640 U/L, creatinine phosphokinase (CPK): 190,000 U/L; Hgb: 12.1 g/dL; WBC: 11.4 x 10^3; ethanol level < 3 mg/dl. Urinalysis: cloudy; SG: 1.019; protein > 300 mg/dL; glucose: 100; blood: large; leukocyte esterase: trace; RBC 10-15; WBC 10-15/ HPF. Urine total protein: 536.9 mg/dL; urine creatinine: 158.6 mg/dL; urine protein-to-creatinine ratio (UPCR): 3.4 g/day which peaked to 6.6 g/day. Patient underwent emergent dialysis which continued for the next 12 days. Repeat urinalysis showed dysmorphic red blood cells which in addition to nephrotic range proteinuria led to further workup with renal biopsy as serology results have been negative. Interestingly, drug induced acute interstitial nephritis and IgAN was found. Patient markedly responded to steroid treatment and was discharged one week after initiation of therapy with creatinine of 1.4mg/dl and UPCR less than 500 mg per day.

Discussion: It is well established that there is a spectrum of IgAN presentations however, to our knowledge there have been no reports of IgAN with simultaneous complications like rhabdomyolysis and drug induced AIN. Though myoglobin tubular toxicity can cause severe renal failure the degree of proteinuria and hematuria observed is usually in the subnephrotic range and typically not characterized by active urine sediment.

PUB510

Severe Hypokalemia as First Clinical Manifestation of Lung Cancer Rohini Prashar, Ginius Pradhan, Deepak K. Malhotra. *Univ of Toledo Medical Center, Toledo, OH.*

Introduction: Ectopic ACTH Production by malignant neoplasms is well known to cause severe metabolic derangements. We report an interesting case in which the workup for hypokalemia helped uncover underlying lung cancer.

Case Description: A 67 year old male without any past medical history presented with fatigue, confusion, and dyspnea. He had a blood pressure of 220/100 mm Hg. Physical examination was unremarkable except muscle weakness and confusion. Initial tests revealed hypokalemia(1.9 mmol/l), metabolic alkalosis (40 mmol/l) and normal renal function. The patient was intubated due to respiratory failure. His serum potassium did not improve beyond 2.7 mmol/l, despite aggressive replacements up to 150 meq KCl for 10 days. At that juncture, nephrology was consulted. Further workup for hypokalemia revealed a TTKG of 12 and a Aldosterone to Renin Ratio(ARR) of 16. In the setting of hypokalemia, metabolic alkalosis, high TTKG, uncontrolled hypertension, new onset diabetes mellitus and normal ARR the diagnosis of hypercortisolism was entertained. Hypercortisolism was confirmed with a positive dexamethasone suppression test and an elevated ACTH level (215 pg/ml). No abnormality was detected on CT scan of the brain; therefore, an ACTH producing paraneoplastic syndrome was suspected. Further imaging revealed a lung mass with extensive metastatic disease. Biopsy of the mass confirmed the diagnosis of small cell lung carcinoma. The patient was started on potassium sparing diuretics along with potassium supplements and his levels improved. Unfortunately his respiratory failure did not improve. Due to the extensive nature of his disease, the family decided to withdraw care.

Discussion: Ectopic ACTH secretion(EAS) occurs in about 10% of all cases of Cushing's syndrome, and about 25% of cases of ACTH-dependent Cushing's syndrome. EAS due to malignant neoplasms has been reported to have earlier and more aggressive metabolic effects. Our case emphasizes the importance of suspecting EAS in a patient with severe hypokalemia, metabolic alkalosis and rapid clinical deterioration. The diagnosis may easily be overlooked unless the clinical suspicion is high. Failure to diagnose EAS may result in increased morbidity and even death.

PUB511

A Case of the Primary Membranous Nephropathy with the Necrotizing Cellular Crescent Yukinao Sakai,[1] Yuichiro Sumi,[1] Shizuka Yui,[1] Masami Sukegawa,[1] Anna Suzuki,[1] Koji Mugishima,[1] Yusuke Otsuka,[1] Tomoyuki Otsuka,[1] Akira Shimizu,[3] Shuichi Tsuruoka.[2] *[1]Dept of Nephrology, Nippon Medical School Musashikosugi Hospital, Kawasaki, Kanagawa, Japan; [2]Dept of Nephrology, Nippon Medical School, Tokyo, Japan; [3]Dept of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Introduction: The patient was a 66-year-old Japanese man. He was referred to our hospital, because of BUN 81.4 mg/dL, Cr 4.45 mg/dL and proteinuria. Autoimmune and viral serological tests showed no significant abnormalities. Neither monoclonal gammopathy nor Bence Jones proteinuria was detected by immunoelectrophoresis. Serum complement levels were normal. Urinalysis showed proteinuria (0.54 g/day) but no hematuria.

Case Description: Several glomeruli exhibited diffuse thickening of the peripheral capillary walls. PAM staining revealed variable basement abnormalities such as diffuse spike formation. Some glomerulus shows partial necrosis of the capillary tuft overlaid by

the cellular crescent and disruption of the basement membranes. Also, the endocapillary proliferation was found. No tubulointerstitial lesions were evident. IF staining produced strong glomerular staining of IgG and C3 globally in the peripheral capillary loops. EM analysis revealed discrete subepithelial deposits with spike formation of basement membrane material and electron-lucent areas.

Discussion: Based on the above histological and immunohistological findings, we diagnosed this case as MN (Ehrenreich-Churg Stage II - III). The oral administration of PSL was initiated at a dosage of 45 mg/day. After 4 weeks, CR of proteinuria was achieved. The PSL dosage was reduced to 40 mg/day; urinalysis remained negative for the next 4 weeks and the patient was discharged. In addition, we screened the malignant tumor, but there were no significant findings. Primary MN was diagnosed. The membranous change by immune complexes deposition to glomerular basement membrane is the main characteristic of the MN, and it is usually said that crescent formation and endocapillary proliferation are not associated. We experienced a rare case of the primary MN.

PUB512

Recovery of Residual Renal Function in a Patient That Restarted Peritoneal Dialysis after Temporary Inpatient Intermitent Hemodialysis Alejandra Mena- Gutierrez, Dumitru Rotaru. *Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Residual renal function (RRF) is an indicator of remaining glomerular filtration rate, endocrine functions, including erythropoetin production and bone metabolism, and in different series has shown association with mortality and quality of life. Prospective clinical trials have come to the conclusion that patients on peritoneal dialysis (PD) have 65% lower risk of RRF loss compared to those on hemodialysis (HD). Hemodialysis can alter hemodynamics and solute concentrations affecting RRF which is inversely correlated with frequency of treatments and number of years on this modality.

Case Description: 44 year old male with history smoldering multiple myeloma (SMM) and end-satge renal disease (ESRD) secondary to focal and segmental glomeruloesclerosis (FSGS). Renal biopsy revealed collasing glomerulopathy, chronic interstitial nephritis, mild to moderate arterionephrosclerosis and was negative for amyloidosis, light chain deposition disease or cast nephropathy. He had been on peritoneal dialysis with no complications. PD adequacy was monitored periodically and he had good RRF with urine output of more than 1 L/day. During his 2nd year on PD the SMM progressed to overt disease. At the request and insistance of his myeloma team he was transitioned to intermittent hemodialysis (IHD), while inpatient treatment with chemotherapeutic agents and autologous stem cell transplant was undertaken. During his 31days long hospitalization patient became oligo-anuric without evidence of significant hypovolemia, tumor lysis syndrome or nephrotoxin use as a possible cause. After hospital discharge patient had increase in urine output up to 800 ml/day. At his PD clinic follow up his RRF was 1.06.

Discussion: We presented a PD patient that developed anuria while receiving temporary IHD and then unexpectdly had recovery of RRF upon restarting PD as outpatient. While rapid loss of RRF has been described in patients on IHD and SDHD, this regain of RRF has not been described in the literature. Such clinical outcome should be sought in other settings where PD patients receive temporary HD for different medical reasons.

PUB513

Membranoproliferative Glomerulonephritis and Renal Cell Cancer: Case Report Epitácio Rafael da Luz Neto, Suellen Klein, Alcino Pires Gama, Lectícia Jorge, Cristiane B. Dias, Luis Yu, Viktoria Woronik. *Div of Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

Introduction: Glomerular diseases can occur in context of neoplasms. Several histopathological patterns have been described in association with different types of cancer. Membranoproliferative glomerulonephritis (MPGN) is a clinical-pathological entity due to infections, autoimmune diseases, plasma cells dyscrasias, tumors or idiopathic. We report a case of a patient with nephrotic syndrome, as result of kidney cancer-associated MPGN.

Case Description: A 40 year-old man presented to outpatient of a tertiary hospital complaining of generalized edema and hypertension for 4 months. The laboratory evaluation revealed creatinine 2.8 mg/dl; urea 86 mg/dl; hemoglobin 10.8 g/dl; serum albumin 1.9 g/dl; total cholesterol 362 mg/dl; C3 21 mg/dl (90-180); C4 4 mg/dl (10-40); FAN, Anti-DNA and cryoglobulins negatives; rheumatoid factor 80 IU/ml (<20). The urinalysis shows +100 erythrocytes/field. The 24-hour proteinuria was 21.6 g. The HBV, HCV and HIV serologies were negative. Abdominal CT scans showed solid nodule in lower pole of left kidney. Partial nephrectomy was performed. The pathological study shows clear cell renal cell carcinoma stage T1aN0M0 with adjacent MPGN. Persistent hematuria, nephrotic syndrome, and complement consumption were still present 6 months after the tumor resection and patient underwent to dialysis.

Discussion: Paraneoplastic glomerulopathy pathogenesis involves immune activation mediated by tumor associated antigens, re-expressed fetal antigens, or viral antigens. Glomerular injury may be due to circulating immune complexes or formed *in situ*. Nephrotic syndrome improvement can be associated with the successful tumor treatment and resection. Immunosuppression is not indicated due to risk of neoplasia progression. In contrast to showed case, in literature there was a case-report in which there was laboratory and clinical improvement after 7 months of neoplasm resection. Two possible reasons for the differences are persistent disease since surgery was not curative or the diseases are independent and complement consumption would be a MPGN idiopathic marker. The patients follow-up may help to elucidate this question.

Funding: Government Support - Non-U.S.

PUB514

Salisylate Induced Pulmonary Edema - Dialysis or No Dialysis? Girish Singhania, Gurjit Dhatt, Charles S. Wingo. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Salicylate ingestion is a common cause of poisoning in children and adolescents. It can be acute or chronic. Salicylate induced pulmonary edema (SIPE) is a rare complication from salicylate intoxication. Management of it is always a question. We present a severe case of salicylate intoxication presented with SIPE.

Case Description: 28 y/o female was complaining of headache, dyspnea and fevers. There were multiple BC powder wrappers around her per EMS. Exam showed BP: 128/67 mmHg, Pulse: 141/min, RR: 19/min went to 35-40 in next hour, afebrile, 84% saturation on room air. There were crackles in lungs. Labs showed sodium: 140 mmol/L, potassium: 3.3 mmol/L, Chloride: 107 mmol/L, Bicarbonate: 17 mmol/L, S. Creatinine: 1.0 mg/dL, Glucose 156 mg/dL, Alb: 2.9 g/dL, Salicylate: 48 mg%, Serum pH: 7.18, Urine pH: 6.0. Chest X-ray showed pulmonary edema. CT showed early changes of cerebral edema. She was intubated. We were consulted for further management of salicylate poisoning. In the next 2 hours, she was aggressively hydrated with normal saline and isotonic bicarbonate. She made more than one litre of urine. ICU team asked us for hemodialysis due to SIPE and early cerebral edema but due to good renal function, we didn't dialyse her. We recommended to continue aggressive hydration and alkalanization of urine. Over the next 48 hours, patient was clinically improved.

Discussion: Salicylates are absorbed within 15-30 minutes and is metabolized quickly but in overdose, the half life increases due to hepatic enzyme saturation. In Acidosis, there is increased penetration in tissues. SIPE is a serious complication which can occur in both acute and chronic users and should be managed aggressively. Absolute indications for dialysis are renal, cardiac or hepatic compromise. Relative indications are salicylate level >120mg%, pulmonary edema, refractory acidosis, severe CNS manifestations. Misdiagnosis can lead to a significant increase in morbidity and mortality. In the recent review, there were no clear guidelines exist on when to use dialysis in salicylate intoxication or SIPE. However, they suggest the use of dialysis in patients with organ damage, such as pulmonary edema, CNS disturbances, and renal impairment.

PUB515

Drug Induced Acute Interstitial Nephritis Coupled with Crescenteric Glomerulonephritis in a HIV Positive Patient Purna Bindu Nandigam, Muhammad R. Syed, Talal A. Khan, Kenneth Lau, Azka Arif, Muhammad Awais Arif, Arif Jan, Hasan Arif, Sandeep Aggarwal. *Div of Nephrology, Drexel Univ, Philadelphia, PA.*

Introduction: Acute kidney injury is common in human immunodeficiency virus (HIV) infected patients, and has been associated with increased morbidity and mortality. AKI remains a significant problem in the antiretroviral era, and is still commonly attributed to infection or nephrotoxic medications.

Case Description: A 50-year-old African American male with history of HIV, diabetes mellitus type 2 and chronic kidney disease stage III was admitted with complaints of hematuria. He was started on Bactrim and Doxycycline for an infected back wound 5 days ago. On initial evaluation he was found to have acute kidney injury with a creatinine of 3.46 mg/dL up from a baseline of 1.6 mg/dL. Urine microscopy revealed many RBCs, but did not reveal any casts or eosinophils. Serological tests revealed a positive ANA titer (1:160). Anti GBM Ab, c-ANCA, p-ANCA, ASO Ab, serum cryoglobulins and HCV PCR were all negative. Serum complements were within normal limits. Spot protein to creatinine ratio was 8.4 grams per day. A Peripheral blood smear showed no evidence of schistocytes. A kidney biopsy showed crescents in 8/23 glomeruli with 70-80% podocyte effacement and scattered sub-endothelial, sub-epithelial and intramembranous fine granular electron dense deposits. Immunofluoresence was positive for granular staining in the mesangium with C3 and IgM. There was also a dense tubulo-interstitial inflammatory infiltrate consistent with acute interstitial nephritis (AIN). These findings suggested multiple injury patterns with crescenteric Glomerulonephritis (GN) secondary to post infectious GN coupled with AIN.

Discussion: Our case illustrates an uncommon presentation of rapidly progressive GN with hematuria in an HIV positive patient. With multiple patterns of injury in an immunocompromised host the dilemma was in choosing the treatment modality. We stopped the offending antibiotics and elected to treat with high dose pulse steroids followed by a short taper. This resulted in improvement in renal function to near baseline without the need for hemodialysis.

PUB516

A Case of Primary Hyperaldosteronism with Unusual Serum Bicarbonate Disha Narula, Amit A. Deshpande, Monalisa Joseph, Hasan Arif. *Div of Nephrology, Drexel Univ.*

Introduction: Primary hyperaldosteronism is a well known cause for uncontrolled HTN coupled with hypokalemic metabolic alkalosis. However, we present a case in which a patient was found to have primary hyperaldosteronism with an unusually low serum HCO3. This case is an example of diagnostic challenges with complicated acid-base and electrolyte disturbances in patients with concomitant medical problems.

Case Description: 55-year-old AA male with history of HTN and CVA with residual left sided weakness presented to the ER for nausea and vomiting for 1 day. He was found to have a BP of 230/115. Labs showed potassium of 1.9, bicarbonate of 19, Cr 0.65. His arterial blood gas showed a pH of 7.7, a PCO2 of 18, a PO2 99, HCO3 of 22 and O2 sat 99%. He was admitted to medical ICU and started on a nicardipine drip for his blood pressure. His potassium was aggressively repleted, but he had persistent hypokalemia. For his respiratory

alkalosis, a CT scan for PE was negative. A secondary HTN workup revealed a plasma aldosterone of 50 ng/L, plasma renin 0.39 ng/L, urine metanephrines 199 ug/24hours and plasma metanephrines 290ug/24hours. Renal US with dopplers showed normal sized kidneys with no detectable renal artery stenosis. Urine K+ was found to be 60meq/L. TTKG was calculated to be 14. Plasma aldosterone/renin ratio was 128. A CT scan of the abdomen revealed bilateral adrenal hyperplasia. Patient was tapered off the nicardipine drip and started on spironolactone. His hypertension and hypokalemia significantly improved.

Discussion: In view of high plasma aldosterone coupled with uncontrolled hypertension and hypokalemia, a diagnosis of primary hyperaldosteronism was made. On first glance, it appears that the patient's serum bicarb is not consistent with metabolic alkalosis and makes the diagnosis difficult to make. However, given that the patient had primary respiratory alkalosis the expected compensation for his chronic respiratory alkalosis would lead to a serum bicarb of 11meq/l. However in the presence of primary hyperaldosteronism his serum bicarbonate was higher than expected. Our case represents an unusual presentation of Primary Hyperaldosteronism with unusual serum bicarbonate due to concomitant medical problems.

PUB517

Successful Patient and Renal Outcome in p-ANCA Vasculitis Inspite of Worst Prognostic Factors Ruchira Sengupta,[1] Egbert C. Liquete,[2] Sarika Deshmukh.[2] *[1]Internal Medicine, Henry Ford Hospital; [2]Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Introduction: ANCA associated vasculitis is a rare disease. It is associated with high morbidity and mortality due to systemic inflammation as well as treatment side effects especially in elderly population. We present a case with features of P-ANCA associated vasculitis in an elderly patient. Its successful outcome was dependent on early recognition, immediate initiation of immunosuppressant therapy and continuous renal replacement therapy using regional citrate anticoagulation method.

Case Description: A 68-year-old lady, with no significant medical history, presented with progressive worsening of shortness of breath over the course of 3 weeks. Patient had acute respiratory decompensation requiring mechanical ventilation. Bronchoscopy showed active diffuse alveolar hemorrhage. She had auric AKI and *p-ANCA* titers of 1:80. Kidney biopsy showed focal segmental necrotizing glomerulonephritis, 56% global sclerosis, 16% segmental sclerosis, 3% cellular crescent, with moderate tubular atrophy and interstitial fibrosis. She had pulse dose intravenous methylprednisolone 1 gm daily for 3 days then maintained on oral maintenance dose; 10 sessions of plasmapheresis, and oral cyclophosphamide (induction and maintenance) carefully dosed based on her age, AKI requiring dialysis status. She had full recovery of kidney function after requiring dialysis for 7 weeks. Her serum creatinine is 1.5 mg/dL with proteinuria less than 1 gm.

Discussion: Our patient with microscopic polyangitis presented with risk factors that have been associated with the highest mortality, including age, active pulmonary hemorrhage with respiratory failure, and acute kidney injury requiring daily dialysis. Despite the predicted poor prognosis, she had significant recovery in renal function and overall functional ability. Our case illustrates successful use of oral cyclophosphamide, with no adverse complications, or relapse in first year. We believe that along with high index of suspicion, prompt initiation of immunosuppression, unique availability of continuous renal replacement therapy with regional citrate anticoagulation helped to decrease morbidity and rapid recovery.

PUB518

Unexplained Hypomagnesemia in an Adult Roshan A. Patel, Viral G. Gandhi, Salwa Rhazouani, Maritza Brown. *Nephrology, Elmhurst Hospital Center, Icahn School of Medicine, Elmhurst, NY.*

Introduction: Case of a patient presenting to renal clinic with Magnesium (Mg) level < 1 mg/dl in spite of daily intravenous Mg repletion.

Case Description: A 61 year old Tibetan woman with a history of hypertension was referred for profound hypomagnesemia. She had been admitted to an outside hospital for weakness and paresthesias, which were attributed to severe hypomagnesemia. Omeprazole was discontinued and she was discharged on daily intravenous Mg infusion. On evaluation, the patient's fractional excretion of Mg was 21.6 % with a serum Mg level of 1 mg/dl and 24 hour Urine Mg of 738 mg. On follow up, her Mg had dropped to 0.9 mg/dl and she was admitted to the hospital. Bicarbonate and Potassium level were not consistent with Gitelman's Sydrome. Intravenous repletion was changed to oral Mg; three days later serum Mg remain unchanged at 1 mg/dl but urine Mg declined to 110 mg. Though the urine Mg improved, it remained relatively high considering the patient's low serum Mg.

	Clinic Visit	Hospital Admission	Hospital Discharge	2 months after Discharge
Serum Mg	1.6	1	1	1.1
Urine Mg	42.3	-	4.4	-
Serum Potassium	3.9	3.7	4.3	4
Serum Calcium	9.4	9.1	9	8.6

Differential Diagnosis
Gitelman's Syndrome
Bartter's Syndrome
Medication (PPI, Diuretic, Aminoglycoside)
Hypercalcemia
Uncontrolled Diabetes Mellitus
Familial hypomagnesemia with hypercalciuria and nephrocalcinosis
Epidermal growth factor gene mutation
Cyclin M2 mutation

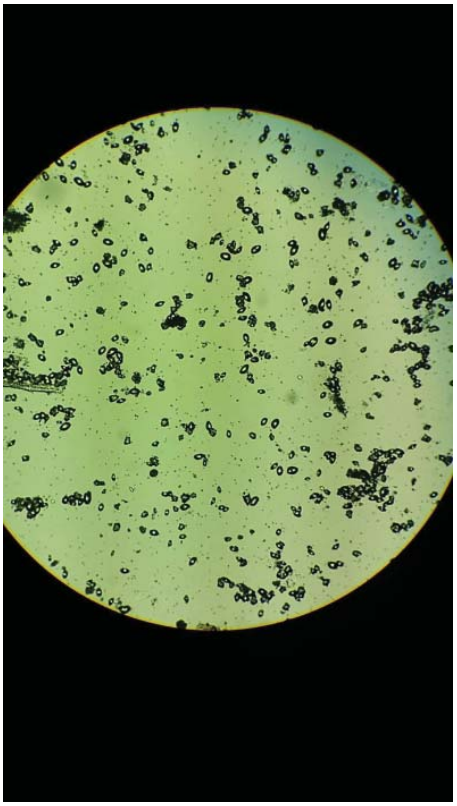
Discussion: Severe Hypomagnesemia is a serious clinical condition associated with life threatening arrhythmias and neurologic manifestations. Few adult cases with persistent isolated severe hypomagnesemia despite treatment have been described in the literature. In Mg deficiency, the kidneys can normally reduce the 24-hour urinary Mg excretion to less than 10 to 30 mg or a Fractional excretion of Mg < 2%. Moreover, acquired renal Mg wasting can result from many known medications. Several inherited renal tubular disorders such as Gitelman's and Bartter's syndrome are associated with loss of Mg but have other electrolyte disturbances. A rare hereditary tubulopathy manifested solely by isolated hypomagnesemia has been described in the literature.

PUB519

Acute Kidney Injury Secondary to Sulfamethoxazole Crystals in an AIDS Patient Sandeep M. Patil, Karina Sulaiman. *Div of Nephrology,Dept of Medicine, Louisiana State Univ Health Sciences Center-Shreveport, Shreveport, LA.*

Introduction: Pneumocystis jiroveci pneumonia (PJP) commonly causes opportunistic infections in patients with Acquired Immune-Deficiency Syndrome (AIDS) and the standard therapy consists of Trimethoprim-sulfamethoxazole (TMP-SMX). Acute kidney injury (AKI) secondary to obstructive uropathy from TMP-SMX crystalluria has not been reported. We report a case of TMP-SMX crystal induced AKI in an AIDS patient with PJP.

Case Description: A 51 year old African American man presented with fatigue, malaise, chest congestion and shortness of breath for a 2 months. He was vitally stable and physical exam was remarkable for lower lung field crackles. Chest x-ray showed bilateral patchy infiltrates and he tested positive for HIV.His renal function was normal and urine analysis (UA) was unremarkable. Blood and fungal cultures were drawn. He was started on TMP-SMX 320mg-1600 mg orally every 8 hours for empiric treatment of PJP.Over the next four days he developed AKI and oliguria. His serum creatinine increased to 2.5mg/dl, peaking at 6.5mg/dl and repeat UA was notable for sulfa crystals as depicted in fig 1.



Adding acetone to the urine dissolved the sulfa crystals.Urine Wright's stain was negative for eosinophils. He became anuric and required dialysis once. TMP-SMX was stopped and intravenous fluid administered. Renal function and urine output subsequently improved. No crystals were seen in a repeat UA.

Discussion: Sulfa-containing medications can cause crystal-induced AKI from intratubular deposition in addition to allergic interstitial nephritis. Crystalluria is rarely reported with newer sulfonamides. Sulfamethoxazole can also precipitate in the kidneys and cause AKI from tubular obstruction. Treatment includes drug cessation, aggressive fluid resuscitation and alkalinization of urine to a target pH of 7.5.

PUB520

A Case Report of Valproic Acid Toxicity and the Role of Renal Replacement Therapy Amit A. Deshpande, Disha Narula, Hasan Arif. *Drexel Univ.*

Introduction: Valproic acid is a branched-chain carboxylic acid first introduced in 1978 for the treatment of seizure disorders and various psychiatric conditions. Occasionally patients prescribed the medication will present with signs of toxicity.

Case Description: 15 y.o. F. with pmh of bipolar disorder, multiple suicide attempts, and hypothyroidism presented to ER by paramedics following a suicide attempt after ingesting 8 valproic acid tabs (500mg tabs). On initial evaluation in ER, patient was noted to be lethargic and falling asleep during encounter. Labwork revealed mixed acid base disorder on ABG: pH 7.30, pCO2 41.7, bicarb of 23, valproic acid level of 161 and ammonia level of 53 in setting of normal LFTs. Vitals remained stable except for a heart rate of 113, BMP and CBC were within normal limits. Pt. was intubated in ER for airway protection as her mental status began to decline. A stat CT head was performed revealing possible cerebral edema. Pt. was transferred to medical ICU. Gut decontamination was performed with activated charcoal, and the pt. was started on carnintie. Nephro was consulted for possible RRT. Initial plan was to start hemodialysis, but after much discussion, the decision was made to hold treatment given the lack of strong evidence based data supporting RRT in the setting of such low valproic acid levels. The patient was observed in ICU setting. LFTs, ammonia levels, valproic acid levels were trended every 4-12 hours and neuro checks were performed routinely until valproic acid levels returned to therapeutic range. Patient was extubated successfully 3 days after presenting to the ER and transferred to a telemetry floor.

Discussion: The role of RRT in the setting of valproic acid toxicity is grossly under investigated. Available data has shown RRT to be beneficial in such toxicity, especially at levels greater than 850mg/L. Unfortunately no significant trials have been conducted to establish appropriate drug levels at which to initiate treatment. Most evidence available is based on a minute number of case series and review articles. A review of available literature can help clinicians have a clearer sense of when to utilize renal replacement therapy as a potentially life-saving treatment modality.

PUB521

Oral Acyclovir, Nephrotoxicity, and Herpes Simplex Virus Prophylaxis in a Patient with Multiple Myeloma Judy K. Tan, Girish N. Nadkarni, Ioannis Konstantinidis, Achint Patel, Vijay Lapsia. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Acyclovir is commonly used as prophylaxis for herpes simplex virus (HSV) during chemotherapy for multiple myeloma. Intravenous acyclovir is well known to cause crystal induced nephrotoxicity leading to acute kidney injury (AKI). About a third of patients may also experience a transient increase in serum creatinine levels during therapy, thought to be secondary to interference in renal handling of creatinine. It is often difficult to distinguish between these two entities early on and may impact clinical decision making for infection prophylaxis.

Case Description: A 61-year man with no previous medical history presented with anorexia, back pain and weight loss. He was found to have anemia (hemoglobin 8.3 gm/dL) and hypercalcemia (10.6 gm/dL) with elevated creatinine to 1.7 mg/dL. A bone marrow biopsy revealed 15% plasma cells with binucleated forms and serum electrophoresis showed 10gm/dL of IgG lambda. He was admitted to the hospital for initiation of chemotherapy with bortezomib, cyclophosphamide and dexamethasone. In addition, acyclovir was started at 400 mg twice daily for HSV prophylaxis. After receiving 2 doses of acyclovir, his creatinine acutely trended up to 2.7 from 1.7 mg/dL; however, other markers of kidney function including urea nitrogen improved (from 27 to 23 mg/dL). Initial workup for other causes of acute kidney injury (AKI) was negative. After discontinuation of acyclovir, creatinine trended down almost immediately to baseline value of 1.6 mg/dL. The patient was safely switched to valacyclovir for prophylaxis.

Discussion: Drug induced nephrotoxicity is a serious adverse reaction that can be deleterious. AKI induced by oral acyclovir is uncommon and early identification and discontinuation may prevent further morbidity.

PUB522

A Case of Metformin-Induced Lactic Acidosis Complicated by Ketoacidosis Sharad D. Patel,[1] Leslie F. Thomas.[2] *[1]Nephrology Fellowship, Univ of California Los Angeles; [2]Div of Nephrology and Hypertension, Mayo Clinic Arizona, Phoenix, AZ.*

Introduction: Uncommonly, metformin use may promote the development of lactic acidosis. Mortality is high (83%) in those individuals in whom severe acidemia ensues (pH < 6.9). Known risk factors for the development of lactic acidosis in metformin users include end stage liver disease, congestive heart failure, and renal insufficiency. Heretofore, associated ketoacidosis has not been described as an associated feature of metformin-induced acidemia. Here, we describe the successful treatment of a patient in whom metformin-induced lactic acidosis and associated ketoacidosis produced a severe metabolic acidemia (pH <6.671).

Case Description: A 65-year-old woman with a history of type 2 diabetes mellitus without known history of kidney disease presented with four days of progressive nausea, vomiting, generalized weakness, and one day of anuria. Her only medication was metformin 1000 mg by mouth twice daily. Initial examination revealed significant tachypnea but was otherwise normal. Initial arterial blood gas revealed a pH < 6.671 (rechecked twice). Other labs at presentation included a serum bicarbonate < 5 (22-29 mmol/L), anion gap (AG) 49, creatinine 8.3 (0.6-1.1 mg/dL), lactate 19.1 (0.6-2.3 mmol/L), and metformin 55.1 mcg/mL (therapeutic range 1-2 mcg/mL). Shortly after her arrival, the patient became hemodynamically unstable, and she was placed on a norepinephrine infusion. Emergent hemodialysis was performed, and she subsequently demonstrated improved hemodynamics and blood pH (7.224). Within 24 hours, the patient's AG persisted at 31 despite normalization of lactate (1.0 mmol/L). At that point, a beta-hydroxybutyrate level was measured and found to be 53.3 (< 0.4 mmol/L). The patient was subsequently treated for ketoacidosis with normalization of the AG. The patient subsequently recovered renal function and was discharged without serious sequelae after five days.

Discussion: Significant accumulation of beta-hydroxybutyrate may occur in patients with acute renal failure and metformin-induced lactic acidosis. This complicating factor may potentially lead to deleterious outcomes if not recognized swiftly. Proper treatment for patients with metformin-induced lactic acidosis should include prompt hemodialysis and recognition and treatment of ketoacidosis.

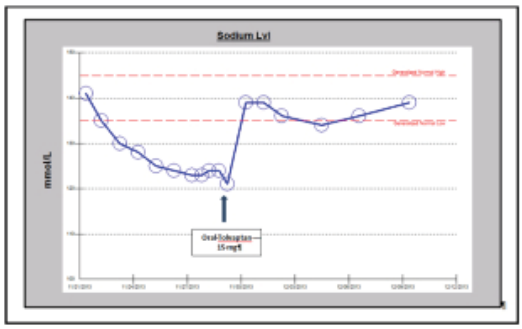
PUB523

Rapid Normalization of Post-Traumatic Severe Symptomatic Acute Hyponatremia after a Lone 15 mg Tolvaptan Dose: A Mayo Clinic Health System Trauma Unit Experience – A Call for Caution with Tolvaptan in Younger Patients with Preserved Renal Function Macaulay A. Onuigbo,[1,2] Nneoma Agbasi.[3] *[1]Medicine, Mayo Clinic College of Medicine, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Psychiatry Nursing, North East London NHS Foundation Trust, London, United Kingdom.*

Background: Tolvaptan is established treatment for hyponatremia from SIADH. Over rapid correction can cause fatal pontine demyelination. We report the dramatic rapid correction of hyponatremia after one 15 mg dose in a young man with normal kidney function (eGFR of 126).

Methods: Case report.

Results: A 32-year old Caucasian male was admitted after a MVA with altered consciousness, rib fractures, a large scalp hematoma, and subarachnoid hemorrhage. Na fell from 141 to 121 mEq/dL despite fluid restriction (800 ml/day), oral NaCl tablets and repeated IV 3% NaCl. Symptoms were blurred vision, poor memory and cognitive impairment. Following a single dose of Tolvaptan, 15 mg, urine volume quintupled with increased thirst. Serum Na swiftly increased to 139 mEq/dL over 18 hours. AVP was 1.4 pg/mL consistent with SIADH. After 2 days, symptoms resolved. He was discharged. A week later, asymptomatic but for persistent left gaze diplopia, Na was 139 mEq/dL.



Conclusions: Earlier studies on oral Tolvaptan for symptomatic hyponatremia (SALT-1, SALT-2, EVEREST, SALTWATER) recruited older patients, age 64-67 years, with baseline serum creatinine ~1.3-1.4 mg/dL and utilized doses of 30 mg/d or higher. The very rapid correction of hyponatremia in our young patient after a single oral dose of 15 mg of oral Tolvaptan is the most recorded. Kidney function was normal an eGFR of 126 ml/min/1.73 sq. m BSA. We recommend lower doses of Tolvaptan (≤15 mg/d) in younger patients with preserved kidney function to prevent over-rapid correction of hyponatremia and risk potentially fatal central pontine myelinolysis.

PUB524

Electrocardiogram (EKG) Changes of Hyperkalemia in Patients with Normal Renal Function and with Chronic Kidney Disease (CKD) Sairah Sharif,[1] Leonel Carrasco,[2] Amin Paulino,[2] Jose M. Sosa Popoteur,[2] Mei-An Ty-Arias,[2] Rose Calixte,[1] Sudhanshu Jain,[2] Damian Kurian,[2] Jeffrey D. Wallach.[2] *[1]Winthrop Hospital, Mineola, NY; [2]Harlem Hospital, New York, NY.*

Background: Potassium (K+) is the major intracellular cation and its ratio to the extracellular K+ determines resting cell membrane potential. Hyperkalemia can lead to serious cardiac arrhythmias. It increases rate of repolarization and slows conduction velocity manifested as peaked T waves and prolonged PR interval. It has been suggested that patients with advanced CKD tolerate hyperkalemia better than patients with normal renal function. EKG is a clinical tool to assess potential toxicity of hyperkalemia. We tested if patients with advanced CKD demonstrate lesser EKG abnormalities in the setting of hyperkalemia compared to patients with normal renal function.

Methods: We reviewed records of patients ≥18 years seen in the emergency or inpatient setting from 2008 to 2011 with hyperkalemia (5.5 to 8.8 meq/l) and normokalemia (3.5 to 5.1 meq/l) who had an EKG done within 4 hours of the determination. We excluded patients who received treatment to reduce K+, had hemolyzed samples, had pacemakers, or unreadable EKG deemed by cardiologist. 71 patients were selected and demographics, serum K+, serum creatinine, EKG parameters were measured. The association of serum K+ with changes in EKG parameters was examined and comparisons made among populations with normal renal function (NRf), chronic kidney disease stage 4 and 5 (CKD4/5), and hemodialysis patients (CKD5D).

Results: Using Wilcoxan rank sums we found that hyperkalemic patients had significantly elevated mean T/R ratios and mean PR intervals compared to normokalemic patients (p values 0.049 and 0.034). However there was no difference in mean T/R ratios or PR intervals when comparing patients with NRf, CKD4/5 and CKD5D.

Conclusions: Hyperkalemic patients with CKD4/5 and CKD5D did not have significantly different T/R ratios and PR intervals compared to patients with NRf. Thus CKD may not provide protection from the EKG manifestations of hyperkalemia.

PUB525

Amiodarone-Induced Hyponatremia- A Rare but Life Threatening Adverse Effect Ujwala Koduru, Nishkarsh Saxena, Vaishali Thudi, Radhika Kakarala, Arvind R. Kunadi. *Internal Medicine, McLaren Regional Medical Center/ MSU, Flint, MI.*

Background: We describe a case of chronic hyponatremia that was misdiagnosed for years as cerebral salt wasting syndrome (CSW), which was later diagnosed as SIADH secondary to amiodarone. Our literature search found a recent review article highlighting only 12 previous cases.

Methods: Our patient is a 93-year-old female who was admitted for weakness and debility, and was found to have acute hyponatremia with a sodium level of 119 mEq/L. She had known chronic hyponatremia with baseline sodium of 128 mEq/L. Her medications included amiodarone (for 10yrs), metoprolol, miralax, omeprazole, clopidogrel and acetaminophen. On admission, She did not have any orthostatic blood pressure changes. She was started on normal saline at 75 ml/hr for 24hrs. Her serum sodium level did not improve even after 24 hours. Lab studies revealed serum and urine osmolality levels (248 mOsm/kg and 351 mOsm/kg), urine sodium 60 mmol/L, uric acid 1.5 mg/dL, TSH 3.50 uIU/mL and random serum cortisol 18 ug/dL. She underwent echocardiogram (echo) to evaluate the inferior venacava (IVC), which was not collapsible. Other echo findings include ejection fraction 60%, sclerotic aortic valve with trivial aortic insufficiency, mild to moderate mitral regurgitation and trivial tricuspid regurgitation. Her hyponatremia was thought to be secondary to amiodarone, which was stopped. As fluid restriction failed, she was put on tolvaptan 15 mg orally once a day for three days. Her serum sodium level gradually increased to 138 meq/L by third day. Outpatient follow-up after one month revealed that she was doing well with sodium levels maintained above 135 mEq/L.

Conclusions: Amiodarone causing SIADH has previously been reported to occur, few days to few months after starting treatment. Elderly men are especially prone to this side effect. The management requires stopping amiodarone and symptomatic treatment with restriction of fluids, hypertonic saline or tolvaptan. In conclusion, our case demonstrates the importance of vigilance for commonly used medication's adverse effects, especially in elderly patients.

PUB526

Lactic Acidosis due to Lymphoma Tumor Burden Jack Rubin, Milan Rohit Sheth, Ricky Mac, Heena M. Contractor.

Background: Lactic acidosis (LA) and hypoglycemia (HG) related to lymphoma tumor burden portends a grave prognosis.

Methods: Ms. X, a 141 kg, 241 cm, presented 1 yr before her death with a presacral mass compressing the thecal sac. Biopsy was c/w low grade follicular lymphoma treated by XRT and 3 cycles of CHOP-R. After 5 months a pathologic right elbow fracture and pancytopenia evolved and the bone marrow (BM) was now c/w high grade B cell lymphoma with c-myc and bcl-2 rearrangements. She was treated with 3c HyperCVAD but repeat BM showed progression. After 8 months a mild LA resolved after a cycle of chemotherapy (4.4>2.2 mEq/L). During the terminal 4 weeks (12th month) there was persistent LA and HG. Hepatomegaly (on CT) and elevated liver enzymes were noted. Another ALL protocol (ECOG 2993) was tried. Her LA level initially improved but then increased stabilizing around 20 meq/L. She required D5 1/2 NS and 50 meq NaHCO3/L @ 150 ml/hr to maintain glucose over 80 mg%. Steroids and diazoxide were eventually started and HG was controlled. Due to edema from the infusion +/- diazoxide she was tried on combinations of diuretics, oral Bicitra and NaHCO3 plus IV replacement. She started refusing these interventions as need for care became more then she wanted to tolerate (fluid + Lasix > bathroom and refused Foley). She had a fatal cardiac arrest.

Results: The IV bicarbonate infusion may have precipitated edema but decreased at rest tachypnea of 30/min. D-lactic acid was negative; C-peptide and insulin level were appropriately suppressed. Cortisol level confirmed adequate adrenal function. Growth hormone was normal. IGF-2 was 431 ng/ml and Igf2/Igf1 = 8 (both in normal range). Boh-butyrate was not elevated. The anion gap remained 25 to 29 with Lactate accounting for the increase in the gap (6.3 and 5.8 at Day 1 and 2 to 14 - 21 meq/L after the 9th day of hospitalization). Arterial ph was measured twice with a ph 7.21 and 7.24, pCO2 35, 38 and pO2 84, 63 Torr respectively.

Conclusions: Base replacement was used to keep the ph over 7.2 in a patient who had inadequate respiratory compensation due to morbid obesity. Although IGF-2 and IGF1 levels were normal the ratio approached 10 suggesting IGF-2 had a role in the HG. As reported LA and HG related to tumor burden portends a grave prognosis.

PUB527

Acute Psychosis in Two Patients with Bartter Syndrome Kathryn K. Ridout,[1] Matthew D. Willis,[2] M. Khurram Faizan.[3] *[1]Dept of Psychiatry, Butler Hospital; [2]Dept of Psychiatry, Bradley Hospital; [3]Dept of Pediatrics, Hasbro Children's Hospital, Providence, RI.*

Background: Bartter syndrome is an inherited condition affecting NaCl reabsorption in the loop of Henle. Loss of Na^+ causes volume depletion, increased renin and aldosterone release and K^+ and H^+ losses leading to hypokalemia, metabolic alkalosis, and hypotension. We report 2 patients with Bartter syndrome presenting with psychosis requiring inpatient psychiatric hospitalization.

Methods: Retrospective case series, 2013-14.

Results: Case 1: 18 y.o. male with a PMH of Bartter syndrome, depression, and previous episode of delusional ideation and grandiosity presents with a 1 wk history of disorganized thought process, auditory hallucinations, hyper-religious delusions, suspicions, and decreased sleep. On presentation, Na^+ 128 mEq/L, K^+ 4.7 mEq/L, CO_2 15 mEq/L, BUN 25 mg/dl, creatinine 1.35 mg/dl. With increase in his olanzapine and initiation of lorazepam his catatonic and psychotic symptoms improved and his BUN and creatinine normalized. He remained hyponatremic during the entire stay, (126-133 mEq/L). He was discharged on day 15 with notably improved mental status. **Case 2:** 15 y.o. male with a PMH of Bartter syndrome and no prior psychiatric history presented with hypokalemia (K^+ 2.6 mEq/L) after medication refusal. After hypokalemia resolution, on hospital day 4, pt reported auditory and visual hallucinations, paranoid delusions and hyper-religiosity. His mental status exam was notable for a guarded attitude, psychomotor retardation mixed with agitation, tangential thought process, and auditory and visual hallucinations. His psychosis resolved with initiation of risperidone. During his hospital stay, his creatinine and Na^+ remained normal.

Conclusions: We describe 2 cases of Bartter syndrome presenting with acute psychosis. Psychotic symptoms did not specifically correlate with their metabolic or electrolyte disturbances. To our knowledge, these are some of the first reports of Bartter syndrome associated with psychosis. Abnormal neuronal ion transport or aberrant acid-base status may underlie shared pathophysiology between these disorders. Further investigation is needed to elucidate potential mechanisms relating these two rare conditions.

PUB528

Controlled Correction of Severe Hyponatremia due to Heart Failure in an ICU Setting Birinder S. Singh, Panupong Lisawat. *Internal Medicine, Danbury Hospital, Danbury, CT.*

Background: The most important factor in the treatment of severe hyponatremia in a patient with CHF, receiving a diuretic, is the emergence of rapid water diuresis. This causes a sudden correction of sodium and may lead to osmotic demyelination. We illustrate a case of severe hyponatremia in a patient with CHF and successful use of DDAVP to prevent this sudden rise of sodium.

Methods: A 61 y/o female with history of hypertension was brought in the hospital for ischemic CVA and received tPA. She was found to have dilated cardiomyopathy of unclear etiology with E.F. of less than 15%. After 24 hours, she showed significant improvement in her mental status and was transferred out of ICU. Five days after the primary event, she suddenly developed confusion and was increasingly SOB. She was on a heparin drip with D5W as rider and water as her only oral intake for the last 3 days. P/E revealed crackles and bilateral 2+ pitting edema. A chest x-ray confirmed her volume overload state. Lab work uncovered a sodium level of 99. The patient's last sodium level 4 days ago was 132. At this point, she was given furosemide and her sodium increased to 108. As this rate of correction was above the goal correction rate of 6-8 mEq in the first 24 hours, the patient was started on D5W; which was problematic due to her CHF. DDAVP was used intermittently to help prevent water diuresis, and thereby control the rate of correction. Furosemide was given based on her urinary output and the sodium level was checked every 1-2 hours. On the 2nd day after stopping DDAVP, her sodium level corrected rapidly above goal rate; DDAVP was subsequently restarted. After 4 days of slow correction, the patient's sodium level reached 132 and DDAVP was stopped.

Conclusions: Various modalities have been designed to correct chronic hyponatremia as a result of CHF; however acute management of hyponatremia in CHF remains an area of research. One of the challenges in treatment of hyponatremia in CHF is the emergence of water diuresis. To overcome this, we used DDAVP with a loop diuretic, and were successful in controlled correction of sodium at a goal rate without side effects. Hence, we propose using this treatment modality in a similar setting.

PUB529

Evaluating Hypokalemia and Renal Potassium Handling: Time to Recycle the TTKG? Sajeet S. Sawhney,[1,2] Richard M. Treger.[1,3] *[1]Nephrology, Greater Los Angeles VA Healthcare System, Los Angeles, CA; [2]Nephrology, Cedars-Sinai Medical Center, Los Angeles, CA; [3]Nephrology, David Geffen School of Medicine, UCLA, Los Angeles, CA.*

Background: TTKG has been used as a clinical estimate of the tubular fluid potassium (K^+) concentration in the cortical collecting duct; although more recently its reliability has been questioned. The assumption underlying the TTKG, that the majority of osmoles delivered to the medullary collecting duct are not reabsorbed, is not valid in light of intrarenal urea recycling (IUR). The IUR has been described primarily in rat and mouse models and the clinical significance of IUR and its effect on TTKG in humans are unknown.

Methods: A case series was constructed of patients with hypokalemia.

Results: 6 patients were included (Table 1). All patients had urine osmolality that was greater than serum osmolality and normal serum magnesium levels. 5 patients had clinically apparent causes of renal potassium wasting. All 5 patients had TTKGs significantly > 3 and urine K^+-to-creatinine (Cr) ratios > 13 mEq/gm [even patients B and C despite low urine sodium (Na+)]. Patient F had gastrointestinal K^+ loss due to diarrhea. The TTKG was < 3 and urine K^+-to-Cr ratio was < 13 mEq/gm, consistent with known extrarenal K^+ loss.

Patient	Serum K^+	Ur Na^+	Ur K^+	Ur K^+/Cr	TTKG	Diagnosis
A	3.0	58	40.7	60.0	11.1	Diuretic-induced
B	*2.6-->3.9	23	90.7	35.3	11.49	Primary Hyperaldosteronism
C	3.4	<10	26.9	17.0	8.4	Vomiting, Gastroparesis
D	3.3	115	49.9	66.2	8.9	Renal Artery Stenosis
E	3.5	79	59.7	49.7	10.6	Primary Hyperaldosteronism
F	3.3	33	10.5	8.1	2.6	Diarrhea, Crohn's disease

*Prior to treatment

Conclusions: Our case series suggests that TTKG may be a reliable and clinically useful test. Although IUR plays a role in the excretion of K^+, it may not contribute a clinically significant effect in humans. Rats and mice excrete a substantially more concentrated urine compared to humans. Therefore in humans IUR may only play a minor role in K^+ excretion. More robust data is necessary to definitively evaluate the clinical utility of the TTKG. Regardless, the urine K^+-to-Cr ratio may be the preferred test in the evaluation of hypokalemia given its simplicity and reliability.

PUB530

A Severe Case of Alkalemia in Advanced Kidney Disease

Myriam C. Vela-Ortiz, Jose Albert Avila, Sukhminder Singh, Rich W. Snyder. *Internal Medicine, Easton Hospital, Easton, PA.*

Background: A 44 year old Caucasian gentleman with type 1 diabetes mellitus, chronic kidney disease with a baseline creatinine of 4.0 to 4.95, and gastroparesis presented with a two day history of nausea and vomiting. On admission, vital signs showed relative hypotension, tachycardia, absence of fever with a normal respiratory rate and oxygenation. Initial investigation showed acute renal failure with sodium 125, potassium 2.8, chloride 65, carbon dioxide 40, anion gap 20, calcium 10, albumin 4.7. An ABG showed severe alkalemia with a pH of 7.72, a pCO2 of 27.3, and a bicarbonate of 34.7. Other laboratory data showed WBC 19.5, lactic acid 2.9.

Methods: The patient had been on torsemide, pantoprazole, metoprolol, diltiazem, metoclopramide and insulin. At presentation, he had not yet been started on dialysis. Due to severe alkalemia and uremia, the patient was dialyzed emergently in an ICU setting with subsequent improvement in the patient's respiratory and metabolic parameters.

Dialysis parameters	Admission	2nd cycle	3rd cycle
Sodium	130	137	140
Potassium	4	3	3
HCO 3	33	33	30
Blood flow	180-200	250	300

Our patient presented with severe alkalemia due to a combined metabolic and respiratory alkalosis on top of a metabolic acidosis. The anion gap metabolic acidosis was likely due to advanced kidney disease. We suspect the metabolic alkalosis was generated by vomiting and maintained by hypokalemia, volume depletion and diuretic use. His serum bicarbonate was markedly elevated but his pCO2 was unexpectedly low. The etiology of the respiratory alkalosis remained unclear. He was not hypoxic. Salicylate toxicity and sepsis were ruled out and his chest x-ray showed no acute process. He did report anxiety.

Conclusions: There are few, if any, articles in the literature on acute alkalemia in patients with advanced chronic kidney disease, wherein dialysis is required urgently. Our case highlights the importance of recognizing the underlying acid base disturbance in order to afford appropriate treatment in a timely fashion. To our knowledge, this is the first time that such a combined respiratory and metabolic alkalosis has been reported in a patient with advanced kidney disease requiring acute dialysis.

PUB531

Hypermagnesemia-Induced Hypothermia in a Pregnant Patient

Rawan Tayseer Al Odat,[1] Laith Farah Al-Rabadi,[2] Christopher D. Blosser,[3] Jean M. Francis. *[1]Internal Medicine, Al-Khalidi Hospital, Amman, Jordan; [2]Nephrology, Boston Medical Center; [3]Nephrology, Univ of Washington.*

Background: Hypermagnesemia is a rare entity seen mostly in the setting of renal disease. Symptomatic hypermagenesemia is even rarer. Serious side effects include neuromuscular blockage and cardiac conduction defect. Herein,we present a unique case of patient with idiopathic membranous nephropathy who was admitted for induction of labor and received Magnesium sulfate for seizure prophylaxis in the setting of dramatically elevated BP and concern about preeclampsia.

Methods: Case report.

Results: Patient was given a bolus dose of 4 gram then started on continuous infusion of 2 gram per hour. She developed hypothermia, bradycardia and relative hypotension within 24 hours of initiating infusion. Magnesium level was more than 7 mg/dl. Creatinine continues to be stable at 1.6 mg/dl. Other electrolytes were within normal range. Holding Mg Sulfate resulted in reversal of bradycardia and hypothermia. Workup for hypothermia including septic workup came back negative. LFT were normal. Peripheral blood smear, LDH and haptoglobin were not suggestive of hemolysis. Cortisol and TSH were normal. Decision was made for her to undergo caesarian section based on fetus bradycardia. Prior to going to operation room, patient received calcium Gluconate to reverse magnesium toxicity and for cardio-protection effect.

Conclusions: Magnesium hypothetically can cause hypothermia by blocking Calcium channel blocker and causing muscle paralysis in toxic levels. Vasodilator effect is another suggested mechanism for inducing hypothermia. Holding the causative agent may be sufficient to correct hypothermia. However, dialysis may be warranted if severe symptoms persist and failed to respond to conservative management. Therapeutic hypothermia is becoming more common following MI and cerebrovascular event. Treatment of shivering while avoiding the negative consequences of sedative medications is challenging. Magnesium has found therapeutic application in the promising hypothermic protocols as an appealing anti-shivering medication. Hypothermia as a side effect of hypermagnesemia was very rarely reported. Hypermagnesemia should be considered as a potential precipitant of hypothermia.

PUB532

A Greater Anion Gap (AG) Is Present in Mild to Moderate CKD

Tanushree Banerjee,[1] Deidra C. Crews,[2] Delphine S. Tuot,[1] Brenda W. Gillespie,[3] Rajiv Saran,[3] Sharon Saydah,[4] Desmond Williams,[4] Neil R. Powe.[1] *[1]Medicine, UCSF, San Francisco, CA; [2]Medicine, JHU, Baltimore, MD; [3]Medicine, UM; [4]CDC, Atlanta.*

Background: Previous studies have demonstrated an increase in the AG only in relatively advanced kidney disease. Elevated AG is associated with HTN and decreased renal function. Whether a higher anion gap is present even in mild to moderate CKD is not known.

Methods: We conducted a cross-sectional study of 15,133 adults aged≥20 yrs, eGFR≥15 enrolled in the National Health and Nutrition Examination Survey III, 1988-1994. AG was determined from laboratory tests using the traditional AG (serum Na-(serum Cl +serum bicarbonate)), albumin-adjusted AG, and full AG reflecting other electrolytes of serum albumin,Ca,P,and K. We defined moderately increased CKD risk progression as eGFR 45-59, 60-89 or ≥90 ml/min/1.73m^2 and albumin-to-creatinine ratio (ACR)>30mg/g and low CKD risk groups eGFR 60-89 or ≥90 ml/min/1.73m^2 and ACR<30 mg/g. We used ordinal logistic regression to examine moderately increased CKD risk progression groups is associated with a greater AG than the low CKD risk groups adjusting for demographics,education history,income,DM,and HTN. We repeated our analysis with eGFR categories of 15-29, 30-44, 45-59, and ≥60 ml/min/1.73m^2.

Results: 11.8% of the participants had moderately increased CKD risk; the mean age was 62 yrs. A greater traditional AG was evident in this moderate risk group compared to the low CKD risk group (OR[95% CI])=1.5 [1.3-1. 8]) and remained associated after adjustment for the several confounders (1.5[1.2-1.8]). We observed similar associations with the elevated levels of albumin-adjusted (1.2[1.03-1.6]) and full AG (1.5[1.1-1.9]). Results were similar when using eGFR categories as the predictor; an eGFR 45-59 ml/min/1.73 m^2 compared to an eGFR≥60 was associated with a greater traditional AG (1.6[1.2-2.1]); albumin-adjusted AG (1.7[1.03-2.7]); and full AG (1.5[1.1-2.1), adjusted for the covariates.

Conclusions: A greater AG is present even among persons with moderately increased CKD risk. Further research is required to identify the unmeasured anions accounting for the higher levels of AG and to determine their physiological significance.

PUB533

Kidney Biopsy for Renal Tubular Acidosis: A New Paradigm?

Patrick John Sanchez,[1] Lindsey Norris,[1] Jack R. Lewin,[2] Divya Monga,[1] Tibor Fulop,[1] Youshay Humayun.[1] *[1]Internal Medicine, Univ of Mississippi Medical Center, Jackson, MS; [2]Pathology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Renal Tubular Acidosis (RTA) is a well-defined entity. Prevailing diagnostic strategies focus on serum and urine studies but percutaneous kidney biopsy (PKB) is routinely not part of the diagnostic evaluation. We describe a case of unexplained distal (d) dRTA presenting as acute interstitial nephritis (AIN) due to a proton pump inhibitor (PPI).

Methods: A 33 year old male with history of hypertension, GERD, and low testosterone was admitted with complaints of fatigue, weight loss, and unexplained acidosis for 2 months. He had no exposure to lead, gasoline, paints, or adhesives/glues. Prior medications included losartan,omeprazole, potassium chloride, sildenafil, and testosterone propionate injections. Physical exam was unremarkable with a blood pressure of 120/80 mmHg. Initial lab work showed a non-anion gap metabolic acidosis, serum bicarbonate level 16 mM/L, potassium 3 mM/L, Urine pH 6.5, and a positive urine anion gap. Serum creatinine was 1.2 mg/dL and no eosinophilia/eosinophyluria was detected. Renal ultrasound was unrevealing. Renal biopsy results showed findings consistent with AIN and mild (30%) interstitial fibrosis.

Conclusions: dRTA is well described as a chronic tubulointerstitial disease, however it is rarely seen as sole pathologic finding of AIN. In this case, dRTA remained elusive despite extensive blood, urine and imaging testing. Given his normal baseline, we were suspicious for an anatomical process to explain the marked biochemical abnormalities. AIN is often defined as an acute decline in renal function with an inflammation of the kidney interstitium. It can have more subtle presentations as well. It is not uncommon for PPI's to cause an AIN, but it is exceedingly rare for it to present solely as dRTA. Our case underscores the importance of PKB during work-up of otherwise unexplained RTA. RTA is an entity that can have a variable and subtle presentation and traditional laboratory work up may not suffice to fully evaluate the underlying etiology. PKB may be warranted to rule out discrete histopathologic injury such as AIN.

PUB534

A Novel SLC5A2 Mutation in a Patient with Severe Renal Glucosuria and Aminoaciduria Eric E. Gheuens,[1] Karin Dahan,[3] Tania Daems,[2] Ronald Daelemans.[1] *[1]Nephrology, Ziekenhuis Netwerk Antwerpen, Antwerpen, Belgium; [2]Endocrinology, Ziekenhuis Netwerk Antwerpen, Antwerpen, Belgium; [3]Institut de Pathologie et de Génétique, Gosselies, Belgium.*

Background: In the kidney the bulk of glucose is reabsorbed at the S1 segment of the proximal tubule by the high-capacity sodium/glucose co-transporter SGLT2. The protein is encoded by the SLC5A2 gene in the chromosomal region 16p11.2. Several different mutations, scattered throughout the SCL5A2 gene, have been associated with familial renal glucosuria (FRG). Here we describe a case report of a young female (aged 26 y) who was referred for glucosuria without signs or symptoms of diabetes mellitus. She migrated from Iraq to Belgium 4 years earlier and had no medical history. She did state that her mother and sisters experienced renal problems, but she could not define the nature of these problems. She noted frequent urination and an occasional urinary tract infection. Physical exam was unremarkable, and blood pressure was normal (108/74 mmHg). An oral glucose tolerance test was normal, as was the glycosylated hemoglobin. The kidney function was normal, with a normal urinary sediment and absence of proteinuria. There was no metabolic acidosis or electrolyte disturbance.

Methods: Mutational analysis of the SLC5A2 was performed by sequencing of the entire coding region.

Results: Two 24-hour urinary collections (> 3500 ml/day) showed severe glucosuria (84-97 g/ 1.73m²/day). Sodium excretion was slightly elevated (334.3 mmol/day) and aminoaciduria was present for taurine, threonine, serine, asparagine, glutamine, glycine, alanine, tyrosine, phenylalanine and proline. A novel heterozygous mutation **c.12del (p.His4Glnfs*16)** was identified, in the SLC5A2 gene. This deletion is a truncating mutation probably leading to a dysfunctional SLGT2-proteïn. There is also another heterozygous variation, an intronic unclassified variant **c.655+6G>C**.

Conclusions: This report adds to the number of reports of FRG caused by a large number of different mutations. As seen in our patient, severe renal glucosuria reflects the characteristics of autosomal recessive inheritance and has not been shown to have severe clinical consequences.

PUB535

Plasma Homocysteine Levels as a Predictor of Pre-Eclampsia in Pregnancy Bhavna Pandya,[1,2] Martin Myers,[3] Sohan Shah,[1] Noveen Awan.[2] *[1]Faculty of Health and Life Sciences, Univ of Liverpool, Liverpool, United Kingdom; [2]Nephrology Dept, Aintree Univ Hospitals, Liverpool, United Kingdom; [3]Clinical Biochemistry, Lancashire Teaching Hospitals, Preston, United Kingdom.*

Background: Plasma homocysteine levels have been adversely associated with several obstetric complications, including pre-eclampsia. We aimed to compare plasma homocysteine levels in normal pregnancy and pre-eclampsia to assess whether quantification of homocysteine levels can be used as a predictor of disease.

Methods: We conducted a prospective cohort study with 300 pregnant women. Homocysteine levels were measured on 3 occasions during pregnancy: enrolment, 28 weeks and delivery. We also analysed genotype amongst other factors such as folate levels, vitamin B12 levels and smoking.

Results: A total of 203 patients with available outcome of pregnancy records were included in the study. The proportion of pre-eclampsia cases was 4.4% (95%CI: 2.3-8.3). The optimal cut-off point for homocysteine level on ROC curve analysis was 9.3 µmol/L, where sensitivity = 33.33% (95%CI: 7.49-70.07) and specificity = 94.85% (95%CI: 90.72-7.50). The area under the curve was 51% and indicated that the accuracy of homocysteine plasma levels as a diagnostic test is extremely low. However, for every unit (umol/l) increase in homocysteine levels, the odds of pre-eclampsia presence are increased by 21% (95%CI:1–44) (p=0.034). We found that there was a statistically significant difference (p=0.020) in the mean homocysteine level among the three genotypes analysed. Statistically significant relationships were also found between homocysteine levels and the following variables: vitamin B12 levels (rho = -0.2131, p = 0.0008); folate levels (rho = -0.3855, p < 0.001); smoking (z = -4.472, p = 0.001).

Conclusions: With data available from our study, there is no evidence to suggest that homocysteine levels can be accurately used as a screening tool for pre-eclampsia. Several different factors affect the level of homocysteine during pregnancy.

PUB536

Apolipoprotein L1 Is Expressed in the Renal Microvasculature and the Risk Genotype Is Associated with More Severe Arteriolar Hyalinosis Preeti Chandra,[1] Avi Z. Rosenberg,[2] Cinthia Drachenberg,[3] Xiongce Zhao,[4] Cheryl Ann Winkler,[5] Stephen M. Hewitt,[2] Jeffrey B. Kopp.[4] *[1]Int Med, Univ of MD, Baltimore, MD; [2]NCI, NIH, Bethesda, MD; [3]Pathology, Univ of MD, Baltimore, MD; [4]NIDDK, NIH, Bethesda, MD; [5]NCI, NIH, Frederick, MD.*

Background: Variants in *APOL1*, encoding apolipoprotein L1, termed G1 and G2 risk alleles (RA), are strongly associated with kidney disease in African Americans (AA). APOL1 has been reported to localize to the media in arteries and arterioles in focal segmental glomerulosclerosis (FSGS) and HIV-associated nephropathy but not in normal kidney. Our aim was to study, in native kidney biopsies with diagnosis of FSGS, arterionephrosclerosis (ANS) and diabetic nephropathy, associations between *APOL1* genotype and APOL1 expression in microvessels.

Methods: This IRB-approved retrospective study involved 73 native renal biopsy samples, obtained from 18 Whites and 55 AA and included FSGS (35), diabetic nephropathy (25), and ANS lacking another glomerular diagnosis (13). Glomerulosclerosis score was determined as the fraction of glomeruli with obsolescence or solidification. Interstitial fibrosis/tubular atrophy (IFTA), arteriolar hyalinosis and APOL1 staining were semi-quantitatively scored. Paraffin sections were genotyped for G1 and G2 RA, and stained for APOL1 using a rabbit monoclonal antibody (Epitomics).

Results: 54 cases had an *APOL1* low risk genotype (0 or 1 RA) and 19 (26%) had a high-risk genotype (2 RA). Cases with 2 RA had similar scores for glomerulosclerosis, arteriosclerosis and IFTA compared with the low risk group (with and without adjustment for the disease diagnosis.) APOL1 vascular expression (in arterial/arteriolar endothelia/walls) was similar in high-risk and low-risk subjects, in the entire study group and in the disease subgroups.Individuals with 2 RA manifested similar degrees of arteriosclerosis but more severe arteriolar hyalinosis ($p<0.05$).

Conclusions: APOL1 expression in the renal microvasculature is a typical feature of common renal diseases, including those associated and unassociated with the risk genotype, and is not influenced by genotype. The *APOL1* risk genotype is associated with more severe arteriolar hyalinosis.

PUB537

Renal Replacement Treatment Effects on Global DNA Methylation Pattern in End-Stage Renal Disease Patients Karin Luttropp,[1] Peter F. Barany,[2] Olof Heimburger,[2] Peter Stenvinkel,[2] Louise Nordfors.[2] *[1]Dept of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [2]Dept of Clinical Science, Intervention and Technology, Karolinska Univ Hospital, Stockholm, Sweden.*

Background: It has been found that chronic kidney disease (CKD) patients display differences in DNA methylation compared to healthy controls. However, the effect of renal replacement therapy (RRT) on methylation status is still a quite novel field of research. In this study, we investigated the effect of RRT on global DNA methylation.

Methods: 12 kidney recipients (RTx) and 12 patients starting dialysis (8 on peritoneal dialysis, 4 on hemodialysis) were included. Baseline samples were collected before therapy initiation and a second sample was obtained after 12 months on RRT. 24 age-matched healthy controls were also included. DNA was prepared from whole blood and analysed by the Illumina HumanMethylation450 BeadChip, which measures DNA methylation at 450 000 CpG sites. The patients were compared to the controls using the lumi package in R.

Results: When comparing pre-RTx patients to controls, we found 39085 significantly (adjusted p-value < 0,05) differentially methylated CpG sites (see Table 1); post-RTx patients versus controls 12708 sites; pre-dialysis patients versus controls 34321 sites; and post-dialysis patients versus controls 11428 sites. For RTx patients, 10854 of the statistically significantly differentially methylated CpG sites remained significant over time; for the dialysis patients, this number was 9479 sites.

Significant CpG sites	Baseline	12 months
RTx vs controls	39085	12708
Dialysis vs controls	34321	11428

Table 1

Conclusions: Following start of dialysis as well as after RTx, the difference in number of differentially methylated CpG sites between patients and controls was markedly reduced. This could indicate a normalisation process, where the DNA methylation profile of CKD patients gradually approaches the one seen in healthy subjects. Closer investigation regarding the genes and regions displaying differences in methylation after initiation of dialysis and transplantation is currently being performed.

PUB538

APOL1 Genotype Is Associated with Glomerular But Not Tubular Injury in HIV Infection Vasantha Jotwani,[1] Michael Shlipak,[1] Rebecca Scherzer,[1] Rulan S. Parekh,[2] Wen Hong Linda Kao,[3] Michael R. Bennett,[4] Mardge H. Cohen,[5,6] Anjali Sharma,[7] Phyllis Tien,[1] Chirag R. Parikh,[8] Mary A. Young,[9] Michelle M. Estrella.[3] *[1]UCSF; [2]Univ of Toronto; [3]Johns Hopkins; [4]Cincinnati Children's Hospital; [5]Rush Univ; [6]Stroger Hospital; [7]Albert Einstein; [8]Yale; [9]Georgetown.*

Background: *APOL1* risk alleles are associated with advanced kidney disease in African Americans, but their specific effects on glomerular and tubular health are unknown.

Methods: This cross-sectional study of 431 HIV-infected African American women from the Women's Interagency HIV Study evaluated associations of *APOL1* risk alleles with albumin-creatinine ratio (ACR) and urine biomarkers of tubular damage: interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), and a1-microglobulin (a1m).

Results: Women with 2 risk alleles had higher ACR levels (median 24 versus 11 mg/g, p=0.0002) and higher prevalence of ACR>30mg/g (47% versus 21%, p=0.0011) compared to women with 0/1 risk allele. These differences persisted after multivariable adjustment (**Figure 1**). *APOL1* genotype showed little association with IL-18/cr, NGAL/cr, or detectable a1m in adjusted analyses. The presence of 2 *APOL1* risk alleles was associated with lower KIM-1/cr, but showed weaker association with unstandardized KIM-1 levels (-15%, 95%CI: -35,13).

Figure 1: Multivariate-adjusted[1] associations of 2 vs 0/1 *APOL1* risk alleles with biomarker levels

	% Estimate (95% CI)	P-value
Continuous outcomes		
ACR (mg/g)	104 (29,223)	0.0023
IL-18/Cr (pg/mg)	-5 (-24,18)	0.64
KIM-1/Cr (pg/mg)	-20 (-36,-1)	0.044
NGAL/Cr (ng/mg)	10 (-26,64)	0.64
	Prevalence Ratio (95% CI)	**P-value**
Dichotomous outcomes		
ACR >30mg/g	2.00 (1.17,3.44)	0.012
Detectable α1m	1.13 (0.65,1.97)	0.66

[1]Adjusted for age, hypertension, diabetes, BMI, HCV, HIV viral load, eGFR, and ancestry

Conclusions: Among HIV-infected African American women, *APOL1*-associated kidney injury appears to localize to the glomerulus, rather than the tubules.

PUB539

Exome Sequencing Identifies a Novel Mutation in APOL1 as the Cause Gene of Focal and Segmental Glomerulosclerosis in a Chinese Pedigree

Guisen Li, Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Studies of familial FSGS have identified the variation of genes related to podocytes. These results were not confirmed in Chinese Han population. Therefore, the purpose of this study was to identify the causal mutations of FSGS in Chinese pedigree.

Methods: Sequence of the exon 8 of *ACTN4*, exon 2,5,12,and 13 of *TRPC6*, as well as exon 2,3,and 4 of *INF2 was performed in the proband of one family. Then, exome sequencing in probands of a familial FSGS was done. By PCR sequencing methods, we detected candidate causal mutaions in all members of this family. And then, we tested the variations in other 97 sporadic FSGS patients and 96 normal controls.*

Results: This pedigree was an identical twins pedigree, no mutation was detected from those exons of *INF2*, *ACTN4* and *TRPC6 in* the proband. We identified the mutations of *APOL1*(c.C761T) in the proband and her sister, their parents did not have this mutation.

Conclusions: The strategy that we use the exome sequencing for FSGS pedigree was demonstrated successfully for the first time in the Chinese Han population. We identified a new missense mutation of *APOL1* from a Chinese FSGS pedigree by using exome sequencing.

Exome Sequencing Identified MYH9 as a Candidate Gene for a Familial Focal and Segmental Glomerulosclerosis

Guisen Li, Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Studies identified that the variation of genes related to podocytes were associated with the pathogenesis of FSGS. These results were not confirmed in Chinese Han population. Therefore, the purpose of this study was to identify the causal mutations of FSGS in Chinese Han population.

Methods: Sequence of the exon 8 of *ACTN4*, exon 2,5,12,and 13 of *TRPC6*, as well as exon 2,3,and 4 of *INF2* was performed in the proband of this family. Causal mutaions were detected by exome sequencing in the probands of this family. By PCR sequencing methods, we detected candidate causal mutaions in this proband. And then, we tested the variations in other 97 sporadic FSGS patients and 96 normal controls.

Results: This pedigree was with autosomal dominant inheritance, no mutation was detected from those exons of *INF2*, *ACTN4* or *TRPC6 in* the proband. We identified the mutations of *MYH9*(c.G3282C) in the proband, while the mutation effect on protein function remains unknown.

Conclusions: The strategy that we use the exome sequencing for FSGS pedigree was demonstrated successfully for the first time in the Chinese Han population.We identified a new missense mutation of *MYH9* from a FSGS pedigree by using exome sequencing.

PUB541

Predictive Value of Genome Copy Number Variation to ShenQi MoShen Recipe in the Treatment of Idiopathic Membranous Nephropathy

Lin Wang,[1] Shihui Li,[2] Xianwen Zhang,[1] Chunsong Zhang,[1] Jiao Li,[1] Siyu Zhao,[3] Yueyi Deng,[1] Jianhui Tian,[1] Minping Qian,[2] Lin Wan,[4] Yiping Chen.[1] *[1]Longhua Hospital, China; [2]Peking Univ, China; [3]Shanghai Univ of TCM, China; [4]Chinese Academy of Sciences, China.*

Background: Idiopathic Membranous Nephropathy (IMN) is one of the leading causes of nephrotic syndrome (NS) in adults. Current treatment of IMN is far from satisfactory. ShenQi MoShen Recipe (SQMSR) is a Chinese herbal medicine prescription used to treat IMN in Long Hua Hospital for decades. To explore the correlation between Genome Copy Number Variation (CNV) of the patients of IMN and the clinical response of SQMSR, we compared the differences of gene background among the IMN patients with different clinical outcomes.

Methods: Eighty patients were divided into four groups according to the treatment and outcomes: the complete remission (CR) group of SQMSRwas indicated as the TCR group (36 cases); the no remission (NR) group of SQMSR as the TNR group (11 cases); the CR group of the immunosuppressive agent (IA) as the ICR group (18 cases); the NR group of IA as the INR group (15 cases). Genomic DNA from peripheral blood was extracted and genotyped with the Affymetrix Genenome-Wide Human SNP Array 6.0. CNV analysis was performed on the raw data by the software of CNV hac.

Results: The most significant CNVs regions among groups were located on chromosome 5, 6 and 8, on which patients of TCR group showed no loss while patients of TNR group showed loss (P<0.05). The CNV of HLA gene family which located on chromosome 6 showed amplification on patients of TCR group, but loss on patients of TNR group. However, there were no significant CNVs between ICR and INR group.

Conclusions: The differences in genetic background of IMN patients might be the cause of different clinical response of SQMSR. The CNVs of HLA gene family could become the predictive factor of the treatment of SQMSR and be worthy of further study.

PUB542

Lower eGFR Is Associated with Worse Muscle Fatigue and Muscle Quality among Older Adults

Baback Roshanravan,[1] Kushang V. Patel,[2] Linda F. Fried,[3] Cassianne Robinson-Cohen,[1] Ian H. de Boer,[1] Ann M. O'Hare,[1] Michael Shlipak,[4] Anne B. Newman,[3] Bryan R. Kestenbaum.[1] *[1]Kidney Research Institute, Univ of Washington; [2]Anesthesiology and Pain Medicine, Univ of Washington; [3]Univ of Pittsburgh; [4]UCSF.*

Background: CKD promotes malnutrition and inflammation leading to sarcopenia. The association of CKD with objective muscle fatigue and dynamic muscle impairment is unknown. Here we investigate the association of renal function with muscle function by isokinetic fatigue testing and assess the potential contribution of body composition in older adults.

Methods: We studied 1993 adults in the Health, Aging and Body Composition Study who had isokinetic muscle fatigue testing and Cystatin C collected at the year 3 visit. DXA scans were performed to assess body composition. Fatigue index ([final torque/initial peak torque]*100) represented fatigue resistance over 30 knee extensions. Total knee extension work was measured. We estimated associations of GFRcysc with total work and fatigue index using multivariable linear regression adjusting for demographics, BMI, smoking, cognitive function, diabetes, CAD, cerebrovascular disease, and physical activity. We used linear regression to estimate the association of CKD (eGFRcysc<60) with each isokinetic index and the potential contribution of body composition.

Results: Average participant age was 75.5 ±2.8 with 50% females, 37% African Americans and average eGFRcysc of 85.6 ±19. CKD was associated with lower fatigue index (greater fatigue) and lower muscle work compared to non-CKD.

	Fatigue Index (%)		Total work(Joules)	
	Mean (SD)	β (95% CI)	Mean (SD)	β (95% CI)
non-CKD (n=1782)	73.8 (17.4)	Reference	1070 (454)	Reference
CKD (n=211)	70.9 (17.6)	-3.0 (-5.48, -0.53)	922 (387)	-106.6 (-154.7, -58.5)
Per -10ml/min/1.73m^2		-0.44 (-0.87, -0.01)		-20.1 (-28.9, -111.3)
P- value		0.045		<0.001

Adjustment for leg lean mass, but not fat mass, modestly attenuated the association of CKD with fatigue index and total work, but associations remained statistically significant.

Conclusions: Lower eGFRcysc is associated with greater lower extremity fatigue and diminished muscle quality. The association of CKD with fatigue and total work is independent of lean mass.

PUB543

Nursing Home Status Among Older Adults with Incident End Stage Renal Disease C. Barrett Bowling,[1,2] Rebecca H. Zhang,[2] Harold A. Franch,[1,2] Yijian Huang,[2] Anna Mirk,[1,2] William M. McClellan,[2] Theodore M. Johnson Ii,[1,2] Nancy G. Kutner.[2] *[1]Atlanta VA Medical Center; [2]Emory Univ.*

Background: End-stage renal disease (ESRD) patients who require nursing home (NH) care may be at risk for adverse health outcomes. The Centers for Medicare and Medicaid Services (CMS) revised the Medical Evidence Report Form CMS-2728 in 2005 to include data collection on NH institutionalization. While these data provide an opportunity to describe the utilization and outcomes associated with NH care, the validity of NH institutionalization status on CMS-2728 has not been reported.

Methods: There were 27,913 patients ≥ 75 years of age with incident ESRD in 2006, which constituted our analysis cohort. We determined the accuracy of the CMS-2728 using a matched cohort that included the CMS nursing home Minimum Data Set (MDS), a previously employed "gold standard" metric for identifying patients receiving NH care. We calculated sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for the CMS-2728 nursing home item. Additionally, among those with MDS data indicating NH institutionalization, we compared characteristics and mortality risk for those with (true positive) versus without (false negative) a CMS-2728 NH indicator.

Results: The sensitivity, specificity, PPV and NPV of the CMS-2728 for nursing home status were 33%, 97%, 80% and 79%, respectively. Among 7,801 patients with MDS data indicating NH institutionalization, the CMS-2728 NH indicator was associated with an inability to ambulate (41% versus 8%), inability to transfer (25% versus 3%), and need for assistance with activities of daily living (57% versus 12%). Among those with MDS data, multivariable adjusted hazard ratios (95% CI) for mortality for those with and without the CMS-2728 NH indicator were 1.54 (1.46–1.63) and 1.47 (1.41–1.53), respectively.

Conclusions: The CMS-2728 may underestimate NH institutionalization among older adults with incident ESRD, but identifies a group likely to have received NH care. Despite a higher prevalence of functional impairment among those identified as requiring NH care by both the MDS and CMS-2728, regardless of source, NH institutionalization was associated with an increased risk for mortality.

Effective Control of Hypertension in Elderly with Chronic Kidney Disease Eleni Chelioti,[1] Dimitrios Athanasopoulos,[2] Evdokia Efthimiou,[1] Alexia Papalexandrou,[1] Maria Sotiraki,[1] Maria Tsilivigou.[1] *[1]Dept of Nephrology, General Hospital of Piraeus, Athens, Greece; [2]Health Centre of Dimitsana, General Hospital of Tripoli, Tripoli, Greece.*

Background: The new guidelines of JNC 8 emphasize control of systolic blood pressure (SBP) and diastolic blood pressure (DBP) with age and comorbidity. In patients 18 to 59 years of age without major comorbidities, and in patients 60 years or older who have diabetes, chronic kidney disease (CKD), or both conditions, the new goal blood pressure level is <140/90 mmHg. ***Aim*** *of the study was to* examine the effective control of hypertensionin elderly with CKD according the new guidelines of JNC8.

Methods: A cross-sectional observational study was done. The study included elderly with CKDin the outpatient nephrology clinic during one year. Adequate blood pressure control (ABPC) was defined as SBP<140 and DBP<90mmHg on time 0 and 12months. Estimated glomerular filtration rate (eGFR ml/min/1.73m^2) was calculated using CKD-EPI formula. All patients were receiving three or more antihypertensive drugs.

Results: *130 patients were studied (52%men, mean age77±7years-old, mean serum creatinine 1,9±0,8mg/dl).*There are not statistically differences between mean eGFR on time 0 and 12 months (31,9±10,7 and 32,6±11,6 ml/min/1.73m^2 respectively). Statistically differences found between mean SBP on time 0 and 12 months (135±14,7 and 130±14,2mmHg respectively) whileno found statistically differences between mean DBP on time 0 and 12 months (73,5±13 and 72±13 mmHg respectively).*Among elderly with CKD, 63,7% had ABPC on time 0 and 82,9% on 12months and we found that there is a* statistically significant difference between ABPC on time 0 and 12.

	Time 0	Time 12	p
eGFR Mean(SD)	**31,9(10,7)**	**32,6(11,6)**	**NS**
SBP Mean(SD)	**135(14,7)**	**130(14,2)**	**<0,001**
DBP Mean(SD)	**73,5(13)**	**72(13)**	**0,33**
ABPC (%)	**63,7**	**82,9**	**<0,001**

Conclusions: Our study suggests that new guidelines for hypertension control in elderly with stable CKD is possible, but it requires close follow-up and antihypertensive drugs.

PUB545

Effective Control of Anemia in Elderly and Very Elderly with Chronic Kidney Disease? Eleni Chelioti, Evdokia Efthimiou, Alexia Papalexandrou, Maria Sotiraki, Maria Tsilivigou. *Dept of Nephrology, General Hospital of Piraeus, Athens, Greece.*

Background: Chronic kidney disease (CKD) is a growing problem due to our aging population, many of who have increased comorbidities. Anemia emerges as a main independent modifiable risk factor of cardiovascular and renal damage. Knowledge of anemia medication patterns use allows identifying opportunities for improving care.The **aim** of the study was to evaluate the effective control of anemia in elderly and very elderly patients with CKD.

Methods: A prospective study was carried out. The study included elderly ang very elderly patients with CKD and eGFR<60ml/min/1.72m^2, who follow-up in the outpatient nephrology clinic over 12 months. The anemia management evaluated in two visits: at baseline and 12-month visit. Anemia was defined as severe (Hb <11g/dL) or mild (Hb: 11–12 g/dL). The patients divided in 2 age groups (AG): AG1 65-79, and AG2 >80 years old. Estimated GFR was calculated using MDRD formula.

Results: A total of 125(85 AG1/40AG2) patients were studied (52,3 %men, mean eGFR 31±18ml/min/1.73m^2). The percentage of severe and mild anemia at baseline for the AG1 was: 41,2% and 58,8% respectively, while for the AG2 was 45% and 55% respectively. At 12 months, the percentage was 32,6% and 67,4% for the AG1 while for the AG2 was 43,6% and 56,4% respectively. The correlation between severe and mild anemia in both of age groups at baseline and at 12months was not statistically significant and not statistically significant with the age.

Conclusions: Our results suggest that the effective control of anemia in the elderly and very elderly populations with CKD, seems to be unexpectedly difficult and likely is a result of poor management.

PUB546

Hemoglobin Stability in Elderly with Chronic Kidney Disease Eleni Chelioti,[1] Dimitrios Athanasopoulos,[2] Alexia Papalexandrou,[1] Evdokia Efthimiou,[1] Maria Sotiraki,[1] Maria Tsilivigou.[1] *[1]Dept of Nephrology, General Hospital of Piraeus, Athens, Greece; [2]Health Centre of Dimitsana, General Hospital of Tripoli, Tripoli, Greece.*

Background: Hemoglobin(Hb) variability is common not only in patients with end-stage kidney disease on dialysis, but also in chronic kidney disease (CKD) patients who are not yet on dialysis (non-dialysis CKD). The reported prevalence of hemoglobin variability in non-dialysis CKD patients varies between 61 to 86%. Hb levels in individuals with CKD fluctuate frequently above or below the recommended target levels within short periods of time even though the calculated mean hemoglobin remains within the target range of 11 to 12 g/dl. **The purpose** of the study was to assess the prevalence of Hb stability in CKD elderly patients.

Methods: The prospective study was carried out in a outpatient nephrology clinic over a period of 12 months. The study included elderly patients with CKD and eGFR<60ml/min/1.72m^2. The stability of Hb levels (10-12g/dl**)** with administration of erythropoiesis-stimulating agents, evaluated in two visits: at baseline and 12-month visit.Estimated GFR was calculated using CKD-EPI formula.

Results: A total of 170 patients were studied (53,5% men, mean age 77±11 years-old). The mean differences of eGFR and Hb levels between baseline and 12-months was not statistically significant (33±12 versus 33±12,4ml/min/1.72m^2 and 12,1±1,7 versus 12,1±1,4g/dl, respectively). The correlation between hemoglobin stability and gender and age was not statistically significant. The percentage of patients who had stable Hb levels was only 27,6% (47/170).

[table 1]	***Baseline***		***12-months***		***P value***
Stages of CKD	Stable Hb levels (n)	Percentage (%)	stable Hb levels (n)	Percentage (%)	
Stage 3	*20*	*19,6*	*20*	*19,6*	*NS*
Stage 4	*25*	*40,9*	*23*	*41,8*	*NS*
Stage 5 (non-dialysis)	*2*	*28,5*	*4*	*30,7*	*NS*

Conclusions: *Our results suggest that the* maintaining stable hemoglobin levels *in elderly with CKD* is unexpectedly difficult in the setting of tertiary nephrology care.

PUB547

Clinical Outcomes of Geriatric Kidney Transplantation in Korea Kyung Don Yoo,[1] Su-Kil Park,[2] Dong-Wan Chae,[1] Yun Kyu Oh,[1] Yon Su Kim,[1] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine; [2]Internal Medicine, Asan Medical Center and Univ of Ulsan College of Medicine.*

Background: Elderly individuals who underwent kidney transplantation are growing rapidly. In Korea, proportion of kidney transplant recipients older than 60 years increased from 2.3% to 11.4% between 2000 and 2013. However, clinical outcomes in elderly patients were not well evaluated in Asian population.

Methods: This is a multicenter cohort study including adult patients underwent kidney transplant between 1997 and 2011 in 5 tertiary hospitals in Korea. A total of 2642 kidney

transplant patients were enrolled. Patient survival, allograft survival, and biopsy-proven acute rejection were monitored as end-points in elderly transplant patients comparing with younger population.

Results: Participants older than 60 years old was 8.5%(N=223). Their mean age was 63.2±2.7 years old. Total patients were divided into 5 groups according to transplant age by 10 years. The male patients(69.5%),diabetes mellitus(39.0%), and history of pretransplant ischemic heart disease(16.9%) were more in oldest age group. Deceased donor transplantation was more frequent. The over-all mortality rate was significantly higher in the oldest group(1yr survival 94.6%, 5yr survival 91.9%). However, age did not affect allograft survival(1yr survival 94.1%, 5yr survival 91.9%). In addition, the prevalence of BPAR conversely decreased as the age increased(*p<0.001). In recipients older than 60 years, BPAR was an independent risk factors for allograft loss after adjusting for age, gender, donor age, donor relation, and HLA mismatches (P=0.032, hazard ratio 3.10, 95% confidence interval 1.11-8.74).*

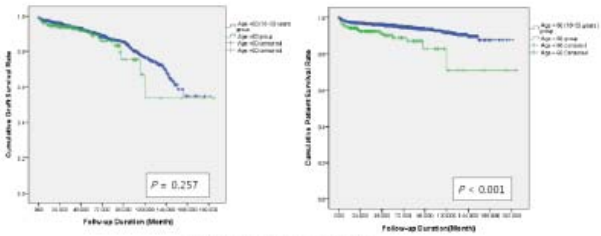

Figure 1. Comparision of Graft Survival and Patient Survival between Adult Patients (18~59 years) and Geriatric Patients (Over 60 years) by Kaplan-Meier curve

Conclusions: Kindey transplantation in the elderly was comparable to younger age in Korean. Episode of acute rejection decreased as the age increased and could significantly affect allograft survival.

PUB548

Rethinking and Reevaluating the Biomedicalization of the Very Oldest: Should We Recommend Automatically Dialysis Treatment for Octogerian Patients? Time for Improving Dialysis-Decision Making Capacity and Implementing Succesfully Advance Care Planning. Experience of a French Region in an Aging France Achour Laradi,[1] Francois Babinet,[1] Alain Cremault,[1] Stephanie Lanoiselee,[1] Maryvonne Hourmant,[2] Cécile Couchoud.[3] *[1]Nephrologie- Dialyse, ECHO-CMCM, Le Mans, France; [2]Nephrologie -Transplantation, CHU Hôtel Dieu, Nantes, France; [3]Coordination Nationale du Rein, Agence de Biomedecine, Saint Denis-Paris, France.*

Background: The societal changes that have taken place over two decades are a major medical issue and an important societal challenge with the fastest growing of Chronic Kidney Disease (CKD)in elderly patients (Epts) over 75 years old.The medical community is concerned by the appropriateness of dialysis therapy(DT) for these pts at high risk of cognitive impairment or dementia with societal pressures influencing medical practices.

Methods: Epts represents 40 % of incidents pts in France.We report here the clinical characteristics and the outcomes of 101 incidents pts treated by DT in our institution between 2007 and 2011 and using data of the Pays de Loire region from the french dialysis network REIN.

Results: The median age was 71.7 years and 56.6 % of these incidents pts were over 75 years old.Diabetes accounts for 30.8 % in 2009 and 41.7 % in 2012. Hypertension was present in 85 % of pts and 31.6 %. In 92 prevalent pts in 2012, 58.7 % were over 75 yeays old, 2 or more chronic heath conditions were present and 15.2 % suffer from disability.Visual impairments were affecting 8.7 % of pts.15 % were on the kidney transplant waiting list with 2 pts experiencing a combined transplantation.The death rate one year after initiation of DT is high and 15.7 % dying less than three months after initiation of DT.Survival rate after 5 years is 15 %.

Conclusions: The older dialysis population has a high burden of comorbidities and a high risk of death particulary at the start of dialysis. There is a delicate balance between benefits and risks in these pts.Clinical judgement,improving dialysis decision making to avoid routinization of automatically recommending dialysis to pts with poor outcome resulting from appropriate prognosis tools n favor or against initiation of DT.

PUB549

A Novel Method of Six-Day Intensive Locking with Urokinase Combined with Heparin for Treatment of Long-Term Catheter Dysfunction: Efficacy and Safety Data from Sixteen Patients Tian Xu, Xiaoliang Zhang, Rining Tang, Hong Liu, Yinfeng Guo. *Nephroloy, Zhongda Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Long-term central venous catheter dysfunction seriously affects dialysis adequacy. In this study, we established a novel method to prevent and treat catheter dysfunction.

Methods: Inclusion criteria: Regular hemodialysis patients with long-term central venous catheter were hospitalized for catheter dysfunction, and have received thrombolytic therapy with urokinase (Single thrombolytic treatment) before. Exclusion criteria: Patients with coagulation disorder or vein stenosis. Catheter dysfunction is defined as failure to attain a sufficient extracorporeal blood flow less than 200mL/ min. Six-day Intensive treatment : urokinase (100,00U/ml) used in daily morning(8:00) and heparin (4000U/ml) used in daily afternoon (16:00), lasted six days. Research programme: The time from patients firstly received thrombolysis treatment to their enrollment is considered as observation time. We observe the incidence of catheter dysfunction in the observation time as well as the equal observation time after the intensive therapy by a self-controlled method.

Results: A total of 16 patients were enrolled, aged 60~89 years old, male 7 cases, female 9 cases; The observation time of prior treatment and post treatment was 170.4 ± 92.7 days respectively. The rate of catheter dysfunction after intensive therapy is 0.98%, which is significant lower than single therapy 51.9% (P<0.01). The first time to recurrence of catheter dysfunction was significantly shorter after single therapy compared with Intensive therapy (3.0 days versus 167.6 days, P<0.001). The successful declotting rates for catheter at three time points (the second, forth, and sixth injection urokinase/heparin) were 25%, 50%, and 25% respectively. Besides, the study showed no significant difference on PT and APTT after intensive therapy.

Conclusions: Six-Day Intensive Locking with Urokinase Combined with Heparin can treat catheter dysfunction and prevent recurrence of clotting episodes effectively, which is safe to application in clinic.

PUB550

Lack of Utility of Indium Tagged Leukocyte Scintigraphy in Clinically Suspected Arteriovenous Graft Infections Jonathan T. Lin, Ioannis Konstantinidis, Francis Scott Nowakowski, Girish N. Nadkarni, Rabi Yacoub, Victoria J. Teodorescu, Joseph A. Vassalotti. *Dept of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Vascular access infections are a common cause of morbidity in hemodialysis patients, but the role of indium-tagged leukocyte scintigraphy in evaluating arteriovenous graft (AVG) infections is unclear. We assessed the utility of indium scans in evaluating clinically suspected AVG infection.

Methods: All charts with indium scans and AVGs from this single tertiary referral hospital during the years 2000-2013 were reviewed for demographic, blood culture, clinical, and outcome data. Scans performed for suspected AVG infections were compared to those performed for non-access infections (controls).

Results: Of the 30 scans with complete data, 14 were for suspected AVG infection (cases) and 16 were controls. Demographic and clinical characteristics in the two groups were similar. There was a trend for a greater proportion of positive scans (defined by AVG uptake) in cases than in controls (8/14[57%] versus 3/16[19%], respectively; p=0.07). Comparing ongoing clinical evidence of infection as a standard, the sensitivity (Sn), specificity (Sp), positive predictive value (PPV), and negative predictive value (NPV) were 57%, 81%, 73%, and 68%, respectively (Table 1). In 24/30 patients with bacteremia, the results were Sn 29% and Sp 86%. A positive scan did not significantly affect AVG revision rates (22% versus 25%; p=0.71).

Table 1: 2x2 contingency table showing positive scans in clinically suspected AVG infections with summary statistics (n=30)

		Clinically Suspected AVG Infection		
		Positive	**Negative**	**Total**
Indium Scan AVG Uptake	**Positive**	8	3	11
	Negative	6	13	19
	Total	14	16	30

Conclusions: Although the proportion of positive scans was higher in patients suspected of having AVG infection compared to controls, a positive scan was of moderate Sn and Sp. The lack of correlation between treatment decisions and scan results suggests limited utility of costly indium scans in evaluation of AVG infections.

PUB551

Why Are Catheters Still Used to Initiate Hemodialysis Treatment of ESRD? Tanya Tocharoen Tang, Sumedha Dhar, Sadaf S. Khan, Antonio Alvarado, Shubhada N. Ahya, James J. Paparello, Murray L. Levin. *Nephrology, Feinburg School of Medicine, Northwestern Univ, Chicago, IL.*

Background: Complications of long-term use of tunneled catheters for hemodialysis involve a high risk of infection, thrombosis and high risk of mortality. This study aims to identify why an unacceptably large number of chronic hemodialysis patients in the United States are initiated on dialysis using tunneled hemodialysis catheters despite increased mortality, hospitalizations and expense.

Methods: We conducted a 13-question survey of 20 CKD patients who had been newly initiated on dialysis through a tunneled central vein dialysis catheter during their hospital admission in a university hospital from December 2013-June 2014.

Results: Of 20 subjects, 12 were male and 8 female. Subjects' mean age was 60 years old. Demographics included 12/20 (60%) African Americans, 5/20 (25%) Hispanics, 2/20 (10%) Caucasians and 1/20 (5%) Asian. Ninety-five% of patients were seen by a physician within the past year, had labs obtained and had been told their kidney function was poor. Fifteen% (3/20) of patients were not referred to a nephrologist. Eighty% of patients (16/20) were referred to a nephrologist and fifteen% (3/20) did not schedule an appointment due to noncompliance. Only 13 patients saw a nephrologist, 7 of whom were not referred to a

surgeon for access. Two of the latter were being evaluated for transplant. Of the 6 patients referred to a surgeon for access, 2 patients were non-compliant, and 4 had non-functioning access placed. Thus, of 20 patients starting hemodialysis with a catheter, only 4 had seen a surgeon for access placement.

Conclusions: Based on our study, there are numerous points in the path to arteriovenous access where attrition occurs. Patients and primary doctors need to be aware of the importance and causes of delay to access placement. Primary care physicians or nephrologists should oversee proper follow up and follow through to successful access placement prior to dialysis initiation of patients. Nephrologists need to recognize who is likely to progress, and how fast. Surgical fistula success rate is another important determinant of whether patients require catheters for their first dialysis.

PUB552

Usefulness of the Ultrasound Scan in the Implantation of Temporary Catheters in Femoral Vein Maite Rivera, Nuria Rodriguez Mendiola, Victor Burguera, Viviana Raoch Michaels, Rodrigo Hernandez Loyola, Sandra Elias, Fernando Liano, Carlos Quereda, Maria Teresa Tenorio. *Nephrology, Hospital Univ Ramón y Cajal.UAH.Irycis, Madrid, Spain.*

Background: The clinical guides recommend, with high level of evidence that ultrasound-guided canalization is mandatory for jugular venous catheters .Nevertheless, it is not well established for the implantation of femoral venous catheters.

Methods: We performed a prospective study that included all the temporary catheters implanted in the femoral vein (FC) during one year. 146 FC were implanted for renal replacement therapy. Patients were divided into two groups,Group 1: ultrasound-guided FC and iGroup 2: FC was implanted with conventional landmark localization. Nephrologists chose using ultrasound or not according the clinical situation of the patient and their own experience with FC implantation. Data regarding the number of attempts, failures, and complications were recorded.

Results: 95 patients in Group 1, 51 in Group 2. Mean age was lower in Group 1 (66 years versus 72 years (p = 0.007). There were no differences with respect to: number of platelets, INR or patients with double antiaggregation and anticoagulation.The number of patients with severe hepatic disease was higher in Group 1 (18 % versus 6 % (p=0.038)). Complications derived from the catheter insertion are showed in Table 1.

	Ultrasound-guided (n=95)	Anatomical landmark(n=51)	p
Catheter Side: *Right *Left	 63 (66 %) 32 (34%)	 38 (74.5 %) 13 (25.5%)	 ns
Nº of attempts * one * more than one	 66 (69.5 %) 29 (30.5%)	 29 (57 %) 22 (43 %)	 ns ns
Complications No : Complications Yes:	82 (86 %) 13 (14 %)	42 (82 %) 9 (18 %)	ns ns
Catheter disfunction	2 (2.1 %)	3 (5.9%)	ns
Cannulation failure	2 (2.1 %)	2 (3.9 %)	ns

Conclusions: In our work, ultrasound-guided femoral vein cannulation for HD was not superior to conventional technique. The success of implantation with the first puncture and complications were similar in both groups. The great proportion of catheters in femoral location with respect to jugular in our centre and the experience of the nephrologists in this area might explain this fact. Our work adds to the lack of evidence about the advantage of channeling FC with ultrasound.

Retrospective Observational Study of Fistulograms Conducted in a Single UK Renal Unit on End Stage Renal Failure Patients with Arterio-Venous Fistula Sourjya Kar, Suresh Mathavakkannan. *[1]Renal Medicine, Lister Hospital, Stevenage, Hertfordshire, United Kingdom.*

Background: Preparation and creation of arterio-venous fistula is an integral part of haemodialysis patients. In certain situations there is malfunctioning of fistula and to ascertain the cause a radiological investigation named fistulogram is undertaken. Depending on the findings different approaches are undertaken – surgery, angioplasty or even conservative management. We hereby present a single UK renal centre study of all the fistulograms of either predialysis or haemodialysis patients conducted over a period of 2 ½ years analysing the indications, findings of fistulograms and the eventual outcomes in relation to demographics.

Methods: Retrospective data collection for 2 ½ yrs of all the fistulograms performed in haemodialysis and predialysis patients in Lister Hospital. Data collected from medical notes and renal software - analysed by exel sheet.

Results: 94 patients had undergone fistulograms during the period specified of which 24 had repeat procedures. The average time duration from fistula creation to fistulogram performed is 24 months which differs in various demographics. The most common indication for fistulogram is poor maturation (30%) and swollen arm (27%). The most common findings are no stenosis (29%), draining vein stenosis (26%) and central venous stenosis (24%). Intervention was not required in most (31%). The fistula was working in 60% of cases after undergoing procedure. On subanalysis it was noted that 67% of fistulae were working after radiological intervention (versus 79% post surgery). Finally demographics of patients with solely non-functioning fistula were analysed in comparison to baseline demographics. Only slight increase of failure rate more in diabetics (30% versus 25.2%).

Conclusions: Most common indication for fistulogram was poor maturation and the most common finding was no stenosis. Surgery had slightly better success rate than radiological intervention if required. Most fistulae failed as intervention was not possible. Except slight prevelance with diabetics there was no demographic difference related to malfunctioning fistulae.

PUB554

Influence of Calcium-Phosphate Product on Ateriovenous Fistula (AVF) Maturity: A Pilot Study Azreen Syazril Adnan,[1] Azlima Ali,[1] Tauqeer Hussain Mallhi,[2] Fauziah Jummaat,[3] Azhar Amir Hamzah,[1] Amer Hayat Khan,[1,2] Nurul Jannah Ambak,[1] Yusra Habib Khan,[2] Muhammad Salman.[1,2] *[1]Chronic Kidney Disease Resource Center, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia; [2]Dept of Clinical Pharmacy, Univ Sains Malaysia, Penang, Malaysia; [3]Dept of Obstetrics and Gynecology, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia.*

Background: An Arteriovenous fistula (AVF) is considered as the best long-term vascular access for hemodialysis patients. Adequate blood flow and lower complications rate made it quite durable vascular access. However, the maturity of AVF access is influenced by various mechanical and medical factors.

Methods: A prospective cohort study was conducted at Chronic Kidney Disease Resource Centre, Hospital USM from March to June, 2013. After applying inclusion and exclusion criteria, agreed patients were recruited in this study. Consent forms were signed by participants. Blood levels of calcium, phosphate and urea were recorded before surgery. Postoperative follow-up was done at 2nd, 4th and 6th week. Maturity of AVF was assessed by rule of 6s.

Results: Fifteen patients with mean age 45±20 years underwent surgery for AVF creation. Majority of patients were 60 years or above. The prevalence of early AVF maturity was 23.1% (95% CI 0.2, 46.0). Percentage of patients with diabetes mellitus in early AVF maturity was 17.71% whereas in late AVF maturity was 82.29%. Hyperlipidemia was present in all late AVF maturity. The mean value of calcium - phosphate product was 37.07±11.78 mg^2/dl^2. Calcium - phosphate product was higher in late mature AVF than early mature AVF group (46.37 mg^2/dl^2 versus 36.82 mg^2/dl^2).

Conclusions: Calcium - phosphate product may influence AVF maturity and low levels may predict early maturity of AVF. Optimization of these parameters might result in successful outcome of vascular access.

PUB555

Survival in Tunnelized Catheters Installed in the Superior and Lower Segment in Maintenance Hemodialysis Patients Gerardo Guillermo Corpus, Manolo Ramos Gordillo, Marco Antonio Carmona-Escamilla, Daniel Diaz, Ivanna Rocha, Laura Elisa Caballero Castellanos, Jose C. Pena. *Nefrologia, CEDIASA Grupo Angeles, Mexico, DF, Mexico.*

Background: Tunneled hemodialysis catheters is widely utilized in patients requiring long-term hemodialysis. The vascular access located in the upper segment (jugular and subclavian) generally are preferred over the lower segment (femoral). However, the femoral approach may offer some advantages, similar or superior to the upper segment (Left jugular and subclavian).

Methods: A retrospective study of all tunneled hemodialysis catheters placed between January 2012 and April 2014 (27 months) was done. During this study period 733 in cuffed catheters were placed. All procedures were performed by a single interventional nephrologist. Catheters in the upper segment were compared with the vascular access in the lower segment. The functional survival of the catheters and the presence of infection were estimated overall.

Results: The average age of the whole population was 53.5 years±15.33. 379 Men (52%), 354 women 48.2%. Sixty percent of patients had diabetes. The catheters placed in the upper segment were 615 (83.7%), right internal jugular 549 (89.2%), left internal jugular 43 (6.9%), subclavian left and right 23 (3.7%) and 118 (16.0%) in the lower segment. Overall survival of the catheters was 95.7% at 27 months. The survival rate of the upper segment catheters was 96.3% and 93.2% in the lower segment at 27 months; Log-rank p< 0.03. Mean value of survival time in months was 26 CI (26.04 - 26.43). In 29 percent of all patients an AVF was performed Catheter related infections occurred in 25 cases of the 733 catheters (3.4%) during the study period; culture-proved bacteremia was demonstrated in 16 patients (2.2%).

Conclusions: The survival of tunneled catheters placed in the upper right jugular vein is superior compared with tunneled catheters placed in the lower segment. However after the failure of the right jugular access the lower segment was a second option instead of the other upper veins as is the usual procedure. This approach allows the vascular surgeons to use the left arm more freely to built an AVF and reduces the risk of upper vein obstruction.

PUB556

A MWPNC Physician Survey of Physical Restrictions in Dialysis Patients Deepa H. Chand,[1] Susan F. Massengill.[2] *[1]Pediatrics, Rush Children's Hospital, Chicago, IL; [2]Pediatrics, Levine Chidren's Hospital, Charlotte, NC.*

Background: One goal in the treatment of pediatric hemodialysis (pHD) patients is to allow patients to engage in "regular activities". Also, regular exercise has cardiovascular and psychosocial benefits in dialysis patients. However, the data supporting limitation

of activities is scarce. We would like to better illicit provider practices when advising pHD patients on limitation of exercise and activity. **Objective:** We aimed to determine if variability and evidence-based rationale exist in regards to physical restrictions placed on pediatric pHD patients.

Methods: This was a cross-sectional survey of pediatric nephrology attending physicians within the MWPNC, who were asked what physical restrictions they placed on pHD patients.

Results: A total of 12 respondents completed the survey. For patients with an AVF/AVG for pHD access: 50% stated they allow patients to lift weights; all respondents restrict patients from football, wrestling, and martial arts; all respondents stated no patient had lost an access after engaging in sports. Respondents stated they did not have evidence for practice, but rather practice was based on "experience", "institutional practice", or "how I was taught". In patients with a CVL for pHD access: all allow the patient to shower, but only 3 allow a "bath"; no providers allow swimming. Six episodes of CVL infection were reported in the past 6 months.

Conclusions: Pediatric HD providers rely on experience or personal bias to advise patients regarding restrictions in the care of their HD access. This study highlights the need for longitudinal data collection for the creation of evidence based clinical practices.

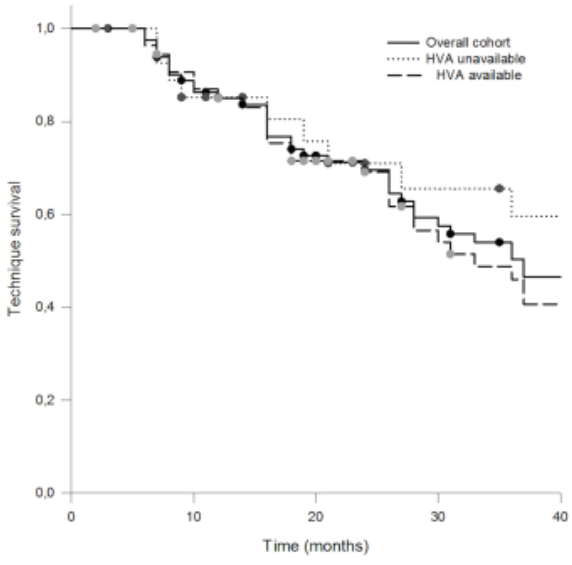
PUB557

Utility of Home Visit Audits in Home Hemodialysis Karlien Francois, Christopher T. Chan. *Div of Nephrology, Univ Health Network Toronto General Hospital, Toronto, ON, Canada.*

Background: Home visits (HV) and HV audits (HVA) are standard practice in home dialysis programs however with limited clinical evidence.

Methods: We performed a single-centre retrospective cohort study in patients starting home hemodialysis (HHD) at University Health Network to ascertain the impact of HVA on technique survival. The HVA is a questionnaire addressing the practice of home hemodialysis and patient well-being. All incident HHD patients starting dialysis at home between July 18, 2008 and June 30, 2013 were included in the cohort and were followed until death, kidney transplantation, transfer to another center or study end, December 31, 2013. Demographic data and information on HVA recordings during the HV when the patient started HHD, were collected. Data are presented as mean±SD or median with IQR. Technique survival is assessed by Kaplan Meier analysis.

Results: 84 patients initiated HHD during the study period. All patients had a baseline HV at the start of HHD and a HVA was surveyed in 56 patients. Overall, patients were 45.8±14.1 years old and 51.2% were male. ESRD was secondary to glomerulonephritis, diabetic and ischemic nephropathy in 33.3, 14.3 and 9.5% of subjects respectively. 67.9% of patients started HHD with a central venous catheter as vascular access. Age, gender, training duration, follow-up time, ESRD cause, vascular access and co-morbidities were similar in the patient group with surveyed HVA (HVA+) compared to those without (HVA-). Technique survival, censored for death, kidney transplantation and transfer to another center, was similar for HVA+ and HVA- groups (p=0.91) [figure 1]. The ascertainment of deficiencies through HVA did not influence technique survival (p=0.84).



Conclusions: HV aim to assure quality of care in patients undergoing HHD. Our results raise questions in establishing the appropriate metrics to ensure patient safety with optimal use of resources.

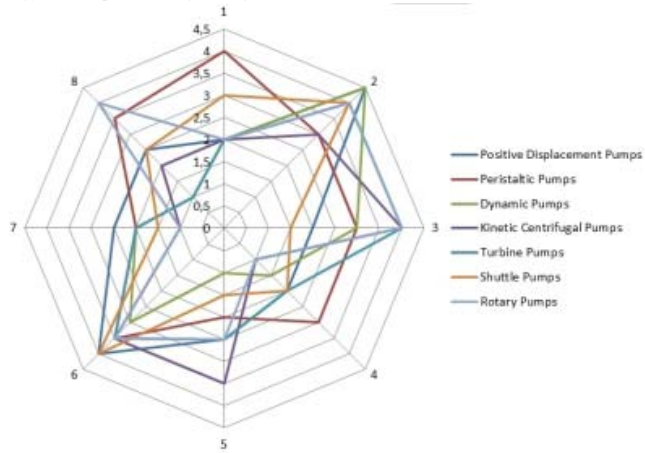
PUB558

Pumps in Wearable Ultrafiltration Devices Paolo Armignacco, Francesco Garzotto, Mauro Neri, Claudio Ronco. *IRRIV (International Renal Research Institute Vicenza), Italy.*

Background: The Wearable Artificial Kidney(WAK) is a device that allows prolonged and frequent dialysis treatments for ESRD patients;its functioning is strictly related to its pumping system,that is responsible for propelling blood and dialysate through the tubing of extracorporeal circuits.The aim of this poster is to analyze in detail the WAK pumping system,with the production of a radar graph comparable of different pumps'performances.

Methods: The WAK consists of a battery,an external flowmeter,a dialyzer and three basic systems:one for regenerating the dialysate,an alarm/shutoff one and a pumping one.A pump is a device that moves fluids by mechanical action;in the case of WAK,the pumping system is responsible for propelling blood and dialysate through the tubing of extracorporeal circuits.So,many of the WAK most important characteristics are strictly related to its pumping system.Many different pumps designs have been suggested for WAK.In the actual prototype,the pumping system is mainly constituted by blood and infusion pumps.Blood pumps can be distinguished,according to the way they work,in positive displacement,peristaltic,dynamic,kinetic centrifugal,turbine,shuttle and rotary pumps;they are all characterized by different values of the most important parameters defining their quality:hemolysis,biocompatibility,precision,flow rate,energy consumption,weight,ergonomics,size and cost.

Results: The following graph,comparative of blood pumps performances,considers eight parameters,(1-8),that respectively are:1Hemolysis;2Biocompatibility;3Precision;4Energy consumption;5Weight;6Ergonomics;7Size;8Cost



Conclusions: This pumps' performances comparison permits to define the characteristics of a perfect pump.It would allow:high safety rates,elevated biocompatibility,infinite MTBF,mean valued flux speeds,fluxes compatible with the subject's well-being,low hemolysis,small dimensions and cheap production costs.

PUB559

Is Self-Cannulation a Weak Link in the Uptake of Home Haemodialysis? Anuradha Jayanti, The Basic-Hhd, Sandip Mitra. *Dept of Nephrology, Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: Self-cannulation(SC) empowers patients and brings together the possibility of home haemodialysis (HD) and haemodialysis commencement with native AVF. It ensures consistent technique for needling, once expert skills are attained. Published literature in SC of vascular access is limited to cannulation technique and related complications. This study provides the a comprehensive evaluation of the subject from a patient perspective.

Methods: In a cross-sectional, multicentre study (BASIC-HHD study) 3 cannulation-related questions were posed to patients (n=535). Demographic and clinical data were also obtained. SCQ1How well do you tolerate needle insertion for blood tests? SCQ2Could you do the same if required, for dialysis treatment? SCQ3What aspect of needling one's self for dialysis bothers you most? 3 study cohorts included 212 predialysis, 200 hospital HD and 97 home HD patients, with complete responses. Participants also completed the depression (BDI), anxiety inventory (STAI) and Autonomy Preference Index.

Results: There is a statistically significant difference between the cohorts in their responses to the SCQ1, with 13% of hospital HD cohort 'fearful' of routine phlebotomy (p=0.002). 60% of the predialysis cohort (A) and 43% of hospital HD cohort (B) feels able to consider SC (SCQ2). Over 20% of concerns from A, were modifiable and were related to skill and fear of potential procedural complications. Pain as the sole cause for concern was perceived by 10% in ALL cohorts. 5 significant variables from HD cohorts were identified from multivariate analysis- response to SCQ1, education, employment, care-giver type, 3MS score with a cut-off of 80 in home and hospital cohorts. Negative response to SCQ1 and trait anxiety score >39 were predictors of a negative disposition to SC in predialysis cohort. In a logistic regression model, the predictive accuracy of the response to SCQ2 dichotomised into Yes or No, selected from hospital and home cohorts and validated in the predialysis cohort was 63.2%.

Conclusions: Self-cannulation fears are a surmountable barrier to uptake of home HD, in a significant number of patients. Targeted interventions in the predialysis phase will help promote self-care HD.

PUB560

Nephron+ Wearable Artificial Kidney for Continuous Dialysis Frank Simonis,[1] Karin G. Gerritsen,[2] Maarten Wester,[2] Jaap A. Joles.[2] *[1]Nanodialysis, Oirschot, Noord Brabant, Netherlands; [2]Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: The Nephron+ wearable dialysis system enables a slow and continuous 24/7 dialysis treatment resembling the functioning of healthy kidneys. Hereby variations of concentration levels in the blood can be kept to a minimum and blood clearance can be improved with obvious health benefits. Patients will benefit in quality of life while being mobile during dialysis.

Methods: Nephron+ makes use of a new technology requiring only 100 ml of dialysate being continuously refreshed with sorbents (150 grams) in combination with catalytic oxidation of toxins. This allows for a wearable device of about 2 kg. Hereby the system can dialyze 150 hours per week, a factor 10 slower then in-center hemodialysis. Blood tubings and dialyzer filter can be downsized to pediatric size. Excess water is removed in ultrafiltration mode. A range of sensors is used to control the blood clearance and to secure a safe operation. Examples are sensors for K, Ca and pH, conductivity, pressure, temperature sensors and redox state. Sensor data, messages and alarms generated by the operating system are being sent and logged to a smartphone and webportal. Both doctor and patient have access to the history and actual status of the device and the running treatment.

Results: Prototype versions have been submitted to extensive invitro efficacy tests and invivo tests using a goat as animal model. Adequate clearance of electrolytes, urea and other organic toxins was obtained. Biocompatibility studies using endothelial cell lines show no side efects sofar but more proof is needed.

Conclusions: The efficacy of the Nephron+ concept has been proven both by invitro and invivo tests. In order to prepare the system for clinical trials, research effort is now directed to assess the biocompatibility aspects in depth.

Dialysate Regeneration in a Wearable Artificial Kidney by Electro-Oxidation and Activated Carbon Does Not Induce Oxidative Stress or Endothelial Cytotoxicity Hendrik Gremmels,[1] Diënty Hazenbrink,[1] Frank Simonis,[2] Maarten Wester,[1] Walther H. Boer,[1] Jaap A. Joles,[1] Karin G. Gerritsen.[1] *[1]Nephrology, UMC Utrecht, Utrecht, Netherlands; [2]Nanodialysis, Oirschot, Netherlands.*

Background: We are developing a wearable artificial kidney (EU FP7 project NEPHRON+), based on continuous regeneration of a small volume of dialysate by adsorption and electro-oxidation (EO). Clinically relevant degradation of urea and creatinine was achieved using EO in series with activated carbon (AC) for removal of chlorine by-products. Major concern of EO is that toxic, in particular oxidative, by-products are generated that are not removed by AC. Therefore we investigated the effect of EO combined with AC on oxidative status and endothelial cytotoxicity of uremic plasma and dialysate.

Methods: Human plasmapheresis plasma (1L, urea 24-43mM) was dialyzed for 1h and dialysate was recirculated in countercurrent direction through an EO-unit in series with AC. Oxygen radical adsorbance capacity was assessed using fluorescein. Oxidation reduction potential (ORP) was measured using a platinum electrode and Ag/AgCl reference electrode. Endothelial colony forming cells isolated from umbilical cord blood were exposed to EO- and AC-treated fluids. Induction of intracellular reactive oxygen species was evaluated using CM-H2DCFDA. Resazurin, neutral red and MTT were used to assess cell viability. Electric cell-substrate impedance sensing was used to monitor real-time cell proliferation. Data (n=3 plasma's x 3 cell donors) were normalized to PBS- or medium-treated controls.

Results: EO plus AC had no influence on total anti-oxidant capacity of dialysate and plasma as compared to treatment by AC alone. Remarkably, while ORP remained stable during treatment by AC, EO-plus-AC-treated fluids changed from an oxidative into a reductive state (plasma: 133±59 to -131±43mV; dialysate: 113±59 to -165±47mV; $p<0.05$). No effects of EO and/or AC treated dialysate and plasma were observed on intracellular generation of ROS, cell viability and cell proliferation.

Conclusions: Our data suggest that dialysate regeneration by EO combined with AC does not increase oxidative status or endothelial cytotoxicity of dialysate and uremic plasma as compared to AC without EO.

PUB562

Three Hour Daily Dialysis Is Associated with Long Term (4 Year) Control of Mineral Metabolism Steven Achinger,[1] Nora Angelica Fuentes,[2] Juan Carlos Ayus.[2,3] *[1]Wason Clinic, LLP, Lakeland, FL; [2]Hospital Italiano, Buenos Aires, Argentina; [3]Renal Consultants of Houston, Houston, TX.*

Background: Abnormal mineral metabolism increases the risk of death in persons receiving hemodialysis. Three hour daily dialysis in one year studies has been shown to improve mineral metabolism goals (*JASN* 2005; 16:2778-88). However, it is not known to what extent three hour daily dialysis will lead to long term mineral metabolism control.

Methods: We conducted a non-randomized, controlled trial of the effect of 3 hour daily dialysis (DHD) (six sessions/week of three hours each) versus conventional hemodialysis (CHD) (three sessions/week of four hours each) hemodialysis on mineral metabolism. We enrolled 77 patients, 26 DHD and 51 CHD matched conventional hemodialysis patients. We collected baseline, yearly and up to 48 month measures of phosphorus, calcium, calcium x phosphorus product and intact parathyroid hormone. Baseline characteristics were similar between groups.

Results: At 48-month follow-up, daily hemodialysis was associated with improved attainment of mineral metabolism goals for phosphorus (adjusted HR 3.6, P = 0.002) and phosphorus product (adjusted HR 3.66, P = 0.001) **(Table 1).** Moreover, a sensitivity analysis was performed in which the goal phosphorus was changed to < 5.0 mg/dL of phosphorus and the crude hazard ratio was 1.5 (0.6 to 3.8) and adjusted HR was 2.7 (1.06 to 6.9). There were no differences between the two groups in terms of attainment of calcium and parathyroid hormone goals **(Table 1).**

Mineral metabolism goal	Crude HR (95% CI)	p	Adjusted HR (95% CI)	p
Phosphorus (3.5 - 5.5 mg/dl)	2.5 (1.6 - 5.4)	0.019	3.6 (1.6 - 8.2)	0.002
Calcium (8.4 - 9.5 mg/dl)	2.1 (1.02-4.3)	0.045	2.15 (0.95 - 4.9)	0.064
Calcium phosphorus product (< 55 mg2/dl2)	3.08 (1.7 - 5.6)	< 0.001	3.66 (1.9 - 6.9)	< 0.001
Parathyroid hormone (150-300 pg/ml)	1.57 (0.54- 4.5)	0.4	2.44 (0.77 - 7.8)	0.13

Conclusions: Three hour daily hemodialysis, compared with conventional hemodialysis leads to maintenance long-term improvements in phosphorus and calcium-phosphorus product which are known surrogates of poor outcomes among hemodialysis patients.

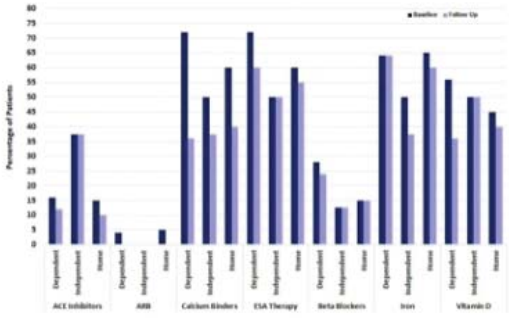
PUB563

Unique System of Nocturnal Dialysis Sunita Nair, Michael A. Copland, Lee Er, Mercedeh Kiaii, Adeera Levin. *[1]Nephrology, Vancouver General Hospital, Vancouver, BC, Canada; [2]Nephrology, St Pauls Hospital, Vancouver, BC, Canada; [3]Statistics, B C Renal Agency, Vancouver, BC, Canada.*

Background: Description of a Nocturnal Hemodialysis (ND)programe.

Methods: Home Hemodialysis (HHD) was established as a dialysis option in 2004 in BC. 50% of patients were on Home ND (HND). Barriers to uptake were prohibitive home situations, or clinical instability. To overcome this, two facility based (FB) options were evaluated. In 2009, a facility based independent nocturnal hemodialysis (FBIND) program started, and in 2011 a FB dependent ND (FBDND)was started. This cohort study describes the outcomes of those patients who commenced in one of these programmes between 1st Jan 2011 and 31st October 2012. Follow up was a year after start, or until the termination of program. Outcomes included change in biochemical parameters and medications pre/post study period. For continuous variables, mean with SD or median with inter-quartile were presented. Frequencies and percentages were reported for categorical variables. All tests were 2-sided and performed in SAS software version 9.3 (SAS Institute,NC).

Results: Of 71 patients on NHD, 46% were in the FBDND, 14%in FBIND and 40% in HND. Biochemical parameters did not change substantially over time, nor was it statistically significant between the three groups. All groups had reduction in medication:median number of medications in FBDND was 4 to 3 at the end of follow up, in FBIND 2.5 to 1.5 and in HHD from 4 to 3



Conclusions: Our study shows that irrespective of co-morbidities and dialysis location,biochemical outcomes are similar. Medication reduction is possible in those who underwent ND. The uniqueness of our system allows patients to undergo ND in center before they move to home. This allows patients to undergo ND independently within the facility, who otherwise cannot dialyse at home. This allows room for respite care and helps patients sustain their chosen modality.

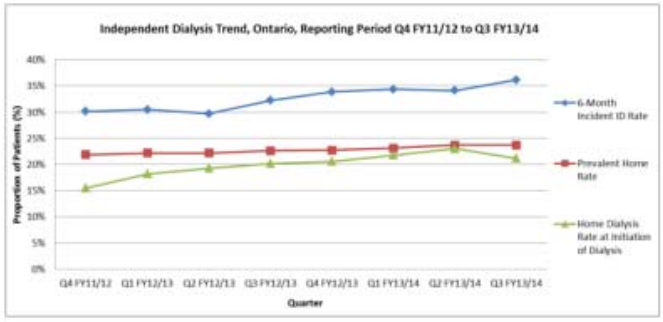
PUB564

Increasing Uptake of Independent Dialysis in Ontario, a Strategic Initiative of the Ontario Renal Network Andreas Pierratos,[1,2,4] Gokulan Kandasamy,[4] Graham Woodward,[4] Gihad E. Nesrallah,[1,3,4] Camila Iraheta,[4] Kiren Handa.[4] *[1]Nephrology, Humber River Hospital, Toronto, ON, Canada; [2]Medicine, Univ of Toronto, Toronto, ON, Canada; [3]Medicine, Univ of Western Ontario, London, ON, Canada; [4]Ontario Renal Network, Toronto, ON, Canada.*

Background: Uptake of Independent Dialysis (ID) is a key strategic priority in Ontario. **ID is defined** by Ontario Renal Network (ORN) as dialysis independent of in-centre facilities. The **key metric** of success is the **6-month ORN incident ID rate**. It is **defined** as the patients on ID within 6 months of starting dialysis, over the patients who stayed on dialysis long enough (6 months) to be given such an opportunity. The Ontario Renal Plan **goal** for the 6-month ORN incident ID rate is **40%** by March 31, 2015. Some of the **supportive initiatives** launched to date are: patient-based funding (including frequent home hemodialysis); promotion of patient education; creation of a 'collaborative' network for newly-funded ID coordinators; establishment of a yearly ID conference.

Methods: The objective was to **report the interim results of the ID strategic initiative** including the **6-month ORN incident ID rate** as well as conventional home dialysis incident and prevalent rates in Ontario. Data reported to the Ontario Renal Reporting System (**ORRS**) starting in Q3 2011/12, were analyzed on a quarterly basis and reported.

Results: Figure 1 depicts the ID trends in Ontario.



Attrition rate from home dialysis was 25% per year. Patient follow up in CKD clinic >1 year associates with higher ID incident rate.

Conclusions: ORN initiatives led to **the 6-month ORN ID incident rate increase from 30 to 36%.** Similar trends were observed in home dialysis rate at initiation of dialysis. The improvement of the prevalent home dialysis rate is smaller partially related to the high attrition rate.

PUB565

"The Self Dialysis Ladder". An Educational Program in Self Hemodialysis Willy Aasebo, Liliana Monica Bivol, Carl Erik Halvorsen. *Dept of Nephrology, Akershus Univ Hospital, Lorenskog, Norway.*

Background: Home hemodialysis may improve the quality of dialysis, reduce costs and increase the patient's well-being. To become independent of help may in itself be desirable to many patients, even when treated in hospital.

Methods: From October 2012 through 2013 hemodialysis patients were considered for the program. During 2013 all suitable patients started directly in the program. The patients had to be physically fit to handle the machine, be mentally prepared to learn and be able to take charge of their own treatment. "The Self Dialysis Program" is a stepwise educational tool describing how to perform hemodialysis and consists of a practical section, "the Self Dialysis Ladder", and a theoretical section with information and procedures, "the Self Dialysis Teaching Document". Procedures of every aspect of the training are described in great details in an everyday language in the teaching document. "The Self Dialysis Ladder" provides an overview of the requirements the patients should learn. Color codes give a quick overview of where the patient is in the training process. The code "Red light" means that the patient has started the teaching process by being showed and explained the procedure. "Yellow light" means that the patient is doing the procedure with guidance of a nurse. When the nurses have observed that the patient knows and does the procedure correctly without guidance, the patient has become independent in this topic and reached "Green light", after which the patients perform these tasks independently.

Results: A total of 31 patients were included in the program. During 2013 34% of all new hemodialysis patients were included. Seventeen patients completed the education, of whom 16 % reached full independence. Fourteen did not finish the education, of whom 4 converted to peritoneal dialysis, 5 received a transplant, 1 regained kidney function and 4 were still training.

Conclusions: "The Self Dialysis Ladder" is a useful tool in teaching patients to become independent of help in hemodialysis. The patients soon required less help compared to ordinary patients and express more self confidence and well-being compared to the others.

PUB566

Analyses of Urate-Lowering Effects by Calcium Channel Blockers Nobuyuki Onizawa,[1,2] Go Tsuchiya,[1,3] Takayuki Hori,[1,3] Promsuk Jutabha,[1] Motoshi Ouchi,[1] Hajime Hasegawa,[2] Hirotsugu Fukuda,[3] Naohiko Anzai.[1] *[1]Dept of Pharmacology and Toxicology, Dokkyo Medical Univ School of Medicine, Mibu, Tochigi, Japan; [2]Dept of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan; [3]Dept of Cardiovascular Surgery, Dokkyo Medical Univ School of Medicine, Mibu, Tochigi, Japan.*

Background: Hyperuricemia is associated with hypertension and is now recognized as a risk factors for cardiovascular diseases. Among anti-hypertensive drugs, ARB losartan is known to have urate-lowering effects in addition to its class effect. However, some calcium channel blockers (CCBs) has been reported to decrease serum uric acid level. Here, we sought to elucidate the molecular mechanism of the urate-lowering effects found in CCBs.

Methods: We measured [^{14}C] urate uptake using stable cells expressing human urate transporter 1 (HEK-URAT1) together with mock cells (HEK-mock) to evaluate the uricosuric action of CCBs. Next, we measured the activity of human xanthine oxidase (XO) to clarify whether CCBs have inhibitory effects on urate production. Nifedipine, amlodipine, nitrendipine, benidipine hydrochloride, verapamil, diltiazem hydrochloride, nilvadipine, nisoldipine, nicardipine hydrochloride, and efonidipine hydrochloride were used in this study.

Results: Among these, nifedipine, nitrendipine, verapamil, nisoldipine and efonidipine hydrochloride demonstrated the inhibitory effect on URAT1-mediated urate uptake. On the contrary, urate production mediated by XO was not inhibited by the CCBs tested here.

Conclusions: URAT1, a major contributor of renal urate reabsorption and a major target of uricosuric drugs such as losartan and benzbromarone, interacted with several CCBs, whereas XO, a major enzyme involved in urate production in the body, did not interact with CCBs. These results suggested that the urate-lowering effects of CCBs are associated primarily with the inhibition of renal urate reabsorption via renal urate transporters such as URAT1.

The Sunny Side of Blood Pressure Regulation: Skin UV Exposure and NO Release Richard Beresford Weller.[1,2] *[1]Centre for Inflammation Research, Univ of Edinburgh, Edinburgh, United Kingdom; [2]Dept of Dermatology, Univ of Edinburgh, Edinburgh, United Kingdom.*

Background: High blood pressure (BP) is the leading risk factor for disability adjusted life years lost globally, and underlies 12% of all deaths. Population BP correlates directly with latitude and is lower in summer than winter. The ultraviolet (UV) B component of sunlight is necessary for vitamin D synthesis. Individuals with serum Vitamin D levels in the lowest quartile are twice as likely to have hypertension as those in the upper quartile, yet meta-analyses of oral vitamin D supplementation studies show no effect on BP. UV is the major environmental risk factor for skin cancer, yet there are no data showing that sunlight increases all-cause mortality. Individuals with non-melanoma skin cancer have half the relative risk of all-cause death as the general population. Increasing sun seeking behaviour dose dependently correlates with reduced all-cause mortality (and increased skin cancer) after correcting for major confounders. Human skin contains large stores of nitrogen oxides, particularly nitrate (NO_3).

Methods: 24 healthy volunteers were irradiated for 20 minutes with 2 Standard Erythemal Doses (SED) of UVA or a temperature matched sham irradiation. Active/sham irradiation of the forearm was performed in 12 volunteers while measuring blood flow by plethysmography and intra-brachially infusing the NOS antagonist L-NMMA.

Results: UVA reduced BP and raised HR during and for 1 hour after irradiation. Contemporaneously circulating NO_3 fell and nitrite rose. Sham irradiation reduced BP during the irradiation period only and did not induce nitrate reduction. Vitamin D levels were unaltered. Active, but not sham irradiation vasodilated NOS antagonised arteries.

Conclusions: We have identified a vitamin D independent mechanism by which UV radiation lowers BP. We suspect that photoreduction of cutaneous NO_3 with export of NO activity to the systemic vasculature is responsible. This mechanism may account for the

reduced cardiovascular and all-cause mortality associated with sun-seeking behaviour. Public health advice on sun-avoidance needs to be revised and based on reduction of all-cause mortality.

PUB568

Effects of the SGLT2 Inhibitor, Empagliflozin, on Blood Pressure and Urinary Excretion of Sodium in Salt-Treated Obese Rats Yui Takeshige,[1,2] Hiroaki Ogata,[1] Akira Nishiyama.[2] *[1]Internal Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Kanagawa, Japan; [2]Pharmacology, Faculty of Medicine, Kita-gun, Kagawa, Japan.*

Background: Studies were performed to examine the effects of the sodium-glucose co-transporter 2 (SGLT2) inhibitor, empagliflozin, on blood pressure and urinary excretion of sodium in salt-treated obese Otsuka Long Evans Tokushima Fatty (OLETF) rats.

Methods: Sixteen-week-old obese OLETF rats were treated with 1% NaCl (in drinking water, n = 10) and vehicle (0.5% carboxymethylcellulose, n = 10) or empagliflozin (10 mg/kg/day, p.o., n = 10) for 5 weeks. Blood pressure was continuously measured by telemetry. Glucose metabolism and urinary sodium excretion were evaluated by oral glucose tolerance test and high salt challenge test, respectively.

Results: High salt plus vehicle-treated obese OLETF rats developed non-dipper type hypertension (136+/-2 mmHg in waking time and 132+/-2 mmHg in sleeping time). Compared with high salt plus vehicle-treated animals, high salt plus empagliflozin-treated OLETF rats showed an approximately 1,000-fold increase in urinary glucose excretion and improved glucose metabolism. Furthermore, empagliflozin significantly decreased blood pressure and improved blood pressure circadian rhythm to a dipper profile, which were associated with increases in urinary sodium excretion of 30%.

Conclusions: These data suggest that empagliflozin elicits beneficial effects on both glucose metabolism and hypertension in salt-treated obese rats.

PUB569

Aggravated Renal Damage by Disturbed Circadian Rhythm of the Intrarenal Angiotensinogen and Angiotensin II Type 1 Receptor in Anti-Thymocyte Serum Nephritis Rats Shinsuke Isobe,[1] Naro Ohashi,[1] Hideo Yasuda,[1] Yoshihide Fujigaki.[2] *[1]1st internal medicine, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; [2]Medicine, Teikyo Univ School of Medicine, Itabashi-ku.*

Background: We previously reported the disturbed circadian rhythm of intrarenal renin-angiotensin system (RAS) activation that is evaluated bythe urinary angiotensinogen (AGT) may lead to renal damage and hypertension, which are associated with diurnal blood pressure (BP) variation. Our purpose is to clarify the contribution by disturbed circadian rhythm of the intrarenal RAS components to renal damage and BP.

Methods: Anti-thymocyte serum (ATS) nephritis rats were made as chronic progressive glomerulonephritis models (A group) and compared with control rat (C group). Rats with ATS nephritis in AO group or AH group received olmesartan or hydralazine, respectively to lower BP equally to that in C group. Rats were sacrificed every 6 hour (7:00 am, 1:00 pm, 7:00pm and 1:00 am, respectively) after urine collection and BP measurement. The levels of the intrarenal RAS components were evaluated.

Results: The degrees of fibrotic renal lesions were significantly increased in A group compared with C group, and attenuated in AO group but not AH group compared with A group. The results were shown at 1:00 pm when the circadian rhythm of each parameter was disturbed in A group compared with C group. The levels of BP and urinary protein and AGT excretion in A group were significantly higher than those in C group and those in AO group were significantly lower than those in A group. Although AH group showed significantly lower BP than A group, the levels of urinary protein and AGT excretion in AH group were not significantly different from those in A group. The levels of intrarenal AGT and angiotensin II type 1 receptor (AT1R) protein expression in A groups were significantly increased 3.9- and 3.2-fold compared with those in C group, and those in AO group were significantly decreased to 51% and 35% of those in A group, respectively. However, AH group did not change the parameters compared with A group.

Conclusions: Enhanced AGT and AT1R proteins at 1:00 pm may aggravate the renal damage independent of BP in ATS nephritis rats.

PUB570

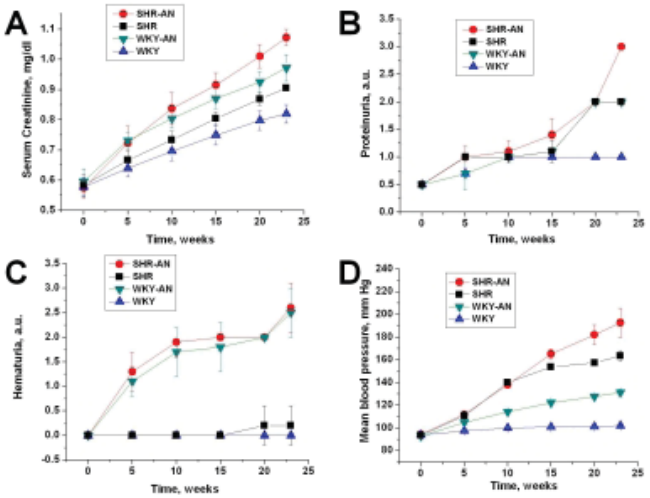
Hypertension Increases Chronic Kidney Injury in 5/6 Nephrectomy Rats Sergey V. Brodsky, Kyle M. Ware, Navin S. Muni, Lee A. Hebert, Metin Gurcan, Jessica Hemminger, Iouri Ivanov, Gyongyi Nadasdy, Anjali A. Satoskar, Tibor Nadasdy, Brad H. Rovin. *The Ohio State Univ, Columbus, OH.*

Background: Hypertension (HTN) is a leading cause of end stage kidney disease worldwide. With the pandemic of obesity, chronic kidney disease (CKD) with progressive nephron loss, a form ablative nephropathy (AN) is becoming more common. Early studies demonstrated the short-term effects of HTN on kidney function and morphology in AN rats. The aim of this study was to investigate the long-term consequences of HTN in the AN model.

Methods: AN was created by 5/6 nephrectomy in spontaneous hypertensive (SHR) and genetically similar normotensive Wistar Kyoto (WKY) rats. Blood pressure (BP), serum creatinine (SCr), hematuria and proteinuria were monitored weekly for 23 weeks. Kidney morphology was assessed at the end of the study. Sham-operated rats from both strains were used as controls.

Results: AN resulted in increases of SCr, hematuria and proteinuria in both SHR and WKY. The increase in SCr was accelerated in SHR-AN as compared to WKY-AN (Fig 1A). Similarly, SHR-AN had earlier onset and higher proteinuria than WKY-AN (Fig 1B). Hematuria was similar in SHR-AN and WKY-AN rats (Fig 1C). Mean BP was higher in SHR-AN than in SHR, as well as in WKY-AN than in WKY, but not that high as in SHR-AN (Fig 1D). Histologically, SHR-AN had enlarged glomeruli and increased interstitial fibrosis as compared to WKY-AN.

Conclusions: HTN increases long-term kidney injury in AN. On the other hand, AN increases BP in SHR. We propose that a vicious cycle occurs in which HTN accelerates kidney injury, which consequently increases HTN.



PUB571

SIRT1 Activation Protects the Endothelial Dysfunction By Inhibiting FGF and TNF-α Generation Hideyuki Negoro. *Medicine, Harvard Medical School, Boston, MA.*

Background: SIRT1 is a conserved NAD(+)-dependent deacetylase and possesses beneficial effects against aging-related diseases, but little information is available on a putative role of SIRT1 in endothelial and vascular homeostasis. Endothelial senescence causes endothelial dysfunction to promote atherosclerotic change and contribute to age-related vascular diseases. Growth factors, such as fibroblast growth factor (FGF) or tumor necrosis factor (TNF)-α can be produced by additional cells involved in the pathogenesis of arteriosclerosis and play an important part in the progression of age-related vascular diseases.

Methods: We established an in vitro senescence model by prolonged culture of primary endothelial cells isolated from bovine aorta. The freshly isolated young endothelial cells gradually underwent senescence during 1 month of repetitive passages. We knocked down SIRT1 to evaluate the protein levels of LKB1, phosphorylated AMPK, FGF and TNF-α in the knocked down cells.

Results: It was observed that protein expressions of SIRT1 were decreased time dependently in the senescent endothelial cells. In contrast, the protein levels of LKB1, a serine/threonine kinase, the phosphorylation of its downstream target AMP-activated protein kinase (AMPK), FGF and TNF-α generation were dramatically increased in the senescent cells. On the other hand, resveratrol activated SIRT1 in the endothelial cells. SIRT1 activation with resveratrol inhibited the increase of LKB1, AMPK. At the same time, SIRT1 activation with resveratrol reduced FGF and TNF-α generation in the endothelial cells significantly. We knocked down SIRT1 and the protein levels of LKB1, phosphorylated AMPK, FGF and TNF-α elevated in the knocked down cells. The protein levels of LKB1, phosphorylated AMPK, FGF and TNF-α generation did not changed in the SIRT1 knocked down cells even if they were stimulated with resveratrol.

Conclusions: These findings indicate that activation of SIRT1 provides beneficial effects against the endothelial dysfunction to promote atherogenesis by inhibiting FGF and TNF-α generation.

PUB572

Role of the Renal Nerves and Angiotensin II in a Model of Postmenopausal Hypertension Rodrigo Maranon, Chetan N. Patil, Carolina Dalmasso, Huimin Zhang, Jane F. Reckelhoff. *Physiology and Biophysics, Univ of Mississppi Medical Center, Jackson, MS.*

Background: Hypertension in postmenopausal women is not as well controlled in men regardless of ethnicity of the cohort. In our model of postmenopausal hypertension, the aging female spontaneously hypertensive rats (PMR), we found that blood pressure remains 110 mm Hg despite concomitant treatment antagonists of angiotensin AT1 receptors, endothelin ETA receptors and 20-HETE synthesis inhibitors. We have also shown that the sympathetic nervous system and the renal nerves contribute to the hypertension in PMR. In the present study, we determined whether renal denervation in combination with AT1 receptor antagonists would reduce BP below that found with triple therapy.

Methods: PMR (aged 18 mos, n=5-6/grp) underwent uninephrectomy, and two weeks later, unilateral renal denervation (RD) or sham (S) surgery and telemetry transmitter

implantation. After two weeks recovery, mean arterial pressure (MAP) and heart rate (HR) were recorded for 5 days. Then PMR were treated with losartan for 5 days, and kidneys were removed for measurement of norepinephrine (NE) content (D. Mattson, MCW).

Results: Renal NE content was higher in S-PMR than RD-PMR (S: 137.9±12.6 versus RD: 33.4±10.5). Renal denervation attenuated the hypertension in PMR by approximately 11% compared with shams (MAP: S: 188±6 versus RD: 167±6 mmHg; p<0.01). Losartan reduced MAP in both groups by similar percentages (9-11%) (S: 166±6 versus RD: 151±7 mmHg, p<0.001), but failed to normalize the BP.

Conclusions: These results suggest that while renal denervation and AT1 receptor antagonism attenuation the hypertension in PMR, other mechanisms, likely endothelin and 20-HETE also contribute to their hypertension. These data also suggest that multiple interventions including pharmacotherapy may be required to control BP in postmenopausal women. Supported by NIH R01HL66072, P01HL05971 and AHA 14POST18640015.

PUB573

New Histone Modification, H4 Lysine 20 Acetylation Is Associated with Gene Repression and Induced in Cardiac Hypertrophy Jun-Ya Kaimori,[1] Masaki Hatanaka,[3] Yoshitsugu Obi,[3] Satoko Yamamoto,[3] Shiro Takahara,[1] Hiromi Rakugi,[3] Yoshitaka Isaka.[3] *[1]Advanced Technology of Transplantation, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Geriatrics and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Hypertension is known to cause cardiac hypertrophy, whose mechanistic insights were largely unknown. We focused uncharacterized histone modification, H4 lysine 20 acetylation (H4K20ac). The existence of H4K20ac in mammalian cell was confirmed by mass spec study with Hela-S3 cells. Making use of a feasible H4K20ac specific antibody, we performed ChIP-seq analysis using HeLa-S3 cells. Interestingly, H4K20ac was accumulated around the transcription start sites (TSSs) of low expressed and silent genes, in contrast to most histone acetylation that occur around TSSs of expressed genes, which is totally opposite to conventional view of histone acetylation as a transcriptional activator. A correlation analysis with known histone modification (H3K9me3, H3K27me3, H3K9ac, and H3K4me3) revealed that H4K20ac is a new class of suppressive mark. The motif search in H4K20ac-enriched sequence and transcription factor binding based on ENCODE ChIP-seq data revealed that most transcription activator is excluded from H4K20ac-enriched genes and only a transcription suppressor NRSF/REST was co-localized with H4K20ac. At the same time, the gene ontology study using H4K20ac-enriched genes reviled that H4K20ac is related to cardiac hypertrophy signaling pathways. Coincide with these data, H4K20ac was increased in angiotensin II stimulated rat smooth muscle cells and mouse transverse aortic constriction induced cardiac muscle cells. H4K20ac may regulate cardiac hypertrophy by repressing proliferation-associated genes. In conclusion, this new histone modification may be a key marker to change the gene expressions associated cardiac hypertrophy.

Differences of Antihypertensive Treatment in Older Adults Are Related to Gender Status and Kidney Function, the Berlin Initiative Study (BIS) Antonios Douros,[1] Elke Schaeffner,[2] Olga Jakob,[3] Reinhold Kreutz,[1] Natalie Ebert.[2] *[1]Clinical Pharmacology, Charité; [2]Nephrology, Charité; [3]Clinical Epidemiology, Charité.*

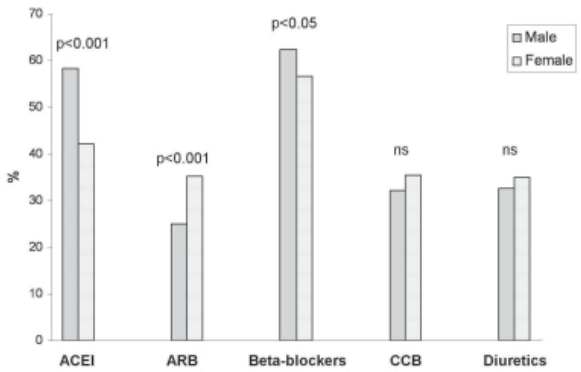
Background: Arterial hypertension (AHT) is a well-known risk factor for cardiovascular and renal diseases and has a high prevalence in older adults. Here, we examined the antihypertensive medication of elderly participants of BIS with regard to gender, cardiovascular risk factors, and kidney function (KF).

Methods: BIS is a population-based cohort study initiated in 2009 in order to evaluate KF in individuals ≥ 70 years. Medication was assessed through personal interviews. Treated AHT was defined as intake of antihypertensive medication. Cockcroft-Gault equation was used for creatinine clearance (eCrCl) estimation.

Results: Prevalence of treated AHT was 79% (1627 of 2069 participants). Table 1shows main characteristics of patients.

	Patients with treated AHT (n = 1627)
Age (y) - Mean (± SD)	81 (± 7)
Female sex, n (%)	851 (52)
eCrCl (ml/min/1.73m²) - Mean (± SD)	57 (± 18)
Diabetes mellitus, n (%)	478 (29)
Albuminuria, n (%)	470 (29)
Myocardial infarction, n (%)	272 (17)
Stroke, n (%)	159 (10)

Gender-specific intake of antihypertensive drugs is displayed in Figure 1.



Individuals with eCrCl < 60 ml/min/1.73m² received more often beta-blockers (BB) and diuretics than individuals with eCrCl ≥ 60, while use of angiotensin converting enzyme inhibitors (ACEI), angiotensin receptor blockers (ARB) or calcium channel blockers (CCB) was similar in both groups.

Conclusions: The different frequency of ACEI and ARB use between men and women cannot be interpreted based on current guidelines and may be associated with gender-specific differences in drug selection by physicians or tolerability. The increased intake of BB and diuretics among individuals with poorer KF may reflect the lower anticipated risk of adverse effects, e.g. hyperkalemia, of these agents in this cohort.

PUB575

Side Effects and Adverse Events Associated with Intravenous Angiotensin II in Humans - A Systematic Review and Meta-Analysis Divya M. Chalikonda,[1] Laurence W. Busse,[2] David H. Yoo,[1] Lakhmir S. Chawla.[3] *[1]GWU; [2]Inova Fairfax Hospital; [3]Veterans Affairs Medical Center, DC.*

Background: Angiotensin II (ATII) is a naturally occurring hormone with important endocrine and hormonal effects. It has recently been evaluated in a prospective randomized controlled trial for the treatment of high output shock. ATII has been administered to patients with a variety of medical conditions, and has only been shown to exacerbate one underlying disease, asthma. To date, however, there has been no effort to systematically review the side effects and adverse effects associated with exogenous ATII administration.

Methods: We performed a comprehensive literature search of the administration of ATII to humans. Keywords included "intravenous administration, intravenous Injection, intravenous infusion, and angiotensin II." We identified all studies which reported physiologic effects associated with the administration of ATII, as well as associated doses. Side effects were defined as physiological effects that were unintended or incongruous with the known effects of ATII. Adverse events were defined as deaths or serious morbidities that were attributable to ATII.

Results: 1193 studies were screened. 137 studies (2653 participants) reported physiologic effects associated with ATII. The most commonly cited side effects and adverse events included altered renal function (23 studies),hyperaldosteronism and other disturbances of the renin-angiotensin-aldosterone axis (21 studies), other endocrine abnormalities (13 studies), and electrolyte disturbances (9 studies). The most serious side effect was bronchoconstriction, which was reported in 2 studies. The dose range for ATII across all studies was 3.56 ± 6.62 ng/kg/min to 12.16 ± 16.84 ng/kg/min. No deaths or serious adverse events were reported. Significant heterogeneity in study design prevented meta-analysis of results.

Conclusions: The incidence of side effects associated with ATII is uncommon, and side effects are generally mild, with exacerbation of asthma being the most serious. In aggregate, ATII appears to be safe in humans. Further studies of the therapeutic use of ATII at a dose range of 1ng/kg/min to 20ng/kg/min are warranted.

PUB576

Periodic Limb Movements of Sleep and Nocturnal Hypertension Ivan E. Porter,[1] William E. Haley,[1] Nabeel Aslam,[1] Bhupendra Rawal,[4] Vichaya Arunthari,[2] Paul A. Fredrickson.[3] *[1]Nephrology and Hypertension, Mayo Clinic, Jacksonville, FL; [2]Allergy and Pulmonary Medicine, Mayo Clinic, Jacksonville, FL; [3]Psychiatry, Mayo Clinic, Jacksonville, FL; [4]Health Sciences Research, Mayo Clinic, Jacksonville, FL.*

Background: Studies have demonstrated the association between obstructive sleep apnea and nocturnal hypertension (NH) where activation of the sympathetic nervous system in a repetitive sequence contributes to increased cardiovascular risk. Ambulatory blood pressure monitoring (ABPM) can detect the presence of NH, missed on office visit blood pressure monitoring. NH and a non-dipping pattern (<10%) increases the risk of adverse renal and cardiovascular outcomes. A growing body of evidence suggests that periodic limb movements of sleep (PLMS) influence vascular morbidity. The present study investigates the relationship between PLMS and NH.

Methods: A retrospective review from January 1, 2010 to December 31, 2012 of subjects at our institution with both ABPM and polysomnography performed within a six month timeframe was performed. This criterion was met by 190 individuals: 56% male and 91% white. Charts were reviewed for demographic data, results of 24 hour ABPM and polysomnography, concurrent medication use by class, comorbid conditions and serum/urine lab data. 8 patients were excluded due to incomplete measurements on ABPM.

Results: Patients with NH were more likely to be diabetic, have worse sleep efficiency and, as expected, have an elevated apnea-hypopnea index (AHI, number of events per hour of sleep). There was not an association of NH with limb movement index (LMI) (OR=1, p-value=0.88) though there was a trend with the total number of arousals per hour of sleep (p-value=0.06). Controlling for age, the LMI was associated with all type arousals (OR=1.07, p=0.019). Patients with a LMI>25 were, however, more likely to be older, have a fib and DM. Analysis of this data suggests a possible correlation between NH and all type arousals.

Conclusions: Elevated arousal indices were more prevalent in those with NH. This analysis does not confirm an association between NH and PLMS however; further investigation is warranted in light of evidence suggesting a relationship with vascular morbidity.

PUB577

Strikingly High Prevalence of Blunted Circadian Rhythm of Interdialytic Blood Pressure in Chinese Dialysis Patients Wenjin Liu, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Management of hypertension is one of the fundamental interventions in dialysis patients. However, the profile of interdialytic blood pressure (BP) in Chinese dialysis patients remains elusive. We aim to investigate this issue as well as the effect of antihypertensive medication in this population.

Methods: 44-hour ambulatory blood pressure was monitored in ninety patients on maintenance hemodialysis. Patients were classified as "Dipping", "Non-Dipping" or "Reverse-Dipping" based on night/day ratio(N/D) of systolic blood pressure on nondialysis day.

Results: The prevalence of blunted circadian BP pattern was strikingly high (92.2%), with more than half of the patients (55.6%) were classified as reverse-dipping. There was a closely association between high erythropoietin dose used and deteriorated circadian rhythm. Patients in the Dipping group also displayed a dipping state for heart rate (HR) compared with the other two groups (N/D of HR: 81.5±6.6 versus 92.1±6.0 and 91.3±10.7, p=0.02). Only 26.7% patients have a controlled nocturnal BP. Patients with bedtime dosing had lower N/D of SBP compared with patients without (100.1±7.0 versus 105.2±7.1, p=0.01).

Conclusions: Nondipping and reverse-dipping are highly prevalent in Chinese patients. Erythropoietin use and autonomic dysfunction may contribute to the blunted circadian rhythm. More tightly control of night-time BP is an urgent need and bedtime dosing may be beneficial.

PUB578

Moderate Atherosclerotic Renal Artery Stenosis Is also Associated with Hypertension Arend Jan Woittiez,[1] Sicco Braak,[2] Myrthe Vestering,[2] Huib J. Van den Hout.[2] *[1]Internal Medicine, Hospital Group Twente, Almelo, Netherlands; [2]Radiology, Hospital group Twente, Almelo, Netherlands.*

Background: Recently it has been suggested to reconsider the role of so-called moderate (30-70% lumen reduction) atherosclerotic renal artery stenosis (ARAS) in the development of renovascular hypertension, given the negative results of angioplasty trials, using a cut-of point of 50-70% stenosis. This prompted us to undertake a study, comparing three degree of stenosis: mild (<30%), moderate (30-70%) and severe (>70%) ARAS and the incidence of hypertension.

Methods: We reviewed 418 consecutive CT-scans (Siemens Somatom 128 slice) of renal arteries, made for several clinical reasons. Degree of stenosis was calculated using the Siemens MPR system. Hypertension was defined as either an office blood pressure of >140/90, and/or the use of antihypertensive drugs. Clinical data for cardiovascular morbidity and renal function were collected.

Results: Clinical data of 22 patients were not available. On 50 CT-scans renal arteries were not sufficient visible, so 344 CT-scans remained for analysis. In the 208 patients with mild ARAS 68 %, in the 92 moderate stenosis 86%, and in 44 with severe stenosis 98% had hypertension (p<0.001, moderate versus mild stenosis). The median eGFR in the severe stenosis was 47 versus 65 ml/min in the moderate stenosis group (p=0.01); other clinical data were not different. The moderately and severely stenotic groups had more cardiovascular diseases (stroke, coronary heart disease and heart failure) than the group with mild stenosis (p<0.01).

Conclusions: In this study we found evidence that also moderate (30-70%) ARAS is associated with increased incidence of hypertension, whereas mild stenosis (<30%) shows a background-incidence of hypertension. Whether ARAS is a cause of renovascular hypertension, or a consequence of advanced cardiovascular disease in the moderate and severe groups could not be determined. Our data provide evidence to re-establish the threshold for so-called significant ARAS, and to consider also patients with moderate ARAS suitable for angioplasty.

PUB579

Five Year Review of Health Status - Health and Kidney Clinics for World Kidney Day Events in Liverpool, UK Sohan Shah,[1] Bhavna Pandya.[1,2] *[1]Faculty of Health and Life Sciences, Univ of Liverpool, Liverpool, United Kingdom; [2]Nephrology Dept, Aintree Univ Hospitals, Liverpool, United Kingdom.*

Background: World Kidney Day (WKD) is an annual kidney awareness event. Since 2009, we have held health and kidney awareness clinics for the public in Liverpool, UK to identify any risk factors and to determine their general health. the events were organised in the hospital for hospital staff and visitors, and in the shopping mall for the public.

Methods: Participants attending various World Kidney Day events over the last 5 years volunteered for various health tests: blood pressure (electronic blood pressure monitor), random capillary blood glucose (CBG) (blood glucose meter), random blood cholesterol (blood cholesterol meter), urinalysis (automated urinalysis machine) and manual heart rate assessment.

Results: There were a total of 903 records of visits from 2009-2013 with a F:M ratio of 3:1; of these, 43 returned to give data on numerous occasions. The median age was 54.2 (IQR:42.8-68.3). Hypertension (>140/90) was present in 372 (47.8%) patients with 4 cases of systolic BP >200 mmHg. The median systolic and diastolic BP was 137 (IQR:123-152) and 80 (IQR:73-89) mmHg respectively. Hypertesion was most prevalent (68%) in 70-79 year old patients. Median heart rate was 76 bpm (IQR:68-86). CBG was normal in 73% of patients whilst 8 individuals had glucose >10 mmol/L (median 5.2; IQR:4.6-5.9). Data from urinalysis showed that 18.5% had some degree of haematuria and 27% some degree of proteinuria. Only 1.5% of patients had severe haematuria (+++) and some form of proteinuria. There were 2.2% of patients with haematuria, proteinuria and leucocyturia. Fifteen patients showed positive (+) nitrate results suggestive of infection. Median cholesterol was 5.03 mmol/L (IQR:4.5-5.7) with a level >6.5 found in 8.7% of patients.

Conclusions: The above analysis shows that hypertension, urine abnormalities and hypercholesterolaemia are prevalent in the community. Regular events like this help to discover undiagnosed patients and increase confidence thus improving health check-up attendances. It also helps identify and prevent severe consequences of undiagnosed and prevalent risk factors in the community.

PUB580

Incorporating *APOL1* Genetic Testing in Primary Care: A Randomized Controlled Trial of the IGNITE Network (Implementing GeNomIc medicine in pracTicE) Girish N. Nadkarni,[1,2] Rennie Negron,[1] Kadija Ferryman,[3] Noura S. Abul-Husn,[2] Stephen B. Ellis,[2] Saskia Sanderson,[1] Ebony Madden,[4] Heather A. Junkins,[4] Emilia Bagiella,[1] Mayra Rodriguez,[1] Diane Hauser,[5] Neil S. Calman,[5] Carol Horowitz,[3] Erwin P. Bottinger.[1,2] *[1]Div of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Charles Bronfman Institute of Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Dept of Health Evidence and Policy, Icahn School of Medicine at Mount Sinai, New York, NY; [4]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; [5]The Institute for Family Health, New York, NY.*

Background: Two alleles(G1/G2) in the *APOL1* gene confer five-fold increased risk for development/progression of kidney disease in hypertensive, non-diabetic African Americans(AA's).Since 14% of AA's carry 2 *APOL1* risk alleles, hypertension management in AA's with high-risk *APOL1* genotypes is an important genomic medicine opportunity. This study is a randomized controlled trial incorporating *APOL1* risk information into primary care of hypertensive AA's.

Methods: We will recruit hypertensive,non-diabetic adults with no kidney disease and self-reported AA ancestry from 10 primary care practices and randomize them to *APOL1* testing at baseline(intervention) or 1 year(control). We will educate providers about genomic medicine/*APOL1* risk alleles through training sessions,electronic medical records-clinical decision support (CDS) and educational materials. Genetic counselor-guided trained staff will return results to patients with educational materials.During encounters, providers will receive point-of-care CDS to alert them of patients' *APOL1* risk status and provide recommendations.

Results: At 3 and 12 months, we will assess primary outcomes(blood pressure reduction to recommended goals and urine albumin/creatinine) and secondary psycho-behavioral outcomes, comparing 3 patient groups:increased genetic risk, no increased genetic risk, and genetic risk not yet assessed.

Conclusions: This study constitutes a novel approach to implement genomic medicine in practice and will help to establish the incorporation of *APOL1* risk status in the management of hypertensive AA's at high risk of kidney disease.

PUB581

Renin Angiotensin Aldosterone System Antagonists as First Line Therapy in Malignant Hypertension Neetika Garg, Kambiz Zandi-Nejad. *Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Prognosis of malignant hypertension (MH) remains poor despite significant advances in hypertension (HTN) management. MH and scleroderma renal crisis (SRC) share many characteristics and are associated with massive overproduction of renin and aldosterone. Unlike SRC where angiotensin converting enzyme inhibitors (ACEI) are the mainstay of therapy and are associated with improved renal and patient survival, current guidelines do not recommend use of renin angiotensin aldosterone system (RAAS)

antagonists in MH. Furthermore, presence of acute kidney injury (AKI) may further deter physicians from using them. We examined current management practices regarding use of ACEIs/ angiotensin receptor blockers (ARBs) in MH.

Methods: Retrospective chart review of 453 patients from Harvard affiliated hospitals since 2000 identified 15 patients admitted for MH, defined as severe HTN (BP ≥ 180/120 mm Hg), AKI, thrombocytopenia and hemolytic anemia.

Results:

Age (Mean ± SD, years)	36.6 ± 11.4
Known diagnosis of Hypertension (n; %)	13; 86.6%
Known diagnosis of chronic kidney disease (n; %)	4; 26.6%
Admission serum creatinine (Mean ± SD, mg/dL)	6.7 ± 3.9
Admission serum potassium (Mean ± SD, mEq/L)	3.5 ± 0.6
Plasma renin activity (n=7) (Median (IQR), ng/mL/h)	10.0 (3.13-16)
Serum aldosterone (n=7) (Median (IQR), ng/dL)	21.9 (17.2-72)

Aldosterone levels > 15 ng/dL and aldosterone renin ratio < 20 suggesting renin dependent aldosterone hypersecretion was seen in 6 (85.7%) of 7 cases where these measurements were available. ACEIs/ ARBs were discontinued in 100% of the patients taking them prior to admission (4; 26.6%). Lisinopril was used for management of MH in only 1 patient. 5 (33.3%) patients were discharged on lisinopril, and 2 (13.3%) on spironolactone due to hypokalemia.

Conclusions: Progressive decline of renal function remains a major problem in patients with MH. RAAS overactivation provides a pathophysiologic basis for use of ACEIs/ ARBs as the mainstay of treatment; yet, they remain highly under-utilized. Early administration of these drugs, even in the presence of AKI, provides early and better blood pressure control, and potentially improved long term renal outcomes.

PUB582

Steroidogensis and the Role of Spironolactone in Hypertensive Young Male Adults: A Pilot Randomized Open Label Head to Head Study of Spironolactone versus Calcium Channel Blocker Byeong Yun Yang,[1] Jangwon Lee,[1] Ihm Soo Kwak,[1] Eun Young Seong,[1] Soo Bong Lee,[2] Dong Won Lee,[2] Il Young Kim,[2] Sang Heon Song.[1] *[1]Internal Medicine, Pusan National Univ Hospital, Busan, Seogu, Republic of Korea; [2]Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Gyeongsangnamdo, Republic of Korea.*

Background: In clinical practice, many hypertensive young male adults (HYMA) hardly reach a recommended level of blood pressure (BP) with commonly used anti-hypertensives. While spironolactone is used as an add-on agent to resistant hypertension, there are few reports describing its value as a beginner therapy in hypertension (HT). We designed a head to head study comparing the effect of spironolactone in HYMA with that of barnidipine, a frequently used calcium channel blocker (CCB) and checked the blood level of peptide and steroid hormones.

Methods: We included HYMA aged 19 to 40 years. They were randomly assigned into spironolactone group (SG; 50mg maximally) and barnidipine group (BG; 15mg maximally). To identify the effect in BP reduction, 24-hour ambulatory BP monitoring (24-ABPM) was done at the initiation and the completion (at 16th week) of the study. Before entering run-in, we measured hormone levels such as aldosterone, renin (plasma renin activity), cortisol, total testosterone, sex hormone binding globulin (SHBG), leptin, and insulin in hypertension group (HG: SG and BG) to compare with those in age and sex-matched healthy control group (HCG).

Results: Forty five patients were enrolled and 22 of them went through the randomization. The initial mean systolic BP (SBP) by 24-ABPM was not different between both groups. At the end of the study, the mean SBP in SG was slightly more reduced than that of BG (SBP reduction: 14.6 ± 10.8 (SG) versus 12.3 ± 13.8 mmHg (BG), p=0.09). In the analysis of hormones, leptin, insulin, and SHBG showed differences between HG and HCG. But only the level of SHBG was statistically significant (29.2±13.1 (HG) versus 58.8±30.2 nmol/L (HCG), p=0.008).

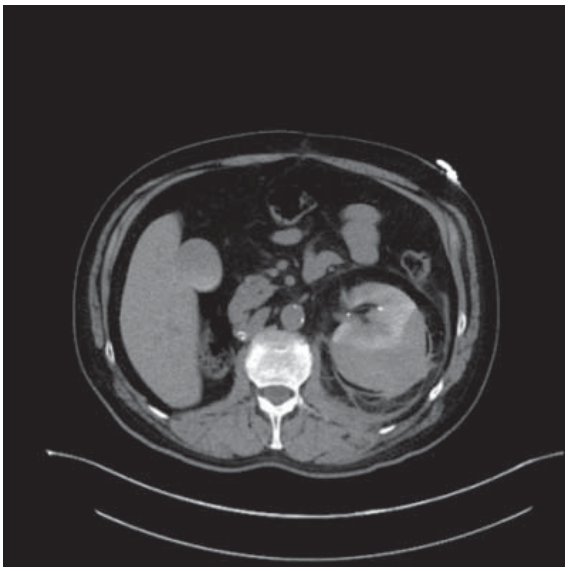
Conclusions: As a single agent, the short-term effect of spironolactone might not be inferior to that of barnidipine in HYMA. The role of steroidogenesis in HYMA should be more studied for specific treatment in this population.

PUB583

Page Kidney following Peripheral Intervention in a Patient with a Solitary Kidney Jordan Bohinc, Halle Elizabeth Field, Madhu Kandarpa. *Internal Medicine, Kettering Medical Center, Kettering, OH.*

Background: Page kidney is a rare form of secondary hypertension due to renal parenchyma compression, typically by a subcapsular hematoma. We present a patient with a solitary kidney and Page kidney physiology.

Methods: A 61 yo male presented with left flank pain after a peripheral vascular procedure. Past history includes renal cell carcinoma treated with total right nephrectomy 2 years prior. Blood pressure (BP) was 177/89mmHg, hemoglobin (Hb) was 10.4g/dL (baseline 13g/dL) and serum creatinine (SCr) 1.77mg/dL (baseline 1.1mg/dL). Non-contrast CT revealed a 3.5 x 8.1cm left renal subcapsular hematoma. Repeat Hb was 7.3g/dL and he was transfused. SCr remained elevated, however urine output was adequate. BP persisted despite Metoprolol and analgesia. Due to a solitary kidney and fear of renal injury from intervention, he was treated conservatively. Hb and SCr returned to baseline. Lisinopril was started with improvement in BP.



CT showing left renal hematoma.

Conclusions: The pathophysiology of Page kidney is likely from compression of renal parenchyma causing microvascular ischemia and activation of renin-angiotensin-aldosterone system (RAAS). Causes include trauma, complications of procedures, extracorporal shock wave lithotripsy or as an incidental finding. There are no guidelines for managing Page kidney. Treatment focuses on improving BP with RAAS blockade, preservation of renal function, and improving anemia. Intervention is indicated for hemodynamic instability, worsening renal function, and ongoing bleeding or pain. Options include nephrectomy/ capsulectomy, percutaneous drainage, or coil embolization. With a solitary kidney, nephrectomy was not desirable, renal insufficiency prevented starting ACE/ARB therapy and stopping anticoagulation ran the risk of in-stent thrombosis. Page kidney is rare but should be considered in patients with refractory hypertension.

PUB584

Flash Pulmonary Edema and Renal Failure in Previously Stented Renal Artery Stenosis/What Is the Best Approach? Syed S. Haqqie, Paul Bradley Brasher, Krishnakumar D. Hongalgi, Arif Asif. *Medicine, Albany Medical College, Albany, NY.*

Background: While major clinical trials have emphasized that medical management should be preferred over angioplasty and stenting for the treatment of RAS, clinical scenarios continue to raise doubts about the optimal management strategy.

Methods: Herein, we present three cases (age:89,85,65Y) that were admitted with flash pulmonary edema (blood pressure [BP]:180-220/100-120 mmHg) and renal dysfunction. All had undergone angioplasty and stent insertion for RAS in the past. Intravenous antihypertensive therapy reduced BP, however, renal deterioration necessitated dialysis in two patients. Both patients underwent angioplasty (for >75% in-stent stenosis) and stent insertion with successful resolution of stenosis. Postoperatively, BP gradually decreased with improvement in serum creatinine. Dialysis therapy was discontinued after a week of its initiation. The third patient became anuric with creatinine increasing to 8.2 mg/dl. Renal ultrasound revealed atrophic left kidney and normal right kidney with plump cortex. An angiogram revealed total occlusion of bilateral renal arteries. Right renal artery angioplasty was performed and flow to the kidney was successfully restored. This was followed by increased in urine out and a gradual decline in serum creatinine to 2.8 mg/dl at discharge and outpatient creatinine of 1.7 mg/dl. At a mean follow-up of 10.6 months, all patients continue be off hemodialysis and do well with BP readings in the 138-154/70-94 mmHg range (on three meds).

Results: Three patients underwent renal revascularization, 2 patients by angioplasty; 1 bypass surgery. BP became easier to control and all came off hemodialysis. Serum creatinine is currently between 1.4 and 1.7mg/dl respectively.

Conclusions: This investigation highlights the importance of percutaneous interventions not only in the management of blood pressure but also in restoring flow, ameliorating ischemic nephropathy and avoiding dialysis therapy in the context of previously treated RAS. The report also calls for increased awareness and appropriate strategies to follow patients who had previously undergone renal artery interventions.

PUB585

Cinacalcet Lowers Serum Magnesium Levels John Sy,[1] P.M. T. Pham,[2] Rohit H. Godbole,[1] P.T. T. Pham,[3] P.C. Pham.[4] *[1]Dept of Medicine, Olive View-UCLA Medical Center, Sylmar, CA; [2]Dept of Medicine, Greater Los Angeles Veterans Administration, Sepulveda, CA; [3]Kidney and Pancreas Transplant Program, David Geffen School of Medicine, UCLA, Los Angeles, CA; [4]Div of Nephrology and Hypertension, Olive View-UCLA Medical Center, Sylmar, CA.*

Background: The calcium sensing receptor agonist (CaSR) cinacalcet provides effective treatment for primary and secondary hyperparathyroidism and parathyroid carcinoma. Congenital gain-of-function mutations of CaSR have been reported to inhibit intraluminal K+ recyling at the renal outer medullary K+ channel in the thick ascending limb of Henle loop thus leading to reduced divalent cation (Ca^{2+}/Mg^{2+}) paracellular reabsorption and Bartter type V syndrome. We aimed to evaluate electrolyte changes, particularly serum magnesium, with cinacalcet use.

Methods: This is a retrospective study performed at Olive-View-UCLA Medical Center involving non-dialysis patients who were prescribed cinacalcet for any reason from April 2006 to December 2013. Patient baseline characteristics, medical history, medications, and laboratory findings including serum potassium, total CO_2, blood urea nitrogen, creatinine, calcium, magnesium, and phosphate were collected and analyzed for any changes following cinacalcet therapy.

Results: There were 5 non-dialysis all-female patients, mean age of 60.0+8.3 years old. A statistically significant decrease in serum calcium (10.79+0.3 to 10.05+0.55 mg/dL, p=0.026) and magnesium (1.92+0.23 to 1.74+0.25 mg/dL, p=0.005) were observed. No differences were noted for any other biochemical factors.

Conclusions: The current case series suggests that cinacalcet significantly reduces both serum calcium and magnesium. Prospective studies to confirm cinacalcet-induced hypomagnesemic effect are warranted.

PUB586

The Association of Demographics and Clinical Variables with iPTH Levels in Hemodialysis Patients: Based on Japanese Society for Dialysis Therapy Clinical Practice J. B. Chen. *Nephrology, Div of Nephrology, Kaohsiung Chang Gung Memorial Hospital and Chang Gung Univ College of Medicine, Kaohsiung, Taiwan.*

Background: The purpose of study was to investigate the association of demographics and clinical variables in a cohort of hyperparathyroidism (HPT) hemodialysis (HD) patients.

Methods: A cohort of regular HD patients in one medical center were enrolled for study. The demographics and a longitudinal 5-year laboratory data including dialysis adequacy indices and cardiothoracic ratio were analyzed. A total of 567 patients were fulfilled the inclusion criteria. The mean of blood iPTH levels in five years was assigned a value for iPTH stratification. The optimal serum Ca, P and iPTH levels in HD patients based on Japanese Society for Dialysis Therapy clinical practice guideline 2012. The recommendations for serum Ca level: 8.4-10.0 mg/dL, P level: 3.5-6.0 mg/dL, iPTH level: 60-240 pg/ml.

Results: The patients were divided into three groups according to iPTH levels, group 1: 122 subjects, iPTH < 60 pg/ml, group 2: 186 subjects, iPTH 60-240 pg/ml, group 3: 259 subjects, iPTH > 240 pg/ml. There were significant comparison between three groups: HD duration (11.7 versus 8.5 versus 9.2 yrs), alkaline phosphatase (68.7 versus 85.0 versus 106.9 IU/L), BUN (73.8 versus 69.4 versus 71.7 mg/dL), Ca (9.1 versus 9.1 versus 9.6 mg/dL), P (4.9 versus 4.9 versus 5.3 mg/dL), CaxP (45 versus 45 versus 51). The ratio of patients' number with recommended Ca,P levels in guidelines in three groups were 91% (group 1), 81% (group 2), 62% (group 3) in Ca levels, 77% (group 1), 79% (group2), 76% (group 3) in P levels. Further analysis in HPT group (group 3), 7% subjects had Ca >10 and P > 6 mg/dL, 13% subjects had Ca 8.4-10.0 mg/dL and P > 6.0 mg/dL, 47% subjects had Ca 8.4-10.0 mg/dL and P 3.6-6.0 mg/dL, 1.93% subjects had Ca 8.4-10.0 mg/dL and P < 3.5 mg/dL.

Conclusions: There were heterogenous distribution of serum Ca and P levels in various iPTH levels. Although the serum Ca and P levels within recommended values, there were patients reaching a criteria of HPT in HD patients.

PUB587

Phosphate Binders: Less Is More Kelly P. Moore, Mary M. Bridgeman, Eileen F. Duffy, Amay Parikh. *Pharmacy/Nephrology, Robert Wood Johnson Univ Hospital, New Brunswick, NJ.*

Background: Along with dietary restriction, phosphate binders are used to inhibit the intestinal absorption of phosphate for patients with hyperphosphatemia and CKD stages 3, 4, and 5 targeting serum phosphate levels 2.5-4.5 mg/dL. Clinical guidelines recommend the addition of other phosphate-lowering agents to help achieve phosphate goals. Dual treatment with phosphate lowering agents is often employed without any known benefit in phosphate control within the inpatient setting.

Methods: 549 patient charts were reviewed in a retrospective study design. Patients were selected between January 1, 2012 and December 31, 2012 with CKD stages 3, 4, 5 who have hyperphosphatemia and have been treated with a single calcium-based or non-calcium-based phosphate binder or a combination of two or more phosphate binding agents during the inpatient hospitalization. 165 patients met inclusion criteria. Patients were determined to be admitted with either one phosphate binder prescribed (SING) or multiple phosphate binders (MULT). The associations between potential confounding factors, such as serum calcium levels, parathyroid hormone levels, use of vitamin D analog, and use of cinacalcet were analysed. Primary outcomes were 1) the number of patients with a phosphate level less than 4 mg/dL and 2) the change in phosphate levels from admission to discharge. Patients were followed through the course of the hospitalization.

Results: 133 patients patients were placed on a single phosphate binder; 32 patients were on combination phosphate binders. No observable differences were noted in patient's baseline characteristics. No differences in achieving phosphate levels less than 4 mg/dl were noted between SING and MULT (p=NS). No difference in the change in phosphate levels from admission to discharge between SING and MULT (p=NS). Significantly higher proportion of MULT patients also were placed on cinacalcet (p=0.007).

Conclusions: When single phosphate binders do not adequately control phosphate levels, other modalities should be considered instead of adding another binder. Dual treatment is often utilized resulting in therapeutic duplication without additional benefit in phosphate control within the inpatient setting.

PUB588

Phosphorus Social Networks Depend on the Dialysis Shift: A Validation Study Avrum Gillespie,[1] Athanasia Polychronopoulou,[2] David Conway,[3] Klemens B. Meyer,[4] Teri Browne,[5] Zoran Obradovic.[2] *[1]Temple Univ School of Medicine; [2]Bioinformatics, Temple Univ; [3]DCI Philadelphia; [4]Tufts Univ School of Medicine; [5]Univ of South Carolina College of Social Work.*

Background: Health behaviors have been shown to diffuse across social networks in chronic disease. In a previous study we modeled inferred social networks within an urban hemodialysis clinic, using simultaneous changes in serum phosphorus as marker of adherence, and found differences in densities among shifts. In this current study, we validate our methodology in another urban clinic and compare the densities of networks between shifts.

Methods: Retrospective data were obtained from 121 active patients at DCI Philadelphia between July 2009 and March 2014. The clinic runs 3 shifts daily. Phosphorus values that were different from the patient's mean and variance were considered significant changes in the patient's phosphorus. Simultaneous significant changes (p<0.0001) in serum phosphorus among patients were considered to be a phosphorus social network link. The number of links per shift was used to calculate the network density. Computer generated random network modeling was used to validate the discovered social links.

Results: The average patient serum phosphorus was 5.5mg/dl and the variance was 1.7 mg/dl. Patients demonstrated on average of 5.7 links (1-14), only 3 patients (2.5%) showed no links. All six of the shifts demonstrated phosphorus social networks with significant link densities when compared to the average density (0.16) of the randomly generated network, 0.16. The highest network density were on the second shifts Monday, Wednesday, Friday (MWF) 0.37 (p <0.0001) and Tuesday, Thursday, Saturday (TTS) 0.31 (p <0.0001). The lowest density was on the newest shift TTS 3rd shift 0.1944.

Conclusions: Once again we were able to demonstrate serum phosphorus networks among patients on the same shift and validate our methodology. Furthermore, as shown in our previous study, the midday shifts have a stronger network than the early shifts. Further research is needed to understand how to positively affect patient interactions and phosphorus social networks to improve adherence and outcomes.

PUB589

Effect of Cholecalciferol on Concentrations of Oxidized PTH in a One-Year Randomized Study in Hemodialysis Patients Pierre Delanaye, Laurent E. Weekers, Xavier Warling, Martial Moonen, Nicole Simone Smelten, Jean-Marie H. Krzesinski, Etienne Cavalier. *Univ of Liège.*

Background: Native vitamin D is recommended in hemodialysis by the K-DIGO. In a one-year randomized study, we showed that cholecalciferol could have a benefit effect on parathormone (PTH) concentrations. Indeed, PTH variations were significantly different in the placebo and treated groups (cholecalciferol, 25.000U every two week). However, we did not observe any significant difference between the two groups at 1-year. Non-oxidized PTH (noxPTH) is the biological active form of PTH. We tested if the conclusions of our study were the same if noxPTH was considered.

Methods: We retrospectively analyzed the samples of the randomized study. The results of 30 patients who completed the study at 1-year were considered. PTH concentrations were measured at baseline and at 1-year with a intact assay (iPTH) (Roche, Mannheim, Germany). The same samples were also measured with the same assay but after treatment with anti-oxidized antibodies that separate the oxidized, inactive form from the non oxidized (noxPTH), active PTH (Immundiagnostik, Bensheim, Germany).

Results: In the placebo group (n=14), the median concentration of iPTH was not different from the treated group at baseline: 240 [195;410] and 285 [185;462] pg/mL, respectively. Similarly, the concentrations of noxPTH did not differ: 27 [18;37] and 30 [20;35] pg/mL. In the placebo group, iPTH increased of 80 [-21;162] pg/mL over the one-year period. In the treated group, the iPTH decreased of -73 [-230;43] pg/mL. The difference between these variations was significant (p=0.0261). The variations of noxPTH results were however not significant : variation of 4 [-1 ;8] and -7 [-15;2] pg/mL (p=0,088) for the placebo and active group, respectively. At one-year, PTH concentrations were not different in the placebo or the treated group. This conclusion was similar considering either iPTH (367[122;542] and 221[154;322], respectively) or noxPTH (32[19;41] and 25[15;44] pg/mL, respectively).

Conclusions: In our study, the measurement of noxPTH has no adding value to describe the effect of cholecalciferol on PTH changes over 1-year. These results must be confirmed in a larger sample.

PUB590

Osteoporosis in Dialysis Patients – Results of Pilot Cross-Sectional Study
Ivan Rychlik,[1,3] Jana Veresova,[1] Petra Ronova,[1] Petra Beranova,[1] Ludmila Brunerova.[2,3] *[1]Dialysis Centre Vinohrady, Fresenius Medical Care, Prague, Czech Republic; [2]Bone Metabolism Unit, Mediscan Euromedic, Prague, Czech Republic; [3]3rd Faculty Med., Charles Univ., Prague, Czech Republic.*

Background: Metabolic bone disease (CKD-MBD) is frequent entity in patients (pts) with advanced CKD, particularly as a result of secondary hyperparathyroidism (SHPT). However, only a little attention is paid to other types of bone disease. The aim of our pilot study was to assess the occurrence and severity of osteoporosis among pts on maintenance dialysis treatment in one dialysis centre.

Methods: 26 pts, mean age 66.7±13.4 years, 73% men, 37% diabetics, mean dialysis vintage 41±15 months, treated with high-volume online hemodiafiltration were enrolled in the study. All pts underwent densitometry (Lunar Prodigy) and laboratory examination of selected bone biomarkers (cross laps, PINP /collagen-1 propeptide/, 25-OH vitamin D, serum calcium and phosphate, and PTH).

Results: Normal bone mineral densitometry (BMD) was found in 5 pts, whereas the decrease of BMD to osteoporotic range (T-score ≤-2.5) was observed in 10 pts (38.5%; mean age 66.7±11.0 years; 60% men). Remaining pts (11) were proofed to have osteopenia /decreased BMD (in men). Among pts with T-score ≤-2.5, high bone turnover (average cross laps 2.9±0.2 ug/l) was observed in 40% out of them, however, severe SHPT was observed only in 1 patient (PTH 1064 ng/l), whereas PTH levels in the others were within recommended range for dialysis pts with the average 299 ±15 ng/l. "Adynamic bone" with markedly decreased bone turnover did not occur in any pts. Only 2 pts were deficient in vitamin D (less than 50 nmol/l, average 40 nmol/l), however, the rest of the pts were either insufficient in vitamin D of normal. All the pts were treated with active analogue of vitamin D. After exclusion of other types of bone disease 9/10 patients with low T-score were diagnosed suffering from osteoporosis although not bioptically proven.

Conclusions: We showed surprisingly high prevalence of osteoporosis mostly in men with ESRD treated with hemodiafiltration. Osteoporosis seems to be an underestimated bone pathology beside CKD-MBD in ESRD. Thus, densitometry and further specific therapy of those pts should be considered.

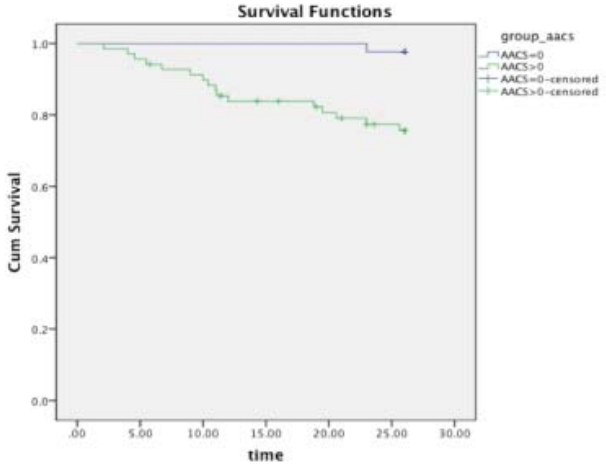
PUB591

The Association Between Aortic Artery Calcification and Cardiovascular Events in Chinese Maintenance Hemodialysis Patients
Xiaonong Chen,[1] Zijin Chen,[1] Xiaobo Ma,[1] Liang Hou,[2] Huawei Ling,[2] Hong Ren,[1] Nan Chen.[1] *[1]Nephrology, Ruijin Hospital,Shanghai Jiao Tong Univ, School of Medicine, SHANGHAI, China; [2]Radiology, Ruijin Hospital,Shanghai Jiao Tong Univ, School of Medicine, Shanghai, China.*

Background: To investigate the relationship between aortic artery calcification(AAC) and mortality in Chinese maintenance hemodialysis(MHD) patients.

Methods: 133 MHD patients from Ruijin Hospital were enrolled in this study in July, 2011. All patients clinical characteristics, baseline biochemical parameters and cardiovascular and death events were collected. AAC was detected by lateral lumbar X-ray plain and evaluated by aortic artery calcification score(AACS).

Results: Among 113 MHD patients, 67 were male and 46 were female. The mean age of MHD patients was 54.9±15.0 years old, the mean dialysis duration 40.6±38.2 months, the mean FGF23 level 27691.42±55646.41 RU/ml. The mean follow-up time was 23.2±6.1 months. 69 MHD patients (61.1%) had AAC from lateral lumbar X-ray, and the mean AACS was 4.1±5.3. During the follow-up, total 16 MHD patients had adverse events, which 9 patients with cardiovascular events(including 2 cases of cerebral hemorrhage, 3 cases of acute myocardial infarction, 2 cases of heart failure and 1 case of lower extremity deep venous thrombosis). Logistic regression analysis showed that plasma albumin and FGF23 were independent risk factor of AAC(Background Logistic, R^2=0.71,P<0.001). Kaplan-Meier survival curves suggested that all-cause and cardiovascular mortality of MHD patients with AAC was significantly higher than those MHD patients without AAC(Log Rank,P<0.05). Cox regression analysis showed that dialysis duration and AAC were independent risk factor of cardiovascular death in MHD patients.



Conclusions: The incidence of cardiovascular event in MHD patients was high. AAC is associated with cardiovascular and all-cause mortality in Chinese MHD patients.

PUB592

Bone Mineral Disorders in Patients on Dialysis and Its Relationship to Death
Mauro Castellano, Walther Douthat, Javier De Arteaga, Pablo U. Massari. *Servicio de Nefrología, Hospital Privado Centro Médico, Córdoba, Argentina.*

Background: Several studies have shown that chronic kidney disease-mineral bone disorder (CKD-MBD) is closely associated with cardiovascular events, hospitalization and death.

Methods: We conducted a prospective study for CKD-MBD in ESRD patients in a dialysis single-center in order to measure their impact on mortality. We included 70 patients, over 18 years old, both incident and prevalent at November 1, 2009. We studied biochemical markers and measured vascular calcifications with X-rays calculating the Adragao and Kaupilla scores.

Results: The average age was 58.0±14.9 years old, 62.0% male. The main causes of CKD were diabetes and nephroangioesclerosis (28.2 and 23.5% respectively). 81.7% were on hemodialysis, with an average time from onset therapy of 41.6 months. 54.7% had secondary hyperparathyroidism, with an average iPTH level of 536±481 pg/mL. The serum calcium and phosphorus were 8.4±0.8 mg/dL and 5.2±.8 mg/dL respectively. FGF23 values showed wide variations with a mean of 166±196 pg/dL, whereas fetuin A show lower values, of 0.5±0.3 mg/dL. The Adragao and Kaupilla scores were 3.4 and 8.1 respectively. No association between vascular calcification and FGF23 or Fetuin A were found. The follow-up time was 36 months. 27.5% of patients were transplanted, 34.8% continuing on dialysis and 37.7% died. The main cause of death was cardiovascular (42.3%). Those who died showed a higher phosphatemia and iPTH than those who stayed alive (6.1±2.2 versus 5.2±1.6 mg/dL, p=0.05 and 808.7±662.6 versus 481.1±426.2 pg/dL, p=0.06, respectively). Patients who died showed lower values of FGF23 (60.8±86.9 versus 203.6±210.7 pg/dL, P=0.05) and a greater tendency to vascular calcifications quantified by Adragao score (4.54±2.96 versus 2.94±3.19, p=0.14). In multivariate analysis, the increase of one unit of the calcium-phosphorus product resulted in an increase of 3% on risk of death with statistical significance (p=0.02).

Conclusions: Our data shows a high prevalence of secondary hyperparathyroidism, with an association between serum phosphorus, PTH levels and calcium-phosphorus product and death. The deceased patient showed a tendency for lower levels of FGF23 and major vascular calcifications.

Interaction of PAT1 and Dicarboxylate (Citrate) Transport in Proximal Tubule Cells
Kathleen S. Hering-Smith,[1] Shijia Zhang,[1] Joycelynn A. Coleman-Barnett,[1] L. Lee Hamm.[1,2] *[1]Medicine/Nephrology, Tulane Univ, New Orleans, LA; [2]Research Service, SLVHCS, New Orleans, LA.*

Background: Recently the Cl^-/ oxalate exchanger PAT1 (SLC26A6) has been shown to inhibit the major kidney dicarboxylate and citrate transporter NaDC1, while NaDC1 was shown to stimulate PAT1. (Ohana 2013) This mutual regulation was demonstrated in heterologous expression models and in animals with knockout of PAT1. The mutual regulation of these 2 apical transporters may have significant implications for calcium stone formation.

Methods: To further characterize and to determine whether this mutual regulation could be exploited to modify citrate transport, we used established cell lines that constitutively express citrate transport.

Results: In each of the cell lines studied, we found that PAT1 mRNA and protein were expressed. We tested the effect of DIDS, which has been shown to inhibit PAT1, hypothesizing that citrate transport would be stimulated. Addition of 100 μM DIDS inhibited ^{14}C-Citrate transport in OK cells (43±5 % inhibition), and immortalized mouse S1 and S2 cells (39±4 and 28±9 % inhibition, respectively). However, DIDS had no effect on HRPE cells with overexpressed NaDC1. We also tested succinate, the usual model substrate for NaDC1, a dicarboxylate transporter; DIDS had similar inhibition of succinate transport as with citrate. In OK cells, and in other proximal tubule cells, we find calcium-sensitive citrate and succinate transport which we have hypothesized represents a novel apical process, not NaDC1 transport. Interestingly, DIDS did lessen or eliminate the calcium-sensitivity. Oxalate, which should stimulate PAT1 transport, was hypothesized to inhibit NaDC1. With 100 μM oxalate, no significant inhibition of citrate or succinate transport occurred in OK, S1, or S2 cells, and in fact citrate uptake was stimulated in S1 and S2 cells.

Conclusions: In sum, DIDS and oxalate did not alter citrate transport in the direction anticipated based on the reported mutual interaction/regulation of PAT1 and NaDC1. This interaction needs to be further explored to understand the full nature and possible utility for manipulation of citrate excretion to prevent calcium stones.

PUB594

Predictors of Urinary Supersaturation of Calcium Phosphate in Stone Formers Jason M. Scovell,[1] Adam B. Hollander,[1] Jatinder K. Hothi,[2] Wesley Mayer,[3] Charles G. Minard,[4] Richard E. Link,[1] Sreedhar A. Mandayam.[2] *[1]Urology, Baylor College of Medicine, Houston, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX; [3]Urology, Houston Methodist Hospital, Houston, TX; [4]Statistics, Baylor College of Medicine, Houston, TX.*

Background: 24-hour urine collection is a cornerstone of the metabolic evaluation of stone formers. There is an incomplete understanding of how urine components associate with supersaturation of calcium phosphate (SSCaP) and calcium phosphate stones.

Methods: To determine the relationship between saturation of calcium phosphate and the urine metabolic profile in recurrent stone formers we performed a retrospective analysis of our 24-hour urine database of stone formers ≥ 18 years of age. We included only the initial valid metabolic stone work-up. Data was normalized by log transformation. Associations between SSCaP and urine parameters were evaluated using univariable and multivariable linear regression. Significant covariates (0.05) on univariable analysis or clinically significant covariates were included in final multivariable analysis.

Results: 363 metabolic stone workups (male n=186, female n=178) were included in analysis. Multivariable analysis found a positive association between supersaturation of calcium phosphate and calcium, pH, phosphorus and a negative relationship to 24-hour volume, ammonium, citrate, and age. There was no correlation between SSCaP and urine oxalate, sodium, weight, or BMI (p>0.05).

Variable	β	P
logCa	0.40	<.0001
logVol	-0.65	<.0001
pH	0.54	<.0001
logP	0.40	<.0001
logNh4	-0.15	<.0001
logCit	-0.08	0.03
Age	-0.002	0.007

Conclusions: Contrary to the usual wisdom that calcium phosphate supersaturation and calcium phosphate stones occurs in obese middle aged women with impaired glucose tolerance, we found no association between SSCaP and BMI or gender. Not surprisingly there is a significant correlation between urine calcium, phosphorus, volume, alkaline pH and SSCaP. Interestingly we found a negative correlation with urine ammonium, urine citrate which could be due to the co-existence of distal renal tubular acidosis in these stone formers. Minor changes in urine volume have dramatic impact on urine SSCaP.

PUB595

Predictors of Urinary pH in Stone Formers Jason M. Scovell,[1] Adam B. Hollander,[1] Jatinder K. Hothi,[2] Wesley Mayer,[3] Charles G. Minard,[4] Richard E. Link,[1] Sreedhar A. Mandayam.[2] *[1]Urology, Baylor College of Medicine, Houston, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX; [3]Urology, Houston Methodist Hospital, Houston, TX; [4]Statistics, Baylor College of Medicine, Houston, TX.*

Background: 24-hour urine collection is a cornerstone of the metabolic evaluation of stone formers. There is an incomplete understanding of how many urine components associate with urinary pH in stone forming patients.

Methods: To determine the relationship between urine pH and the urine metabolic profile in recurrent stone formers we performed a retrospective analysis of our metabolic stone database of stone formers ≥ 18 years of age. We included only the initial valid metabolic stone work-up. Data was normalized by log transformation. Associations between pH and urine parameters were evaluated using univariable and multivariable linear regression. Significant covariates (p<0.05) on univariable analysis or clinically significant covariates were included in final multivariable analysis.

Results: 363 metabolic stone workups (51% male) were included in the analysis. Multivariable analysis found a positive relationship between urine pH and volume, uric acid, sodium,calcium, and oxalate. pH was negatively associated with age, weight, phosphorus, and ammonium. There was no statistically significant association between urinary pH and protein catabolic rate or sulfur (p≥0.16).

Variable	β	P
logVol	0.35	<.0001
logUA	0.24	0.028
logNa	0.18	0.008
logCa	0.14	0.002
logOx	0.18	0.008
Age	-0.005	0.017
Weight	-0.56	0.004
logP	-0.46	<0.001
logNh4	-0.14	0.035

Conclusions: The urinary pH increases with increasing volume, UA, Na, Ca, and Ox, and decreases with increasing age, weight, phosphorus and ammonium. We found a trend towards a higher pH as volume increased. Surprisingly, there was a trend towards basic pH with increasing uric acid, and an acidic pH with increasing ammonium. It is possible that these constituents are markers of other biological processes that affect urinary pH rather than major drivers themselves. Clinically, this could suggest that in treating urate nephrolithiasis; it may be more clinically relevant to increase pH with alkalinizing agents or to increase urinary volume.

PUB596

Evidence of Early Atherosclerosis in Pediatric Nephrolithiasis Patients Kirsten A. Kusumi, Evan Barr-Beare, Vijay Saxena, Sally Smith, Andrew L. Schwaderer. *Nationwide Children's Hospital, Columbus, OH.*

Background: Kidney stones are a common affliction for adults, and pediatric nephrolithiasis is increasing with approximate incidence of 3% annually. Adults with nephrolithiasis have 60% increased risk for carotid atherosclerosis. The objectives of this study: 1) determine if nephrolithiasis associated atherosclerosis has pediatric origins 2) determine if kidney stones induce expression of genes responsible for atherosclerosis.

Methods: Case control study of 9 controls and 5 experimental patients aged 12-17 years. Experimentals were diagnosed by ultrasound or computed topography within the last two years. Carotid ultrasounds were done with Phillips iU22 Ultrasound (Philips Healthcare, Andover, MA) and measurements of carotid intimal thickness (cIMT) were made with Q lab software. Kidney stones were induced in mice by intraperitoneal oxalate. Normal saline was used for controls. Renal tissue mRNA expression was evaluated with the mouse Atherosclerosis RT² *Profiler*™ PCR Array (Qiagen) which profiles 84 genes related to atherosclerosis. Statistical analysis of the cIMT data was evaluated by paired t test. PCR data was evaluated by RT2 Profiler PCR Array Data Analysis.

Results: Left carotid bulb measurements' mean 0.43±0.029mm in controls and 0.48±0.25mm in experimental group (95%CI -0.04-0.13); right carotid bulb 0.44±0.02mm in controls and 0.45±0.03mm in experimental (95% CI -0.07 -0.03). Neither side showed significance; there is a trend consistent with our hypothesis. Per our initial sample size calculations a total of 20 participants are needed to reach significance. The mouse atherosclerosis arrays revealed 19 atherosclerosis genes unregulated by greater than 4 fold in experimental versus controls (p< 0.01). These genes included secreted phosphoprotein 1, tumor necrosis factor and vascular cell adhesion protein 1.

Conclusions: Evidence of early signs of atherosclerotic disease is present in pediatric nephrolithiasis patients. Kidney stones induce expression of factors associated with atherosclerosis in an animal model. Expansion of the cIMT samples size and evaluation for the presence of the of up regulated atherosclerosis factors in pediatric nephrolithiasis patients is ongoing.

PUB597

Optimal Dietary Recommendation in Calcium Oxalate Stone Formers with Idiopathic Hyperoxaluria Maryam Taheri,[1] Elani Streja,[1] Fatemeh Taheri,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Tarbiat Modares Univ, Tehran, Iran.*

Background: Calcium oxalate stones (COS) typically occur in healthy people whose risk factors are attributed to diet and life styles. There are currently no established dietary guidelines to decrease hyperoxaluria in calcium oxalate stone formers (CSFs). We sought to synthesize results from major randomized controlled trials (RCTs) of dietary interventions in CSFs.

Methods: We searched MEDLINE using the terms "low oxalate diet" and "diet and hyperoxaluria" up to April 2014 and included all RCTs investigating dietary interventions in CSFs and those with idiopathic hyperoxaluria with at least one 24-hr urinalysis.

Results: We examined dietary interventions in 13 identified RCTs with 1637 participants examining specific metabolic interventions. In 4 RCTs, dietary recommendations were made according to urine metabolic abnormalities and main nutrients included high fluid intake (urine output>2L/day), low oxalate (80-100 mg/day), low salt (<2400 mg/day or<140 mEq/day), adequate calcium (1000-1200 mg/day), low protein intake (15% of energy) and low fat (≤25% of energy), resulting in a significant decrease in urinary oxalate or calcium oxalate supersaturation index. Another study examining protein, fluid, sodium, calcium, and oxalate also showed in a significant decrease in urinary oxalate. 5 trials assessing the relation between oxalate absorption and calcium availability in the intestine showed dietary calcium to be an important component in oxalate absorption and urine excretion. In another study, recurrent CSFs with mild hyperoxaluria were found to have higher fasting urinary oxalate and an exaggerated urinary response to an oral oxalate load. In the last study we examined, dietary oxalate restriction did not yield substantial benefit in all of the hyperoxaluric patients.

Conclusions: The most common dietary intervention in CSFs in RCTs is low dietary oxalate, low salt and normal calcium intake without intervention on other main nutrients of food content which largely impact urinary metabolic abnormalities. Further studies are needed to determine if a low oxalate diet versus controlled metabolic diet or balanced diet more effectively improve outcomes in CSFs.

PUB598

Serum Calcium Is a Leading Determinant of Fibroblast Growth Factor-23 Levels in Young Dialysis Patients Michael Freundlich,[1] Marta A. Azocar,[2] Iris Delgado,[2] Maria F. Ugarte,[2] Francisco Cano.[2] *[1]Pediatric Nephrology, Univ of Miami School of Medicine, Miami, FL; [2]Pediatric Nephrology/Calvo Mackenna Children's Hospital, Univ of Chile Faculty of Medicine, Santiago, Chile.*

Background: Elevated FGF23 levels, a known cardiovascular risk factor, are further increased following calcitriol (Ct) treatment. In animals, FGF23 levels are mainly determined by serum calcium (SCa) but in dialysis patients (Dp) data are conflicting. We hypothesized that SCa may be an important determinant of FGF23 levels in Dp and that low-dose Ct may prevent marked elevations of FGF23.

Methods: In 31 (age 8.3±4.6 yr) peritoneal Dp, intact FGF23 (Immutopics), Klotho (Ko), SCa and other analytes were measured at various timepoints throughout 12 months. Correlation and logistic regressions analyzed associations of multiple variables with FGF23 levels.

Results: All Dp required Ca-carbonate and n=21 received Ct (0.05±0.07 mcg/kg/week). Baseline FGF23 and Ko levels (215±304 pg/ml, >20-fold normal; 132±58 pg/ml, 40%<normal, respectively) remained stable without significant changes after 1 year (195±301; 133±29 pg/ml, respectively). Baseline and final SCa (9.9±1.1; 9.4±0.9 mg/dl), P (5.4±1.2; 5.3±1.3 mg/dl), PTH (331±273; 321±205 pg/ml), 25-OHD (34±6.8; 25±6 ng/ml) and 1,25$(OH)_2$D (27±22; 28±21 pg/ml) were similar. Daily Ca and P intake, normal at baseline, remained >70%normal by month 12. logFGF23 correlated only with SCa and the CaxP product at months 1, 6 and 12 (all p<0.05), and not with P or any other analyte. By multiple regression analysis, SCa emerged as the strongest variable determining FGF23 levels at months 1, 6 and 12. Potential interactions with P revealed robust positive associations of SCa with logFGF23 (p<0.02 at all 3 timepoints) when P was < 6mg/dl but weaker associations when P>6 mg/dl (p=NS at same 3 timepoints).

Conclusions: We demonstrate that in Dp: (1) SCa was the strongest determinant of FGF23 levels, particularly when P remains <6mg/dl, (2) low-dose Ct helps prevent further FGF23 elevations, and (3) calcitriol treatment is associated with stable circulating Ko levels. The impact of these findings on improved clinical outcomes requires further studies.

Parathyroid Hormone Response to Cholecalciferol Treatment in Hemodialysis Patients Laura Sola, Susana B. Gonzalez, Juan Carlos Diaz, Maria C. Sehabiague. *HD Center, CASMU, Montevideo, Uruguay.*

Background: Vitamin D deficiency is frequent in hemodialysis (HD) patients (Pts). Its treatment has not shown consistently a reduction in PTH levels. We aimed to determine if cholecalciferol supplementation (Chol Sup) in HD Pts allows obtaining normal serum 25-hydroxyvitamin D (25VD) status and reduce serum Parathyroid Hormone (PTH).

Methods: Cohort study of Pts on HD for ≥ 3 months and 25VD < 30 ng/mL. Before and after treatment calcium (Ca) phosphorus (P), 25VD, PTH, alkaline phosphatase (AP) Hb, Ferritin, C Reactive Protein (CRP), Erythropoietin (epo) dose and resistance index (epo IU/wk/kg/Hb) were recorded. PTH >300 risk was assessed by logistic regression. 25VD severe deficiency (25VD-SD) defined as <10ng/ml. Pts were given Chol Sup for 8 weeks (15000 IU/wk). Protocol aproved by Ethics Committee. Pts signed inform consent. Response was analyzed according basal PTH <150 or ≥ 150 ng/ml. Data were compared by t test or chi square as needed. Was considered significant p <0.05.

Results: Were 91 Pts, 55 men (60.4%), 69.5 ± 13.2 years, 31 (34.1%) diabetics, on dialysis for 35.1 ± 40.9 months. PTH>300 risk increased significantly with 25VD-SD (OR 5.71, 1.28-25.50) adjusted to gender, body mass index (BMI), diabetes, AP and CRP. After Chol Sup, 25VD increased (12.2 ± 5.9 to 31.7 ± 10.7 ng/ml) and 48 (52.7%) normalized. PTH significantly decreased (470±356 to 426±351ng/ml) with 20% reduction in 38.5%. Ca increased (8.88 ± 0.61 to 9.45 ± 0.79 mg/dL), with no differences in P, epo/Hb index or CRP. Pts with PTH<150 had lower BMI (23.6 versus 27.0), P (4.32 versus 5.36) and higher CRP (17.5 versus 8.4), ferritin (709 versus 477), epo/Hb index (12.1 versus 5.8). In Pts with PTH<150, PTH significantly increased (87±36 to 124±62) as Ca and 25VD, with no difference in P. In Pts with PTH≥150, 25VD (12.1 ±5.0 to 31.7 ± 10.7) and Ca (8.88 ± 0.6 to 9.45±0.8) increased, and PTH significantly decreased (470± 356 to 426± 351 ng/ml) with no change on P, Hb or epo/Hb index.

Conclusions: Chol Sup for a short period of time significantly increase 25VD and frequently normalize 25VD levels. Its effect differ according PTH level and benefits both low and high basal PTH levels, with a significant decrease only in the latter. Ca levels needs to be followed-up.

PUB600

Determinants of [FGF23] in Stages 3-4 CKD Kenneth R. Phelps,[1] Darius Mason,[2] Kim Stote.[3] *[1]Stratton VAMC, Albany, NY; [2]Albany College of Pharmacy and Health Sciences, Albany, NY; [3]SUNY Empire State College, Saratoga Springs, NY.*

Background: The serum phosphorus concentration ($[P]_s$) equals E_P/C_{cr} + TR_P/C_{cr}, where E_P = urinary excretion rate and TR_P = tubular reabsorption rate of P. Influx of P (I_P) determines E_P, and FGF23 reduces TR_P/C_{cr}. [FGF23] varies directly with I_P even if $[P]_s$ does not change, but [FGF23] also correlates with $[P]_s$ in CKD. We analyzed this paradox with data from a study of secondary hyperparathyroidism (Clin Nephrol, in press).

Methods: Control subjects (C; n = 28) were studied once. Patients with stages 3 and 4 CKD (n = 29) were seen 5 times at 4-wk intervals. Consent was obtained at visit 1. A 4-wk course of vitamin D was provided at visit 2. Dietary P restriction was prescribed at visit 3 and continued through visit 5. At visit 4, patients were randomized to placebo or sevelamer carbonate (2400 mg) with meals. At all visits, intact [FGF23] (Immutopics) and serum and urine [cr] and [P] were measured in fasting specimens. E_P/C_{cr} was calculated as $[P]_u[cr]_s/[cr]_u$ and TR_P/C_{cr} as $[P]_s - E_P/C_{cr}$. Pertinent linear regressions were examined.

Results: In C, $[P]_s$ correlated with TR_P/C_{cr} but not E_P/C_{cr}; determinants of [FGF23] were not identified, and TR_P/C_{cr} did not vary with [FGF23]. In CKD, at each visit, $[P]_s$ correlated with E_P/C_{cr} and TR_P/C_{cr}, and [FGF23] correlated with $[P]_s$ and E_P/C_{cr} ($P < 0.05$ for all regressions). TR_P/C_{cr} varied with [FGF23] at visit 4 only ($P = 0.007$).

Visit	2	3	4	5	C
Regression	**R^2**	**R^2**	**R^2**	**R^2**	**R^2**
$[P]_s$ on E_P/C_{cr}	0.42	0.56	0.52	0.39	0.05
$[P]_s$ on TR_P/C_{cr}	0.28	0.50	0.37	0.38	0.95
[FGF23] on E_P/C_{cr}	0.26	0.16	0.14	0.35	0.09
[FGF23] on $[P]_s$	0.15	0.24	0.42	0.20	0.03
TR_P/C_{cr} on [FGF23]	0.001	0.09	0.24	8×10^{-4}	0.01

Conclusions: In CKD, [FGF23] correlated with E_P/C_{cr} and $[P]_s$ whether TR_P/C_{cr} varied with [FGF23] or not. Because $[P]_s$ was affected similarly by E_P/C_{cr} and TR_P/C_{cr}, [FGF23] should have been associated with both ratios consistently if $[P]_s$ was the sole determinant of [FGF23]. We speculate that P influx, as measured by E_P/C_{cr}, influenced [FGF23] and $[P]_s$ independently; [FGF23] then correlated with E_P/C_{cr} and $[P]_s$ while remaining dissociated from TR_P/C_{cr}.

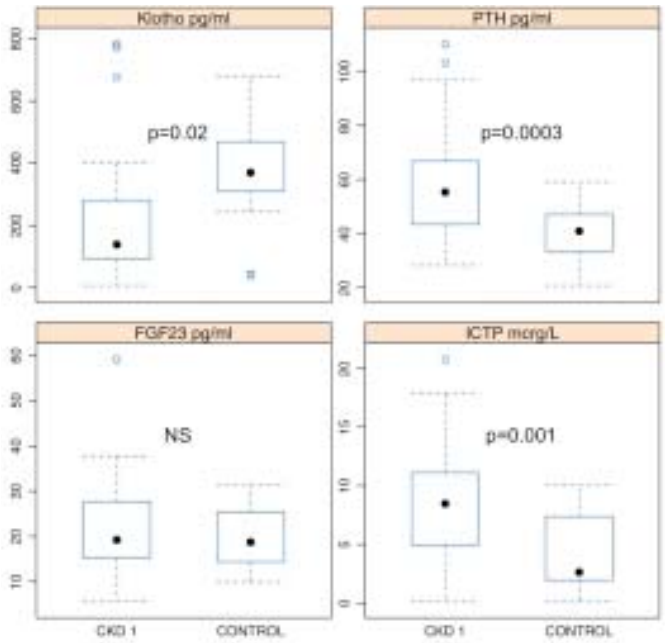
PUB601

A Reduction in Klotho May Be the Key in the Earliest Development of Secondary Hyperparathyroidism Isabel Martinez,[1] Ramon M. Saracho,[2] Yolanda Almaden Peña,[5] Adriana S. Dusso,[3] Mariano Rodriguez.[4] *[1]Nephrology, Hospital de Galdakao, Usansolo, Vizcaya, Spain; [2]Nephrology, Hospital Univ Araba, Vitoria, Alava, Spain; [3]IRBLleida, Lleida, Alava, Spain; [4]IMIBIC, Córdoba, Spain; [5]IMIBIC, Córdoba, Spain.*

Background: In the course of CKD, the onset of SH precedes the elevations in calcium and phosphate levels. Our prior demonstration that in CKD 1, the elevations in serum PTH also precede those of FGF23 led us to examine the contribution of klotho loss to the onset of abnormalities in the tight reciprocal control of the PTH/calcitriol/calcium and FGF23/calcitriol/phosphate axis in early CKD.

Methods: Thirty three patients with CKD stage 1 of different etiology who were not receiving calcium, vitamin D, calcimimetic or biphosphonate were compared with 17 normal controls. Chemistries included serum levels of calcium, phosphate, 25OHvitaminD, calcitriol, PTH, FGF23, soluble klotho, and serum carboxy-terminal telopeptide of type I collagen (IRCP) as a marker of bone resorption, and 24h urinary calcium, phosphate and creatinine. GFR was estimated by CrCl adjusted for 1.73 m2 body surface.

Results: Both PTH and ICRP were higher in CKD1 patients than in normal controls (PTH: 58.1 versus 41.4 pg/ml, p=.0003; ICRP:8.8 versus 4.4µg/L, p=0.001). These differences in serum PTH persisted after adjustment for age and gender. In contrast, serum levels of soluble klotho were lower in CKD1 patients (218.8 versus 374.8 pg/ml, p=0.02), while there were similar serum levels of FGF23, total and ionized calcium, phosphate, 25OHvitamin D and calcitriol, and urinary calcium and phosphate excretion. As expected, fractional excretion of phosphate was higher in CKD1 patients.



Conclusions: The lower levels in serum soluble klotho in CKD 1 suggest that decreases in renal klotho that precede actual reductions in GFR could limit FGF23 suppression of PTH secretion thereby increasing bone resorption and PTH-driven phosphaturia.

Transfer from Oral Alfacalcidol to Oral Calcitriol in the Treatment of Secondary Hyperparathyroidism in Chronic Hemodialysis Patients

Sandrine Rauscher,[1] Jean-Philippe Lafrance,[1] Vincent Pichette,[1] Robert Zoël Bell,[1] Thomas D. Nolin,[2] Denis Ouimet,[1] Martine Leblanc,[1] Caroline Lamarche,[1] Sarah Bezzaoucha,[1] Michel Vallee.[1] *[1]Nephrology, Maisonneuve-Rosemont Hospital, Univ of Montreal, Montreal, QC, Canada; [2]Univ of Pittsburgh.*

Background: There is no clear evidence in the literature regarding the optimal vitamin D(Vit-D) therapy for the treatment of secondary hyperparathyroidism(SHPT) in chronic hemodialysis patients. Recent animal studies suggest that uremia is associated with hepatic enzymatic dysfunction altering Vit-D 25-hydroxylation. Therefore, in uremia, calcitriol, the fully hydroxylated active form of Vit-D, could be more effective than alfacalcidol, a precursor that is lacking 25-hydroxylation. The goal of this study was to compare the efficacy of calcitriol and alfacalcidol for the treatment of SHPT in chronic hemodialysis patients.

Methods: We switched the treatment of SHPT of 36 chronic hemodialysis patients. The initial Vit-D analog, alfacalcidol, was switch for calcitriol at a dose about 20% lower. We then compared the different components of the mineral metabolism at baseline and at 2,4,6 and 8 weeks post conversion.

Results: We observed a significant increase of 1,25-(OH)2Vit-D level of 23.4 pmol/L (p=0.0002), with a mean value of 57.2 at baseline and 81.1 pmol/L at 8 weeks post switch. The level of 25-(OH)Vit-D also increased by 4.0 nmol/L (p=0.0014) at 8 weeks. There was no significant statistical reduction of PTH, with a mean difference of -0,89 pmol/L (p=0.49). The mean corrected calcium for albumin increased by 0.07 mmol/L (p=0.045). There was no significant change in phosphorus levels.

Conclusions: Despite a 20% decrease in dosage of calcitriol compared to alfacalcidol, calcitriol was as effective at maintaining serum PTH levels and was associated with a significant increase of serum 1,25(OH)2 Vit-D and total corrected calcium. Bypassing hepatic 25-hydroxylation appears to be associated with better efficacy of calcitriol at increasing serum 1,25(OH)2 Vit-D, intestinal calcium absorption, serum calcium and inhibiting PTH secretion. These observations must be taken into consideration before choosing a vitamin D analogue or switching from one to the other.

Prescription Habit Changes in Spain following the KDIGO Recommendations on Vitamin D (Cholecalciferol or Calcifediol) Repletion in Dialysis Patients: Two-Year Follow-Up

Jose Mora-Macia,[1] Angeles Juan-Perez,[1] Manuel Praga,[2] Rosa Ramos,[3] Ines Palomares,[3] Jose Ignacio Merello.[3] *[1]Clinica Granollers, Fresenius Medical Care, Granollers, Barcelona, Spain; [2]Servicio Nefrología, Hospital 12 de octubre, Madrid, Spain; [3]Dept Médico, Fresenius Medical Care, Madrid, Spain.*

Background: To describe clinical practice regarding 25(OH)D (C25) level repletion over 2 years in patients with CKD stage 5D-HD, 3 years after the publication of the KDIGO Guideline for CKD-MBD.

Methods: Treatment prescription was reviewed for active vitamin D (A-VD) (alfacalcidol, calcitriol or paricalcitol), and non-active VD (NA-VD) (cholecalciferol or calcidiol), as well as its impact on biochemical MBD parameters in 1134 patients at 54 Fresenius Medical Care clinics in Spain. Subjects were on dialysis for at least 24 months (April 2012 to March 2014). Three groups were defined: group 1) patients treated with NA-VD only; group 2) patients treated with A-VD only; and group 3) patients not treated with VD.

Results: 349 patients (37.64 % females), 71 ± 14 y.o. (on dialysis for 87.41 ± 83.60 months) were reviewed. In patients who were not treated with NA-VD (groups 2 and 3), serum C25 levels distributed as follows: 27.05 % had < 10 ng/mL; 67.97 % had 10-30 ng/mL; and 4.98% had > 30 ng/mL.

Table. Patient MOM biochemical data

Groups	n	Ca mg/dl	P mg/dl	iPTH ng/l	25(OH) VD ng/ml
1	68	9.0±0.3	4.3±0.87	350±254**	21.4±7.7***
2	172	9.0±0.4	4.2±0.8	400±238	15.6±9.3
3	109	8.8±0.4*	4.3±1.3	305±231	16.0±8.4
Total	349	9.0±0.4	4.35±1.0	361±242	16.8±9.0

mean±standard deviation *significative vs 1 and 2 **significative vs 3 ***significative vs 2 and 3

Over the study period, prescription of cholecalciferol and calcidiol increased (0.4 to 4.2%, and 4.9 to 14.4% respectively).

Conclusions: The KDIGO recommendations to "normalize" C25 levels have been adhered to rapidly by Spanish nephrologists. Patients who do not receive VD have lower serum calcium levels. Treatment with NA-VD is associated with higher levels of C25. Normal and target C25 levels in dialysis patients remain to be defined. Spanish nephrologists appear to prefer calcifediol over cholecalciferol.

PUB604

Alkaline Phosphatase, iPTH and Bone Turnover Markers in Advanced CKD Patients

Yueming Liu, Qiang He. *Nephrology, Zhejiang Provincial People's Hospital, Hangzhou, Zhejiang, China.*

Background: Some bone turnover markers are available in clinical care for CKD patients for many years. The aim of this study was to describe any changes of these biochemical markers of bone remodeling and evaluate the correlation among them in CKD patients.

Methods: Total 317 advanced CKD patients(58 CKD3, 38 CKD4, 221 CKD5) were enrolled in the study. We measured serum intact-PTH(iPTH), N-terminal midfragment (N-MID) osteocalcin, P1NP, β-CTx, total alkaline phosphatase (ALP), 25-Hydroxyvitamin D in accordance with manufacturers' instructions.

Results: Levels of iPTH, N-MID osteocalcin, P1NP, and β-CTx and serum phosphorus all reached statistical significance between different stages of CKD. ALP and vitamin D (25-OH) serum levels were higher in HD patients than PD patients. ALP, osteocalcin and P1NP were significantly higher in dialysis patients than conservative treatment patients. The relation between iPTH, ALP and levels of N-MID osteocalcin, P1NP, and β-CTx were significant but weak. No correlation was observed between vitamin D and iPTH or ALP.

Conclusions: Measuring N-MID osteocalcin, P1NP, and β-CTx with iPTH may be useful in assessing CKD-MBD.

PUB605

Treatment of Secondary Hyperparatiriroidism (shpt) with Paricalcitol in Patients on Hemodialysis (hd)

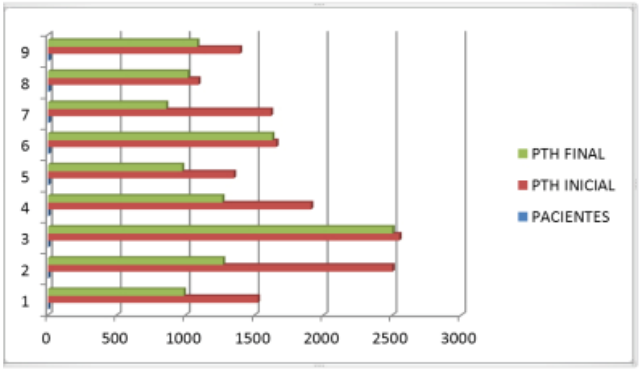
Cristobal Santacruz. *Clinica de los Rinones Menydial, Quito, Ecuador.*

Background: We know about the alterations in the balance of calcium, fosfate and PTH metabolism in patients (CRD) starting with clearance < 60ml/min, until stage 5D when the manifestations are evident in the skeleton and other organs.All start with a decrease in the production of the calcitriol and hipocalcemia, the phosphate retention and resistance to the calcemic effect of the PTH; however a close normal free blood calcium because of an secondary HPTS compensation. This metabolic disorder chronically maintained in the patients generate some abnormalities named renal osteodistrophy. The treatment and control of the bone disease, hyperfosfatemia and the HPTS is mandatory because if not done it increases the morbility and mortality.

Methods: A prospective interventional clinical assay not controlled, not randomized was done with nine patients 6 men and 3 women who were selected to use the drug, the medium age was 45,7 years (from 27 to 61 years), average HD time 9 years (from 5 to 15 years), PTH levels above of 300 UI and seric calcium and fosfate normal; all of them receive an average dosis of 0.08 mcg/kg after hemodialysis treatment, nobody of the patients did respond to previous oral calcitriol more phosphate binders treatment.

Results: 66% of the patients respond very well to the paricalcitol IV and decrease like group 38% of the initial level of PTH and it was statistical significant (p=0.009) applying the t for paired samples means matched.

Figura 3. Evolución en los niveles de PTH en todos los pacientes.



Fuente: Clinica de los riñones Menydial

PATIENTS	INITIAL PTH	FINAL PTH	PARICALCITOL DOSIS
1	1523	985	0.08
2	2500	1270	0.07
3	2550	2500*	0.07
4	1909	1265	0.08
5	1349	973	0.09
6	1657	1628*	0.1
7	1618	857	0.1
8	1092	1015*	0.07
9	1393	1083	0.07
AVERAGE	1732.33	1286.22	0.081111111

Conclusions: The paricalcitol IV showed to be an option in treating uncontrolled patients with long time on HD and high PTH levels, who developed a severe HPTS and had failed treatment with oral calcitriol more phosphate binders previously.

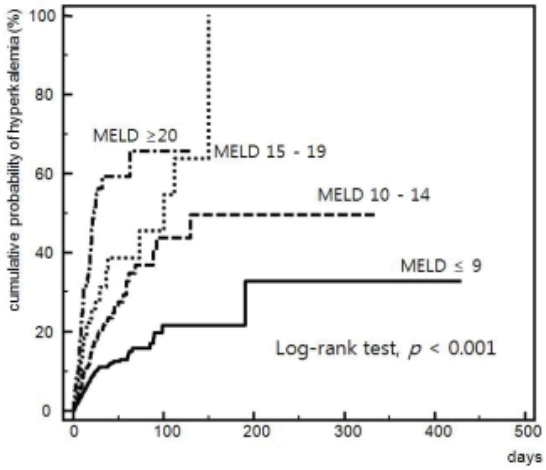
PUB606

The Model for End-Stage Liver Disease Score Is Potentially a Useful Predictor of Hyperkalemia Occurrence Among Hospitalized Angiotensin Receptor Blocker Users Inwhee Park, Eunjung Kang. *Dept of Nephrology, Ajou Univ School of Medicine, Suwon, Gyeonggi-do, Korea.*

Background: Angiotensin receptor blockers (ARBs) are medications commonly used for treating conditions such as hypertension. However, ARBs are frequently associated with hyperkalemia, a potentially critical adverse event, in high-risk patients. Although both the liver and the kidney are major elimination routes of ARBs, the relationship between hepatorenal function and ARB-related hyperkalemia has not yet been investigated. The purpose of this study was to evaluate the risk of hyperkalemia, in terms of various hepatorenal functions, for hospitalized patients newly initiated on ARB treatment.

Methods: We evaluated ARB-related hyperkalemia in a cohort of 5530 hospitalized patients, who had not previously used ARBs, between April 12, 2004 and May 31, 2012. Hepatorenal function was assessed by the Model for End-Stage Liver Disease (MELD) score. Hyperkalemia risk was assessed by hepatorenal function, risks were categorized into the four MELD scoring groups, and the groups were compared with one another.

Results: The MELD score was significantly different between the hyperkalemic and non-hyperkalemic groups (independent t-test, $p < 0.001$). The MELD score 10-14, 15-19, and ≥20 groups showed higher risks of hyperkalemia than the lowest MELD score group {log-rank test, $p<0.001$; multiple Cox proportional hazard model, hazard ratios 1.478 ($p=0.003$), 2.285 ($p<0.001$), and 3.024 ($p<0.001$), respectively}.



Conclusions: The MELD score showed a stronger predictive performance for hyperkalemia than either serum creatinine or estimated glomerular filtration rate alone. Furthermore, the MELD score showed good predictive performance for ARB-related hyperkalemia among hospitalized patients. The clinical implications and reasons for these findings merit future investigation.

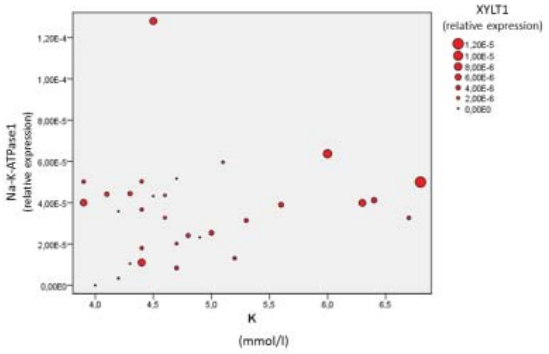
Expression of XYLT1 in Human Muscles Correlates with Serum Potassium and Na-K-ATPase1 Expression Michael Fischereder,[1] Franz Xaver Beck,[2] Antje Habicht,[3] Ulf Schoenermarck,[1] Peter J. Nelson,[1] Manfred J. Stangl.[4] *[1]Renal Div, Medizinische Klinik IV, Klinikum der LMU, Munich, Germany; [2]Dept of Cellular Physiology, Physiologisches Institut, LMU, Munich, Germany; [3]Transplant Center, Klinikum der LMU, Munich, Germany; [4]Dept of Surgery - Grosshadern, Klinikum der LMU, Munich, Germany.*

Background: We have previously shown that inter-individual and highly variable tissue concentrations of sodium can be found in human muscle. This high variability may be due to osmotically inactive sodium, bound to glycosaminoglycans (GAG). GAG synthesis is initiated by XYLT1 which correlates with tissue sodium concentrations. We now sought to better characterize this regulation of XYLT1 expression in human muscle.

Methods: We studied 27 dialysis patients. 21 live kidney donors served as healthy controls. There was no clinically detectable edema. During transplant surgery, abdominal muscle and arteries were biopsied. Expression of XYLT1, Na-K-ATPase1 and Na-K-ATPase2 were determined by real-time PCR (n= 31), normalized to s18 RNA and correlated with clinical data. Intracellular sodium concentration was measured by electron microprobe analysis (n=16).

Results: Na-K-ATPase1 expression was significantly higher in men than women (4.4 x 10E5 versus 2.4 x 10E5; p = 0.017). On univariate analysis, XYLT1 expression was significantly correlated with serum potassium (r = 0.508; p = 0.004), serum urea (r = 0.305, p = 0.095) and muscular expression of Na-K-ATPase1 (r = 0.392; p = 0.029) and Na-K-ATPase2 (r = 0.359, p = 0.047). On multivariate analysis, XYLT1 expression was significantly correlated with serum potassium (p = 0.005) and Na-K-ATPase1 expression (p = 0.041).



Conclusions: XYLT1 expression in human muscles is correlated with serum potassium concentrations and Na-K-ATPase1 expression. This may form a pathophysiologic basis for the understanding of myopathy in patients with hyperkalemia, e.g. in advanced renal failure.

PUB608

A Case Report of Ondansetron Induced Bartter Like Syndrome in Pregnancy Ashish Gummadi,[1] Wajid M. Choudhry.[2] *[1]Dept of Internal Medicine, Unity Health System, Rochester, NY; [2]Nephrology, Univ Of Rochester, Rochester, NY.*

We report a case of severe hypokalemia in 30 year old pregnant Caucasian woman. She developed hyperemesis gravidarum during first trimester of pregnancy. She received ondansetron 4 to 8 mg 2-3 times a day. At 29 weeks gestation, she was admitted to the hospital because of severe lower extremities weakness. She had normal Physical exam with heart rate of 80 beats/min and blood pressure of 92/50mmHg.Labs: serum sodium of 139mEq/L, potassium 2.1mEq/L, chloride 99mEq/L, carbon dioxide of 26 mmol/L, Bun 7 mg/dl, Creatinine of 0.66 mg/dl, calcium 8.2mg/dl, albumin 3.7gm/dl, magnesium 1.7 mg/dl, phosphorus of 3.1 mg/dl, uric acid 2.9mg/dl, CK 3501 U/L and TSH 1.29uIU/ml. She was treated with IV hydration, IV potassium and magnesium supplements. Her serum potassium remained low at 2.8mEq/L. 24-hour urine with a total volume of 2700ml and 1.58 grams of excereted creatinine showed sodium 392mEq, potassium of 86 mEq, chloride 440 mEq and calcium 502mg. Inappropriate hyperkaliureia and hypercalciuria in the setting of hypokalemia and hypocalcemia is consistent with Bartter like syndrome. We stopped her ondansetron and she was discharged home on 40 mEq of potassium chloride TID. After a few days of ondansetron cessation she did not require any further potassium and magnesium supplements. Her serum potassium remained stable at around 4.1 mEq/L. Cases of polyvalent cations like aminoglycosides causing Bartter like syndrome have been reported in literature. Ondansetron is also a bivalent cation with two methyl groups. We hypothesize that ondansetron may also have calcimimetic action which could have caused bartter like syndrome in our patient.

PUB609

Dynamic, Not Static Diagnostic Approach Can Predict Overcorrection of Hyponatremia Sae Aratani,[1] Masahiko Nagahama,[1] Takuya Fujimaru,[1] Yuki Heath,[1] Fumika Taki,[1] Osamu Takahashi,[2] Yasuhiro Komatsu.[1] *[1]Nephrology, St. Luke's International Hospital, Chuo-ku, Tokyo, Japan; [2]Clinical Epidemiology, St. Luke's International Hospital, Chuo-ku, Tokyo, Japan.*

Background: Treatment of hyponatremia becomes difficult when spontaneous water diuresis emerges during therapy, which may lead to rapid increase of serum sodium (SNa) and to serious neurological sequelae. There is a paucity of information regarding the prevalence and risk factors for overcorrection. The aim of the present study is to clarify the prevalence and the predictive factors of overcorrection to establish effective preventive strategies.

Methods: We analyzed clinical and biochemical parameters of 58 patients whose SNa was below120 mEq/L on admission at St. Luke's International Hospital in Tokyo from March 2012 to April 2014. Standardized management protocol, which was reported previously (ASN 2001), were applied. All patients were monitored closely in ICU, with serial measurement of urine volume, electrolyte and osmolality and serum electrolyte.As per our protocol, we used parenteral 5% dextrose in water (D5W) or DDAVP to avoid overcorrection which is defined as the rate of correction of SNa over 10 mEq/L in 24 hours and 18 mEq/L in 48 hours.

Results: Among 58 patients, 23 patients (39.7 %) required management of overcorrection prevention with DDAVP or D5W. The mean age of the patients was 70±17.4 (mean+/-S.D.) yr, the male/female ratio was 29/29. The mean initial SNa was 117.2±5.6 mEq/L, sum of urinary sodium and potassium (UNa + UK) was 90±65.1 mEq/L and urinary osmolality (UOosm) was 352±172 mEq/kg. On univariate analysis, patients who required overcorrection prevention are more likely to have large urine volume in the first 2 hours (P=0.028).Multivariate logistic regression analysis identified urine volume for the first 2 hours was significantly larger in patients with overcorrection (odds ratio =1.003, P=0.025). Neither UOosm nor urinary UNa + UK are predictive for overcorrection.

Conclusions: The present study shows that overcorrection of hyponatremia was found more frequently than we expect. Our study underscores the importance of assessment of urine volume (dynamic approach) rather than UOsm or UNa+UK (static approach) to predict overcorrection.

PUB610

Hyponatremia Is a Risk Factor for Increased Cardiovascular and Non-Cardiovascular Mortality in Incident Hemo- and Peritoneal Dialysis Patients Hakan Nacak,[1] Merel Van Diepen,[1] Marit M. Suttorp,[1] Ewout J. Hoorn,[3] Joris I. Rotmans,[2] Friedo W. Dekker.[1] *[1]Clinical Epidemiology, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands; [2]Nephrology, Leiden Univ Medical Center, Leidne, Zuid-Holland, Netherlands; [3]Internal Medicine - Nephrology, Erasmus Medical Center, Rotterdam, Zuid-Holland, Netherlands.*

Background: Hyponatremia is associated with increased mortality in the general population as well as in dialysis patients. It's unknown whether this increased mortality in dialysis patients is mainly cardiovascular (CV) or non-cardiovascular (non-CV) related. Therefore, the aim of this study is to assess the effect of hyponatremia on cardiovascular and non-cardiovascular mortality in incident dialysis patients.

Methods: The NECOSAD-study is a Dutch prospective multi-center cohort study of incident dialysis patients. All patients with measured plasma sodium 90 days after the start of dialysis were investigated (n=1719, mean plasma sodium [SD]=138.6 [3.5]). Multivariable Cox models were used to estimate the effect of hyponatremia and plasma sodium (per mmol/L) on CV and non-CV mortality in HD and PD patients. In addition, time-dependent (TD) Cox models were used to estimate short-term effects of hyponatremia and plasma sodium.

Results: Hyponatremia leads to a 2.12-fold increased risk (TDadj) for CV mortality and 2.05-fold increased risk for non-CV mortality in HD patients. In PD patients, hyponatremia leads to 1.53 and 1.61-fold increased risk for CV and non-CV mortality, respectively. See table for more detailed results.

	Hemodialysis patients		Peritoneal dialysis patients	
	Hyponatremia (< 135 mmol/L)	Plasma Sodium (per mmol/L)	Hyponatremia (< 135 mmol/L)	Plasma Sodium (per mmol/L)
HR (95% CI)	CV mortality		CV mortality	
Crude	1.28 (0.89-1.83)	0.98 (0.95-1.02)	2.77 (1.60-4.81)	0.90 (0.85-0.95)
Adjusted	1.30 (0.90-1.87)	0.98 (0.95-1.02)	2.35 (1.30-4.24)	0.91 (0.85-0.97)
TD Crude	1.99 (1.48-2.68)	0.93 (0.90-0.96)	1.93 (1.20-3.11)	0.91 (0.86-0.96)
TD Adjusted	2.12 (1.57-2.87)	0.92 (0.87-0.95)	1.53 (0.93-2.50)	0.92 (0.87-0.98)
HR (95% CI)	Non-CV mortality		Non-CV mortality	
Crude	1.49 (1.10-2.03)	0.95 (0.92-0.98)	2.21 (1.16-4.22)	0.97 (0.90-1.03)
Adjusted	1.46 (1.06-1.99)	0.96 (0.93-0.99)	2.11 (1.06-4.19)	0.98 (0.91-1.05)
TD Crude	1.96 (1.50-2.57)	0.91 (0.88-0.93)	2.04 (1.26-3.30)	0.92 (0.87-0.98)
TD Adjusted	2.05 (1.56-2.71)	0.90 (0.87-0.93)	1.61 (0.97-2.66)	0.93 (0.88-0.99)

* Adjusted for age, sex, primary renal disease, cardiovascular disease, diabetes mellitus, and anuria.

Conclusions: Hyponatremia is a strong and independent risk factor for both CV and non-CV mortality in incident HD and PD patients.

PUB611

Urinary Sodium Excretion One Year Post Transplantation Does Not Predict Subsequent Transplant Failure Hasnain Raza, Harsha Wodeyar Kagodu Surendranath, Matthew L.P. Howse. *Nephrology, Royal Liverpool Univ Hospital, Liverpool, United Kingdom.*

Background: There is evidence in patients with CKD that high sodium intake limits the antihypertensive and antiproteinuric effects of angiotensin converting enzyme inhibitor (ACE-I) and hence leads to progression of CKD independent of blood pressure (BP) control. (J Am Soc Nephrol 23: 165-173, 2012).However there has not been any study in patients with renal transplant and the effect of high sodium intake on renal transplant survival.

Methods: Data was retrospectively collected from the 385 patients who had renal transplant from 2000 to 2005. All patients performed 24 hour urine collections. To allow for incomplete collections Na excretion was corrected for urinary creatinine excretion. Death with function graft was counted as graft failure.

Results: Out of all (385) 303 transplant recipient were included in analysis due to completeness of data. Some patients were excluded due to early graft failure within one year. (Male 182 Female 121) Mean age was 46 years Mean BP at 1 year was 138/80 mm Hg with Median BP of 140/80mm Hg Mean serum creatinine at 1 year was 163umol/L with median creatinine of 146umol/L Mean Na/creatinine at 1 year was 19meq/day with median 18meq/day Mean Total Na excretion at 1 year was 201 with median 192 Mean 24 hour urine protein excretion was 0.46 gm/L with median 0.2gm/L Mean HLA-A, B, DR 0.8-0.8-0.4 with median of 1-1-0 Follow up was until 1st April 2013. Statistical tests (T-Test) were done to determine if the one year urinary sodium had any effect on renal graft survival .There was no statistically significant difference in 1 year urinary Na/creatinine with subsequent transplant failure until last follow up.

Conclusions: We have shown that dietary sodium intake measured as urinary sodium excretion one year post renal transplantation does not predict subsequent graft failure. This was an unexpected result.We have shown that factors other than sodium intake, such as serum creatinine at one year and urinary protein excretion are far more powerful predictors of Graft survival.

PUB612

The Relevance of Significant Discrepancy between Brain Extracellular and Serum Potassium Mohammad Ali Shafiee, Masih Rikhtehgar. *Medicine, Toronto General Hospital, Univ of Toronto, Toronto, ON, Canada.*

Background: Brain function comprises a series of action potentials (AP) which are influenced by membrane voltage and extracellular fluid potassium concentration (ECF [K]). Nevertheless, each AP releases a significant amount of K, which could interfere with ongoing brain function. **Hypothesis:** Since optimum brain function is crucial, we hypothesized that even with significant K release in each AP; ECF [K] should be relatively constant to allow optimal brain function. **Objective:** To propose a physiology-based model of K buffering system in the brain.

Methods: Seventy-two English-language articles (cross-sectional, book chapters, and case-control studies) were reviewed in which Serum [K] and Central Nervous System (CNS) ECF [K] were simultaneously measured in 511 normal human subjects, 52 uremic, and 291 CNS-diseased patients. Hypo/Hyperkalemic symptomatology was reviewed in articles as well as reference texts. The conventional mechanisms of maintaining CNS ECF [K] were critically appraised. Considering significant flaws in the explanation, a new model is proposed.

Results: No study identified significant CNS signs and symptoms in hyper/hypokalemic states. CSF [K] is maintained in a remarkable tighter and lower range (2.9±0.22) regardless of substantial variations of serum [K] (4.49±0.43) in healthysubjects of different ages (1 week-80 years). The same result was observed in uremic patients with extreme serum K fluctuations (range 2.2-8.1). However, CSF [K] altered in some neurological disorders such as Alzheimer, seizure, and coma. CNS potassium is maintained by a supporting system including spatial K buffering, siphoning, net uptake, and blood brain barrier.

Conclusions: A new physiology-based model in conjunction with conventional mechanismsis offered, which demonstrates K buffering yet availability to neurons in an economically efficient manner. In such model released K by each AP will be buffered locally via exchange with sodium and protons in addition to reversible binding with organic anions. Furthermore, the CNS ECF [K] change in neurological disorders makes the proposed model a new avenue for better understanding of CNS disorders like Alzheimer disease.

PUB613

Correction Rate of Severe Hypernatremia and Morbidity and Mortality in Hospitalized Patients Ameer Abdulrazzak, Mina El-Kateb, Minas Melidonian, Heather L. Henderson, Joel Topf. *Internal Medicine, St.John Hospital and Medical Center, Detroit, MI.*

Background: Hypernatremia is common among hospitalized patients and has been associated with hospital mortality. Guidelines for the rate of correction in adult patients are based on studies in children. Current recommendations state that the rate of correction should not exceed 10-12 mEq/L/day. The study objective is to determine whether the rate of serum sodium correction in hospitalized adult patients with severe hypernatremia affects morbidity or mortality.

Methods: This is a retrospective, observational, chart review, to look at neurologic and patient outcomes according to the rate of correction of hypernatremia in hospitalized adult patients admitted with sodium more than 160 mEq/L. Data collected included demographics, comorbidities, neurologic status at admission and discharge, and fluids given during the first 72 hours of admission or until normalization of serum sodium. We evaluated the correction rate at the first 24, 48, and 72 hours. The primary outcomes were mortality during hospitalization and change in neurologic status between admission and discharge.

Results: Fifty nine patients met the inclusion criteria (mean age 78.3±16.3 yrs, 35% male, 33% White). There were no significant differences in mortality by demographic factors or comorbidities, except that patients who survived had a significantly higher diastolic blood pressure on admission (69.2±16.0 mm Hg^2 versus 55.7±20.5mm Hg^2, p=0.01 respectively). There was no worsening in the neurologic status between admission and discharge in any of the patients. The mean correction rate of hypernatremia at 24 and 48 hours was significantly faster in patients who survived than those who died (24 hrs: 8.13±7.2 mEq/L/day versus 4.6±2.9, respectively, p=0.01; 48 hrs: 13.6±8.2 mEq/L/day versus 9.5±4.7, respectively p=0.03). No difference was found at 72 hours. In ten patients, the sodium was corrected faster than 12 mEq/L in 24 hours. Mortality in this sub-group was zero compared to 34.8% in patients whose sodium was corrected within the guidelines.

Conclusions: Correction of hypernatremia faster than current guidelines was not associated with increased mortality or poor neurologic outcomes.

PUB614

Prevalence of Uromodulin-Associated Kidney Disease May Be Under-Estimated - Renal Biopsy Based Investigation Tamehito Onoe,[1] Kazunori Yamada,[1] Ichiro Mizushima,[1] Kiyoaki Ito,[1] Shoichiro Daimon,[2] Mitsuhiro Kawano.[1] *[1]Dept of Internal Medicine, Kanazawa Univ Graduate School of Medicine, Kanazawa, Ishiikawa, Japan; [2]Dept of Nephrology, Daimon Clinic for Internal Medicine, Nephrology and Dialysis, Nonoichi, Ishikawa, Japan.*

Background: Uromodulin-associated kidney disease (UAKD) is characterized by urinary concentration defect, hyperuricemia, gout and slowly progressive renal failure. Affected patients usually reach end-stage kidney disease (ESKD) between the fourth and seventh decade. UAKD is caused by Uromodulin (UMOD) gene encoding Tamm-Horsfall protein (THP) which is the most abundant protein in human urine. UAKD is reported to be a rare inherited disease whose prevalence is about one case per million population. However it is suggested that this disease is under-recognized because hyperuricemia is common in patients with chronic kidney diseases.

Methods: To clarify the incidence of UAKD in patients undergoing renal biopsy, immunostaining of THP was performed for patients with renal insufficiency and hyperuricemia under 50 years old without overt urinalysis abnormality from 1992 to 2013 in Kanazawa University and related facilities.

Results: 15 of total 3787 patients were selected for immunostaining. Pathological diagnosis of all these patients was interstitial nephritis or nephrosclerosis. In four independent patients of them, abnormal THP accumulation in renal tubular cells was detected. Only one of the four patients had a strong family history of kidney disease. A novel missense A247P mutation was detected in his affected family members including him. Other three patients had no family history of kidney disease.

Conclusions: Renal biopsy and immunostaining for THP may be a useful tool to diagnose UAKD patients, because abnormal THP accumulation was detected in 4/15 patients who met all the above criteria, despite the little chance for renal biopsy due to the paucity of proteinuria in UAKD patients. It is suggested that a considerable number of UAKD patients may exist and reach ESKD without an exact diagnosis, with more sporadic cases of UAKD existing than reported before.

PUB615

The Differential Diagnosis between Inherited Salt-Losing Tubulopathy and Pseudo-Disorder from Clinical Characteristics Natsuki Matsunoshita,[1] Kandai Nozu,[1] Naohiro Kamiyoshi,[1] Koichi Nakanishi,[2] Norishige Yoshikawa,[2] Kazumoto Iijima.[1] *[1]Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan; [2]Dept of Pediatrics, Wakayama Medical Univ, Wakayama, Wakayama, Japan.*

Background: Bartter's syndrome (BS) and Gitelman's syndrome (GS) are autosomal recessive inherited salt-losing tubulopathy characterized by hypokalemic metabolic alkalosis. Phenotype overlapping frequently occurs in type III BS and GS patients, which are difficult to diagnose from their clinical pictures. Moreover, some unique acquired or inherited cases can occasionally cause BS/GS-like disorder, or pseudo-BS/GS (p-BS/GS) which clinical symptoms are identical to BS/GS. Although it is very important to make the accurate diagnosis for these three diseases, the analysis for clarifying differences in clinical characteristics is rarely performed.

Methods: We retrospectively studied the clinical data from 161 Japanese patients (type III BS:30, GS:88, p-BS/GS:43). All type III BS and GS patients had homozygous or compound heterozygous mutations in *CLCNKB* and *SLC12A3*,respectively, whereas none of p-BS/GS had disease-causing mutations in these two genes.

Results: P-BS/GS patients had significantly higher mean age at diagnosis than type III BS and GS (36.7±2.5 versus 4.2±2.6 versus 18.3±1.8 yr ; $p < 0.05$). When p-BS/GS patients were compared with GS, p-BS/GS patients had significantly higher percentage of female (76.3 versus 44.8 %; $p < 0.05$), lower BMI (17.9±0.7 versus 21.2±0.7 kg/m^2; $p < 0.05$) and lower eGFR (65.1±6.0 versus 99.8±5.8 ml/min/1.73m^2; $p < 0.05$) than GS patients. Furthermore, p-BS/GS patients had significantly higher serum magnesium level (1.95±0.12 versus 1.57±0.07 mg/dL; $p<0.05$) and urinary excretion of calcium (Ca/Cr ratio of 0.07±0.01 versus 0.03±0.01 mg/mg; $p<0.05$) than GS patients.

Conclusions: We could demonstrate clinical distinction between genetically-proven type III BS, GS and p-BS/GS patients. Our results indicated p-BS/GS patients were found mostly in adult female with lower BMI and eGFR. It is helpful in the differential diagnosis of these three diseases to check ages at diagnosis, gender, BMI and renal function in addition to serum magnesium level and urinary excretion of calcium.

PUB616

Application of Whole Exome Sequencing to Detect New Causal Variants in Autosomal-Dominant Steroid Resistant Nephrotic Syndrome Katrina Soderquest,[1,2] Alka Saxena,[3] Efterpi Papouli,[3] Graham M. Lord,[1,3] Andrey S. Shaw,[4] Michael A. Simpson,[2] Ania B. Koziell.[1] *[1]Experimental Immunobiology, King's College London, United Kingdom; [2]Medical and Molecular Genetics, King's College London, United Kingdom; [3]NIHR Biomedical Research Centre, Guy's and St Thomas' Hospitals, United Kingdom; [4]Pathology and Immunology, Washington Univ.*

Background: Whole Exome Sequencing (WES) is now a popular choice for finding uncommon genetic variants of high effect in rare disease. The technique hypothesizes that these variants are primarily found in the exons of the genome but is hypothesis free in terms of gene candidates. Although studies of SRNS have, to date, found causal variants in > 37 genes, it is clear that not all causal mutations are known. Initial analysis of 3 Caucasian families with Autosomal-Dominant Steroid Resistant Nephrotic Syndrome (AD-SRNS) did not detect mutations in previously published genes. We therefore investigated a role for other candidates using WES.

Methods: Three generations were available for study. DNA was exome-enriched using Agilent SureSelect V5 and sequenced on Illumina HiSeq2000, including donor and acceptor consensus sites. Sequence was aligned to build hg19 of the human genome by Novoalign. Variants were called by SAMtools. Exome sequences were investigated to confirm absence of mutations in known candidate genes. Data were analysed, at first, assuming one dominant variant with complete penetrance.

Results: WES confirmed the absence of mutations in genes previously associated with SRNS. Eight potential new candidates in one family include genes participating in calcium-mediated signaling and encoding DNA binding proteins. Further analysis of samples is underway to allow sufficient refinement for functional confirmation.

Conclusions: Our data indicates that even well-defined cases of AD-SRNS may not have a known podocyte gene mutation, or the mutation may reside outside the exome. Of particular interest is that some patients responded to the Calcineurin inhibitor, Tacrolimus. One patient had a recurrence post-transplant. Analyses of families such as this with respect to phenotypic qualities, including drug response, broadens our understanding of molecular pathways involved in SRNS.

PUB617

Identification of Novel Risk Contributing Loci within Steroid Resistant Nephrotic Syndrome Using Exome Sequencing on a Large National Pediatric Cohort Denis Andrew Baird,[1] Agnieszka Bierzynska,[2] Ania Koziell,[3] Gavin Iain Welsh,[2] Ian N. Day,[1] Moin Saleem.[2] *[1]School of Social and Community Medicine, Univ of Bristol, Bristol, United Kingdom; [2]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom; [3]Dept of Immunobiology, King's College London, London, United Kingdom.*

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is genetically heterogeneous, with highly penetrant single disease causing mutations having been discovered in over 20 genes. Although, some genes have been discovered to contain variants which contribute risk towards SRNS, the non-Mendelian component of the disease remains largely unexplored. Genome Wide Association Studies (GWAS) have been successful in uncovering associated variants from large genotyped cohorts for many common, complex diseases. The development of Next Generation Sequencing (NGS) has made feasible the direct sequencing of large cohorts, which enables the search for risk contributing mutations in rare diseases using a similar statistical methodology as GWAS. An exome-wide association study was run on 64 individuals with childhood SRNS, collected from the UK RADAR Registry, in order to elucidate potential risk contributing variants in novel SRNS genes.

Methods: Patients with truncating or missense mutations within the SRNS candidate genes were removed from the analysis. Principal Component Analysis (PCA) was performed in Plink and non-European patients removed. Fisher Exact tests were performed on rare point mutations and uni-variate chi-squared tests for common variants. Multiple controls obtained from UK10K were used. Pathogenicity was assessed by Combined Annotation Dependent Depletion CADD tool. Haplotype estimation was carried out in BEAGLE.

Results: 35 loci were detected with significant associations across the non-candidate genes, 10 of which were predicted to be potentially damaging (C-score > 10). The analysis is currently being repeated with 97 further patients to investigate if further associations exist and to confirm the already found ones. This will be followed up with haplotype analysis to determine associated variants with a common point of origin.

Conclusions: The method revealed evidence of associated variants in novel SRNS genes.

PUB618

Diagnostic/Prognostic Tests for All Hereditary Kidney Diseases Lisbeth Silva,[1] Olaya Lamas-Gonzalez,[1] Beatriz Sobrino,[2] M. Lara Besada-Cerecedo,[2] Helena Covelo-Molares,[1] Patricia Regueiro Casuso,[1] Ana Barcia de la Iglesia,[1] Marina García,[1] Jorge Amigo,[1] Francisco Barros Angueira,[2] Angel Carracedo,[2] Candido Diaz Rodriguez,[1] Miguel A. Garcia-Gonzalez.[1] *[1]Group of Genetics and Developmental Biology of Renal Diseases, Health Research Institute of Santiago de Compostela (IDIS). Clinical Univ Hospital (CHUS), Santiago de Compostela, Spain; [2]Galician Public Foundation of Genomic Medicine, Clinical Univ Hospital (CHUS)., Santiago de Compostela, Spain.*

Background: The combination of NGS and Sanger sequencing is a traditional and reliable method of sequencing pools of genes for a particular disease, and thechnology is not a limitation anymore to diagnose hereditary renal disorders. Only level of efficiency, time and costs are the main objectives to develop and efficient strategy for genetic diagnosis and prognosis of patients.

Methods: We have developed a strategy to be used by nephrologists for the diagnosis of genetic renal disorders in an easy, cheap and fast way. Nephrologists tend to classify renal diseases in three main groups: cystic diseases, tubulopathies and glomerulopathies. For this reasons we developed 4 NGS panels considering precious criterias: 1) Panel for common hereditary cystic dieases (8 genes), 2) Panel for Rare and ultra-rare cystic disease (72 genes, for the diagnosis and possible prognosis); 3) Panel for tubular diseases (36 genes), and 4) Panel for glomerular diseases (26 genes).

Results: These panels have the following coverage of the target regions (exons and flanking regions): Panel 1 (common cystic diseases) 98.5%, Panel 2 (rare and ultra-rare cystic disease) 99.6%, Panel 3 (glomerular diseases) 99.97% and Panel 4 (tubular diseases) 99. 7%. We have applied these panels to a cohort of 187 patients with different hereditary renal pathologies, showing impressive results. We also have developed bioinformatic algorithms crossing every single known database of reference, in order to determine in a confident fashion the level of variant pathogenicity. These help us to provide new tools for clinical decision.

Conclusions: Here, we first describe a quick and cost effective strategy for genetic diagnosis of every single known hereditary renal disorder.

PUB619

Estimation of Daily Protein Intake Based on Urea Nitrogen Concentration in Spot Urine in Chronic Kidney Disease Patients Hiroko Kanno,[1] Eiichiro Kanda,[3] Asako Sato,[1] Kaori Sakamoto,[4] Sanae Watanabe,[4] Yoshihiko Kanno.[2] *[1]Clinical Laboratory, Tokyo Women's Medical Univ, Japan; [2]Dept of Nephrology, Tokyo Medical Univ, Japan; [3]Dept of Nephrology, Tokyo Kyosai Hospital, Japan; [4]Dept of Clinical Nutrition and Dietetics, Kagawa Nutrition Univ, Japan.*

Background: It is not easy to determine the daily protein intake (DPI) in chronic kidney disease (CKD) management. Recording dietary intake is inaccurate, and estimation from total urea excretion is also not easy because it is difficult for patients to collect whole urine for 24 hours (h). Spot urine has been used in the measurement of daily sodium intake and urinary protein excretion. In this cross-sectional study, we investigated whether urea nitrogen (UN) concentration (C) in spot urine could be used to predict DPI instead of that obtained by 24h urine collection in CKD patients and compared it with UNC in healthy adults we reported previously.

Methods: One hundred forty-eight Japanese CKD patients (male 46.3%) provided their urine samples collected over 24h. After the 24h urine collection, they provided one spot urine sample. DPI was estimated using the Maroni formula and data from 24h urine collection. Multivariate linear models adjusted for patients' characteristics were used to predict protein intake on the basis of UNC. Variable selection was examined by backward elimination procedure.

Results: The following results were obtained: mean estimated glomerular filtration rate (±standard deviation), 52.1±29.5 ml/min; UN excretion, 6.08±2.19 g/day; and estimated DPI, 47.7±13.95 g/day. Diabetes mellitus (DM) was observed in 54.4%. A univariate liner model showed that the UNC in spot urine was associated with DPI [β=0.027±0.0070, p=0.0001]. The following final model showed that UNC in spot urine could predict the amount of 24h UN excretion: DPI = 36.69 + 8.66×gender (male=1, female=0) - 10.91×DM (yes=1, no=0) + 0.22 × UNC in spot urine, adjusted R^2=0.21, p=0.0001.

Conclusions: The findings of our present study suggest that UNC determined by the spot urine test can be used to estimate DPI and that the prediction formula would be useful for nutritional control in CKD patients.

PUB620

A 7 Year Analysis of Inflammatory and Nutrition Markers Predicting Cardiovascular (CV) Events in Predominantly African-American (AA) Patients with End Stage Renal Disease (ESRD) on Hemodialysis (HD) Sairah Sharif,[1] Srijan Shrestha,[2] Mallika Pradhan,[2] Sudhanshu Jain,[2] Rose Calixte,[1] Jeffrey D. Wallach.[2] *[1]Winthrop Univ Hospital, Mineola, NY; [2]Harlem Hospital, New York, NY.*

Background: CV disease is the leading cause of death in ESRD. ESRD patients have higher levels of oxidation, inflammation, and malnutrition leading to CV morbidity and mortality. It is suggested that that AA patients may be protected from the effects of inflammation relative to Caucasians. Studies show that higher CRP, higher phosphate (P), lower bicarbonate (B), lower albumin (A), lower prealbumin (PA) correlate with adverse CV outcomes in ESRD patients. We studied monthly trends of these markers and tested for associations with adverse CV outcomes.

Methods: The electronic records of 116 ESRD patients, >90% AA were reviewed from 2006 to 2012. Monthly levels of CRP, PA, A, P and B were recorded. We used group-based trajectory model to understand the changing course of each marker over 84 months. Patient demographics, comorbids and adverse CV events (myocardial infarction, stroke, amputation, congestive heart failure (CHF), cardiac arrest and death) were noted. Pearson's exact chi-square was used to test for an association between clinical outcomes and each marker. Covariate analysis by logistic regression was performed.

Results: Of the 116 patients, 53 patients had one or more adverse outcomes as outlined above. A was associated with the presence of any adverse outcome (p-value = 0.036). Patients with low A were 7.33 times more likely to have an adverse event as compared ones with normal A (p-value = 0.019). PA was associated with combined adverse events (p-value = 0.031). Patients having low PA were 5.85 times more likely to experience an adverse event than ones with normal PA (p-value = 0.009). The cardiovascular event most strongly associated with these two markers was CHF. CRP was strongly associated with future amputation. No other associations were found between CRP, P, or B and any CV event or death.

Conclusions: In a largely AA ESRD population on HD low A and PA are strongly associated with CHF whereas CRP, high P and low B are less predictive of CV events or death.

PUB621

Protein Intake and Metabolic Acidosis in Stages 3 and 4 of Chronic Kidney Disease Larissa Rodrigues Neto Angeloco, Miguel Moyses-Neto, Elen Almeida Romao, Paula Garcia Chiarello. *Internal Medicine, Ribeirao Preto Medical School – Univ of São Paulo, Ribeirao Preto, Sao Paulo, Brazil.*

Background: Metabolic acidosis is a common complication in Chronic Kidney Disease (CKD) and a factor that can produce negative effects on the energetic-proteic nutritional status. The aim of this study was to investigate whether protein intake interfere with acid-base balance in stages 3 and 4 CKD.

Methods: Anthropometric measures (weight, height), laboratory analysis (creatinine, serum bicarbonate, urine pH) and estimated protein intake using protein nitrogen appearance (PNA) were evaluated in patients with CKD stages 3-4 in a High Complexity Hospital. The glomerular filtration rate (GFRe) was estimated using the Modification of Diet in Renal Disease formula. Metabolic acidosis was defined as serum bicarbonate < 22 mEq/L. Data are reported as means+SD and Spearman's correlation was used to measure associations between variables, considering p <0.05.

Results: The sample consisted of 48 patients, where 60% were male. Most patients (74%) were in stage 3 CKD. A median of 36.3 ml/min/1,73m^2 for GFRe was observed (ranging 15.8-59.5 ml/min/1,73m^2). The mean age of patients was 56.8±8.6 years. We found an average of 29.1±5.9 kg/m^2 for the Body Mass Index and 66% were overweight. The average PNA was 0.98±0.3 g protein/kg/day (ranging from 0.45 and 1.93g protein/kg/day), indicating that 65% of patients had a protein intake above the KDOQI recommendation for this population. Metabolic acidosis was present in 17% of cases. Serum bicarbonate levels were not correlated with PNA or GFRe and there was a positive correlation between serum bicarbonate levels and pH urine (r = 0.46, p = 0.001).

Conclusions: Most patients were overweight, especially patients in stage 3 of CKD, and although no correlation was observed between protein intake and acid-base balance, the total protein intake was above recommendation for this group. Further details about quality of this protein, regarding vegetable source or the acid load of the diet, and its relations with acid-base balance will certainly be useful for guiding diet interventions for a better metabolic control and nutritional status for these patients.

PUB622

Malnutrition, Inflammation, and Frailty in Hemodialysis Patients Masataka Tsunoda,[1] Ryota Ikee,[2] Naomi Sasaki,[3] Nobuo Hashimoto.[3] *[1]Dept of Nephrology and Dialysis, H.N.Medic Sapporohigashi, Sapporo, Hokkaido, Japan; [2]Dept of Nephrology and Dialysis, H.N.Medic Kitahiroshima, Kitahiroshima, Hokkaido, Japan; [3]Dept of Nephrology and Dialysis, H.N.Medic, Sapporo, Hokkaido, Japan.*

Background: Frailty is a condition in which the individual is vulnerable to develop increased dependency and/or mortality when exposed to a stressor. Sarcopenia is a major cause of frailty and its prevalence is high in hemodialysis (HD) patients. The association between sarcopenia and malnutrition prompted us to examine the relationship between frailty and nutritional markers in HD patients.

Methods: We enrolled 80 patients with HD duration ≥ 1 year in the present study. We made a diagnosis of frailty based on FRAIL scale, which includes simple 5 physical components, and Tilburg Frailty Indicator (TFI), which includes 15 physical, social, and psychological components.

Results: The diagnosis of frailty was made in 18 patients (22.5%) by FRAIL scale and in 50 (62.5%) by TFI. FRAIL scale-based frailty was associated with higher age, female sex, and lower Barthel index. On the other hand, TFI based-frailty was associated with a lower serum albumin level and lower creatinine generation rate. The number of positive components of FRAIL scale and TFI positively correlated (FRAIL scale: r = 0.469, p < 0.001; TFI: r = 0.335, p = 0.002) with malnutrition-inflammation score (MIS). Receiver-operating characteristic analysis showed that when the cut-off value of MIS was set at 4.5, the sensitivity and specificity for detecting FRAIL scale-based frailty were 72.4% and 60.8%, respectively (AUC 0.699). If the cut-off value of MIS was set at 3.5, the sensitivity and specificity for detecting TFI-based frailty were 75.0% and 69.7%, respectively (AUC 0.817).

Conclusions: Frailty was significantly associated with nutritional markers including MIS, although the proportion of the patients who were diagnosed with frailty markedly differed between the 2 sets of frailty criteria.

PUB623

Inflammatory Stress Exacerbates the Progression of Non-Alcoholic Fatty Liver Disease via the Activation of CXCL16/CXCR6 Pathway Kun Ling Ma, Wu Yu, Jing Liu, Yang Zhang, Zebo Hu, Bi-Cheng Liu. *Institute of Nephrology, Southeast Univ, Nanjing City, Jiangsu Province, China.*

Background: CXC chemokine ligand 16(CXCL16) and its receptor CXC chemokine receptor 6 (CXCR6) were recently found to participate in the process of recruiting inflammatory cells and mediating intracellular uptake of oxidative low density lipoprotein (oxLDL). This study aimed to investigate the effects of inflammation on the activation of CXCL16/CXCR6 pathway in non-alcoholic fatty liver disease (NAFLD).

Methods: Sixteen apolipoprotein E knockout mice were fed with the Western diet for 8 weeks in the absence or presence of 10% casein injection (casein) to induce an inflamed NAFLD model *in vivo* and *HepG2* cells were treated by IL-1β or with CXCL16 siRNA *in vitro*. The effects of inflammatory stress on lipid accumulation in liver were evaluated by hematoxylin-eosin staining and Filipin staining and in HepG2 cells were examined by Oil red O staining and a quantitative assay of intracellular cholesterol. The protein expression of CXCL16, CXCR6, human a disintegrin and metalloprotease 10 (ADAM10), fibronectin, and collagen type I in tissues and cells was checked by immunohistochemical staining, Real-time polymerase chain reaction (PCR), and Western Blot.

Results: Serum levels of lipid profile (total cholesterol and triglyceride, LDL and high density lipoprotein) in flamed mice were significantly decreased compared to the controls. However, inflammatory stress increased lipid accumulation in liver and HepG2 cells. Furthermore, inflammatory stress increased the protein expression of CXCL16, CXCR6, and ADAM10 in livers, accompanied with increased the expression of fibronectin, collagen type I, α-SMA, and decreased E-cadherin. These effects were further confirmed by *in vitro* studies.Further analysis showed that the activation of CXCL16/CXCR6 pathway was correlated with lipid accumulation and the production of extracellular matrix.

Conclusions: Inflammatory stress induced lipid accumulation and extracellular matrix excretion and exacerbated the progression of NAFLD via activation of CXCL16/CXCR6 pathway.

PUB624

Nutritional Status Assessment in Patients on Maintenance Hemodialysis at a Tertiary Care Dialysis Center Syed Rizwan Bokhari,[1] Mirza Faizan Ali,[1] Hafiz I. Ahmad,[1] Javeria Ikram,[1] Muhammad Zaman Khan Assir,[1] Arif Asif.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: Malnutrition is commonly seen in dialysis population and is associated with significant morbidity and mortality. Nutritional assessment is a neglected area in patients undergoing hemodialysis in developing countries. We studied the frequency of malnutrition in our patients and its associations with several factors.

Methods: All 58 ESRD patients on maintenance hemodialysis (HD) in our dialysis unit were considered for this cross sectional study, 9 patients refused to participate. The nutritional status was assessed by a predesigned questionnaire including subjective global assessment (SGA), a semi-quantitative scale for estimating nutritional status. Anthropometric measurements, peripheral neuropathy and pertinent laboratory parameters were checked. The duration on HD of the study patients ranged between 3 months to 10 years (mean 4 ± 1.5 years).

Results: Of these 49 patients, 26 (53%) were males with a median age 45 (25-76) years. Fifteen patients (31%) were well-nourished and 34 (69%) were under-nourished including 9 (19%) patients classified as severely malnourished according to SGA. Malnutrition appeared more prevalent in males 80% versus 56%., however, this did not reach statistical significance (p-value 0.063). On univariate and multivariate analysis, no significant between-group differences were found across well-nourished and malnourished patients in terms of age, BMI, calorie count, duration and frequency of dialysis, dry weight, inter-dialytic weight loss or gain in last 6 months, body fat percentage, serum albumin, blood pressure, intra-dialytic hypotension,URR, Kt/V, peripheral neuropathy and co-morbidities. Psychosocial factors were identified in 24 (49%) patients with 19 (79%) having some degree of malnutrition but the finding did not reach the statistical significance.

Conclusions: In our cohort, 2/3rd of the participants had malnutrition. Surprisingly, the traditional factors studied in previous trials have not shown any significant association to malnutrition in our study.

PUB625

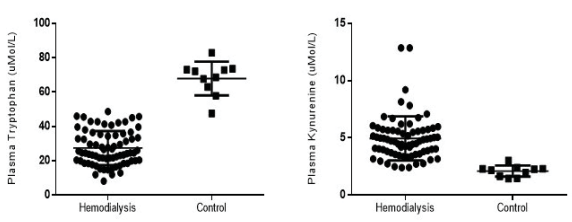
A Pilot Study on the Relationship between Tryptophan, Its Metabolites, Sleep, Depression and Fatigue in Hemodialysis Patients Rakesh Malhotra,[1,5] Vanja Persic,[5] Weifang Zhang,[2] Garry J. Handelman,[2] Laura Rosales,[5] Mark L. Unruh,[3] Fredric O. Finkelstein,[4] George A. Kaysen,[5] Peter Kotanko.[5] *[1]VUMC; [2]U Mass; [3]U New Mexico; [4]Yale; [5]RRI.*

Background: Sleep and mood disorders are common in hemodialysis (HD) patients. Tryptophan (TRP) and its metabolites play prominent roles in neural pathways related to sleep, fatigue, and depression. Here we report levels of TRP and its metabolite kynurenine (KYN) and their association with sleep, non-physical fatigue and depression in HD patients.

Methods: In this prospective study we measured pre-dialysis levels of TRP and kynurenine (KYN) by high-performance liquid chromatography (HPLC). We performed a concurrent survey which included 3 self-reported questionnaires: Medical Outcomes Study Sleep Scale (MOS-Sleep); PROMIS Short form Fatigue 8a questionnaire (PROMIS-F); and Patient Health Questionnaire (PHQ-9). Spearman rank correlation coefficient (r_s) was used to assess correlations.

Results: We enrolled 72 HD patients (age 60.0±15.6 yrs, 62% male). Compared to healthy controls, TRP levels were decreased (27.3±10.0 µmol/L) and KYN levels were elevated (4.9±1.9 µmol/L) in HD patients. MOS-sleep scores confirmed poor sleep quality. PROMIS-F T score was 54.0±12.2, indicating a trend towards moderate fatigue. PHQ-9 score was 6.3±5.6, revealing the presence of mild depression. We found negative correlation between TRP levels and sleep disturbances. A positive correlation was found between CRP, KYN and depression severity. TRP and KYN levels were not correlated with indicators of fatigue (r_s=.101 and 0.184, respectively).

A



B

	Correlation Coefficient	TRP	Kyn	CRP
Sleep Problem Index		-.307**	-.199	.332*
PROMIS Fatigue T score		.101	.184	.102
PHQ-9 score		.248***	.232***	.238***
* P<.005; ** P <.01, *** P<.05				

Conclusions: Our study indicates disturbed metabolism of the essential amino acid TRP, poor sleep health, fatigue, and depressive symptoms in HD patients. Low TRP levels relate with sleep disturbances. A larger sample size is necessary to explore the potential spectrum of interactions between TRP status and patient reported outcomes.

PUB626

Gut Microbiota Lactbacillus Protects against the Progression of Renal Impairment through the Modulation of Gut Environments in Rats Ayumi Yoshifuji, Shu Wakino, Junichiro Irie, Kazuhiro Hasegawa, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio Univ, Tokyo, Japan.*

Background: Gut microbiota has been shown to play some roles in the pathogenesis of various diseases and was altered in CKD condition. We previously reported that Lactbacillus (Lact) decreased in CKD rats and oral activated charcoal adsorbent AST-120 (AST) improved renal function with the concomitant recovery of Lact. In this study, we elucidated the significance of Lact in the pathogenesis of CKD.

Methods: Six-week-old spontaneously hypertensive rats (SHR) were rendered CKD by 5/6th nephrectomy (Nx). The rats were divided into five groups and kept for 8 weeks; sham-operated SHR (SHR), SHR with Nx (Nx), Nx given AST(Nx+AST), Nx given Lact (Nx+Lact,), and Nx given AST plus Lact (Nx+AST+Lact). AST was orally given at a dose of 4g/kg/day and Lact at $1*10^{10}$ CFU/kg/day. The gut flora population was analyzed by T-RFLP and RT-PCR. Next, we administered antibiotics for the eradication of microbiota to Nx rats and kept for 8 weeks with or without the supplementation of Lact. Gut permeability was assessed by serum Diamine oxidase (DAO) levels. Human colon cell line, Caco-2 cells were treated with uremic toxin precursor, indole in the presence or absence of Lact or OxPAPC, an inhibitor of toll-like receptor 2 (TLR2) and TRL4 recognizing Lact.

Results: The decrease in Lact in Nx was restored in Nx+AST, Nx+Lact, and Nx+Lact+AST. Both serum indoxylsulfate and serum IL-6 increased in Nx. These increases were ameliorated in Nx+AST, Nx+Lact, and Nx+AST+Lact, although the additive effects by the combination therapy were not observed. The decrease in the tight junction proteins Occludin and Zo-1 in Nx were mitigated by AST and/or Lact. The elevation of serum DAO in Nx was mitigated by Lact. In the germ free condition, Lact supplementation decreased the urinary protein excretion of Nx rats. In Caco-2 cells, the downregulations of Occludin and ZO-1 by indole were ameliorated by Lact, which effects were attenuated by OxPAPC.

Conclusions: The recovery of Lact in the gut of CKD rats improved the gut environment and systemic uremic condition. This probiotic therapy can provide novel therapeutic strategy against the progression of CKD.

PUB627

Inflammation and Quality of Life in Hemodialysis: A Cross Sectional Study Marcelo Rodrigues Bacci, Daniela Gimenes Grilli, Andson Jesus Santos, Renato R. Bertagna, Fernando R. Adami, Winter R. Figueiredo, Victor Couto Rosa Jordão, Felipe R. Bruniera, Felipe Moreira Ferreira, Fernando Luiz Affonso Fonseca. *General Practice, Faculdade de Medicina do ABC, Santo Andre, Sao Paulo, Brazil.*

Background: CKD is highly prevalent worldwide.Pacients with CKD on hemodialysis are more likely to present behavioral changes and worse quality of life as a result of their routine and complications.They have also higher levels of cytokines.The aim of this study is evaluate the inflammatory profile in relation to their quality of life measured by the KDOQL-SF36 in hemodialysis out-patients.

Methods: We included patients on hemodialysis for at least 6 months,aged 21 years with a week regular basis of treatment.The exclusion criteria was existence of previous depression,cancer,infection or antibiotic usage at the time of inclusion and hospitalization for the previous 30 days.It was evaluated anthropometric parameters and serum inflammatory markers:interleukin6(IL6),high sensitive C-reactive protein,tumour necrosis factor alpha(TNF-@)and homocystein.Quality of life was acesses with the KDOQL-SF36 questionnary by the same interviewer for every patient.Samples were collected in the first session of the month before the initiation of dialysis.Analysis of data distribution was made with Shapiro-Wilk test.The alpha level was 5%.Pearson correlation was used to analyze the relationship between inflammatory parameters and quality of life.

Results: Thirty patients consented to answer the KDOQL-SF36 and participate in the study.Demographic data are shown in table 1.Homocystein levels were correlated with worse GFR and creatinine(p=0.003;p=0.002).IL6 was not correlated with worse nutritional status taking into account BMI(p=0.83)in contrast to TNF-@ which was positively correlated with albumin(p=0.008), nutritional status by BMI(p=0.04)and nutritional status taking into account the circumference area of the arm(p=0.04).IL6 was correlated with activity limitation(p=0.02) and homocystein with working condition(p=0.04).

Conclusions: Homocystein is related with nutritional status and inflammatory markers. In this population the majority of sections in the KDOQL-SF36 were not correlated with the levels of cytokines.

PUB628

Uric Acid and Carotid Intimal Media Thickness Associated with Kidney Dysfunction in Rheumatoid Patients Suad Ma Hannawi,[1] Issa A.L. Salmi.[2] *[1]Dept of Medicine, MOH Hospital, Dubai, Dubai, United Arab Emirates; [2]Dept of Medicine, MOH Hospital, Muscat, Oman.*

Background: Rheumatoid arthritis(RA) patients develop kidney dysfunction(KD) over time. Cardiovascular disease(CVD) and associated factors play a major role. In addition, RA with KD may lead to an increase in morbidity from CVD progress. Uric acid(UA), is a metabolic product of purine metabolism, that may function as an antioxidant, linked to CVD in general population and in RA, even after adjustment for traditional CVD risk factors. Also, UA is an independent predictor of KD in RA. The association of UA and cIMT(an independent predictor of CVD in RA) had never been investigated in RA. We recorded UA and studied cIMT to determine whether UA is correlated with CVD in RA.

Methods: 36 patients, aged 44.7 yrs(min 24, max 73) satisfying 1978 ACR criteria for RA diagnosis were included. UA was related to demographic factors, disease activity variables, established cardiovascular risk factors [i.e., cholesterol, high density lipoproteins, low density lipoproteins, triglycerides---etc] and common cIMT; measured by carotid duplex scanning.

Results: A simple linear regression shows that UA is positively correlated with age(p=0.02,CI 0.00,0.02). The correlation remained significant after adjustment for sex(p=0.033,CI 0.001,0.024). UA was positively correlated in linear relationship with cIMT(p=0.031,CI 0.113, 2.26), and negatively with high density lipoprotein(p=0.017,CI -0.569, -0.060). Creatinine and glomerular filtration rate, were correlated significantly with the level of UA(p=0.000 for both). Urine microalbumine and urine albumin creatinine ratio, another marker of KD, showed a significant positive linear relationship(p=0.037 and 0.024, respectively). Multiple linear regression model confirmed the significant positive relation with age(p=0.018),cIMT(0.024) and GFR(p=0.000), with R-squared =0.59.

Conclusions: This study shows for the first time that atherosclerotic burden as manifested by cIMT is positively associated with increase in UA in RA patients. Data suggest that increase in cIMT predicts presence of underlying KD in RA and its value is a good non-invasive tool to screen for predicting KD.

PUB629

Cross-Sectional Examination of Metabolites and Metabolic Phenotypes in Uremia Sahir Kalim,[1] Clary B. Clish,[2] Joseph James DeFerio,[1] Guillermo Ortiz-Sanjuan,[1] Ravi I. Thadhani,[1] Eugene P. Rhee.[1,2] *[1]Nephrology Div, Massachusetts General Hospital, Boston, MA; [2]Broad Institute, Cambrdige, MA; [3]Cardiology Div, Massachusetts General Hospital, Boston, MA.*

Background: Although metabolomic approaches have begun to document numerous changes that arise in end stage renal disease (ESRD), how these alterations relate to established metabolic phenotypes in uremia is unknown.

Methods: We used partial least squares discriminant analysis to identify metabolites that best discriminate individuals with or without diabetes, and across tertiles of body mass index, serum albumin, total cholesterol, and systolic blood pressure among 200 incident hemodialysis patients.

Results: Our data do not recapitulate metabolomic signatures of diabetes and obesity identified among individuals with normal renal function (e.g. elevations in branched chain and aromatic amino acids) and highlight several potential markers of diabetes status specific to ESRD, including xanthosine-5-phosphate and vanillylmandelic acid. Further, our data identify significant associations between elevated tryptophan and long-chain acylcarnitine levels and both decreased total cholesterol and systolic blood pressure in ESRD. Higher tryptophan levels were also associated with higher serum albumin levels, but this may reflect tryptophan's significant albumin binding. Finally, an examination of uremic retention solutes captured by our platform in relation to 24 clinical phenotypes provides a framework for investigating mechanisms of uremic toxicity.

Conclusions: In sum, these studies leveraging metabolomic and metabolic phenotype data acquired in a well-characterized ESRD cohort demonstrate striking differences from metabolomics studies in the general population, and may provide clues to novel functional pathways in the ESRD population.

PUB630

Diet Record Could Not Predict the Real Protein Intake in Chinese CKD Patients with Low Protein Diet Xiaoyan Peng,[1] Limeng Chen,[1] Hailong Li,[2] Yan Qin,[1] Wei Zhang,[1] Wei Chen,[2] Xue-Mei Li.[1] *[1]Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Dept of Parenteral and Enteral Nutrition, Peking Union Medical College Hospital, Beijing, China.*

Background: Dietary protein restriction acts as a basic therapy for patients with chronic kidney disease (CKD). The purpose of this study is to identify the compliance of low protein diet education by nutritionist. And to figure out whether daily diet record could present the amount of protein intake.

Methods: The CKD (stages 3b to 4) patients(n=50) were enrolled in this prospective study in PUMCH, Beijing, China. They were recommended and educated to take a low protein diet(0.4-0.6g/kg BW) supplemented with α-keto acid. Diet protein intake was calculated from 24h-urinary urea using Maroni's formula and according a 3-day diet record by the nutritionist. Clinical data, blood and 24h urine samples were taken at baseline, 2wks, 6wks, 10wks and 14wks.

Results: The mean age was 49±13 years old, 46% were male. After 14-weeks study, the overall protein intake didn't change (0.77±0.2 versus 0.77±0.17 g/kg/d), but during the following-up period at different time the level of protein intake fluctuated slightly. At 6 weeks, the intervention of dietary protein reached the lowest, but then slowly began to pick up. There were no statistically significant changes in eGFR (30.2±13.4 versus 31.5±14.3), serum creatinine(221.5±96.9 versus 218.5±97.5), 24h proteinuria(median 0.8 versus1.0), Mean arterial blood pressure (92.8±10.8 versus 91.6±11.9), Hemoglobin(125.7±18.0 versus 127.8±17.3) and serum albumin(44.2±3.0 versus 44.7±2.6). Diet record surely correlated with actual protein intake(r=0.376,*P*<0.001), but is much less than the latter (0.46 ± 0.15 versus 0.77±0.21, P<0.001). Significant correlation between the changes of diet protein and proteinuria were observerd (r=0.334, P<0.001), as well as the changes of serum urea (0.404,P<0.001) and phosphorus(r=0.224,P<0.003).

Conclusions: Despite the regular intervention of nutritionists, compliance of low protein diet varies, and the diet record couldn't correctly reflect protein intake. Daily protein intake correlated with the change of proteinuria, serum urea and phosphorus.

The Relationship between Protein Energy Wasting and Fluid Status in Hemodialysis Patients under Invasion Phase Tomofumi Fushima,[2] Mariko Miyazaki,[1] Tae Yamamoto,[1] Takefumi Mori,[1] Nobuyuki Takahashi,[2] Hiroshi Sato,[2] Sadayoshi Ito.[1] *[1]Blood Purification, Tohoku Univ Hospital, Sendai, Japan; [2]Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Japan.*

Background: The protein energy wasting(PEW) is well documented during maintenance hemodialysis(HD), however, little is known about the management strategy under the critical complication.

Methods: We conducted cross-sectional observational study for 72dialysis inpatients to treat their complications (M/F=49/23, 63±13 years old). We analysed the physical measurement, subjective global assessment(SGA), bioimpedance spectroscopy (InBody10), and laboratory markers for uremia, anemia, nutrition, and inflammation.

Results: Pre-HD ALB were 2.8 ± 0.4 g/dL. The balance of post versus pre-HD ALB(ΔALB) was positive in 53 patients. In 30 of them showed over 40% of post-HD Extra Cellular Water(ECW)/Total Body Water(TBW). Totally, patients' fluid status were classified to 4 groups using cut-off ΔALB and 40% of ECW/TBW.

	A (N=23)	B (N=7)	C (N=12)	D (N=30)
ECW/TBW, Post-pre HD Alb	**<40, ≥0**	**<40, <0**	**≥40, <0**	**≥40, ≥0**

Ferritin ng/mL	94.5±75.9	149±1 4 0	343.8±96.0	399.2±75.9*

Table 1. Fluid status and clinical marker of nutrition, muscle, and anemia

*P<0.05 vs A ANCOVA, adjusted by gender, age, dialysis vintage

The decreased plasma vollume but overhydration (group D) showed malnutrition, muscle weakness, and anemia with disorder of iron utilization.

Conclusions: The fluid status difined by bioimpedance spectroscopy and ALB balancet crossly linked PEW under the critical complecation for dialysis patients. They requires intensive nutrition and fluid management to better outcome.

PUB632

Transient Late Onset Neutropenia (LON) in an Adult Patient on Peritoneal Dialysis (PD) following Treatment of Resistant Nephrotic Syndrome with Rituximab Fabrizio Grosjean, Maria Lucia Scaramuzzi, Giuseppe Sileno, Alessandra Manini, Gianluca Marchi, Pasquale Esposito, Filippo Mangione, Gianluca Fasoli, Antonio Dal Canton. *Nephrology,Dialysis,Transplantation, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy.*

Background: LON has been described after Rituximab treatment for hematologic tumors and rheumatologic diseases. There are only anecdotal cases reported, mainly paediatrics, following Rituximab treatment for resistant nephrotic syndrome, none of them described in patients with ESRD.

Methods: Case description: A 30 year old female patient with steroid resistant nephrotic syndrome secondary to FSGS was treated with Rituximab 375 mg/1,73 m^2 administered weekly for 4 weeks. Because of progressive worsening of kidney function associated with refractory nephrotic syndrome and oliguria she started hemodialytic treatment, subsequently she was shifted to PD without any major complications. Leucocyte count and formula were normal for 11 weeks after the last Rituximab administration (WBC 4420/μl, NEU 2100/μl). Of note haemoglobin levels were kept above 11 g/dl with ESA and the platelet count was constantly normal. Blood count exam performed to evaluate ESA adjustment surprisingly showed severe neutropenia (WBC 3170/μl, NEU 100/μl)at 13 weeks after the last Rituximab administration. EBV and CMV infection were excluded. Neutrophils progressively and spontaneously increased to normal values after 1 week (WBC 7100/μl, 3500/μl). Our patient had no major infectious complications, she underwent successfully two short cicles of oral fluorochinolon treatment (5 days) for a submandibular localized suppurative infection of the skin with palpable reactive regional swollen lymph nodes.

Conclusions: Because Anti-CD20 therapy is increasingly used in the treatment of various patterns of nephrotic syndrome in adults and children, Nephrologists should be aware of the possible onset of LON. Because of its late onset patients must be carefully monitored especially in case of evolution of the kidney disease toward ESRD requiring dialysis, a condition known to induce immunodepression.

PUB633

Thrombotic Microangiopathy Associated with Intravenous Reformulation of Opana Ruth Schreiber, Ryan Hunt, Tal Schiller, Andrew Wu, Chava Kimchi-Sarfaty. *Laboratory of Hemostasis, Div of Hematology, FDA, Bethesda, MD.*

Background: Thrombotic microangiopathy (TMA) have been reported in association with the intravenous abuse of Opana,an opioid which was reformulated to extend the duration of response and prevent adulteration and non-oral administration.

Methods: 1. A Pubmed search was performed to identify reports describing Opana abuse complicated by TMA. Key words: Opana, TTP,TMA. Demographic and clinical characteristics were recorded.**2.** PEO, the excipient of Opana was introduced at various concentrations and time periods to ADAMTS13 expressing HEK293T cells. Expression levels were analyzed using Western blotting and ADAMTS13 specific activity was calculated.

Results: Demographic and clinical characteristics Among the 37 patients described in 7 reports, 15(40.5%) were women. All reported cases were young white adults, age ranging from 22-52 years, 36 patients admitted abusing intravenous Opana. 32(86.5%) patients presented with acute kidney injury, 3(8.1%) with CNS symptoms, 3(8.1%) with respiratory distress and 15(48.6%) with infection. The serum creatinine ranged from 0.5-14.4mg/dL and pltelates counts ranged from 9,000-128,000/mm^3. Kidney biopsies of 3 patients showed evidence for TMA. 16(43.2%) patients underwent plasmapheresis, 2(5.4%) underwent plasma exchange, 2(5.4%) underwent hemodialysis and 2(5.4%) were treated with the combination of both. The short-term kidney outcomes ranged from CKD1 to 5, with no correlation to treatment modality and no mortality. 15(40.5%) patients were treated for infection (sepsis, pneumonia, cellulitis and endocarditis). 20/28 (71.4%) patients demonstrated normal or above 70% ADAMTS13 activity levels, but the timing of this measurements in relation to therapeutic interventions is not clear.**ADAMTS13 expression and activity levels** at 10 and 24 hours were shown to be unaffected at 0.3, 3 and 30µg/mL of PEO in HEK293T cells.

Conclusions: A correlation between Opana abuse and TMA has been established by repeated reports.The short-term kidney outcome in intravenous Opana abusers appears unclear despite treatment, ranging from CKD1 to 5 .PEO does not affect in vitro expression nor activity of ADAMTS13, in a system of HEK293T cells.

PUB634

Survey to Assess the Use of Smartphones in Dialysis Patients Manisha Singh, Channoah Mckindra Williams, Shree G. Sharma, Michelle W. Krause. *Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Adverse events related to errors in medications and missed dialysis prescriptions during transition of care are frequent .The resulting burden of error on patient welfare and healthcare is significant. We hope to enable the patient to carry with him a tool that can be updated easily and reflects his/her current prescription. As a quality improvement measure and as a patient safety tool, we hoped to introduce an appropriate measure to help our patients. Proposed tools are apps for smart phones, and/or hard copies on the patients (wallets or pocket diaries).

Methods: In order to identify the most effective tool, we undertook the present study of verbal survey of patients on dialysis.We attempt to identify the fraction of patients that are comfortable using smart phones and mobile apps. We conducted a verbal survey of the patients on outpatient dialysis. We asked the patients 1. if they had a smart phone and 2. if they had one, how comfortable were they in using apps for medications.

Results: Out of a total of 56 patients asked, 40 had phones, of which 16 had smart phones and most were comfortable using apps. Our preliminary data shows that approximately 71% (40/56) of patients had phones and approximately 30 %(16/56) of patients on dialysis are currently using smart phones/apps. Of the smart phone users, 14 out of 16 (87%) were comfortable using the apps.

Conclusions: Our preliminary data shows that only approximately 30% of dialysis patients in our outpatient center are currently using smart phones/apps. Therefore, we plan to implement pocket diary /wallet (per patient preference) for our patients in the next phase. We recognize the caveat that our study population is small, so we are expanding the pool to include all patients that we meet on dialysis inpatient, outpatient and at different centers. This simple preliminary study helped us recognize the importance of choosing an intervention which will be most helpful and more relevant to the target population. The study also helped us to focus our resources on developing the pocket diary /wallet. After analyzing the data from the second phase of our study we will focus on developing an app.

PUB635

A Measurement Framework for Driving Performance in Renal Care in Ontario Gihad E. Nesrallah,[1,2] Kelly Woltman,[1] Kiren Handa,[1] Camila Iraheta,[1] Jane Ip,[1] Mary Ann Murray.[1,3] *[1]Ontario Renal Network, Cancer Care Ontario, Toronto, ON, Canada; [2]Keenan Research Cenre, The Li Ka Shing Knowledge Institute, Toronto, ON, Canada; [3]Nephrology, The Ottawa Hospital, Ottawa, ON, Canada.*

Background: The Ontario Renal Plan (ORP), developed through extensive stakeholder engagement, provides a roadmap through which the Ontario Renal Network promotes optimal patient outcomes, experience of care, and sound stewardship of public dollars. An effective and evidence-based measurement framework is central to these efforts, and must be developed *de novo*. The second ORP will launch in early 2015.

Methods: Goals of this methodological framework are: 1) To improve outcomes for Ontario residents with CKD by developing and applying a novel provincial measurement strategy based on clinically meaningful, feasible, scientifically sound, and actionable measures. 2) To create a culture of quality improvement in the Ontario renal community. 3) To minimize data collection and reporting burden for renal programs. 4) To align measurement with quality improvement practices using the knowledge-to-action (KTA) cycle.

Results: We developed a project plan comprised of 8 workstreams: 1) knowledge syntheses to identify outcome, process, and structure variables in each of the clinical domains outlined in the ORP-II; 2) development of a prioritization strategy for selecting the most useful measures; 3) construction of conceptual and statistical models to empirically validate candidate measures using provincial data-sets; 4) finalize measurement sets drawing on the best validated measures; 5) develop primary data collection tools including facility level surveys; 6) alignment of data needs with the The Ontario Renal Reporting System (provincial renal database) development cycle; 7) application of the KTA framework at the regional program and facility level (including KTA gap and barrier management); and 8) a formative and summative evaluation of the measurement framework.

Conclusions: We describe a novel framework for identifying, validating, and measuring quality and performance measures that align with stake-holder identified priorities in renal care in Ontario, and a strategy for incorporating measurement into renal health systems improvement.

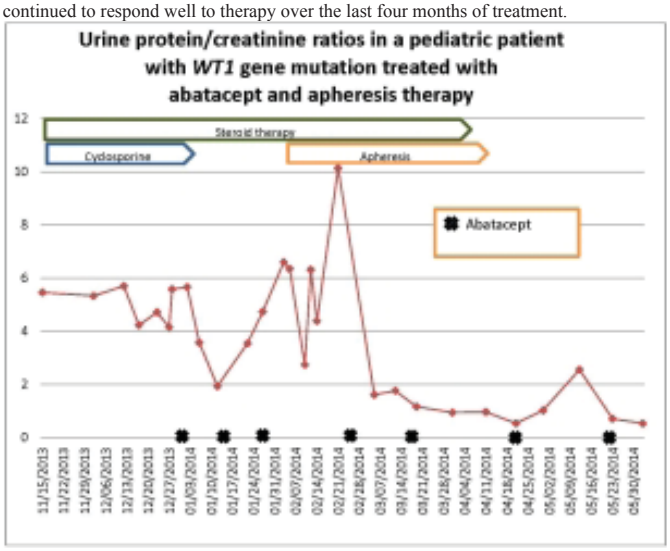
PUB636

Successful Treatment of Collapsing Focal Segmental Glomerulosclerosis Associated with WT1 Mutation in a Pediatric Patient with Combined Abatacept and Apheresis Therapy Robert M. Haws,[1] Deepa Bassi,[2] Syed M. Sajjad.[2] *[1]Pediatric Nephrology, Marshfield Clinic, Marshfield, WI; [2]Pathology, Marshfield Clinic, Marshfield, WI.*

Background: Wilms Tumor 1 (WT1) gene mutations are associated with a variety of childhood glomerulopathies. WT1-associated renal diseases respond poorly to immunosuppressive therapy and usually culminate in end stage renal disease. Cytotoxic T lymphocyte-associated antigen 4-immunoglobulin fusion protein (Abatacept), a B7-1 (CD80) inhibitor is posited to stabilize ß1-integrin activation in podocytes and reduce proteinuria in patients with glomerular disease. We report the first successful treatment of WT1-associated steroid resistent nephrotic syndrome (SRNS) with combined abatacept and apheresis therapy.

Methods: Focal segmental glomerulosclerosis (FSGS) with collapsing features on renal biopsy was identified in a 12 year old female with SRNS. Genetic testing revealed a WT1 gene mutation in exon 8 unique to the patient and not present in either parent. Severe combined hyperlipidemia (TC 703 mg/dl and TG 1238 mg/dl) despite pharmacologic therapy was treated with apheresis. Abatacept administered at a dose of 500 mg intravenously on day 0, 15, 30 and monthly thereafter combined with 19 apheresis treatments resulted in resolution of nephrotic range proteinuria and severe hyperlipidemia.

Results: Abatacept treatment over a six month window in conjunction with apheresis was associated with a clinically significant decline in proteinuria in the patient. The patient continued to respond well to therapy over the last four months of treatment.



Conclusions: This is the first report of response to combined abatacept and apheresis therapy in a patient with a WT1 gene mutation presenting with FSGS. The treatment holds promise for patients with SRNS, potentially delaying or negating the need for renal transplantation.

PUB637

The Pediatric Renal Replacement Therapy: The Fitted Pumps and Catheters Francesco Garzotto, Paolo Armignacco, Anna Lorenzin, Mauro Neri, Claudio Ronco. *Nephrology-IRRIV, St. Bortolo Hospital, Italy.*

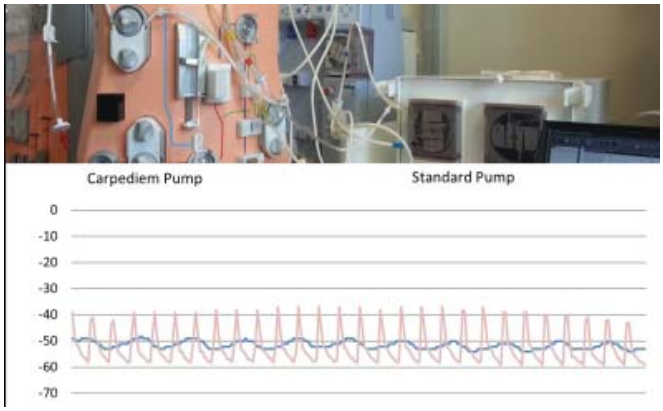
Background: Provision of CRRT to small children require particular procedures and prone patients to additional risks.Catheterization with larger catheters may impair venous drainage and thrombosis;in addition circuit survival is shorter.Functional survival of the circuit increased significantly using larger catheters.The aim of our study was to evaluate

the different caractheristics of the arterial pressure when different pumping system, carpe diem(CArdioRenalPEdiatricDIalysisEmergencyMachine)and adults pumps,are conected to a small catheter.

Methods: To evaluate the trend of the arterial pressure induced by the 2 pumps connected to small catheters(4FR 5cm and 5FR 6cm)we utilized a dedicated instrument with a sample frequency of 1s.

Results: The fluid trapped between two rollers form a pillow of fluid.Alternating pillows and voids cause fluid flow to be pulsated,rather than smooth and continuous.As show in figure 1 for the 5 Fr catheter,the amplitude of the oscillations for 15 ml/min of Blood Flow where 22 mmHg(-50.2±6.6)(-5 to-36) for the Standard pump and 4mmHg(-51.4±0.7)(-53to-49)for the carpediem pumps.Table 1 sumarize the results for the 4 FR catheter at different flows.

Conclusions: Circuits connected to small catheters and standard adults pumps show a wide spike of pressure, not present with small pumps.This phenomena increase capillary shear forces favoring the reduction on protein layering,decreasing membrane clotting with a prolongation of filter life.Per contro a worst negative effect is the increased stress on the proximal portion of the dialyzer causing clotting.Concluding the small pump is adequate to drive blood into a thin catheter avoiding dangerous spike and,in consequence,favor the circuit survival



Qb ml/min	Standard av (min - max) mmHg	Carpediem av (min - max) mmHg
10	-18.9 (-26 -6)	-17.1 (-20 -15)
15	-50.6 (-52 -49)	-63.4 (-71 -52)
30	-178.3 (-184 -169)	-159.5 (-161 -152)

PUB638

Eculizumab Use in the Treatment of Atypical Hemolytic-Uremic Syndrome: A Pediatric Patient Case Series from the United Arab Emirates

Gurinder Kumar, Omar Nihad Al Masri. *Pediatric Nephrology, Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates.*

Background: Atypical hemolytic-uremic syndrome (aHUS) is a rare and life threatening disease. It results from uncontrolled alternative complement pathway activation resulting in thrombotic microangiopathy(TMA). Prognosis had been poor using plasma as the majority of patients (pts) ended up with significant renal morbidity or death. Eculizumab (Ecu) has changed the course of aHUS.

Methods: We report our experience of 7pts with aHUS in our centre.

Results: Age at diagnosis and time from diagnosis to initiation of Ecu are shown in Table.

	Patient						
	1	2	3	4	5	6	7
Age at aHUS onset (months)	5	24	3	3	8	35	22
Time from diagnosis to Ecu initiation (months)	35	2.5	72	72	2	8.1	0.25
Number of TMA manifestation pre Ecu/post Ecu	2/0	1/0	2/0	6/2	1/0	1/0	1/0
Dialysis pre Ecu	No	Yes	Yes	No	Yes	No	No
Dialysis post Ecu	No	No	No	No	Yes	No	No
Antihypertensives	2	3	3	4	1	1	0
Lab parameters(at initiation of Ecu and after 12 and 24 months Ecu)							
Protein /creatinine ratio	3.0 6.95 6.68	0.19 0.6 0.57	3.6 1.56 0.57	1.73 2.78 2.91	- - -	0.66 0.68 0.80	3.3
eGFR (mL/min/1.73m²)	2/0 182 258	35 62 78	93 71 73	63 71 73	5 7 -	11.35 88.64 122	43.63

On initial referral to our clinic, all pts were managed with plasma. 4/7 had serious renal dysfunction. # 4 had received Ecu while resident abroad, but discontinued upon arriving in UAE. Ecu was reinstated after a pause of 5 months. Duration of Ecu administration ranges from 1–46 months. All pts except #5 had significant renal recovery. Dialysis was discontinued in #2 and #3. There were no TMA manifestations during Ecu treatment except for # 4 who had TMA manifestations after initiating Ecu, first after interruption of therapy and a second episode due to inadequate dosing probably due to significant proteinuria. No pts experienced adverse events during Ecu treatment. We were able to discontinue treatment successfully in #6 after 1 yr (with no identified genetic mutation).

Conclusions: The long-term efficacy of Ecu in treating aHUS was confirmed in our cohort and treatment was well tolerated. Despite recovery in eGFR, most pts continue to require antihypertensive medication and have variable degree of proteinuria. Outcomes were found to be dependent on factors like early initiation of Ecu and proper dosing schedule.

PUB639

Successful Treatment with Eculizumab in a Plasma Exchange-Dependent Child with Persistent Complement Factor H Autoantibodies

Ludmila Podracka,[1] Magdalena Riedl,[2] Gabriel Kolvek.[1] *[1]Dept of Pediatrics, Safarik Univ, Kosice, Slovakia (Slovak Republic); [2]Dept of Pediatrics, Innsbruck Medical Univ, Innsbruck, Austria.*

Background: Atypical hemolytic-uremic syndrome (aHUS) is a rare, life-threatening disease characterized by systemic thrombotic microangiopathy (TMA). Prognosis is poor; despite intensive plasma-exchange (PE), >60% of patients die, require dialysis or sustain permanent renal damage. aHUS is caused by chronic complement activation, caused by complement protein mutations or autoantibodies. We report long-term follow-up of a 9 year-old girl who presented in 2009 with aHUS due to CFH autoantibodies.

Methods: Initial investigations revealed low hemoglobin (Hb; 8.2 g/dL) and platelet (plt) count ($30x10^9$/L), and high serum creatinine (sCr; 250 µmol/L) and lactate dehydrogenase (LDH; 36.9 µkat/L, range 1.2-3.5 ukat/L). aHUS was diagnosed and initial clinical improvement was seen with PE. Several attempts to withdraw or reduce frequency of PE led to severe manifestations of TMA. Weekly PE for 12 months controlled symptoms but progressive renal decline (eGFR; 70 mL/min/1.73m^2), proteinuria and hypertension (multiple antihypertensive drugs necessary) with left ventricular hypertrophy was evident. Persistently low serum C3 (0.4 g/L) was noted and immunogenetic analysis revealed a homozygous CFHR1 deletion and CFH autoantibodies (788 AU/mL).

Results: In May 2012 eculizumab (Ecu) was initiated (900 mg qw x4, 1200 mg q2w) and PE was discontinued 1 month later. After ~4 months on Ecu, Hb (12.6 g/dL) and plt count ($287x10^9$/L) were normal and eGFR increased to 85 mL/min/1.73m^2. CFH autoantibodies were 408 AU/mL. At last follow-up, March 2014 (22 months of Ecu), Hb was 13.3 g/dL, eGFR 88 mL/min/1.73m^{2}LDH 2.83 µkat/L and plt count $254x10^9$/L, and C3 levels were normal. Blood pressure was 115/70 and controlled with ramipril and amlodipine (5 mg each). No adverse events have been noted, and the child has normal growth and development.

Conclusions: Ecu inhibited TMA in a pediatric patient with aHUS due to CFH autoantibodies and allowed the discontinuation of chronic PE and improved quality of life. Hematological and renal parameters were normalized and maintained long-term.

Clinicopathological Analysis and Genotypic Features of X-Linked Alport Syndrome in 12 Children

Yanjie Huang, Xia Liu, Xiaoqing Yang. *Pediatrics, The First Affiliated Hospital of Henan Univ of Traditional Chinese Medicine, Zhengzhou, Henan, China.*

Background: To analysis the clinicopathological features and genotypic features of children with X-linked alport syndrome(XLAS).

Methods: The clinical features, laboratory and pathological findings, and type IV collagen expression in the kidney were retrospectively analyzed in 12 children, including 11 boys and 1 girls, with XLAS in our hospital between 2008 and 2013.Genetic mutation of COL4A3, COL4A4, COL4A5 were detected using exon trapping-the second generation sequencing technology in 3 families.

Results: In this study, all patients had microscopic hematuria, 6 in 12 patients (50%) presented with nephrotic syndrome, 2 in 12 patients (16.7%) had the intermittent attacks of macroscopic hematuria.Among 12 patients, the small amount of crescents were observed by light microscopy in 3 cases, the weak positive staining for IgG and IgA in mesangial region respectively was showed by Immunofluorescence in 2 cases, and the small amount of dense deposition in mesangial region was presented by electronic microscopy in 2 cases. Renal immunofluorescence examination showed that 2 in 11 male patients had capsular expression of COL4α5, and 1 female patients had segmental expression of COL4α3 and COL4α5 in glomerular basement membrane (GBM). Two glycine replacement missense mutations were identified in COL4A5 gene in 2 families, including Gly 515 Arg and Gly 539 Val, which were not reported previously. One nonsense mutation of Arg373Ter was found in COL4A5 in one girl with NS for four years, who have renal failure family history, showing segmental staining of COL4α3 and COL4α5 in GBM.

Conclusions: XLAS patients may partly accompany with the pathological immuno-inflammatory injury. Heterozygous XLAS females in the nonsense mutation shoud not be considered to be benign carriers.

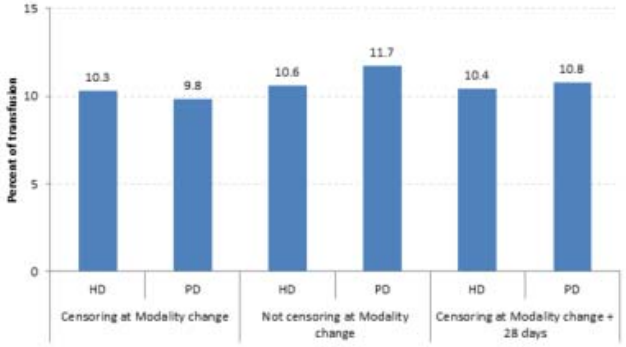
PUB641

Calculation of Transfusion Rates in Peritoneal Dialysis and Hemodialysis Patients Yi Peng,[1] David T. Gilbertson,[1] Deborah Kim,[2] Keri Monda,[2] Brian D. Bradbury,[2] Allan J. Collins.[1] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]Amgen Inc, Thousand Oaks, CA.*

Background: Recent changes in the U.S. dialysis PPS have created incentives for home therapy, particularly PD. Little is known about transfusion use in PD pts, who have little or no blood loss exposure compared with HD pts. We studied transfusion use in PD and HD pts, and compared different methods of calculation.

Methods: Pts receiving dialysis on 1/1/2010 were selected from the Medicare ESRD SAF and followed for up to 6 months. Dialysis modality (HD/PD) was defined as of 1/1/2010. All analyses were censored at the end of 6 months, death, loss to follow-up, or kidney transplant. Three additional censoring schemes were compared: (1) censor or (2) not censor at modality change; (3) censor at 28 days after modality change. Transfusion events were assessed during the follow-up periods.

Results: When follow-up was censored at modality change, a lower percentage of PD than HD pts received a transfusion (9.8% versus 10.3%). However, when follow-up was not censored at modality change, a higher percentage of PD than HD pts received a transfusion (11.7% versus 10.6%). Similarly, with censoring at 28 days post-modality change, a slightly higher percentage of PD pts received transfusions (10.8% versus 10.4%).



Conclusions: Transfusion rates for PD versus HD pts are sensitive to censoring criteria. Censoring at modality change attributes events to the subsequent modality, when, in fact, precipitating events may have begun under the prior modality. A short post-modality change window more appropriately allows attribution of these events, and suggests that transfusion rates in PD pts may be similar to or higher than in HD pts.

PUB642

Clinical and Physiologic Parameters in Silent "De Novo" Ascitis Developed in PD Patients Javier De Arteaga,[1,2] Fabian Ledesma.[1,2] *[1]Nephrology, Hospital Privado, Cordoba, Argentina; [2]Nephrology, Fundacion Nefrologica de Cordoba, Cordoba, Argentina.*

Background: Silent ascitis developed "de novo" on PD may sometimes be tricky to diagnose, turning physiologic parameters of importance: 4 pts from our historic PD cohort exhibited a sudden and unusually high UF despite a high transport state. Further studies confirmed a previous nondiagnosed hepatic disease. 2 pts entered PD with ascitis. **Objective** to compare fluid and solute transport parameters between cirrhotic-ascitic and non cirrhotic High Transport (HT) pts. **Patients:**We evaluated all of our HT patients (n = 18) followed since 2001. 6 pts are cirrhotic.

Methods: PETS, Minipets and lately UNIPETS are performed yearly and when required extra (UFF) filling an Adequest database.

Results: Cirrhotic (Gr 1) versus non cirrhotic(Gr 2) parameters. Demographic and clinical data.

	Gr1	Gr2	P
N	6	12	-
Age (ys)	58,17 ± 8,26	46,83 ± 15,74	0,12
HVC (+)	33.33 %	16 %	-
KTV (wk)	2,27 ± 0,82	1,90 ± 0,46	0,25
Prot loss in dialysate (gr/vol)	5,99 ± 2,58	9,79 ± 3,34	**0,036**
Serum alb.	3,11 ± 0.55	3,46 ± 0,49	**0.03**
Time PD (ms)	38,40 ± 23,51	25,08 ± 20,60	0,20
D/P Creat 4 hs	0,80 ± 0,03	0,84 ± 0,03	**0,03**
D/P Creat 1 hs	0,60 ± 0,05	0,59 ± 0,12	0.79
DNa T 0 (meq/lt)	131,33 ± 5,57	129,54 ± 2,23	0,33
DNa 60 min (meq/lt)	127,81 ± 5,50	124,54 ± 3,5	**0,14**
Plasma Na (meq/lt)	140 ± 2,86	137,61 ± 3,81	**0,10**
Sodium removal (NAR) 1 hs	75.59 ± 18.06	48,98 ± 27,63	**0.0012**
% FWT	16,83 ± 6,55	35,67 ± 21,24	**0.048**
UF 1 hs (ml)	645 ± 120,29	373,33 ± 172,56	**0,003**
UF 4 hs (ml)	950 ± 265,59	665 ± 139,62	0,089

Conclusions: Cirrhotics have a higher UF and sodium removal (P=0.02). According to a HT state, NA sieving is blunted in both groups (Na difussion correction not done) and this reflects a lower free water transport mostly for cirrhotics (p= 0.04). Daily loss of protein and serum albumin is higher in non cirrhotics (0.03). Sudden UF augmentation, NAR, hypoalbuminemia and lower FWT in HT pts, HVC (+), raises suspicion of "de novo" ascitis.

PUB643

The Association of Preservation Residual Renal Function and Left Ventricular Hypertrophy in Continuous Ambulatory Peritoneal Dialysis Damir Rebic,[1] Senija Rasic,[1] Mirjana Sabljar-Matovinovic.[2] *[1]Clinic for Nephrology, 1Univ Clinical Centre of Sarajevo, Sarajevo, Bosnia and Herzegowina; [2]School of Medicine, Zagreb, Croatia.*

Background: Cardiovascular disease is the leading cause of morbidity and mortality in end-stage renal disease (ESRD) patients on maintenance dialysis. Residual renal function (RRF) has been shown to influence survival of peritoneal dialysis (PD) patients. This study examined the relations between RRF and left ventricular hypertrophy (LVH) before switching on dialysis treatment and observed during 18 months on CAPD treatment.

Methods: A prospective longitudinal study was performed in 50 non-anuric (defined as >200 mL urine output in a 24-hour period) PD patients. Echocardiography, RRF, daily collection of urine and other known risk factors for LVH were determined at study baseline and end of follow-up.Adequacy of dialysis (K_r/V_{urea}) was calculated from weekly total removed urea mass by daily volume of dialysate and urine (K_r) and divided with urea distribution volume (V). RRF was estimated as the mean of renal creatinine clearance (mL/min).

Results: Baseline, in ESRD patients 75 % had LVH, while at the end of follow-up 68%. RRF at the start of the study showed no significant difference between patients with and without LVH, as well as indailycollectionof urine. After 18 months, patients without LVH had better RRF, lower CRP and better Kt/V compared to patients with LVH ($p < 0.001$). Patients with better-preserved RRF not only had significantly higher total Kt/V, but were less anemic and hypoproteinemic, lesser presence of LVH and had a trend towards normal blood pressure ($p<0.05$). Logistic regression analysis showed that the RRF is a negative independent risk factor for the development of LVH. Daily urine collection was independently associated with LVEDD and LA diameter.

Conclusions: This study demonstrated that RRF and LVH are interrelated; they combine adversely to enhance the cardiovascular risk of morbidity in PD patients. Preservation of RRF may result to reduce LVH, subsequently translating to decreased cardiac disease. CAPD in non-anuric ESRD patients the first 18 months has a positive effect on the preservation of RRF and partial regression of left ventricular remodeling.

PUB644

Under (Selective) Pressure: Atypical Mycobacterial Exit Site Infections Associated with Prophylactic Topical Antibiotic Use Bashir El-Khoury, Shubha Ananthakrishnan. *UC Davis Medical Center, Sacramento, CA.*

Background: Peritoneal dialysis is an effective means of renal replacement therapy for many patients with end stage renal disease. Use of prophylactic topical antibiotics at the exit site is often used to decrease peritoneal dialysis related infections. However, its widespread use may select out other less common pathogens. We present 3 cases of rapidly-growing atypical mycobacterial exit site infection (ESI) associated with use of prophylactic topical antibiotics.

Methods: Mr. P is a 52 yo M with DM, HTN, and ESRD on CCPD who presented with erythema and purulent drainage at his catheter exit site. Wound culture was + for AFB, patient started on clarithromycin 500 mg po BID and completed a 6-month course. Mrs. M is a 57 yo F with DM, HTN, and ESRD on CCPD who presented with the same complaints. Culture revealed rapidly growing Mycobacterium, and she was treated with

moxifloxacin 400 mg po QD, azithromycin 500 mg po QD, and linezolid 600 mg po BID for 4 months. Mrs. L is a 57 yo F with DM, HTN, and ESRD on CCPD who presented with similar complaints. Culture demonstrated 4+ AFB. Patient started on moxifloxacin 400 mg po daily and azithromycin 500 mg po daily, continued for total of two week course. All three wound cultures were further identified as Mycobacterium chelonae with clinical resolution and preservation of PD catheters in all cases after treatment.

Conclusions: ESI remains a major cause of morbidity in patients undergoing PD. The routine application of prophylactic topical antibiotics to PD catheter exit sites may select out rare atypical organisms that lead to clinical infection. Recently, there have been numerous reports of atypical mycobacterial ESIs in PD patients who had used gentamicin cream prophylaxis. Here we report a series of three cases associated with use of mupirocin cream. In all 3 cases, clinical resolution was noted and PD catheters could be preserved. There is no uniform guideline on the management of ESI caused by rapidly growing atypical mycobacterium. Early recognition and the development of a uniform treatment strategy may improve morbidity associated with rapidly growing atypical Mycobacterial ESIs.

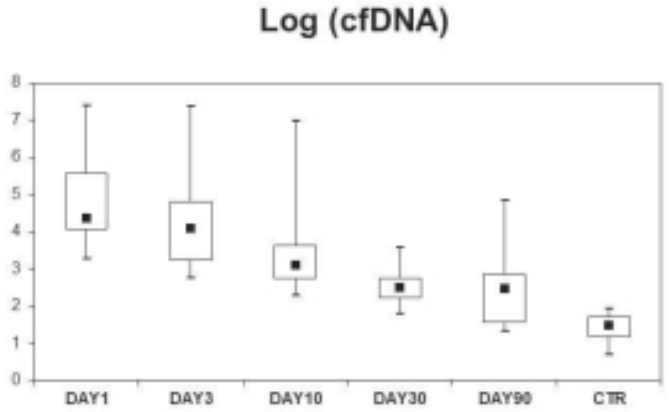
PUB645

Cell-free DNA: An Inverse Index of Peritoneal Membrane Repair Process after Peritonitis Sabrina Milan Manani, Grazia Maria Virzì, Alessandra Brocca, Massimo de Cal, Alessandra Dalla Costa, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology-IRRIV, S Bortolo Hosp, Italy.*

Background: In Peritoneal dialysis (PD), peritonitis cause loss of mesothelium. A better understanding of the molecular peritoneal injury may minimize cell damage. Cell-free DNA (cfDNA) is a circulating extracellular DNA and is released from cells as a consequence of inflammation, cell injury and death. There are no data on the role of cfDNA after peritonitis. The aim of this study was to evaluate cfDNA during peritonitis in PD patients and investigate the repair process of the membrane.

Methods: We enrolled 23 PD(14 M, mean age 68±16 yrs) with an acute peritonitis and without history of systemic inflammation. We collected peritoneal effluents at day1, day3, day10, day30 from the start of peritonitis for WBC counts and cfDNA evaluation. We enrolled 30 PD patients without any history of systemic inflammmation and peritonitis in the last 3 months (CTR). CfDNA was extracted from peritoneal effluents and quantified, in genome equivalents (GE)/ml, by Real time PCR for β-globin gene.

Results: A significant positive correlation was observed between cfDNA concentration and WBC at day1 (rho=.89) and day3 (rho=.5)(both, p<.05). No statistically significant correlation was observed between cfDNA levels and WBC at day10 and day30. Quantitative analysis of cfDNA showed significantly higher levels in PD patients with peritonitis compared with CTR at day1, day 3, day 10 and day30.



Conclusions: Our data suggest that cfDNA correlates with WBC at the beginning of peritonitis. Furthermore, cfDNA is increased in peritoneal effluent of PD patients with peritonitis during the first 30 days from the start of peritonitis progressively decreasing. cfDNA could potentially serve as a specific marker for noninvasive monitoring of tissue damage after peritonitis. cfDNA could be an inverse index of peritoneal membrane repair process.

PUB646

cfDNA in PD-Related Peritonitis: A Noninvasive Marker for Monitoring the Recovery Process of the Peritoneal Membrane Grazia Maria Virzì, Sabrina Milan Manani, Massimo de Cal, Alessandra Brocca, Sonia Berti, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco, Silvia Pastori. *Nephrology-IRRIV, St Bortolo.*

Background: Peritoneal dialysis (PD) is complicated by peritonitis that cause loss of mesothelium by cell death. Cell-free DNA (cfDNA) is clinically used as a diagnostic and prognostic marker of cell injury. cfDNA is present in the peritoneal effluent of stable PD patients (pts). The biological role and the levels of cfDNA in PD-related peritonitis have not been yet investigated. The aim of this study was to evaluate cfDNA trend in the peritoneal effluent in PD pts whit peritonitis from the first day and during follow up period.

Methods: We enrolled 23 PD pts whit diagnosis of peritonitis (14 male, mean age 68±16 years). We collected peritoneal effluent samples from the first day of peritonitis until the 120th day. CfDNA was extracted from all peritoneal effluents and was quantified by Real time PCR in Genome Equivalent (GE)/ml for β-globin gene. We enrolled also 30 PD pts without any history of systemic inflammmation and peritonitis in the last 3 months, as control group (cfDNA: 31 GE/ml; IQR:16-51).

Results: All 23 PD pts were treated and clinically recovered from peritonitis after 13.5 days±5.4. The median concentration of cfDNA in the peritoneal effluent at the first day of peritonitis was very high (25523 GE/ml; IQR 18831-459541); subsequently cfDNA level tends to progressively decrease during follow up period.

	1	2	3	4	5	10	15	20	25	30	60	90	120
1	100.0	27.1	12.7	7.4	4.8	1.3	0.6	0.4	0.2	0.2	0.0	0.0	0.0

From this decreasing curve, we estimated that serve 49days to reach the value of 51 GE/ml (75percentile in controls) and 63days to reach 31 GE/ml (median in controls).

Conclusions: Our data demonstrated that cfDNA is increased in peritoneal effluent of PD pts with acute peritonitis and decrease progressively. cfDNA in peritoneal effluent could be a potential good biomarker to monitoring the recovery process of the membrane in PD-related peritonitis.

PUB647

The Effects of Icodextrin on Metabolic Indices and Patient Survival in Non Diabetic CAPD Patients Jiyun Park, Yang Gyun Kim, Kyung-Hwan Jeong, Chun-Gyoo Ihm, Ju-Young Moon, Sang Ho Lee, Tae Won Lee. *Internal Medicine, Kyung Hee Univ School of Medicine, Seoul, Korea.*

Background: Icodextrin based peritoneal dialysis has shown favorable metabolic effects over conventional glucose based peritoneal dialysis in CAPD patients. However, no studies have been conducted only in non-diabetic CAPD patients on whether icodextrin based peritoneal dialysis improves metabolic control and survival.

Methods: We reviewed 84 cases of non-diabetic CAPD patients who were on CAPD for 3 years retrospectively. Sixty four were treated with conventional glucose based peritoneal dialysis (glucose group : mean age 54.5 ± 15.5years) and the other 20 were treated with 3 glucose based solutions during the day and 1 icodextrin dwell during the night (icodextrin group : mean age 57.0 ± 17.3 years). We measured variables related to lipid status, HbA1c, and left ventricular ejection fraction and compared all-cause mortality and cardiovascular mortality.

Results: There were no significant differences between age, gender, BMI, blood pressure, history of dyslipidemia, total cholesterol, LDL, HDL, triglyceride, HbA1c, and left ventricular ejection fraction of the two groups. Serum LDL (p<0.001) and HbA1c (p=0.005) improved in icodextrin group after 3 years but total cholesterol, HDL, triglyceride, and left ventricular ejection fraction of the groups were not different. Seven patients of glucose group developed non-insulin dependent diabetes mellitus during peritoneal dialysis (p=0.182). There were no significant differences in all-cause mortality rate (p=0.131) and cardiovascular mortality rate (p=0.290) between two groups.

Conclusions: These results provide that icodextrin improves metabolic indices in non-diabetic CAPD patients, which is similar to earlier findings. However, mortality rates were not significantly different between two groups and these results may be related to better glycemic control in non-diabetic patients. To confirm this data, large randomized prospective studies are needed.

PUB648

Take on Characteristics of Incident PD Patients in Poland, Romania, and Hungary at Integrated Care Clinics for Renal Services Belen Marron Ochoa,[1] Janusz Ostrowski,[4] Delia Timofte,[2] Marietta Torok,[3] Jose C. Divino-Filho.[1] *[1]Home Therapies Medical Office, Diaverum, Munich, Germany; [2]Diaverum, Bucharest, Romania; [3]Diaverum, Budapest, Hungary; [4]Diaverum, Wloclawek, Poland.*

Background: Our institution as a Renal Service provider is committed to integrated care, offering all types of RRT and focusing in patient´s choice. **Objectives:** To analyze HD and PD take on and its relationship with the type of previous referral and provided care.

Methods: Retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD Diaverum clinics in 2012. Early referral (ER) considered if patient known ≥ 3 months in Nephrology, and scheduled initiation of dialysis with a permanent access was considered planned (P).

Results: Population: 30% diabetes, mean age 64 years, 84% with previous medical care of renal disease, 49 % late referral, 80% modality informed, 58 % unplanned start, 11% PD (3% early switch from urgent HD). PD therapy in non-planned start applied in 5/59 PD patients. No differences in HD/PD take on were observed for gender, diabetes, initial renal and predialysis follow up, at structured units or in elapsed time between early follow up and dialysis start. PD patients (p=0.02) received more modality information than HD (92% versus 78%) and were mainly under 50 years (p <0.001). PD incidence varied according with different studied groups.

Studied group	All patients (N=547)	HD (N=488)	PD (N=59)	p value
ER + P	168 (31)	132 (27)	35 (59)	<0,001
Late referral + P	63 (12)	58 (12)	5 (9)	
ER + Unplanned start	113 (20)	104 (21)	9 (15)	
Late referral + Unplanned start	203 (37)	193 (40)	10 (17)	
Optimal care: ER + modality informed + P	121 (22)	96 (20)	25 (42)	

Conclusions: Despite commitment to offer PD/HD as complementary treatments, PD incidence is still low. Optimal care provision is important to improve outcomes but also to involve patients in their therapy choice.

PUB649

Risk Factors for Death From Peritonitis in Hospitalized Peritoneal Dialysis Patients From the USRDS Noble Iwuagwu,[1] Irene Nicolette Falk,[1] Rhonda E. Colombo,[1] Stephanie L. Baer,[1,2] Lulu Huber,[1] Mufaddal F. Kheda,[1] Thomas Ryan Gallaher,[1] Jordan T. Powner,[1,2] N. Stanley Nahman,[1,2] Kristina Weis Kintziger.[1] *[1]Dept of Medicine, Georgia Regents Univ, Augusta, GA; [2]Dept of Medicine, Charlie Norwood VAMC, Augusta, GA.*

Background: Peritonitis (PTN) in peritoneal dialysis (PD) patients with septic symptoms or severe abdominal pain may be admitted for management. We have shown that PTN in PD in-patients is associated with DM, bacteremia (BAC) and MRSA infection (J Invest Med 62:554, 2014). In the present work we queried the United States Renal Data System (USRDS) to assess risk factors for mortality in PD patients hospitalized for PTN.

Methods: All incident PD cases from the years 2005-2008 were included and defined according to dialysis modality on the most recent form 2728. PTN and all comorbidities were defined by ICD9 diagnosis codes. Only PD at PTN diagnosis was included in this study. Survival analysis was performed using Cox regression.

Results: There were 24,522 patients and PTN occurred in 3575 (14.6%). Demographics: 54% male, 72% Caucasian and 64% < 65 yr. 27.9% of patients on PD died (39.4% of PTN, 25.9% of non-PTN). Co-variates conferring the greatest risk of death (hazard ratio (HR), 95% confidence intervals (CI)) included decubitus ulcer (HR 3.74, CI 3.41, 4.09) and age > 65 years (HR 3.36, CI 3.20, 3.52). Those with HR > 2.0: cirrhosis, BAC, PVD, endocarditis, C. difficile colitis, BAC with SIRS, candidemia, and pancytopenia. DM and MRSA infection showed HR of 1.76 and 1.79, respectively. The most common covariates with significant HR for death included age > 65 years (N=8,679, 35.4%), DM (N=7,550, 30.8%), PTN, BAC (N=2,197, 9.0%), PVD (N=1,993, 8.1%), and BAC w/SIRS (N=1,788, 7.3%).

Conclusions: PTN leading to a hospital admission occurred in nearly 15% of incident PD patients. Older age, DM and infectious complications are common morbidities with an increased risk of death. Less common conditions also confer an increased risk of death, but we would speculate they may represent surrogate markers for disease severity. Aggressive treatment of PTN in older diabetics, with any suggestion of systemic infectious complications, is supported by this study.

The Role of Peritoneal Dialysis in Acute on Chronic Liver Failure Maria Jimena Mucino-Bermejo, Renhua Lu, Carla Estremadoyro, Sara Samoni, Aashish Sharma, Carlo Crepaldi, Claudio Ronco. *IRRIV Vicenza, Vicenza.*

Background: The ability of peritoneal dialysis to achieve ultrafiltration and middle-molecular weight solute clearance at low haemodynamic cost makes it an attractive therapy in situations of hemodinamyc instability, needance of multiple high flux intravenous devices, or hemorrhagic diathesis, allof them may be present on cirrhotic patients.

Methods: Review of current literature: 100 articles; 55 reviews, 32 case reports, 1 experimental study and 12 case series.

Results: In cirrhotics AKI is related to circulatory disturbances that include diminished peripheral vascular resistances because of splachnic vasodilation triggered by portal hypertension and increased endogenous vasodilators. Also there is vasoconstriction via the renin-angiotensin-aldosterone axis, sympathetic nervous system activation and arginine hypersecretion. Dilutional hyponatremia, ascites and hepatorenal syndrome are manifestations of the same pathogenic axis. A second renal injury can trigger AKI, the fifth leading cause of hospitalization and the third leading cause of ICU admission among cirrotics. In patients with liver and renal failure, PD represents a reasonable treatment since it avoids anticoagulation, allows removal of ammonia, bilirubin, and free fatty acids, and even allows for partial and progressive draining of the ascitic fluid. Its use has been limited because of fear of excessive bleeding during catheter placement, inadequate ultrafiltration, removal of solutes in the presence of ascites, increased risk of bacterial peritonitis and hypoalbuminaemia. Peritoneal dialysis has been described to be a safe and efficient treatment in hepatorenal syndrome type 1, refractory ascites due to portal hypertension in autosomal dominant polycystic kidney disease, and as renal replacement therapy in end-stage renal disease patients with chronic liver disease and ascites. Reported benefits include amelioration of quality of life, diminished hospitalization days and increase in hemoglobin, total serum protein and albumin levels.

Conclusions: On cirrhotic patients, PD may be a reasonable treatment option in some clinical setting. Randomized large clinical studies are still needed to asses its safety and efficacy.

PUB651

Proteomic Analysis of Peritoneal Fluid of Patients Treated with Continuous Ambulatory Peritoneal Dialysis and Automated Peritoneal Dialysis Magdalena Luczak,[1] Lukasz Marczak,[1] Dorota Formanowicz,[2] Elzbieta Pawliczak,[2] Lidia Koziol,[2] Maria Wanic-Kossowska.[2] *[1]Polish Academy of Science, Poznan, Poland; [2]Poznan Univ of Medical Sciences, Poznan, Poland.*

Background: Long-term peritoneal dialysis (PD) is associated with progression of peritoneal fibrosis and lead to functional deterioration of the peritoneum. The development of new prognostic biomarkers assessing changes in peritoneum during long-term PD seems to be essential. The major goal of this study was proteomic analysis of peritoneal fluid (PF) in order to identify of differential proteins between CAPD and APD dialysate. Additionally, we sought to determine whether there are any protein biomarkers characteristic for patients treated for a longer time with CAPD.

Methods: Our studies involved patients treated with APD (11 cases) and CAPD (21 cases) - cured with distinct period of time, ie. for 24 and 48 months. Label-free proteomic approach using LC-MS/MS to analysis of PF proteome was used. Qualitative and quantitative differences in the accumulation of the individual proteins were determined.

Results: As a result, PF proteomes of CAPD and APD patients were demonstrated. 235 (CAPD) and 198 (APD) unique proteins were identified. Quantitative differences in accumulation of albumin, lysozyme C, antithrombin-III, apolipoprotein III, chondroadherin-like protein, Ras-GEF protein, transcription initiation factor, apolipoprotein A-IV, AI and hemopexin were detected. Increased accumulation of transthyretin, apolipoprotein CIII, peroxidasin homolog, beta-2-glycoprotein 1, kininogen 1, basigin and serotransferrin were revealed in CAPD patients treated for 48 months. Interestingly PCA test revealed that this group of patients clearly differed from CAPD (24 months) and also APD patients. Moreover, also PCA indicated that these differences were not related with an inflammatory process (CRP level).

Conclusions: Obtained data indicate that treatment modality (CAPD versus APD) and treatment period strongly influence on PF proteome. Increased kininogen level may indicate the enhanced neoangiogenesis process in CAPD patients with longer treatment time. Identified proteins may serve as potential markers of PD modality and represent potential therapeutic targets.

PUB652

Peritoneal Dialysis Patients Preserve Residual Renal Function and Reduce Oxidative Stress during the Initial Period of Dialysis Therapy Atsushi Ueda,[1] Kei Nagai,[3] Aki Hirayama,[2] Chie Saito,[3] Kunihiro Yamagata.[3] *[1]Nephrology, Hitachi General Hospital, Hitachi, Japan; [2]Integrated Medicine, Tsukuba Univ of Technology, Tsukuba, Japan; [3]Nephrology, Univ of Tsukuba, Tsukuba, Japan.*

Background: In 2012 ASN meeting, we reported the dialysis patients with preserved the residual renal function (RRF) showed lower oxidative stress at 24 months after the initiation of renal replacement therapy (RRT). However, the modification of oxidative stress remains unclear. To answer this issue, we investigated the changes of RRF and oxidative stress markers of hemodialysis (HD) and peritoneal dialysis (PD) patients.

Methods: We employed retrospectively 54 HD and 23 PD patients. HD patients treated regularly 4 to 5 hours and 3/week. PD patients treated 4 bag changes a day or automated PD

with low glucose dialysate. Daily urinary volume, serum asymmmetric dimethylarginine (ADMA), pentosidine and indoxyl sulfulic acid (IS) as oxidative stress markers from the start of RRT until 36 months in every 6 month (0, 6, 12, 18, 24, 30, 36 months) were measured. And survival rate were examined.

Results: Urinary volume at the start of RRT in HD group was 974±499 mL/day, and decreased rapidly from 6 months (598±442) to 36 months (250±667). In PD group, urinary volume at the start of RRT was 1424±579mL/day and decreased at 12 months (961±523), however, maintained till 36 months (1173±629). Urinary volume in PD group was larger than that in HD group at every observed point. ADMA level in PD group at 0, 6 and 12 month were decreased significantly compared to HD group. Pentosidine level in HD group was increased gradually from the start of RRT (0.22±0.09μg/mL) until 36 months (0.45±0.19), and was continuously higher than that of PD patients during the whole observation period. IS level in PD group was also declined at 6 and 12 months significantly. However, there was no difference in survival rate between HD and PD groups.

Conclusions: Our study demonstrated that PD patients showed an advantage to preserve RRF and to reduce the oxidative stress in the initial period of RRT, howeverfor the small number of cases this could not revealed the beneficial effect for the prognosis,but may expect to have a good prognosis.

PUB653

Dialysis Quality Analysis of Single-Center Peritoneal Dialysis Patients

Tu Qiudi, Qiang He, Yueming Liu. *Nephrology, Zhejiang Provincial People's Hospital, Hangzhou, Zhejiang, China.*

Background: Analyze the data of all peritoneal dialysis (PD) patients in a single PD center and search for the counter measures of continuous quality improvement.

Methods: All 113 patients undergoing PD were retrospectively studied from 1st January 2007 to 31th December 2012. We investigated causes of PD withdrawal and death, analyzed demographic characteristics, laboratory data according to their medical record. Incidence of peritonitis, drop out rate (DOR) and length of the time of PD therapy (TOT) were calculated.

Results: Total of 113 patients were enrolled, 12 patients have died. The causes of death were cancer (1 Patient), pulmonary infection (2 patients), cerebrovascular disease (1 patient), cardiovascular disease (1 patient) and other reasons (4 patients). 16 patients were transfered to hemodialysis, and peritonitis (7 patients) and volume overload (6 patients) were two main reasons. There were 22 episodes of peritoitis among 10 patients in 2012. The major cause was non-standard operating (13 episodes in 6 patients). TOT and DOR were 19.59m and 23.61% respectively. There are 71 patients still been followed, include 41 men and 24 women. In these patients, 27.6% had dissatisfied KT/V(<1.7), 31.3% had a hemoglobin blood-level lower than 90g/L, 25.3% had an albumin blood-level lower than 30g/L, 59.7% were hyperphosphatemia (P>1.45mmol/L), and 45.2% PTH concentrations>300 pg/ml.

Conclusions: In our PD center, causes of death were various. PD associated infection was the first reason for transfering to hemodialysis. DOR is related to many factors, including age structure, education and so on, many aspects remain to be researched and improved in our center.

PUB654

Percutaneous and Conventional Surgical Insertion of Peritoneal Dialysis Catheter: A Comparative Study of Outcome and Technique Survival

Raj K. Sharma, Narayan Prasad, Amit Gupta, Anupama Kaul. *Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, UP, India.*

Background: The study was planned to compare the outcome of percutaneous peritoneal dialysis catheter placement which can be performed by the Nephrologists at bed side and permits rapid initiation of CAPD. We prospectively compared 230 percutaneous insertions and 1200 surgical dissection PD catheter insertions for technique survival and immediate and delayed complications.

Methods: The mean age of the patients was 48.75+16.8 years (3-74 yrs), Male:Female 70: 20. There were more diabetic patients in percutanoeus group 79% versus 40% than in surgical group. Mean break in period was 13.39+4.38 days (1 to 21 days). In percutaneous group peritoneal dialysis was started with in 24 hrs of insertion. Immediate surgical complications were similar in both group except slightly more outflow problems (6.45%) and hemorrhagic outflow (45.2%) in surgical group as compared to percutaneous (2%) and (5.5%).

Results: Exit site and peritonitis rates were similar in both groups. Technique survival was also similar in the two group. There was slightly increased incidence of surgical complications and early catheter failure in surgical insertion as compared to the percutaneous insertion of PD catheter.

Conclusions: Catheter removal was higher in surgical group (46.4%) as compared to percutaneous group (15%) ($p<0.001$). 1 and 2 yr catheter survival was 90% and 80% in percutaneous gr versus 85% and 70% in surgical group. Nephroligsts can safely practice the percutaneous split sheath (guide wire) technique for catheter insertion with similar outcomes like surgical insertion of PD catheter.

PUB655

Comparative Incidence of Peritonitis Between Peritoneal Dialysis Patients Receiving Icodextrin versus Dextrose Based Solutions

Ramanath B. Dukkipati, Anuja P. Shah. *Medicine, Harbor-UCLA Medical Center, Torrance, CA.*

Background: Patients who receive Icodextrin based peritoneal dialysis (PD) solutions may be a high-risk group susceptible to peritonitis. A significant proportion of these patients may have been switched to Icodextrin after they have had peritonitis, which rendered them susceptible to be high transporters or to ultra filtration failure.

Methods: We conducted retrospective analyses among 86 prevalent PD patients originating from one dialysis center during January 2013 to May 2014. We first examined the number of patients who are receiving Icodextrin and evaluated the number of episodes of peritonitis and compared them with the number of episodes of peritonitis in patients who are receiving Dextrose based PD solutions. We then examined associations between various demographic data and type of PD solution using logistic regression adjusted for case-mix and laboratory covariates.

Results: There were 86 PD patients out of which 16 were on Icodextrin and 70 patients were on Dextrose based PD solutions. Patients were receiving Icodextrin for at least 6 months. There were 7 episodes of peritonitis in Icodextrin group and 44 episodes in Dextrose based PD solutions group. There were 2 episodes of fungal peritonitis in the Icodextrin group and none in the Dextrose based group. There was 1 patient in the Dextrose group who had 2 episodes. There was no statistical difference in peritonitis between Icodextrin group versus Dextrose based group.

Conclusions: In PD patients there was no statistically significant difference in incidence of peritonitis and the type of PD solution used. The difference in incidence of fungal peritonitis did not achieve statistical significance. There was no correlation between the number of vintage months on PD and incidence of peritonitis.

PUB656

The Analysis of Outcome and the Risk Factors for Mortality in Peritoneal Dialysis Patients

Nanmei Liu. *Dept of Nephrology, Jimin Hospital of Shanghai, Shanghai, China.*

Background: To analyze the outcome and the risk factors for mortality in peritoneal dialysis (PD) patients in a single peritoneal dialysis center in a period of 27 years, and to discuss the approaches to obtain a better prognosis.

Methods: We retrospectively analyzed patients on PD for more than one month during the period from January 1985 to December 2011 in this hospital. We collected and analyzed their outcomes, and the causes of dropout from PD, demographic characteristics, laboratory data, dialysis, residual renal function, peritoneal transport characteristics, and nutritional status.

Results: A total of 841 patients were enrolled, of whom 431 were females (51.2%). The mean age was 58.53± 16.67 years. The primary diseases were glomerulonephritis (52.3%), hypertension (16.6%), and diabetes (15.3%). The mean peritoneal dialysis duration was 18.63 ± 20.35 months. Up to December 2011, the patients remained on PD in 246 cases (29.2%), died in 296 cases (35.2%), changed to hemodialysis in 152 cases (18.1%), treated with kidney transplant in 64 cases (7.6%), and lost for follow-up in 83 cases (9.9%). The main cause of death was cardiovascular events (41.6%), followed by infection (33.0%) and the cerebral vascular accident (9.5%). The major reason (59.2%) changing from PD to hemodialysis was the PD associated infection. Cox proportional hazards model analysis indicated that the risk factors for mortality were age, diabetes, change of hemodialysis to PD, low serum albumin leve, high C-reaction protein, low creatinine clearance rate and high peritoneal transport status.

Conclusions: In our peritoneal dialysis center, the major cause of dropout from PD was death, followed by the change to hemodialysis. Cardiovascular events was the most important cause of death, and PD-associated infection was the major reason for the change from PD to hemodialysis. Older age, diabetes, malnutrition, inflammation, insufficient peritoneal dialysis, high peritoneal transport status and change of dialysis from hemodialysis to PD predict the higher risk for all cause-death.

Funding: Government Support - Non-U.S.

Salvage of Accidentally Sectioned Peritoneal Dialysis Catheters: Single Center Experience

Arzu Velioglu, Ebru Asicioglu, Derya Guler, Gurdal Birdal, Izzet Hakki Arikan, Serhan Tuglular, Cetin Ozener. *Nephrolgy, Marmara Univ, School of Medicine, Istanbul, Turkey.*

Background: In clinical practice, the accidental cutting of the peritoneal catheters is seen in peritoneal dialysis (PD) units. Although mechanical problems of the PD catheter remain a significant cause of removal of the catheter, several salvaging methods have been also introduced. With the following study, we present our experience on accidentally cut peritoneal dialysis catheters.

Methods: Accidentally sectioned catheters were salvaged using a new transfer set. The catheter was clamped with tweezers under sterile condition. The indwelling catheter was transected with sterile scissors below the cut. A new transfer set was inserted into the catheter. To prevent peritonitis, prophylactic antibiotics were administrated for at least three days. Outcome was measured by the successful return to PD and prevention of peritonitis.

Results: Between 1994 and 2014,a total of 551 peritoneal dialysis patients are followed. Eighteen of them were admitted to the hospital due to a cut of the catheter with leakage of dialysis fluid (mean age: 48.15±16.7; range [21-82 years]; F/M: 14/6; range PD time

[1-125 months]. All of the patients had accidentally cut the catheter with scissors while they were applying the dressing to the exit site. Five of the catheters were totally cut while the others were partially. All of the sectioned catheters were cut minimally 3 cm above the exit site. A salvage method was used in all of these patients. All patients resumed PD in 24 hours. Two patients presented with culture negative peritonitis after the procedure. Both were treated successfully with intraperitoneal antibiotics.

Conclusions: The salvaging of accidentally sectioned PD catheters is a safe and effective method. Nephrologists should be eager and enthusiastic for salvaging of the catheter in this setting.

PUB658

Bioimpedance Spectroscopy before and after Introducing a Daily NUTRINEAL ® Exchange in Peritoneal Dialysis Mario Prieto Velasco1, Benjamin De Leon Gomez, Jose Edgardo Gonzalez Arregoces, Elena Astudillo, Igor Romaniouk Jakovler, Jorge Estifan Kasabji, Aranzazu Sastre, Cristina Lucas. *Nephrology, Complejo Asistencial Univ León, León, Spain.*

Background: To compare the nutrition and hydration status of a group of CAPD patients before and after the introduction of one Nutrineal ® Baxter (PD4 1.1% amino acids) bag in daily exchanges.

Methods: we obtained parameters of body composition and hydration using the BCM ® (Body Composition Monitor, Fresenius Medical Care, Bad Homburg, Germany) before and 6 months after the introduction of Nutrineal in one daily peritoneal exchange. t -student test for comparison of means was performed. Values were calculated as the mean of three consecutives monthly measures.

Results: 16 CAPD patients with an average age of 66.41 years, 56.25% men. The difference in the various parameters before and after the introduction of Nutrineal are shown in the figure 1

Conclusions: Following the introduction of Nutrineal in patients on CAPD, we have not observed any significant difference in body composition or hydration status analyzed by BIA.

PUB659

Preserved Effectiveness of Potassium-Sparing Diuretics in Peritoneal Dialysis Patients to Maintain Normal Serum Potassium Jamie Davidson,[1] Lindsey Norris,[1] Divya Monga,[1] Zsolt Lengvarszky,[2] Mihaly B. Tapolyai,[3] Tibor Fulop.[1] *[1]Nephrology, Univ of Mississippi Medical Center, Jackson, MS; [2]Mathematics, Louisiana State Univ, Shreveport, LA; [3]Dialysis, Semmelweis Univ, Budapest, Hungary.*

Background: Hypokalemia is a vexing problem in end-stage renal disease patients on peritoneal dialysis (PD) and oral potassium supplements (OPS) have limited palatability. Potassium-sparing diuretics (KSD) [spironolactone, amiloride] may have a preserved effectiveness in these subjects.

Methods: We have performed a cross-sectional review of 29 prevalent (vintage >3 months) PD patients with regard to serum potassium (K+), OPS and KSD utilization. We reviewed chart for multiple clinical and laboratory variable, including dialysis adequacy and co-existing medical therapy. Data analysis was performed with SPSS v19. Results were expressed with percent (%) and means (SD).

Results: The cohort was middle-aged: 46.2 (13.9) years and overweight: BMI 28.3 (8.4) kg/m2; 69% female, 79% African-American and 38% diabetic with PD vintage 28 (8.4) months. Weekly Kt/V was 2.14(0.49), creatinine clearance 68.3 (28.5) L/week with total exchanged volume 10.4 (2.8) L. Residual urine output (RUO) measured 453 (525) mL. Three-month average serum K+ measured 3.9 (0.5) mEq/L and 48% of participants was taking K+-supplements (mean dose of K+: 22 (10) mEq/day) and 72% taking KSD (spironolactone dose: 25-200 mg/day; amiloride dose: 5-10 mg/day). Potassium correlated significantly with weekly Kt/V (p=0.03), creatinine clearance (p=0.05) but not with PD modality/vintage, RUO or KSD use. However, PSD use was associated with decrease use of OPS (r: -0.639; p<0.001).

Conclusions: KSD was tolerated in this cohort of PD patients and decreased the need for OPS utilization.

PUB660

Successfull Treatment of *Acinetobacter baumannii* Peritonitis Necmi Eren, Mehmet Tuncay, Sibel Bek, Mustafa Tosun, Betul Kalender, Itir Yegenaga. *Nephrology, Kocaeli Univ, Faculty of Medicine, Kocaeli, Turkey.*

Background: Peritonitis is the major complication in peritoneal dialysis (PD) patients with the risk of technique failure. *Acinetobacter* species are rare gram negative agents of usually nosocomial origin and have remarkable risk of catheter loss in PD patients. Here we present two PD patients with *Acinetobacter baumannii* (*A. baumannii)* peritonitis successfully treated with antibiotics.

Methods: Case 1: A 49-year-old woman on PD for 60 months was admitted to our hospital with acute abdominal pain and cloudy dialysate. She was hypertensive and had an abdominal surgery for gastric cancer 6 weeks ago. Physical examination was unremarkable other than diffuse abdominal tenderness. Her effluent white cell count was 226/mm^3 with 78% neutrophils. Empirical intraperitoneal (IP) cefazolin and gentamicin was started. On the 3rd day, *A. baumannii* sensitive to gentamicin and resistant to carbapenems was identified in effluent culture. Then cefazolin was stopped. Catheter exit-site and blood cultures were negative. On the 4th day of gentamicin treatment, dialysate leukocyte count was less than 100/mm^3 and treatment was continued for 3 weeks. **Case 2:** A 70 year old woman on PD for 72 months admitted to our hospital with abdominal pain, nausea and cloudy dialysate of one day. Physical examination was normal except abdominal tenderness. Effluent leukocyte count was too many to count. Empirical IP cefazolin and gentamicin was started. On the 3rd day dialysate culture revealed *A. baumannii* sensitive to gentamicin and carbapenems and thus we stopped cefazolin. Catheter exit-site and blood cultures were negative. On the 5th day of gentamicin treatment due to persistence of cloudiness in effluent we replaced gentamicin with intravenous meropenem. On the 3rd day of meropenem treatment, the dialysate leukocyte count was less than 100/mm^3. The patient was discharged after 3 weeks of treatment.

Conclusions: Acinetobacter peritonitis is a rare condition, *A. baumannii* is the cause in nearly 90% of the cases with high potential of antibiotic resistance. Our cases demonstrate that the importance of *A. baumannii* in not only nosocomial but also community-acquired infections.

PUB661

Serum Biomarkes of Mineral Metabolism and Peritoneal Dialisys Modalities: Automated versus Continous Ambulatory Rafael Weissheimer, Fellype C. Barreto, Roberto Pecoits-Filho, Daniela Veit Barreto. *School of Medicine, Pontifícia Univ Católica do Paraná (PUCPR), Curitiba, Parana, Brazil.*

Background: Mortality rates in ESRD are unacceptably high. Disorders of mineral metabolism (hyperphosphatemia, hypercalcemia, and secondary hyperparathyroidism) are potentially modifiable. To evaluate the effect of peritoneal dialysis (PD) modalities, APD versus CAPD, over serum alkaline phosphate (AP), calcium (Ca) and phosphate (P) in incident adult patients over one year.

Methods: analysis of a multicenter prospective observational study. Patient who had three first and last months, P, Ca and AP measurements and had been treated exclusively by APD or CAPD during follow-up were included. T-student test, Fisher´s exact or Qui-square test were used for comparisons. ANOVA models were used to evaluate differences between repeated measurements. ANCOVA models were used to evaluate change over time (end-of-study versus baseline) for each parameter, adjusted for previous hemodialysis, baseline serum creatinine, diabetes, BMI, gender and age.

Results: 237 APD versus 228 CAPD patients were evaluated. APD patients were older (61.5±15.6 versus 57.8±149y, p=0.009), had higher baseline creatinine (7.1±3.9 versus 6.3±3.8mg/dL, p=0.027) and were less likely to have had previous hemodialysis (38.8% versus 50.4%, p=0.027). Baseline and end-of-study phosphate was significantly higher in APD patients (5.10±1.28 versus 4.86±1.20, p=0.04 and 5.10±1.53 versus 4.62±1.16mg/dL, p<0.001). Moreover, P reduced significantly over time in CAPD, but not in APD patients (-0.238±1.20 versus 0.004±1.40, p=0.01). Ca was significantly higher but there were no changes over time (0.08±0.87 versus 0.07±0.81, p=0.81). AP did not change over time (-2.15±91.3 versus 4.18±89.5, p=0.83).

Conclusions: It seems that the peritoneal dialysis modalities interferes in control of the match. Randomized controlled studies are needed to better ratings and causality with these outcomes. PD modality seems to have an effect on p levels in incident patients. Further studies warranted to evaluate if the worse P control in APD is associated with negative outcomes.

PUB662

Intraperitoneal Vancomycin Induced Liver Injury Fahad Y. Edrees, Robert Mark Black. *Internal Medicine, Saint Vincent Hospital, Worcester, MA.*

Background: With its efficacious, infrequent dosing and safety profile, intraperitoneal vancomycin (IPV) has long been used to treat peritonitis in peritoneal dialysis patients. Liver toxicity has been reported via intravenous (IV) and oral (PO) routes; however, IPV-associated toxicity has not been reported. We describe a case of IPV-induced liver injury in a patient with peritonitis.

Methods: A 29-year old man with a history of ESRD on peritoneal dialysis, psoriasis, hypertension and hypothyroidism was admitted with one day of abdominal pain, fever, nausea and vomiting. Home medications were limited to levothyroxine, omeprazole,

amlodipine, valsartan, procrit and sevelamer. Initial examination showed a pulse of 120 b/m, BP 124/86 mmHg, and temperature of 98.3°F. Abdominal examination revealed diffuse tenderness, voluntary guarding and sluggish bowel sounds. The remainder of the examination was unremarkable. Significant initial work-up showed a WBC of 20.2 μ/l with 88% neutrophils, BUN 43 mg/dl, creatinine 11.8 mg/dl, and a normal lactate level. The peritoneal fluid was cloudy in appearance and showed 3403 WBC/μl with 85% neutrophils. He was diagnosed with peritonitis and started on 2g IPV once weekly. The pre-treatment levels of ALT/AST were normal; during and post- levels are shown below, along with levels in two similar episodes of peritonitis 1 and 3 years ago.

	1st episode		2nd episode		3rd episode	
	during Rx	after stopping	during Rx	after stopping	during Rx	after stopping
ALT	72	21	133	29	83	35
AST	37	25	62	24	35	23

Conclusions: IV, oral and IP administration of vancomycin have been used. Liver injury has been reported with IV and oral administrations; however, we did not find any published reports of liver injury with IPV. In our case the liver injury was most likely due to vancomycin because there were no other identifiable causes. Furthermore, we observed similar patterns of liver enzyme elevations with institution and discontinuation of vancomycin on three separate occasions. Use of the Naranjo probability score indicated that it was a probable adverse drug associated event. To our knowledge this is the first reported case of IPV-induced liver injury.

PUB663

Providing Care to Peritoneal Dialysis Patients within an Existing Day Care Center Program Ying Ying Terina Seow, Zhenli Yu, Lee Ying Yeoh. *Gen Med, Khoo Teck Puat Hospital, Singapore, Singapore.*

Background: Lack of expertise and knowledge is a major barrier for accepting peritoneal dialysis (PD) patients into an established day care center program. This project was conducted to explore how to empower a day care center to care for PD patients.

Methods: PD patients were referred by different sectors of healthcare professionals. Care staff from St Luke's Eldercare (SLEC) were trained to assist with PD exchanges and adapt the existing rehabilitation program for PD patients. Outcome measures included patient length of stay, peritonitis rate; change of quality of life (SF-12) and depression score (HADS-D) over time; as well ascare center staff knowledge and confidence caring for PD patients.

Results: A total of 64patients were referred, out of which 16 were enrolled. Inclusion criteria included age over 50, no infectious diseases with rehabilitation potential.Participant median age was 66.0 (range 54-85) and 37.5% were in wheelchairs.Median length of stay was 44.5 days (range 1-194). There were no peritonitis episodes while patients were enrolled in the program. Physical functioning was maintained though not improved. Depression scores improved within first few months and then remained relatively stable. Sixprocesses were implemented in the centers: standard operating procedures for PD-related tasks, training manual, problem-solving guide, infection control instructions, staff competency and certification, and emergency contact person. Although initially anxious, care staff built up knowledge and confidence caring for PD patients. A simplified referral process was vital to expedite the use of day care services.

Conclusions: Utilizing a day care service for elderly PD patients is safe and can maintain patients' functionality, improve mental status and alleviate depression.A structured training program is required to build care staff knowledge and confidence.

Elevated Soluble Receptor for Advanced Glycation End Products (sRAGE) Level Is Associated with Indicators of Inflammation and Malnutrition in Peritoneal Dialysis Patients Hui Peng, Tang Li, Yan-Ru Chen, Jun Zhang, Xun Liu, Cailian Cheng, Tan-Qi Lou. *Nephrology Div, Dept of Medicine, the Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: The advanced glycation end-products (AGE) and receptors for AGE (RAGE) interaction may contribute to the inflammatory. It is already known that soluble RAGE (sRAGE) is the inhibitor of AGE-RAGE interaction and it is considered as a protect marker of coronary artery disease, hypertension, metabolic syndrome, arthritis, amongst others. Some studies have showed sRAGE is elevated in the circulation of peritoneal dialysis patients, which correlates with the concentration of sRAGE in spent peritoneal dialysate solution. We conduct this study to investigate whether the level of sRAGE in spent dialysate of PD patients predicts inflammation of PD patients.

Methods: Forty one patients undergoing continual ambulatory peritoneal dialysis (CAPD) from the peritoneal dialysis center of the Third Affiliated Hospital of Sun Yat-sen University were enrolled in the cross-section observational study. sRAGE level in spent dialysate was assessed by enzyme-linked immunosorbent assay(ELISA). Plasma fibrinogen, CRP, Zinc and Cu as the indicators of malnutrition and systemic inflammation were measured as well as other clinical biochemistry parameters.

Results: we found sRAGE level in spent dialysate was inversely correlated with serum hemoglobin (r=-0.320, p=0.042), serum albumin (r=-0.313, p=0.047), serum zinc (r=-0.385, p=0.014) and plasma fibrinogen (r=-0.521, p=0.015). sRAGE showed positive relationship with Cu/Zn ratio(r=0.341, p=0.031). However, we did not found there was correlation between sRAGE and serum CRP.

Conclusions: Our finding shows that sRAGE level in spent dialysate inversely correlates with indicators of malnutrition and inflammation, which suggests that it might become a potential predictor of malnutrition and inflammation state of PD patients.

PUB665

Late Peritoneo-Scrotal Leak in Type 1 Diabetic Patient: A Case Report Katarzyna Madziarska, Jan Penar, Slawomir C. Zmonarski, Maria Magott, Magdalena Krajewska, Hanna Bartosik, Tomasz Golebiowski, Miroslaw Banasik, Maciej Szymczak, Krzysztof Letachowicz, Marian Klinger. *Nephrology and Transplantation Medicine, Medical Univ, Wroclaw, Poland.*

Background: Dialysate leakage represents a major noninfectious complication of peritoneal dialysis (PD) and occurs between 5-10% of PD patients (pts). Early leaks occur within 30 days, late leaks up-to first year. Treatment includes surgical repair, transfer to hemodialysis (HD), low PD dialysate volume or cycled-PD.

Methods: Case Report A 53-year old diabetic patient type 1; 36 years of diabetes; cigarettes smoker and active businessman, was accepted for PD in 2013. He had been under the care of our center since 1990 due to diabetic kidney disease. The Tenckhoff catheter was implanted with laparoscopy in Oct-2013 when urea reached 123 mg/dL, eGFR 12 ml/min. CAPD was started in Jan-2014 using four 2L dwells daily;3x1.5% Glucose, 1xExtraneal at night. He was stable and active for 2,5 months with well-controlled blood pressure, HbA1c 7%, satisfactory peritoneal Kt/V and no peripheral edema. In March 2014, 7 days before admission, he noticed slowly progressing bilateral, painless swelling of scrotum and penis with no signs of inflammation but causing walking problems. Initially he didn't attribute edema to PD. He linked edema with PD after sudden dramatic drop of fluid outflow down to 500 mL together with scrotum enlargement to the size of 2 grapefruits. There was no evidence of inflammation on admission. Inguinal hernia and abdominal swelling were excluded. An immediate HD with Perm-Cath catheter was initiated. The patient disagreed any diagnostics and surgical treatment.Standard treatment (bed rest, scrotal elevation) and HD caused disappearance of scrotal edema within 10 days. The patient decided to continue HD. Now he awaits renal–pancreas transplantation.

Conclusions: In scrotal edema accompanying PD therapy an inguinal hernia needs to be excluded. The presence of edema limited to the scrotum and penis with fast resorption after transfer from PD to HD suggests that the cause of the leakage may be an open processus vaginalis. Any chronic disease causing periodic increase of abdominal pressure, i.e.: chronic cough may contribute to leak.

PUB666

Pathogens and Drug Sensitivity in Peritoneal Dialysis Related Peritonitis in a Single Peritoneal Dialysis Center Chenggang Shi, Mei Li, Qiong-Li Yin, Weizhao Mo, Cailian Cheng. *Dept of Nephrology, the Third Affiliated Hospital of Sun-Yat Sen Univ, Guangzhou, Guangdong, China.*

Background: To investigate the pathogens and their drug sensitivity in peritoneal dialysis-related peritonitis in a single peritoneal dialysis center.

Methods: Pathogens and drug susceptibility test results of 62 cases in 35 peritoneal dialysis(PD) related peritonitis were analyzed retrospectively from January 2008 to May 2014.

Results: Among 62 cases of PD drainage fluid culture, cases were cultured with a positive rate of 61.3%, including 21 cases of gram- positive cocci (51.2%), 19 cases of gram- negative bacilli (46.3%), and 1 cases of fungi (2.4%), mixed bacteria in one episode. Staphylococcus aureus was the most common Gram-positive pathogen, and escherichia coli was the most common Gram-negative pathogen. Drug sensitivity test results showed that Gram- positive cocci showed a high resistance rate of 44.4% (4/9) to cefazolin and 33.3% (5/15) to rifampin and a low resistance rate of 6.3%(1/16) to vancomycin. 78.6% (11/14) of Gram- negative bacilli were resistant to ciprofloxacin and 28.6% (4/14) to gentamycin. There was a low resistance rate of 11.1% (1/9) to imipenem. The total PD withdrawal rate in peritonitis was 17.7%.

Conclusions: Gram- positive cocciis was still the main pathogen in PD related-peritonitis.There is a high resistance rate to cefazolin, rifampin, ciprofloxacin gentamycin and a low resistance to vancomycin, imipenem. Therefore, vancomycin and imipenem can be used as empiric therapy for PD related peritonitis.

Funding: Government Support - Non-U.S.

PUB667

Long-Term Safety and Efficacy of Darbepoetin Alfa in Peritoneal Dialysis Patients Yukinao Sakai,[1] Shizuka Yui,[1] Masami Sukegawa,[1] Yusuke Otsuka,[1] Yuichiro Sumi,[1] Anna Suzuki,[1] Koji Mugishima,[1] Tomoyuki Otsuka,[1] Shuichi Tsuruoka.[2] *[1]Dept of Nephrology, Nippon Medical School Musashikosugi Hospital, Kawasaki, Kanagawa, Japan; [2]Dept of Nephrology, Nippon Medical School, Tokyo, Japan.*

Background: Darbepoetin alfa (DA) was introduced in Japan in 2007. Its effect persists for a longer duration, compared with erythropoietin (EPO), and it has helped improve the quality of life of PD patients. In the present study, we examined the long-term safety and efficacy of DA in PD patients.

Methods: We retrospectively reviewed 17 cases wherein the treatment was switched from a conventional EPO preparation to DA. The mean age of the patients was 60.5 years, whereas the mean PD duration was 55.5 months. We assessed the changes in the

Hb, Ht, Ret, Fe, TIBC, ferritin, iPTH, HANP, BNP, and CRP levels before and after DA administration. The study period was 60 months, and the Dunnett multiple comparison assay was used for analysis.

Results: The average DA dosage was 183.9 μg/month following the switch to DA treatment and 217.5 μg/month 5 years after the switch (ns). Following the switch to DA treatment, the Hb level almost remained unchanged, and remained at approximately 11 g/dL, which was consistent with the target value of the KDOQI guidelines. Moreover, although the Ht level did not show a significant change, the reticulocyte count significantly decreased. With regard to ferrokinetics, the Fe level decreased and the TIBC level increased, although the changes were not significant; furthermore, the ferritin levels significantly decreased. In addition, the iPTH levels significantly decreased, although the HANP, BNP, and CRP levels did not show any significant change. I understand that you mean "not significant" here, but it is unclear what is not significant. Please clarify this point. Please check whether this is what you mean.

Conclusions: Through DA administration, the anemia in PD patients could be well managed for a long duration. As the ferritin levels tended to decrease after switching to DA treatment, we believe that DA is superior in terms of iron mobilization and is more effective for hematopoiesis compared with EPO.

PUB668

Simple Method to Estimate Daily Sodium Intake during Measurement of Dialysis Adequacy in Chronic Peritoneal Dialysis Patients So Mi Kim,[1] Eun Kyoung Lee.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Jeju National Univ School of Medicine, Jejushi, Jejudo, Korea; [2]Div of Nephrology, Dept of Internal Medicine, Dankook Univ Hospital, Cheonan, Chungnam, Korea.*

Background: Restriction of dietary sodium intake for peritoneal dialysis (PD) patients is recommended, but there is limited information on the measurement and monitoring of sodium intake. We have developed a simple method to estimate daily sodium intake during the measurement of dialysis adequacy in PD patients.

Methods: A total of 83 PD patients from the Asan Medical Center were enrolled into the study. The patients were divided into two groups based on residual renal function (RRF). We measured total sodium removal and estimated daily sodium intake using dietary recall for 1 day, during the assessment of dialysis adequacy.

Results: There were 39 patients in the RRF(-) group and 44 in the RRF(+) group.In both groups, and all patients, there were significant positive correlations between sodium intake and total sodium removal: RRF(-) group, r = 0.598; RRF(+) group, r = 0.577; total patients, r = 0.595. There were linear relationships between dietary sodium intake and total sodium removal in both groups: RRF(-) group, sodium intake (mg/d) = 19.28 × peritoneal sodium removal (mEq/d) + 211; RRF(+) group, sodium intake (mg/d) = 15.40 × total sodium removal (mEq/d) + 609. All PD patients, sodium intake (mg/d) = 15.64 × total sodium removal (mEq/d) + 646.

Conclusions: Themeasurement of total sodium removal during the assessment of dialysis adequacy could be an effective and simple method to estimate dietary sodium intake in PD patients. A dietary intake of 2,000 mg of sodium corresponds to a total sodium removal of approximately 87 mEq/d.

PUB669

Urgent Peritoneal Dialysis Start through Percutaneous Catheter Insertion: Technique Survival and Overall Outcome Ramon Medina, Maria Luz Alcantar, Karina Renoirte, Guillermo Garcia-Garcia. *Nephrology, Hospital Civil Fray Antonio Alcalde, Guadalajara, Jalisco, Mexico.*

Background: In Mexico, Peritoneal Dialysis (PD) accounts for 60% of patients (pts) in dialysis. Hospital Civil is a tertiary care facility where >95% of End Stage Renal Disease (ESRD) pts are started urgently on dialysis due to late referral and diagnosis. We aim to evaluate survival of percutaneous urgent PD catheter insertion and early and late complications related to immediate peritoneal dialysis start with a 2-L dialysate volume.

Methods: Prospective, observational study including all pts with first time ESRD diagnosis from April 2013 to May 2014, who underwent PD percutaneous catheter insertion and initiated PD without break-in period. All catheters were evaluated for 90 days (d) survival, integration to CAPD program and complications. All pts started PD with 2-L dialysate volume right after PD catheter insertion.

Results: We enrolled 122 pts (75.4% men), with a follow up period (FUP) of 7-12 months, 60 pts (49.1%) had ESRD of unknown etiology. Catheter survival at 90d was 79.5%, but only 51 pts (41.5%) were integrated to CAPD (average time to integration 105d + 47d). At the end of the FUP 40 pts (39%) were alive and in CAPD; 36 pts (30%) alive and not integrated to CAPD; 30 pts (19%) switch to hemodialysis (HD) and 16 pts (13%) died. The early complication included 1 (0.81%) bowel perforation, 7 pts (5.73%) presented dialysate leakage, 5 pts (4.09%) with infection including 2 tunnelitis and 3 peritonitis, 17 pts (13.9%) with mechanical malfunction of which 5 (29.41%) were rescued. Late peritonitis was the main cause to switch to HD.

Conclusions: Our technique without break.in period is safe for unplanned dialysis patients and the catheter related complications at 90d were similar to other published data. Age and low serum albumin level were predictors of death and PD failure. Late peritonitis was the mayor cause of PD failure.

PUB670

Variances Between Peritoneal Dialysis Catheter Care Patterns and Infection Rates: A Study from the MWPNC Kera E. Luckritz,[1] Ibrahim F. Shatat,[2] Hiren P. Patel,[3] Deepa H. Chand.[4] *[1]Pediatrics, Univ of Michigan, Ann Arbor, MI; [2]Pediatrics, Medical Univ of South Carolina, Charleston, SC; [3]Pediatrics, Nationwide Children's Hospital, Columbus, OH; [4]Pediatrics, Rush Children's Hospital, Chicago, IL.*

Background: Peritoneal Dialysis (PD) is the most common form of RRT for children with end stage renal disease (ESRD). Peritonitis and membrane failure are the most common reasons to transition to hemodialysis (HD). Effective catheter care to prevent peritonitis are essential to successful PD. Objective: Our aim is to investigate whether catheter care practices correlate with infections.

Methods: This study was conducted through the MWPNC, after obtaining IRB approval. Participating dialysis centers were provided electronic copies of Patient, Provider, and Event Questionnaires, which were completed in a de-identified manner. Event forms were completed since catheter placement for all prevalent peritoneal dialysis patients. Peritonitis was defined per ISPD guidelines.

Results: A total of 4 centers (23 patients) participated. There were 17 infectious events among 11 patients (5 peritonitis, 3 tunnel infections, 11 exit site infections). Cefazolin was the post commonly prescribed antibiotic. The primary mode of antibiotic administration was intra-peritoneal with the exception of isolated exit site infections which were predominately treated with oral medications. Time from catheter placement to first infectious event averaged 295 days (1-494). All providers prescribed cleansing site with soap and water. All patients followed these instructions at a minimum, and using some type of dressing. Providers recommended showers and discouraged baths. However, 50% patients stated they took baths v. showers. Swimming restrictions were varied ranging from swimming in private pools only to swimming in the ocean. Using student's T-test there was no difference in infection rates between patients who did and did not follow instructions on swimming or bathing.

Conclusions: Many patients did not adhere to PD catheter care practices as prescribed. Better educational tools and adoption of best practices are recommended.

PUB671

Pharmacokinetics of Polymyxin B in Two Patients on Continuous Venovenous Hemodialysis Eugene K. Essandoh, Serge Cremers, Jai Radhakrishnan, Michael T. Yin, Christine J. Kubin, Maya K. Rao, Zhengxiang Zhu, Sumit Mohan. *Nephrology, Infectious Disease, Pharmacy, Columbia Medical Univ Hospital, New York, NY.*

Background: Polymyxin B is an old antibiotic with increasing clinical relevance in the treatment of multidrug-resistant gram-negative bacterial infections. There is limited data on the pharmacokinetics and the potential need to dose adjust polymyxin B with renal replacement therapies. Objective of this study was to evaluate the pharmacokinetics of polymyxin B in patients on continuous venovenous hemodialysis (CVVHD).

Methods: Two critically ill patients with oliguric renal failure undergoing polyethersulfone filter based CVVHD (Nxstage machine) received intravenous polymyxin B 80mg q12 and 90mg q24 h, respectively. Pre and post-filter plasma and hemofiltrate samples were collected at regular time points at steady state. Plasma and hemofiltrate concentrations of polymyxin B1+B2 were determined by a previously described liquid chromatography-mass spectrometry assay. Non-compartmental pharmacokinetics were calculated using Phoenix Winnonlin pharmacokinetics software.

Results: Polymyxin B concentrations at the end of infusion were 3.2 and 4.1 mg/L respectively, and decreased bi-exponentially with a terminal half-life of 29 and 37 h, to 2.0 and 2.1 mg/L, resulting in area under the plasma concentration time curves of 26.2 and 59.1 h*mg/L. Post-filter plasma concentrations were lower than pre-filter, and dialysate concentrations were even lower resulting in an average sieving coefficient of 0.3-0.4 over time. Over a single dosing interval, 15 and 42 mg were recovered in the dialysate for q12h and q24h, respectively. The rate of appearance in dialysate ranged from 0.9 to 3.5 mg/h, and showed a clear relationship with the plasma concentration of the drug.

Conclusions: Our preliminary data show that polymyxin B is cleared by CVVHD with a Sieving coefficient between 0.3 and 0.4. Investigation of additional subjects and comparison with non-CVVHD patients will allow further characterization of the PK in these patients and will determine the need for dose adjustments in CVVHD.

PUB672

Glycopeptides Pharmacokinetic Comparison during Direct Hemoperfusion by Lixelle Adsorption Column Marco Sartori,[1,2] Sonya Day,[1] Maria Grazia Ricatti,[1] Federico Nalesso,[1] Mirella Zancato,[2] Claudio Ronco.[1] *[1]Nephrology and Renal Research Institute of Vicenza, St. Bortolo Hospital, Vicenza, Italy; [2]Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.*

Background: Different pharmacokinetic properties characterize Vancomycin (VAN) and Teicoplanin (TEC). Extracorporeal therapy is additional kinetic parameter which can extent this disparity. Thus we set up an in-vitro study in order to investigate VAN and TEC adsorption removal by direct hemoperfusion (DHP) with Lixelle S-35 cartridge.

Methods: Mock DHP was performed using VAN and TEC solutions (46.08±0.81 and 74.79±1.24 mg/L per N=6). Solutions were circulated in a closed DHP circuit using Lixelle S-35 (Qb 250 ml/min). Samples were taken at 10, 60 and 120 min from inlet and outlet the cartridge. Drug levels were measured with particle enhanced turbidimetric inhibition immunoassay and fluorescence polarization immunoassay for VAN and TEC, respectively. VAN and TEC mass balance were calculated.

Results: As shown in table, VAN baseline levels decreased rapidly during the first ten minutes of DHP than reached plateau at sixtieth experiment minute: the total mass adsorbed onto Lixelle polymer was 45.68±2.26 mg. The observed reduction of TEC levels greatly exceeded than VAN. The total mass of TEC introduced into the system was completely adsorbed after 10 minutes by Lixelle cartridge (126.86±0.91 mg).

Table I. Vancomycin and Teicoplanin Levels during DHP.

Time [min]	Arterial Concetration [mg/L]	Venous Concentration [mg/L]
Vancomycin		
baseline time [0]	46.08±0.81	—
time [10]	25.67±0.51	22.17±0.68
time [60]	21.93±0.72	20.47±0.62
time [120]	21.90±0.77	21.37±0.83
Teicoplanin		
baseline time [0]	74.79±1.24	—
time [10]	11.98±0.78	LOD
time [60]	LOD	LOD
time [120]	LOD	LOD

LOD indicates Low Limit Of Detection.

Conclusions: Different adsorption kinetics was occured between VAN and TEC. This should be considered when Glycopeptides are used in patients receiving DHP with Lixelle S-35 to avoid potential underdosing: loading dose may be required for both antibiotics. Furthermore, the high Lixelle S-35 sorbent capacity against TEC may represent an option as rescue therapy in accidental overdose.

PUB673

Impact of Rifampicin on Antihypertensive Drug Levels and Their Requirement in CKD5D

Akansha Agrawal,[1] Sanjay K. Agarwal,[1] Thomas Kaleekal.[2] *[1]Nephrology, AIIMS, New Delhi, India; [2]Pharmacology, AIIMS, New Delhi, India.*

Background: Patients with CKD on dialysis (CKD5D) have many fold higher incidence of tuberculosis (TB) than the general population and >95% of them are also hypertensive. Rifampicin, a first-line antitubercular (ATT) drug, is a potent inducer of hepatic cytochrome P450. Hypertensive patients receiving rifampicin-based ATT (RBATT) often have worsening of hypertension. There is potential for pharmacokinetic interaction between rifampicin and antihypertensives that are CYP substrates: amlodipine and metoprolol. However, this hypothesis has not been systematically studied.

Methods: In a prospective cohort study, hypertensive CKD5D patients with TB were followed after RBATT initiation. BP was <140/90mmHg with stable antihypertensives at inclusion. Serum amlodipine, metoprolol and prazosin levels were estimated at baseline and 3, 7, 10 and 14 days after RBATT initiation. Measurement was by HPLC after standardization. BP and antihypertensive requirement were also monitored for 2 weeks or until stabilization. For comparison, numbers and dosage of antihypertensives were computed into units.

Results: 24 CKD5D patients were enrolled. After RBATT initiation, serum amlodipine, metoprolol and prazosin levels declined in all patients (Table).

Antihypertensive	% Patients with decline in level	% Decline in level from baseline		Time to first decline in level (days)		% Patients with decline to undetectable level
		Mean	Range	Mean	Range	
Amlodipine (n=17)	100	82.8±20.4	52-100	3.9±3.2	2-15	47
Metoprolol (n=4)	100	91.9±16.2	67.6-100	5.3±3.9	2-10	75
Prazosin (n=4)	100	98.1±2.7	94.3-100	4.3±3.9	2-10	50

After RBATT, 83.3% patients required increase in drugs to maintain BP <140/90mmHg. Drug requirement increased from 4.5+3.6 (1-14) to 8.5+6.4 (2-29) units (*p<0.0001*). Mean time to first increase in dose was 6.5+3.6 (2-14) days. 46% patients had a hypertensive crisis at a mean of 9.1+3.8 (3-14) days. In 2 patients, rifampicin had to be stopped to control BP.

Conclusions: Rifampicin causes significant decrease in serum levels of commonly used antihypertensives. This decrease in levels correlates well with worsening of BP. Thus, we suggest close monitoring for worsening hypertension after rifampicin initiation.

Tobramycin Kinetics Removal on Renal Replacement Therapy by Carpediem Machine *In Vitro* Model

Marco Sartori,[1,2] Elena Faggiana,[1,2] Elena Barzon,[1] Leopolda Zampieri,[1] Federico Nalesso,[1] Mirella Zancato,[2] Claudio Ronco.[1] *[1]Nephrology and Renal Research Institute of Vicenza (IRRIV), Pharmacology Section, St. Bortolo Hospital, Vicenza, Italy; [2]Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.*

Background: Tobramycin(TOB)is an antibiotic active against Gram(-) frequently used in pediatric patients with sepsis. These patients can develop Acute renal failure requiring renal replacement therapy by the newcomer Carpediem Machine(CM). Therefore,we designed an *in vitro* study to assess TOB extracorporeal kinetics removal by CM.

Methods: Mock hemofiltration was performed in sham mode for 240min using saline solutions and blood(N=6)spiked with TOB(9.36±0.11 and 11.30±0.37µg/mL,respectively).After 5min of priming,each solution(blood;saline)was circulated in the closed system(Qb30mL/min;Quf2mL/min)using 0.25m^2 polysulfone membrane(PS). Samples were taken from arterial,venous,ultrafiltrate ports at 10,30,60,120 and 240 min. Sample levels were measured by TOBR Flex method (Siemens Healthcare,Newark,NJ.,U.S.A.).TOB Sieving coefficient(Sc)and mass balance were calculated.

Results: As shown in table I Sc rose rapidly during first 60 then decreased and increased over 1 indicating a complex drug-membrane interaction in saline solution.On blood, Sc rose till 30min, thereafter it reached plateau likely due to protein cake was formed on PS.Mass balance analysis has shown a different amount of adsorption between saline solution and blood at 240min:744.59±94.23 and 350.35±42.35µg,respectively.This indicate probably TOB adsorption was not concluded in blood.

Table I. Tobramycin Sieving Coefficient and Percentage of Mass Adsorbed.

Time [min]	Sc	%Mass adsorbed
saline		
10	0.50±0.04	10.12%
30	0.92±0.02	8.75%
60	1.04±0.06	8.93%
120	0.91±0.02	4.30%
240	1.10±0.05	21.83%
blood		
10	0.44±0.05	5.63%
30	0.51±0.04	2.13%
60	0.53±0.04	7.90%
120	0.53±0.01	8.88%
240	0.52±0.03	8.50%

Conclusions: Our preliminary evaluation demonstrates that TOB could be adsorbed on PS when CM is used.This finding should be taken in consideration when CM is used in pediatric patients treated with TOB.In this setting,the rate of TOB administration should be modified in order to avoid potential underdosing.

PUB675

In Vitro Extracorporeal Removal of Linezolid by Miniaturized System

Marco Sartori,[1,2] Arianna Loregian,[2] Silvana Pagni,[2] Giorgio Palù,[2] Claudio Ronco.[1] *[1]Nephrology and Renal Research Institute of Vicenza, St. Bortolo Hospital, Vicenza, Italy; [2]Molecular Medicine, Univ of Padua, Padua, Italy.*

Background: Linezolid(LZD) is an alternative antibiotic for patients with gram(+) glycopeptides resistant infections.Septic patients frequently develop acute kidney injury then they require renal replacement therapy(RRT).It is therefore fundamental to understand drug removal by RRT.We performed an *in vitro* study to estimate kinetic removal of LZD.

Methods: We performed sham hemofiltration(SHF)for 240min using blood and saline solutions(N=6)spiked with LZD(11.75±0.08 and 17.24±0.54mg/L,respectively).After 5 min of priming,each solution was circulating in a closed circuit simulating SHF(Qb 30mL/min;Quf 2mL/min)using a 0.25 m^2 polysulfone membrane(PS)and Carpediem Machine. Samples were taken from arterial,venous and ultrafiltrate lines at 10,30,60,120 and 240 min. LZD levels were measured by high performance liquid chromatography.LZD adsorption/release from PS and Sieving Coefficient(Sc)were calculated.

Results: As shown in table Sc values gradually rose during experiments in both conditions(blood;saline).Results subsequent to SHF,primary assessment interval(10 min) mass was 1.93±0.25mg in blood and 3.78±1.89mg in saline indicating a significant reduction to starting mass (4.57±0.04 and 6.70±0.21mg in blood and saline,respectively).After 10 min,in the closed system LZD mass gradually increased till 2.64±0.09mg in blood and 5.91±0.34mg in saline at 240min.

Table I. Linezolid Sieving Coefficient and Percentage of Mass Adsorbed.

Time [min]	Sc	%Mass adsorbed
LZD-Blood		
0	—	—
10	0.66±0.13	57.80%
30	0.77±0.14	53.17%
60	0.81±0.11	47.67%
120	0.82±0.13	45.67%
240	0.91±0.12	42.96%
LZD-Saline		
0	—	—
10	0.35±0.20	43.61%
30	0.69±0.09	44.64%
60	0.81±0.12	40.71%
120	0.91±0.05	29.83%
240	0.95±0.07	18.00%

Conclusions: We observed a great LZD adsorption at the beginning of SHF,later LZD was slowly released by the PS until the end of experiments.This findings suggest that rebound phenomena occurred indeed,after rapid adsorption,LZD was released to the circulating pool.A redistribution should be considered when LZD is administered in patients receiving RRT.

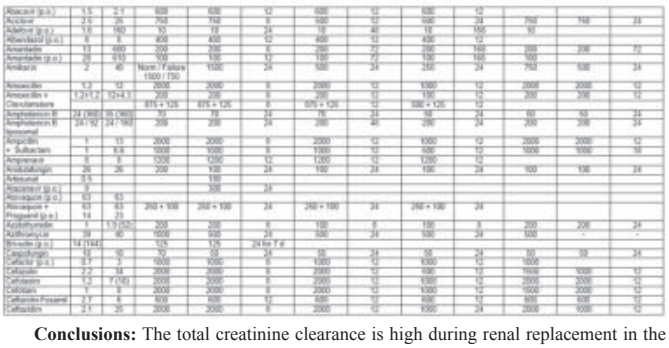
Antibiotic Drug Dosing in Patients with Renal Replacement Therapy: Comparison between Anesthesiology and Medical Intensive Care

Jasmin Frick, Ferrah Okur, Frieder Keller. *Nephrology, Internal Medicine, Univ Hospital, Ulm, Germany.*

Background: Kidney failure increases the risk of drug over dosage with toxic adverse events while renal replacement might increase the risk of under dosage with insufficient efficacy. This makes antibiotic therapy a delicate act of balancing between too much or too less dosing in the intensive care patients.

Methods: In this prospective non-interventional cohort study, we compared the antibiotic dosing in the anesthesiology and the medical intensive care unit (ICU) at our hospital. All patients were included who needed renal replacement therapy during the 10 months study period. We have taken the total creatinine clearance as a combined measure of both, residual kidney function and artificial filtration.

Results: Overall, 57 patients were recorded, 43 men and 14 women. The mean age was 61 years (SD 16). Continuous hemofiltration was preferred as compared to intermittent dialysis (89 % versus 11 %). We recorded 37 different anti-infective drugs with 4 on average per patient. The mean duration of anti-infective therapy was 8 days (SD 5). The average creatinine clearance was 44 ml/min in the patients at anesthesiology ICU and 42 ml/min at medical ICU. The mean dose was 2297 mg/day (SD 3751) in the anesthesiology ICU (632 days) and significantly higher ($p < 0.001$) than the 1664 mg/day (SD 2297) in the medical ICU (1242 days). With regard to the guidelines in our hospital, a significantly higher proportion of cases was not receiving the proposed dose adjustment in the anesthesiology ICU as compared to the medical ICU (51 % versus 41 %, $p = 0.001$).



Conclusions: The total creatinine clearance is high during renal replacement in the intensive care setting and on average > 33 % of normal kidney function. We observed a significantly higher trend to refrain from renal dose adjustment in the anesthesiology ICU as compared to the medical ICU.

PUB677

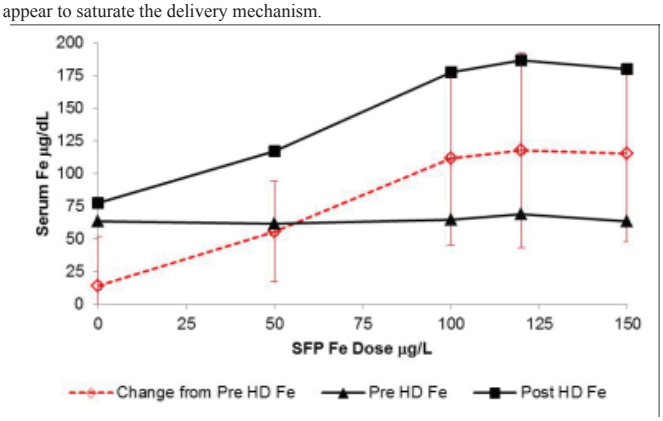
Triferic via Dialysate Reliably Delivers Iron: Clinical Pharmacology in CKD- HD Patients

Raymond D. Pratt, Vivian H. Lin, Carrie D. Guss, Ajay Gupta. *R&D, Rockwell Medical, Wixom, MI.*

Background: Triferic™ is an iron salt, MW ~900, administered via dialysate to replace iron losses and maintain hemoglobin levels in CKD-HD. Triferic directly donates iron and pyrophosphate to human apotransferrin, thereby bypassing the reticuloendothelial system.

Methods: Serum iron, transferrin saturation (TSAT) and unsaturated iron binding capacity (UIBC) data were obtained pre and post HD at intervals in controlled clinical trials of Triferic.

Results: Triferic at doses of 20 to 110 µg Fe/L added to dialysate demonstrated a dose-proportional increase in incremental iron delivery. Doses between 110 and 150 µg/L appear to saturate the delivery mechanism.



The dose of 110 µg/L dialysate was chosen for patients, as it maximized iron delivery, reduced ESA dose, and maintained Hgb. Controlled studies demonstrated similar incremental pre-HD to post-HD increases in serum iron levels of approximately 85.9 to 139.2 µg/dL Fe over basal values. Triferic iron was rapidly cleared from the circulation and serum iron parameters returned to baseline prior to each HD treatment. Dialysis parameters including vascular access type, dialysate flow, membrane type and dialyzer reuse did not affect the delivery of Triferic iron. UIBC values decreased as serum total iron increased indicating donation of iron to transferrin. Pre-dialysis serum iron, UIBC and TSAT values remained at baseline levels throughout the study indicating no accumulation of iron in serum.

Conclusions: Triferic behaves like a middle molecule that traverses the dialyzer membrane and reliably delivers iron with each HD. Clinical trials have demonstrated that sufficient iron is delivered via dialysate to maintain Hgb by compensating for ongoing iron losses due to retained blood in the dialyzer circuit, GI losses and routine phlebotomy. Triferic is a novel iron replacement product delivered via the hemodialysate to replace dialytic iron losses.

PUB678

Development of an RNAi Therapeutic for the Treatment of Primary Hyperoxaluria Type 1

William Querbes,[1] Abigail Liebow,[1] Stuart Milstein,[1] Satya Kuchimanchi,[1] John Knight,[2] Ross P. Holmes,[2] Kevin Fitzgerald.[1] [1]*Alnylam Pharmaceuticals, Cambridge, MA;* [2]*Univ of Alabama Birmingham, Birmingham, AL.*

Background: Primary Hyperoxaluria Type 1 (PH1) is an autosomal recessive disorder of glyoxylate metabolism. Hepatic glyoxylate detoxification is impaired due to mutation of the AGXT gene, which encodes for the liver peroxisomal alanine-glyoxylate aminotransferase (AGT) enzyme. Loss of AGT function to convert the intermediate metabolite glyoxylate to glycine causes accumulation and reduction of glyoxylate to glycolate which is oxidized to oxalate by the enzyme glycolate oxidase (GO). Excess oxalate in PH1 patients is unable to be fully excreted by the kidneys leading to the formation and deposition of calcium oxalate crystals in the kidneys and urinary tract. Renal damage is caused by a combination of tubular toxicity from oxalate, nephrocalcinosis and renal obstruction by stones. Greater than 30% of patients advance to end stage renal disease (ESRD).

Methods: RNA therapeutics are a new class of medicines that work by degrading a specific target mRNA to reduce the production of the disease causing protein. Here we explore the development of an RNAi therapeutic targeting GO using our clinically validated GalNac-siRNA conjugate platform. Conjugation of siRNA to the sugar N-Acetylgalactosamine (GalNAc) mediates targeted delivery to the Asialoglycoprotein receptor (ASGR) on the surface of hepatocytes, the major site of oxalate production. Using bioinformatics we designed a panel of GalNAc-conjugates that were screened *in vitro* and *in vivo* for their ability to silence the GO transcript.

Results: We identified several GalNAc-siRNA compounds from *in vitro* screening in liver cells that potently down regulated the GO transcript. The best group were evaluated *in vivo* with subcutaneous dosing to identify the conjugate demonstrating the most potent, dose responsive silencing of liver GO mRNA. Finally, we tested a lead candidate GO GalNAc-siRNA conjugate in a rodent model of PH1 to characterize the effects on oxalate production.

Conclusions: We conclude that liver silencing of GO with an RNAi therapeutic may have potential in the treatment of PH1.

PUB679

Variability in Response to Albuminuria Lowering Drugs: True or Random? Sergei Petrykiv,[1] Dick de Zeeuw,[1] Frederik I. Persson,[2] Peter Rossing,[2] Hans-Henrik Parving,[3] Ron T. Gansevoort,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Clinical Pharmacy and Pharmacology, UMC, Groningen, Netherlands; [2]Steno Diabetes Center, Gentofte, Denmark; [3]Rigshospitalet, Copenhagen, Denmark.*

Background: Changes in albuminuria are monitored to estimate the response of an individual to albuminuria lowering treatment. However, albuminuria varies from day-to-day in the absence of drug treatment. The change in albuminuria after drug administration may thus reflect a random change or a true response to treatment. If the change represents a true drug response, the initial albuminuria response to treatment should correlate with the change after treatment cessation. We tested this in a series of (published) prospective clinical trials lasting 2 to 6 months.

Methods: We first analyzed the intra-individual coefficient of variation (CV) over 6 months follow-up of a first morning void albumin:creatinine ratio (ACR) in the placebo arm of 7 clinical trials of patients with normo- (n=2), micro- (n=1), and macroalbuminuria (n=4) who were on stable medication. Four of these trials included a wash-out period. In these trials we correlated the change in albuminuria during placebo or active treatment with the change in albuminuria during wash-out (off-treatment). Clinical trials included patients with macroalbuminuria and involved the following drugs: enalapril, losartan, aliskiren, atrasentan, and paricalcitol.

Results: The intra-individual CV was 19 to 25% in the normoalbuminuria range, 41% in the microalbuminuria range, and 21 to 33% in the macroalbuminuria range. In the placebo arm of the clinical trials no correlation between the on- and off-treatment albuminuria change was observed (all R^2<0.01). However, with all drugs, except paricalcitol, we observed a significant correlation between the on- and off-treatment albuminuria change (R^2 0.14 to 0.57). Correlations were stronger for trials with 24-hr albuminuria compared to trials with first morning void ACR.

Conclusions: Despite the natural day-to-day variability in albuminuria, the variability in drug response can be adequately quantified in a clinical trial setting. These data support research to identify which factors determine drug response in order to optimize use of current and new interventions.

PUB680

Quality Analysis following Adoption of Heparin-Free Dialysis with Streamline® Airless Bloodlines (SL) in Large Tertiary Inpatient Hemodialysis Practice Sami Safadi,[1] Mary Ann Ryan,[2] Amanda L. Severson,[2] Fares Alahdab,[3] Marie C. Hogan.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Nursing, Mayo Clinic, Rochester, MN; [3]KER Unit, Mayo Clinic, Rochester, MN.*

Background: Extracorporeal circuit (EC) anticoagulation (AC) with heparin was a key advancement in routine hemodialysis (HD). However, AC in patients at risk of bleeding remains a frequently encountered problem in practice. SL bloodlines eliminate blood-air contact, and reduce turbulence in dialysis circuit. Small outpatient studies suggest that SL reduces heparin use and improves dialysis efficiency. We prospectively evaluated EC clotting event rates, impact on dialysis efficiency, and associated risk factors.

Methods: Patients requiring inpatient HD were prospectively followed during their hospitalization. HD protocols were performed without routine EC heparin. Patients could be on AC, including heparin for other indications. All sessions were performed using SL bloodlines and Fresenius 2008K equipment. HD sessions were observed for clotting events defined as an interruption of dialysis session, loss of dialysis circuit, or inability to return blood to the patient.

Results: In this ongoing study, 145 adult patients received 514 inpatient HD runs (Jan-April 2014). 61% were males, 86% were white, median age 66 yrs. 46% were on antiplatelet agents, and 10% received therapeutic systemic AC with heparin. The main indication for HD was ESRD (76%). Median HD session time was 210 min (IQR 180-220), delivered BFR was 350 ml/min (IQR 350-350), UF 2 liters (IQR 1-2.5), and KTV 1.4 (IQR 1.2-1.7). The clotting rate was 6%. Clotting episodes were associated with a lower delivered KTV (est -0.4, p<0.001), and BFR (est -20, p=0.02). Major risk factors for clotting (table 1) were transfusion of blood products, temporary HD lines, and AKI.

	OR	p
Transfusions	5.4	<0.001
Temporary lines	4.6	0.002
AKI	2.6	0.01

Conclusions: We report new data on inpatient EC clotting rates and prevalent anticoagulant use in hospitalized HD patients. Our data shows that heparin-free HD using SL tubing is feasible, safe, and effective. Clotting rates are comparable to previously reported data with heparin. Further studies are needed to identify best techniques for heparin-free dialysis.

PUB681

Intradialytic Hypotension: Prevalence and Significance in Practice Patterns as Quality Improvement Initiative Marco Formica. *Nephrology and Dialysis Dept, ASLCN1, Cuneo, Italy.*

Background: Intradialytic hypotension (IH) severely affects patients' (pts) tolerance, inducing reduced session's efficiency, high risk of vascular access failure, increasing cardiovascular events and mortality. It is reported in 15 to 50% of the dialysis sessions.

Methods: We prospectively studied 1985 sessions consecutively performed in 110 pts for about 2 months. Dialysate temperature was constant at 36°. Dialysate sodium ranges from 138 to 144 mEq/l. All pts had been on a blood volume control system. IH was defined as arterial blood pressure lower than 90 mmHg (with a drop >20 mmHg from the first measurement) and/or request of a therapeutical intervention (reduction of programmed ultrafiltration rate (UFR), infusion of saline, hypertonic NaCl, mannitol, colloids).

Results: 184 sessions were reported as complicated by IH (9.3%). They regarded 33/110 pts (30%); among these 33 pts, IH episodes ranged from 5.5% to 83% of their sessions. In all the pts but one, <33% of the sessions were complicated by IH.Mean age was 64±13 years and mean dialysis vintage 79±7 months. 26 pts were on bicarbonate dialysis (BHD) with high-flux membrane, 5 in on-line post hemodiafiltration (HDF), 1 in acetate-free biofiltration and 1 in hemodiafiltration with endogenous reinfusion. Mean UFR was 605±198 ml/min. In 59 cases it was sufficient to reduce UFR; in 111 cases infusion of saline, hypertonic NaCl or 18% mannitol was performed; in 2 cases anti-hypertensive therapy was modified and in 11 dry body weight was increased. BHD pts showed a mean of 6.5 IH sessions versus 2 IH sessions for the HDF regimens. None of the session had been stopped before prescribed time.

Conclusions: IH incidence was lower than reported: in this regard may be the regular use of blood control devices could play a role in preventing hemodynamic disturbances. It seems crucial the dry body weight estimate by constant pts surveillance as well as repeated evaluation of home pharmacological therapy. Some pts seem more prone than the mean: in this case shift from BDH to HDF could further improve IH. IH could be a usefull surrogate marker to improve practice patterns, ameliorating dialysis pts comfort and possibly reducing long term complications.

PUB682

Social Work Staffing in For-Profit and Not-for-Profit Dialysis Facilities: Implications for Patient Outcomes Teri Browne,[1] Joseph R. Merighi.[2] *[1]College of Social Work, Univ of South Carolina, Columbia, SC; [2]School of Social Work, Univ of Minnesota, Minneapolis, MN.*

Background: In accordance with a Medicare mandate, a Master's level social worker is required in every U.S. dialysis facility because of the many psychosocial barriers to optimal dialysis outcomes. Studies in the literature indicate that high dialysis social worker caseloads are associated with lower patient satisfaction, less successful patient rehabilitation outcomes, and a decreased ability to provide clinical social work interventions The aim of this study is to assess variations in social workers' practice experiences between for-profit and not-for-profit dialysis corporations.

Methods: A cross-sectional online survey contained 70, multicomponent questions and took 25 minutes to complete. Data were gathered between January 2 and March 1, 2014 using the Council of Nephrology Social Worker listserv. A sample of 617 full-time (32 hrs/wk or more) social workers was obtained from all 50 states and the Northern Mariana Islands.

Results: Overall, full-time social workers in for-profit settings (n=495) experienced greater burdens than their colleagues in not-for-profit settings (n=122). Specifically, significant differences were found between for-profit and not-for-profit providers with regard to workload demands, emotional exhaustion, and caseloads. In each case, employees in for-profit corporations reported higher workload demands (19.1 versus 17.1, p<.001), higher emotional exhaustion (19.2 versus 14.8, p<.001), and higher caseloads (108.8 versus 95.0, p<.01) than employees in not-for-profit settings. Hourly rate did not differ significantly between work settings.

Conclusions: This study represents an important national effort to quantify disparities between for-profit and not-for-profit social work practice settings. The majority of nephrology social workers in the United States are employed by large dialysis chains, and nearly 80% of dialysis patients receive their care from for-profit providers. Unfortunately, the corporate ethos of many for-profit dialysis providers has social workers performing tasks that support the financial goals of the organization and may negatively impact patient outcomes.

PUB683

Direct Hemoperfusion with Lixelle S-35: Can Be a New Option of Hyperbilirubinemia Treatment? Marco Sartori,[1,2] Aashish Sharma,[1,2,3] Mauro Neri,[1] Francesco Garzotto,[1] Davide Giavarina,[1] Claudio Ronco.[1] *[1]Nephrology and Renal Research Institute of Vicenza (IRRIV), Pharmacology Section, St. Bortolo Hospital, Vicenza, Italy; [2]Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy; [3]Nephrology, Indraprastha Apollo Hospitals, New Delhi, India.*

Background: Critically ill patients with acute liver failure have limited, complex and expensive options of treatment, therefore we decided to explore the bilirubin removal capacity of Lixelle S-35 cartridge through an in vitro test by direct hemoperfusion (DHP).

Methods: We tested two separate hyperbilirubinic bags containing plasma and blood obtained from a plasmapheresis and exchange transfusion,respectively.The total bilirubin(TBIL)and direct bilirubin(DBIL)were assessed with Jendrassik-Grof method.All tests were performed in triplicate.TBIL and DBIL baseline concentrations were 17.57±0.53, 12.57±0.23 mg/dL for plasma 23.10±0.47, 15.37±0.24 mg/dL for blood. Mock DHP was

performed for 120 min for each bag(Qb100 mL/min).TBIL and DBIL levels were measured at 10, 30, 60,120 min for samples drawing from inlet and outlet the cartridge.Mass balance analysis were calculated for TBIL and DBIL.

Results: Mass balance analysis is shown in table. TBIL and DBIL levels reached plateau subsequently to DHP. At the end of tests TBIL and DBIL levels were 7.67±0.47, 5.17±0.17 in plasma and 8.37±0.58, 5.37±0.39 mg/dL in blood, respectively.The total removal was seen as TBIL in plasma 55.60%, TBIL in blood 62.16 %, DBIL in plasma 58.87%, DBIL in blood 64.41% at the end of DHP.

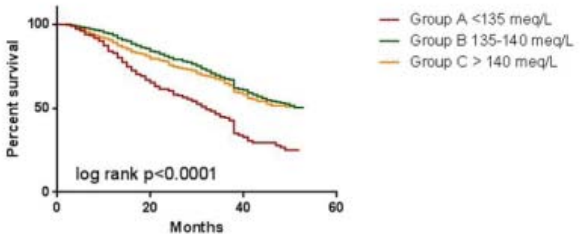
Mortality Associated with Low Serum Sodium Concentration in Chronic Hemodialysis Patients Manolo Ramos Gordillo, Marco Antonio Carmona-Escamilla, Jose C. Pena, Ivanna Rocha, Israel Jeronimo Roque. *CEDIASA, México, D.F., Mexico.*

Background: Hyponatremia is associated with increased mortality in the general population as well as in hemodialysis patients. However the normal extracellular fluid volume balance and the osmo-regulation responsible for this complication is lacking in dialysis patients; so the mechanisms for this low serum sodium are of different etiology than the ones found, in the general population.

Methods: A retrospective study was conducted from January 2010 to March 2014 in nine of our Hemodialysis Units in Mexico City. Our study included 4128 patients, 2078 men (51%) and 2050 women (49%). All patients were treated with high flux hemodialysis during 3 to 4 hours, 3 times per week. Monthly predialysis serum sodium [Na^+] was obtained in all patients. The patients[Na^+] in mEq/L was stratified in three groups: (A:<135; B: 135-140; C: >140). Other variables studied were: BUN, creatinine, hemoglobin, hematocrit, albumin, calcium and phosphorus Data were analyzed for absolute and relative frequencies as well as survival curves (Kaplan- Meier and Cox Regression).

Results: Mean[Na^+] of all patients was 137.9 mEq/L. Groups: A 133.2 ± 1.97; B 137.8 ± 1.34; C 141.2 ± 1.10 ($p< 0.05$). Percent survival analysis at 4 years showed: A: 57% ;B 72% and C 69% (long rank t test 0.001).



Mean value of survival time in months. Groups: A 31 (CI 29.2-33);B 41 (CI 40-41.5) C 39 (CI 38-40).A higher risk of death was found in group A (Fig1). Multivariable adjustment for demographic, clinical and laboratory data, did not appreciably change the results (Hazard ratio 0.772 CI 95% 0.68-.88). However serum albumin in Group C improved survival.

Conclusions: Low serum sodium concentration was associated with a higher risk of death. It is possible that hyponatremia per se is a causal of mortality in this large cohort but with a different etiology than the general population.

PUB685

Migration to Heparin-Free Hemodialysis (HD) with Streamline® Airless Bloodlines (SL) in a Large Medical Center Inpatient Practice Sami Safadi,[1] Mary Ann Ryan,[2] Amanda L. Severson,[2] Marie C. Hogan.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Nursing, Mayo Clinic, Rochester, MN.*

Background: The development of the routine HD practice was facilitated by the introduction of extracorporeal circuit (EC) anticoagulation (AC) with heparin. However, EC-AC carries an increased risk of bleeding, a frequent concern in the hospitalized patients with multiple medical comorbidities including coagulopathies. Conventional HD tubing also involves blood-air contact, typically in the arterial and venous chambers which increases the likelihood of clotting. Streamline® (SL) bloodlines eliminate blood-air contact, and reduce turbulence in dialysis circuit, which decreases the likelihood of clotting. Small outpatient studies suggest that SL reduces heparin use and improve dialysis efficiency. Our inpatient HD units moved to heparin-free dialysis with SL tubing with subsequent reductions in heparin use. Here we report our experience.

Methods: All dialysis staff were trained and assessed in competence for correct setup-up of the air free tubing, spanning one month. Procedural guidelines for set up and critical assessment of the dialysis circuit were implemented across the inpatient practice. Staff underwent training in the assessment of circuit clotting. Fresenius 2008K HD machines were calibrated to meet tubing specifications the night prior, and on the specified date we migrated to the new system. Clotting during HD is now routinely assessed in all inpatient HD sessions through a post rinse-back visual guide. We validated the method showing good reproducibility across all dialysis nursing staff.

Results: Our heparin prescription rates during hemodialysis dropped from an average of 15-25% before the introduction of SL tubing to <1% afterwards. There was no change in the clotting rate (around 2-8%) with the change to heparin-free dialysis with SL.

Conclusions: We have successfully migrated from intermittent extracorporeal AC with heparin to heparin-free airless with SL tubing in a busy inpatient safely. Routine monitoring for extracorporeal circuit clotting should be a standard quality procedure in inpatient dialysis units.

Measurement of Polyvinylpyrrolidone from Un-Primed and Primed Fresenius Dialyzers Subjected to Exaggerated Extraction and Simulated Use Conditions Betsy J. Endrizzi,[1] Candice Moon,[1] Daniel E. Mclain,[2] Sherry Parker,[3] James P. Kennedy,[1] Chih-Hu Ho.[1] *[1]Global Research and Development, Fresenius Medical Care, Ogden, UT; [2]Walker Downey & Associates, Inc., Verona, WI; [3]WuXi AppTec, St. Paul, MN.*

Background: A study was conducted to gain thorough understanding of the polyvinylpyrrolidone (PVP) profile in Fresenius dialyzers. The dialyzer models chosen for this study included electron beam (E-beam) sterilized Optiflux® F200NR, F250NR and Optiflux® Ultra F230.

Methods: Exaggerated extractions of un-primed and primed dialyzers involved a complete filling of the dialyzer with ethanol, water or saline for 24 hours at 50-70°C. PVP was quantified in the extracts using a validated NMR method.

Results: Results indicate that exaggerated extraction of un-primed dialyzers with ethanol, water and saline removed an average of 63, 104 and 91 mg of PVP, respectively. Exaggerated extractions of primed dialyzers removed 52, 17 and 16 mg of PVP with ethanol, water and saline, respectively. Notably, priming the dialyzers as instructed for clinical use significantly ($p<0.0005$) reduced the amount of PVP extracted by exaggerated methods in aqueous solvents, but not with ethanol. Two independent toxicologists calculated the margin of safety (MOS) for PVP in these exaggerated extracts to range from 2-22 for primed dialyzers, with a likely 10-100 fold increase in MOS during actual clinical use conditions.

Conclusions: Even considering the mean values of the exaggerated extraction data plus two standard deviations, the MOS values were still greater than 1 for all extraction solvents and dialyzer models, indicating the likelihood of an adverse event occurring in an exposed patient population would be negligible.

PUB687

Serum Sodium Concentration in Haemodialysis: Is There a Set Point? Eduardo Baamonde,[1] Elvira Bosch,[1] German Perez Suarez,[1] Fatima Batista,[1] Gloria Anton,[1] Mar Lago,[2] Agustin Toledo,[2] Cesar Garcia-Canton.[2] *[1]Nephrology, Avericum, Telde, Las Palmas, Spain; [2]Nephrology, Hospital Univ Insular de Gran Canaria, Las Palmas, Spain.*

Background: In patients on haemodialysis (HD) Serum sodium concentration (SSC) is maintained to a constant individualized level called the "sodium set point". Some observations question this approach **Objective.** To analyze the SSC and variability of a standard HD population, with constant dialysate (139 mEq/l).

Methods: Retrospective study including 261 HD prevalent patients (60.9% males; 51.7% diabetic; mean age 60.04 ± 14.09 years; time in HD 69.64 ± 50.53 months; follow-up time 48.78 ± 19.09 months). SSC was corrected for glucose. 24 measurements were used to calculate the mean and to analyze variability. Demographic, clinical parameters, laboratory test results and mortality rates were analyzed.

Results: 6221 measurements of natremia was made. The mean SSC was 138.26 mEq/l (range: 120.86-151.65 mEq/l); 917 (14.74%) were lower than 135mEq/l. Natremia was negatively correlated with the sodium variation coefficient (VC) (r: -0.243; p<0.000), the inter-dialysis weigth gain (IDWG)(r:-0.254; p<0.000) and the ultrafiltration rate (r:-0.279; p<0.000) and positively with serum albumin (r: 0.169; p:0.006).

Sodium tertiles	<137.49 (n: 87)	137.5-139.11 (n:87)	>139.11 (n: 87)	*p*
Natremia (mEq/l)	135.83 ± 1.54	138.34 ± 0.47	140.49 ± 1.01	*0.000*
DM (%)	52.9	46	46	*n.s*
VC Sodium (%)	2.34	1.74	1.66	*0.014*
DST Sodium	3.17	2.41	2.33	0.024
Glucose (mg/dl)	150.84 ± 60.85	148.14 ± 54.49	145.11 ± 47.46	*n.s*
IDWG (%)	3.08 ± 0.69	2.98 ± 0.70	2.68 ± 0.71	*0.001*
Uf rate (ml/kg/mn)	8.06 ± 1.89	7.67 ± 1.94	6.92 ± 1.75	*0.000*
Albumin (g/dl)	3.62 ± 0.24	3.72 ± 0.27	3.74 ± 0.24	*0.006*

No difference was found in mortality rates or hospitalization days during follow-up.

Conclusions: Pre-haemodialysis SSC is inversely correlated with inter-dialysis hydration. The variability of natremia increases in the lowest tertile, coincidently with more severe overhydration. A positive diffusive sodium gradient between dialysate and plasma could explain these observations.

PUB688

Evaluation of Antihypertensive and Nitrate Use in Patients with Intradialytic Hypotension in the Inpatient Setting Andrew Nishimoto,[1] Benjamin Duhart,[2] David Shoop,[1,2] Robert B. Canada,[3] Joanna Hudson.[1,2] *[1]Methodist Le Bonheur Healthcare; [2]Univ of Tennessee College of Pharmacy; [3]Univ of Tennessee College of Medicine, Memphis, TN.*

Background: Intradialytic hypotension (IDH) is the most common complication of hemodialysis (HD). Administration of antihypertensive medications (AHTs) and nitrates in the inpatient setting often occurs prior to dialysis; however, the influence on the rate of IDH is unclear. The purpose of this study was to evaluate the association of AHT and nitrate therapy on development of IDH and to identify other factors associated with IDH.

Methods: A retrospective chart review was performed to identify patients admitted to Methodist University Hospital with ESRD requiring HD from August 2011 to August 2013 who met inclusion criteria. The study population was divided into IDH and non-IDH cohorts. We evaluated a maximum of five dialysis sessions per patient. AHTs and nitrate use within 12 hours prior to each HD session was compared between groups. The association between development of IDH and serum albumin, pre-HD blood pressure, serum sodium and the ultrafiltration rate during HD was also evaluated. Univariate analyses were used to detect significant differences between groups and multivariate logistic regression identified predictors of IDH.

Results: In 104 patients studied (50 IDH, 54 non-IDH), the proportion of patients receiving AHTs was higher in the IDH group compared to the non-IDH group (82% and 65%, respectively). Additionally, a greater percentage of the IDH cohort had an arteriovenous graft as their HD access (26% versus 5%) and had a higher mean pre-dialysis systolic blood pressure (SBP) (141 versus 134 mmHg). IDH was also associated with higher admission hemoglobin, higher pre-dialysis SBP, and graft access. Subanalysis of only dialysis sessions when IDH occurred demonstrated a negative correlation between total AHT/nitrate doses received and IDH. Graft access was no longer significant in this prediction model.

Conclusions: This study suggests that in addition to the timing of administration of AHTs, other factors including pre-dialysis SBP and hemoglobin are important to consider when evaluating risk of developing IDH.

PUB689

Pre-Haemodialysis Natremia and Body Composition Eduardo Baamonde,[1] Elvira Bosch,[1] German Perez Suarez,[1] Gloria Anton,[1] Fatima Batista,[1] Mar Lago,[2] Agustin Toledo,[2] Cesar Garcia-Canton.[2] *[1]Nephology, Avericum, Telde, Las Palmas, Spain; [2]Nephrology, Hospital Univ Insular de Gran Canaria, Las Palmas, Spain.*

Background: In patients on haemodialysis, sodium serum concentration (SSC) remains stable although with large interindividual variability. Some results have suggested that lower SSC are associated with more severe overhydration. **Objective:** to analyze the relationship between pre dialysis SSC and body composition, especially between SSC and body water.

Methods: Retrospective study included 129 conventional HD prevalent patients (65.9% males, mean age 61.12 ± 13.83 years, 49.31% diabetic). Body composition was analyzed immediately after mid-week dialysis session with a bioimpedance monofrequency monitor (BIA) (AKERN). SSC was calculated by using the last 12 monthly readings before BIA and corrected for glucose.Demographic and clinical parameters, laboratory test results and body composition were analyzed.

Results: The mean SSC was 137.86 ± 2.49 mEq/l. Patiens were grouped into tertles according SSC.

Sodium tertiles	<137.29 (n: 42)	137.3-138.93 (n:44)	>138.93 (n: 43)	*p*
Natremia (mEq/L)	135.24 ± 2.38	138.16 ± 0.51	140.13 ± 0.90	*0.000*
DM (%)	48.4	44.2	43	*n.s*
IDWG (%)	3.45 ± 0.84	3.10 ± 0.74	2.69 ± 0.90	*0.000*
Uf rate (ml/kg/mn)	9.06 ± 2.49	8.08 ± 1.93	7.34 ± 2.72	*0.005*
Albumin (g/dl)	3.63 ± 0.18	3.71 ± 0.16	3.69 ± 0.25	*n.s*
TBW (%)	67.20 ± 13.7	67.36 ± 10.4	68.48 ± 10.33	*n.s*
ECW (%)	58.66 ± 48.86	51.67 ± 7.27	53.31 ± 8.68	*n.s*
ICW (%)	49.39 ± 9.96	46.47 ± 8.57	46.12 ± 9.06	*n.s*
FFM (%)	30.09 ± 7.77	36.72 ± 11.4	36.87 ± 13.79	*0.008*

Pre-dialysis sodium was negatively correlated with: inter-dialysis weight gain (IDWG) (r -0.353; p 0.000), ultrafiltration rate (UR) (r -0.338; p 0.000), and extracellular water (%) (ECW)(r -0.230; p 0.009) and positively correlated with faty free mass (%) (FFM) (r 0.207; p 0.018).

Conclusions: Patients with the lowest sodium levels presented the most severe interdialysis overhydration. No differences were found in the distribution of body water between patients in different tertiles of natremia. Natremia and body water are negatively correlated.

PUB690

Proteomic Evaluation of Low- and High-Flux Hemodialysis Carlo Donadio,[1] Danika Tognotti.[2] *[1]Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy; [2]Istituto di Biofisica, CNR, Pisa, Italy.*

Background: The principal mechanisms of blood depuration by hemodialysis are diffusion, convection and adsorption. Hemodialysis may be performed using low-flux (LF) membranes which remove only small molecules, or high-flux (HF) membranes with remove also bigger molecules. Aim of the this study was to assess, by means of proteomic techniques, the relevance of convection and adsorption of proteins with different membranes.

Methods: Seventeen patients treated with LF polysulphone and with HF membranes (Triacetate; Helixone; Polyamid). Proteomic analysis.30 min after the beginning of the dialysis a sample of ultrafiltrate fluid was analyzed by means of biochemical and proteomic techniques. At the end of the dialysis we assessed the adsorption of proteins on the different dialytic membranes. The proteins in the ultrafiltrates and those eluted from the membranes were analyzed through SDS PAGE, 2DE, and MALDI-TOF.

Results: Biochemical analysis.A very high removal of small molecules was demonstrated, which was similar with all the membranes. The removal of B2M was high with HF membranes and insignificant with LF membrane. The removal of bigger molecules (myoglobin and BNP) was higher with triacetate than with the other HF membranes. **Proteomic analysis.** No convection of small proteins (LMWP) in the ultrafiltrate fluid was found through LF polysulfone. Polyamid and helixone allowed the convection of LMWP. In the ultrafiltrate of triacetate a higher amount of different LMWP was demonstrated. Proteins with different MW were found in the eluates from the different membranes. In particular, albumin and LMWP were demonstrated on the inner part and inside the triacetate membrane. Much more than with the other membranes.

Conclusions: Proteomic technology allows a better understanding of mechanisms of blood depuration of the different membranes.

PUB691

Fluid Status and Impact on Lab Parameters for Adequacy of Hemodialysis Care Kotagal Shashi Kant,[1,2] Heather Duncan,[1,2] Mahmoud T. El-Khatib.[1,2] *[1]Internal Medicine, Div Nephrology and Hypertension, Univ of Cincinnati College of Medicine, Cincinnati, OH; [2]Dialysis Clinic, Inc, Cincinnati, OH.*

Background: Most clinical measures in a dialysis population are targets for medical intervention, and clinic performance is evaluated by the clinic's performance measures for hemoglobin, phosphorous and albumin. As part of CMS associated Quality Improvement Program (QIP) projects, hemodialysis units are monitored for outcome based reimbursement. However, these measures are likely to vary for a number of reasons, not least because of measurement related artifacts. It is likely that fluid status will affect lab parameters via a dilution effect and/or the effects on inflammation and cardiac/pulmonary performance. We examined lab parameters affected by fluid status by comparing several measures collected from hemodialysis patients after the long interdialytic interval versus a short one.

Methods: A retrospective chart review identified instances where the same lab parameter was collected after a short and a long interdialytic interval. Hemoglobin, phosphorous, calcium, albumin, total protein, CO2, creatinine, potassium and weight gains were then compared with paired t-tests.

Results: Measures obtained after both a short and long interval in the same month (n=38) were examined. When measured after a short interdialytic interval (mean weight gain 2.17 kg) versus a long interval (mean weight gain 3.41 kg) hemoglobin, albumin and total protein were higher, while creatinine was lower. These changes are important both for anemia management, ESA dosing, as well as reported quality measures. Phosphorous and calcium were also higher, but still within DOQI guidelines. Neither CO2 nor potassium varied by interdialytic interval.

measure mean	long interval	short interval
hemoglobin g/dL	10.80	11.05*
albumin g/dL	3.82	3.94*
total protein g/dL	6.90	7.00*
creatinine mg/dL	10.62	9.36*
phosphorous mg/dL	4.92	5.20**
calcium mg/dL	8.92	9.23**
potassium meq/L	4.68	4.59ns
CO2 meq/L	22.16	22.66 ns
interdialytic weight gain kg	3.41	2.17*
* P<0.001	** P<0.05	

Conclusions: We propose that outcomes measures and reporting, as well as computer generated algorithms for dose adjustments, should account for the interdialytic interval.

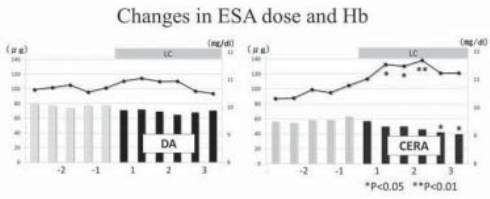
PUB692

Intravenous L-Carnitine Administration Demonstrates Superior Cost-Effectiveness when Combined with CERA Compared to Darbepoietin (DA) for Treatment of Anemia in Hemodialysis (HD) Patients Jyunichiro Hashiguchi,[1] Yoshiaki Lee,[1] Kenji Sawase,[1] Hiroshi Ichinose,[1] Osamu Sasaki,[1] Rica Etoh,[1] Masatoshi Hayashida,[1] Yoko Obata,[2] Tomoya Nishino,[2] Takashi Harada,[1] Satoshi Funakoshi.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Univ, Nagasaki, Japan.*

Background: A number of clinical studies have suggested that LC, a naturally occurring compound involved in bioenergetic processes, may reduce the dose of erythropoiesis stimulating agents (ESA) in the treatment of the anemia of HD patients. In this study, our aim was to evaluate the effect of intravenous administration of LC on hematological parameters and also on monthly requiring dose of DA or CERA in HD patients.

Methods: Seventy-four HD patients receiving various dose of either DA (n=48) or CERA (n=26) biweekly were enrolled in this study after appropriate IC. Intravenous L-carnitine (1000 mg) was administered after each HD session for 24 weeks. The doses of each ESA were adjusted in each patient to keep Hb levels in the range 10-12 g/dL, and other treatment procedures including iron supplementation stayed the same. The weekly requiring doses of DA or CERA and hematological parameters of patients were recorded every other week.

Results: As shown in Figure 1 significant reduction of monthly ESA dose was observed in CERA-treated group after 6 weeks. In DA-treated group, monthly ESA dose tended to decrease, but not significant.



Conclusions: In our study the combination of intravenous LC with CERA was superior to the combination of LC with DA in dose-minimizing effect of ESA, and potentially be cost-effective.

PUB693

Pre-Dilutional Hemodiafiltration Using Xevonta Dialyser Seems to Generate Less Pro-Inflammatory Reaction Carlos Frangié, Rosier Emmanuelle, Thierry Baranger, Frank Berge. *Néphrologie et Dialyse, Polyclinique Bordeaux Nord, Bordeaux, France.*

Background: Chronic inflammation in dialysis patients is correlated with an increase in mortality rate from cardiovascular disease. It is secondary to factors related to the patient and to the dialysis technique, especially with the biocompatibility of the membranes. Cytokines play a crucial role in the development and maintenance of the inflammatory state. We compare in this study the effect on cytokine production of two polysulfone membranes.

Methods: This is a prospective study carried out in two phases. We included ten patients treated by pre-dilutional hemodiafiltration, using biocompatible polysulfone membranes with very high permeability. This is for Phase 1 (P1), a new generation membrane (Xevonta®,BBraun) and for Phase 2 (P2) an older membrane (PF210H®,Gambro). Serum assays of IL-6 (pro-inflammatory), IL-10 (anti-inflammatory), and CRP were performed before and after at the last dialysis of the P1, and after 6 weeks wash-out, at the last dialysis of the P2. The IL6 and IL10 assays were performed by Elisa.

Results: The assay of interleukin 6 and 10 proved to be generally low. The median of IL-6 before dialysis is 6.655 pg/ml (P1) and 6.075 pg/ml (P2), and after dialysis is 6.275 pg/ml (P1) and 5.23 pg/ml (P2). There is no significant difference between the two phases, or within each phase. The median of IL-10 before dialysis is 4.19 pg/ml (P1) and 1.29 pg/ml (P2), with a statistically difference (p=0.0055) and after dialysis to 5.65 pg/ml (P1) and 2.42 pg/ml (P2) with a statistically difference (p = 0.0329). There was a statistically significant difference between before / after dialysis for P2 (p = 0.0329), but not for P1 (0.229). The median PCR is 4.5mg/l, without any correlation with interleukins rates. The results showed that the immunological balance is leaning pro-inflammatory side at P2 while the balance is maintained in the P1.

Conclusions: The rate of interleukins 6 and 10 in pre-dilutional hemodiafiltration is low. The new generation of biocompatible membranes appears to generate less pro-inflammatory reaction. A study involving a larger number of patient is however necessary to confirm these results.

Effects of Shensongyangxin Capsule on Heart Rates Variability and Insomnia in Maintenance Hemodialysis Patients Zhenda Zheng,[1] Cailian Cheng,[2] Chenggang Shi,[2] Xun Liu,[2] Tan-Qi Lou.[2] *[1]Dept of Cardiology, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Nephrology, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: The decrease of heart rate variability is very common and is related to the risk of death in maintenance hemodialysis patients. Shensongyangxin capsule(SSYX) is an Chinese patent medicine.To investigate the effects of SSYX on heart rate variability and insomnia in maintenance hemodialysis patients.

Methods: Sixty-three maintenance hemodialysis patients in the third affiliated hospital of Sun Yat-Sen University from 2013 June to December were divided into two group, control group(n=30) and experimental group(n=33).The experimental group were received SSYX 4capsules QID for eight weeks, all patients received holter test and Pittsburgh sleep quality index were measured before and after the study.

Results: SSYX can improve heart rate variability[SDNN (93.2±1.4) *versus*(82.4±13.1) ms, SDNNi (41.2±12.8) *versus*(28.4±12.2)ms, SDANNi (81.3±21.1) *versus* (73.2±20.7) ms, RMSSD (28.3±13.2) *versus*(21.8±11.9)ms, PNN50 (9.6±7.1) *versus*(7.1±5.8)%, $P<0.05$], the incidence of premature atrial contraction, atrial tachycardial, premature ventricular contraction, ventricular tachycardial and atrial- ventricular blocker decreased significantly($P<0.05$), SSYX also improved sleep quality significantly[PSQI(6.28±2.12) *versus*(14.39±2.84), $P<0.05$].

Conclusions: SSYX is an effective and safe agents to improve heart rates variability and insomnia in hemodialysis patients.

Observation of Clearance Effects of Hemodialysis and Hemodiafiltration on Uremic Toxins in DKD-Caused Uremia Patients Chenggang Shi, Mei Li, Xun Liu, Cailian Cheng, Qiong-Li Yin, Weizhao Mo. *Dept of Nephrology, the Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Uremic Toxins are thought to be involved in many complications of diabetic kidney disease (DKD) caused Uremia Patients.The aim of the current study was to investigate the different blood purification techniques on removal uremic toxins in DKD caused uremia patients with hemodialysis (HD) and hemodiafiltration (HDF). Survey the clearing effects of blood urea nitrogen (BUN), middle molecular substances (MMS),pentosidine and indoxyl sulfate (IS).

Methods: 36 cases DKD caused uremia hemodialysis patients were divided into HD group (n = 24), HDF group (n = 12). Before and after each conventional HD and HDF therapy, blood was sampled for BUN with automatic biochemical analyzer(Olympus company, Japan), MMS with Ultraviolet spectrophotometry, pentosidine with enzyme-linked immunosorbent assay method (from ADL Company, U.S.A.), IS with high performance liquid chromatography method. Single dialysis adequacy (KT/V) was calculated by the formula Daugirdas.

Results: For HDF versus HD, the RR was significantly higher for MMS (29.10± 5.54 versus 22.06 ±6.27%, $p < 0.05$), pentosidine (28.97 ± 6.37 versus 21.45 ± 9.82%, $p < 0.05$). There were no significant differences in the RR for IS (20.09 ±6.60 versus 24.36 ± 8.74%, $p > 0.05$) and BUN (67.70± 8.98 versus 68.05 ±5.52%, $p>0.05$). KT / V were more than 1.3, and KT / V difference was not statistically significant.

Conclusions: HDF may provide an improved form of treatment that achieves significantly better MMS, pentosidine level reduction than conventional HD for DKD-caused uremia patients.

Do Proton Pump Inhibitors Affect Serum Acidity in the Patient on Maintenance Hemodialysis? Youssef El Douaihy, Ninad D. Parekh, Chetana Rondla, Emad Gobran, Mazen Zaarour, Iskandar Barakat, Najamus Sehar, Vera Zaraket, Suzanne E. El Sayegh, Osama Souied, Marc M. Saad. *Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Background: A few case reports mention the effects of proton pump inhibitors on pH. The objective was to investigate associations between PPIs and metabolic acidosis in patients on hemodialysis (HD).

Methods: This is a retrospective analysis conducted at a single HD facility in 2013. The primary outcome was metabolic acidosis (bicarb ≤24mEq/L). The independent variables are shown in table1. T-test and Chi^2(χ^2) analyses were used to compare means and proportions respectively between controls and acidotics. Nominal regression was used to test for predictors and account for confounders.

Results: 154 patients on HD were included in this study.

The t-test comparison of independent means showed a higher mean albumin 4 for the acidotic patients versus 3.7 with statistical significance. χ^2 showed no differences between the comparison groups. The nominal regression analysis confirmed the relationship between albumin and acidosis with a p=.008.

Conclusions: In the sample of randomly selected patients the use of PPI had no correlation to acidosis. However high levels of albumin proved to carry a predictive power of acidosis contrary to what's established. This relationship held its validity even after accounting for cofounders making it worthwhile to investigate its etiology in the future.

PUB697

Association between Serum Bicarbonate and Mortality in Haemodialysis Population. A Single Centre 5-Year Experience Asmaa Y.M. Al- Chidadi,[1] Abdelgalil Abdelrahman Ali.[2] *[1]Faculty Of Epidemiology, London School of Hygiene and Tropical Medicine, London, London, United Kingdom; [2]Nephrology Dept, Midessex Hospitals Trust, Chelmsford, Essex, United Kingdom.*

Background: Many observational studies showed that uncorrected metabolic acidosis can worsen dialysis outcomes. However Dialysis Outcome Practice Pattern Study and other observational studies showed that moderate acidosis was associated with a better nutritional and survival outcomes. We set off to investigate the association of metabolic acidosis with the risk of death in our cohort.

Methods: Data were obtained from electronic records at the Broomfield Centre. 288 patients' dialysis records from Jan 2007 till December 2012 were reviewed. Multivariate analysis of the association between Serum bicarbonate level and all-cause mortality was analysed using Poisson regression model. Serum bicarbonate was divided into 4 categories ranging from >19 to 22, 23-24, 25-26 and >27mmol/l.

Results: 288 participants were studied, of whom 59 were lost to follow up. Over the follow up period, 149 deaths were recorded with a total time at risk of 13619.6 months. The crude rate of mortality in the lowest S bicarbonate group (19-22 mmol/l) was 0.01 with similar crude rates seen in the remaining 3 S bicarbonate groups. Rate ratios were adjusted for age, sex, ethnicity, BMI, dialysis vintage, Kt/V, Haemoglobin level, predialysis systolic and dialstolic BP, WBC and lymphocytes count, and inflammatory markers (CRP, S.Alb, S. Ferritin) Comorbidities (Ischaemic heart disease, CVA, cancer, DM, COPD and smoking). The rate ratios, adjusted for the above variables were 0.61 (95% CI 0.26-1.40), 1 (baseline group which was 23-24 mmol/l), 1.19 (95% CI 0.59-2.38) and 1.82 (95% CI 0.82- 4.05) for the above 4 bicarbonate groups respectively. All rates were not statistically different from each other. The rate of death increased with the higher levels of S bicarbonate. However the sample size was not large enough to detect this statistically.

Conclusions: Mild acidosis did show some protective effect with a trend towards increasing mortality rate after adjustment for various confounders but this did not reach a significant level. A larger sample size is required for future studies.

PUB698

eEOC-Mediated Modulation of Endothelial Autophagy, Senescence, and EnMT in Murine Diabetic Nephropathy Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology and Rheumatology, Univ Hospital Göttingen, Germany.*

Background: *Early Endothelial Outgrowth Cells* (eEOCs) protect mice from ischemic AKI. Autophagy acts as endogenous cellular defense mechanism. Nevertheless, defective autophagy has been shown to promote Stress-Induced Premature Senescence (SIPS) of endothelial cells. Endothelial-to-Mesenchymal Transition contributes to renal fibrosis in CKD and it possibly reflects a state of aggravated endothelial senescence. Aim of the study was to analyze endothelial autophagy, senescence, and EnMT in eEOC-treated murine diabetic nephropathy.

Methods: Diabetes was induced in male, 8-12 weeks old C57/Bl6N mice by intraperitoneal injection of streptocotozin (STZ). Untreated and BMP-5 pretreated syngeneic murine eEOCs were systemically administered at day 2 after the last STZ injection. Animals were analyzed 8 weeks later for renal function, proteinuria, morphology, endothelial autophagy, senescence, and EnMT, respectively.

Results: Renal function and protein excretion were significantly affected / increased at week 8. Intrarenal collagen deposition was increased although not to a significant extent. Endothelial cells diaplayed higher expression of aSMA, indicating EnMT. Administration of native and BMP-5 treated eEOCs protected animals from CKD and proteinuria, the latter was even more diminished in mice receiving BMP-5 treated eEOCs. EnMT was reduced by the cells as well. Both cell populations reduced endothelial SIPS and BMP-5 treated eEOCs diminished endothelial autophagy.

Conclusions: Particularly BMP-5 treated eEOCs act renoprotective in murine diabetic nephropathy. The data suggest that by eEOC-mediated modulation of intrarenal endothelial autophagy and senescence, EnMT is reduced and progression of diabetic nephropathy is inhibited.

PUB699

Bone Marrow-Derived Mesenchymal Stem Cells and its Conditioned Medium Attenuate Fibrosis in an Irreversible Model of Unilateral Ureteral Obstruction Andrei Furlan Silva, Kleiton Augusto Santos Silva, Nestor Schor. *Nephrology, Univ Federal de São Paulo, São Paulo, Brazil.*

Background: Recently the therapeutic potential of Mesenchymal Stem Cells (MSCs) and its Conditioned Medium (MSC-CM) has been extensively studied. It is known about their ability to repair tissue, reduce local inflammation and its immunomodulation. Renal tubular interstitial inflammation induces chronic damage, resulting in fibrosis and progress to CKD. A establish fibrosis model is Unilateral Ureteral Obstruction (UUO). Here, it was evaluated factors influenced by MSCs or MSC-CM in UUO.

Methods: MSCs extracted from rat's bone marrow were cultivated *in vitro* and characterized by flow cytometry and cellular differentiation. Four groups of female rats were used in *in vivo* experiments (n=7): SHAM, UUO, UUO+MSC and UUO+MSC-CM. The MSCs or MSC-CM were administered via abdominal vena cava after left ureter total ligation. After 7 or 14 days rats were killed and serum and obstructed kidney were collected.

Results: It was observed reduction in the amount of fibrosis assessed by deposition of collagen in obstructed animals treated with MSCs or MSC-CM. By Immunohistochemical assays it was observed reductions in the amount of Caspase-3, α-SMA and PCNA in treated animals.

	Sirius Red (7 d)	Sirius Red (14 d)	alpha-SMA (7 d)	alpha-SMA (14 d)	PCNA (7 d)	PCNA (14 d)	Casp-3 (7 d)	Casp-3 (14 d)
UUO	1.2±0.2	1.8±0.2	7.2±1.2	10.8±1.2	3.0±1.1	2.0±1.2	1.8±1.0	7.7±1.0
UUO+ MSC	0.3±0.1*	0.6±0.1*	1.3±0.1 *	2.5±0.3 *	0.5±0.3 *	5.1±0.5 *	0.8±01	3.9±0.4 *
UUO+ CM	0.4±0.1*	0.3±0.1*	1.0±0.0*	1.7±0.2 *	1.0±0.5 *	3.7±0.8 *	1.1±0.2	6.5±1.0

Table 1. Picro Sirius Red staining and immunohistochemistry for alpha-SMA, PCNA and Caspase 3. Values are expressed in % of staining area (mean±SD). * vs UUO group.

Conclusions: Results suggested that administration of MSCs or MSC-CM improves fibrosis progression and change factors involved in apoptosis, inflammation, cell proliferation and epithelial-mesenchymal transition in Wistar rats subjected to unilateral ureteral obstruction.

PUB700

Effect of Bone Marrow Mesenchymal Stem Cells (MSC) or Conditioned Medium (MSC-CM) in Rats with Acute Kidney Injury (AKI) due to Sepsis
Joelma Santina Christo, Nestor Schor. *[1]Nefrologia, Unifesp, São Paulo, Brazil.*

Background: Sepsis is one of the most commonly related causes of death in ICUs, especialy when associated with AKI.Recent studies suggested that AKI can be prevented or repaired by the MSC therapy. This study aims to evaluate this effect.

Methods: MSC were characterized for FACS analysis and were cultured and used at 4th passages.The female *Wistar* rats received E.coli (10^9) by renal one punctures(E.coli group) or PBS (CTL) in a single intrarenal dose (N=06).After 72 hours, the rats received i.v MSC ($1X10^6$cells) or saline or cultured medium from MSC,(MSC-CM,500µl) injection, in one dose.Then after 72 hours blood were collected for creatinine or urea.

Results: After 24 hours it was observed higher values in creatinine and urea in E.coli when compared to CTL (1.3 ± 0,1 versus 0.9±0,1mg/dlp<0.05) and urea (92.1± 0.2versus40.6±0.1 mg/dlp<0.05) characterizing this AKI model.The E.coli+MSC presented lower serum creatinine and urea after 72 hours (1.0±0.2 and 58.0±0.1 mg/dl,p<0.05),respectively.The E.coli+ MSC-CM also had lower values of creatinine (0,5±01 mg/dL) and urea (39.9±1)p<0.05 versusE.coli.Also it was observed an increase in pro-inflammatory cytokines and a decrease in anti-inflammatory in E.coli alone see table 1.These effects were much lower in the animals that received simultaneous E.coli with MSC or CM (p<0.05).

Serum cytokines (pg/mL)	CTL	E.coli 24 hours	E.coli+PBS 72 hours	E.coli+MSC 72 hours	E.coli+MSC-CM
IL-1α	12±04	49.±4	43±2.8	25±2.0*	23±5 #
IL-1β	40±14	290±11	268±12	86±9*	122±12#
IL-10	22±3	35.±5	32.±5.0	84±8*	83±5.7#
TNF α	7±1.2	53.±9	49±8	17±5*	21±4#
IFNγ	29±5	136±2	129.1±7	48±6*	64±3.2#
IL-6	61±9	496±8	457±10	192±9*	246±13#

Values are expressed as the mean±SEM *P<0.05 CTL vc E.coli+MSC 72 hours (n = 5), vs E.coli+ CM

Conclusions: Cell therapy with MSC or its MSC-CM are promising treatment for AKI due to sepsis, particularly in minimizing effects when administered soon after sepsis detection, opening a potential adjuvant therapy for this important disease.

PUB701

Effect of Mesenchymal Stem Cell and Steroid Pulse Therapy in Intractable IgA Nephropathy
Byoung-Soo Cho,[1] Yumi Choi,[1] Hyun Soon Lee,[2] Jin-Soon Suh.[3] *[1]TheAll Medical Hub Kidney Center, TheAll Medibio Research Institute, Republic of Korea; [2]Hankook Kidney and Diabetes Institute, Republic of Korea; [3]Dept of Pediatrics, Bucheon St. Mary's Hospital, The Catholic Univ of Korea, Republic of Korea.*

Background: There is no remedy to cure severe IgA nephropathy (IgAN) with irreversible histologic changes. Cell-based therapy, especially adipose derived stem cells (ASCs) is an emerging treatment modality in the nephrology field. We report the effects of steroid pulse therapy followed by autologous ASCs in patients with IgAN with severe histologic changes and decreased renal function.

Methods: The first case was for a female patient with 44 years old. Before treatment, serum creatinine was 1.6 mg/dL with GFR of 35 ml/min (stage 3 CKD). Renal biopsy showed IgAN (grade IV in H.S.Lee's classification) with sclerotic chanes in 61% of glomeruli. She received six cycles of MP pulse therapy and four cycles of ASCs intravenously with 3 weeks interval. After treatments, her serum creatinine declined to 1.28 mg/dL with GFR 45 ml/min. Furthermore, in follow-up biopsy, the sclerotic changes decreased to 37% of total glomeruli and the immune deposits disappeared. The second case was for a female patient with 31 years old. She had also stage 3 CKD. Before treatment, serum creatinine was 1.37 mg/dL with GFR of 43 ml/min. Her renal biopsy finding showed grade V IgAN with sclerotic changes in 80% of total glomeruli. She received five cycles of MP pulse therapy and 4 cycles of autologous ASCs. After treatments, serum creatinine declined to 1.26 mg/dL with GFR of 43 ml/min. And in follow-up renal biopsy, the sclerotic changes decreased to 55%.

Results: We found that the histopathological findings dramatically improved after MP pulse therapy and autologous ASCs Tx during last 6 months. The serum creatinine and GFR was a little improved in milder CKD, however serum creatinine was stationary in severe case.

Conclusions: In conclusion, MP pulse therapy with autologous ASCs treatment in intractable IgA nephropathy might be a promising therapeutic modality, especially in early stage CKD, although the efficacy and safety of stem cell infusion therapy need long-term follow-up.

PUB702

Gas Gangrene and Acute Respiratory Distress Syndrome in a Renal Transplant Patient with Middle East Respiratory Syndrome Corona Virus Infection
Ebadur Rahman, Muddassar Mahboob, Ramesh Nair, Seddeg Younis, Naveed Aslam. *Nephrology, Prince Sultan Military Medical City(PSMMC), Riyadh, Saudi Arabia.*

Background: Middle East respiratory syndrome corona virus (MERS-CoV) infection is rare and potentially fatal infection and here we report a case of corona virus infection in a renal transplant patient managed in Nephrology department of Prince Sultan Military Medical City.

Methods: We report a 42 years old male diabetic, hypertensive, morbidly obese, renal transplant patient with an average baseline creatinine of 1.5mg/dl since transplant .The patient was admitted under care of surgical team for toe amputation because of gas gangrene. The patient developed chest symptoms a days after uneventful toe amputation. At the same time the Patient became febrile and chest x-ray revealed right middle zone infiltrate .He had a drop of the room air saturation to 80% from base line 96%. The immunosuppressive medications were reduced and intravenous immunoglobulin (IV IG) was administered at a dose of 0.5mg/kg,for five days with the suspicion of MERS-CoV infection which was later on confirmed from the nasopharyngeal swab PCR. All the other viral markers were negative. The patient had mild reversible deterioration of renal function and although he was shifted to I.C.U but he was not ventilated. The patient was discharged in good general condition after 46 days.

Conclusions: MERS-CoV infection can cause reversible acute graft dysfunction and although it has a high mortality, early use of immunoglobulin and reduction of immunosuppressant might be beneficial even with multiple co morbidities and co infections.

PUB703

Towards a Model of Ischemia/Reperfusion Induced Renal Fibrosis
Nathalie Le Clef, Anja Verhulst, Patrick C. D'Haese, Benjamin Arthur Vervaet. *Laboratory of Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: Acute kidney injury (AKI) is an important risk factor for development of chronic kidney disease (CKD), hence renal fibrosis, in humans. Ischemia-reperfusion (I/R) is a widely used model of AKI, the severity of which is dependent on body temperature during, and duration of, ischemia. With the objective of optimizing a I/R induced model of renal fibrosis, we quantified the expression of 4 fibrosis-related genes 12-weeks after I/R of varying severity.

Methods: Male C57BL/6J mice (n=6/condition) underwent unilateral renal I/R with different conditions of ischemic temperature and duration. On the one hand, core temperature was kept stable at 34°C, 35°C, 36°C and 37°C during 30 min of ischemia. On the other hand, ischemic duration was varied from short (15 and 18 min) to long (25 and 30 min) at a fixed temperature of 36°C. Temperature control was achieved using a heating pad with rectal probe feedback. After reperfusion, animals were kept on a hot water pad (37°C) until awakening. Sham operated mice (n=6) were included as controls. Expression of Collagen I, TGFβ, CCN2 (CTGF) and CCN3 (NOV) was assessed by qPCR.

Results: Thirty minutes of ischemia at 37°C causes the most severe renal injury, leading to a 46.0±4.3 (Col I), 18.5±3.8 (TGFβ), 22.4±5.2 (CCN2) and 22.8±5.8 (CCN3) fold upregulation. Lower temperatures during ischemia result in gradually less upregulation of these fibrosis-related genes. The lowest expression is seen with 30 min at 34°C resulting in a 29.0±7.4 (Col I), 12.1±2.4 (TGFβ), 10.4±4.0 (CCN2) and 10.4±4.4 (CCN3) fold upregulation ($p < 0.05$ versus 37°C and Sham). Shorter duration of ischemia (18 min) results in far lower upregulations only of Col I (4.5±4.1), TGFβ (1.5±0.3) and CCN3 (3.4±2.0 ($p < 0.05$ versus 37°C and Sham)). The mildest condition tested, i.e. 15 min at 36°C, did not result in persistent upregulation of fibrosis-related genes.

Conclusions: Unilateral ischemia/reperfusion can induce persistent renal fibrosis. The extent of renal fibrosis, in terms of Col I, TGFβ, CCN2 and CCN3 expression, increases with increasing ischemic temperature and time. These data demonstrate I/R to be a useful model to investigate renal fibrosis.

PUB704

Inflammatory Cell Types of Kidney Allograft Glomerulitis and Peritubular Capillaritis Are Association with Peritubular Capillaries C4d Deposition
Juan Jin,[1] Yiwen Li,[1] Qiang He.[1] *[1]Nephrology, Zhejiang Provincial People's Hospital, Hangzhou, Zhejiang, China; [2]The Kidney Disease Center, The 1st Affiliated Hospital, Medical College, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: The aim of our study was to determine the amount and composition of immune cells within glomeruli and peritubular capillaries (PTCs) and its relationship with PTC C4d deposition.

Methods: Immunohistochemistry staining for C4d, CD3, CD68, granzyme B and Foxp3 were used for phenotyping and enumerating immune cells within intracapillaries. C4d staining was present in 26 biopsy specimens (C4d+ group) and negative in 25 specimens (C4d- group).

Results: The total number of infiltrating cells in glomerulus and PTC in C4d+ group significantly higher than in C4d- group (P<0.001; P<0.0001). Although the C4d+ group showed a significantly higher mean number of macrophages per glomerulus and PTC than in C4d- group (P<0.0001; p=0.001), the C4d- group showed a higher mean number of T cells per glomerulus and PTC than in C4d+ group (P=0.023; P=0.031). Comparing cell counts in diffuse C4d+ and focal C4d+ groups, a significant difference of absolute numbers

of intracapillary cells could be observed in glomeruli and PTCs (P=0.001; P<0.0001). The mean number of macrophages per glomerulus and PTC in diffuse C4d+ were significantly greater than that of the focal C4d+ (P<0.0001;p=0.001). While mean T cells per glomerulus and PTC were less in cases of diffuse C4d+ than in focal C4d+.The differences however, did not achieve statistical significance (p=0.74; p=0.53). Not only glomerular T cells but also PTC's are granzyme B positive T cells totally.

Conclusions: The total number of infiltrating cells in glomeruli and PTCs have association with PTC C4d depositon, the infiltrating cells were predominantly macrophages in C4d+ group, especially in diffuse C4d+. whereas, the infiltrating cells were predominantly T cells in C4d- group. Glomerular and PTC T cells were cytotoxic phenotype completely.

PUB705

To Stent or Not? Management of Transplant Renal Artery Stenosis from an Intimal Flap Helen M. Wijeweera, Angelina Edwards, Ana Paula Rossi, Daniel C. Brennan. *Nephrology, Washington Univ, St. Louis, MO.*

Background: Transplant Renal Artery Stenosis (TRAS) is the most common vascular complication post transplant. Early anastomotic stenosis is often due to trauma to donor or recipient vessels. Less commonly, small intimal flaps or sub-intimal dissections of the vascular wall may lead to scarring and result in narrowing or occlusion of the artery. Rarely, thin, unstable flaps result in variable symptoms. Diagnosis is often delayed due to insidious onset of allograft dysfunction and absence of classic findings on ultrasonography. We present a successfully treated case of ARF attributed to a transplant renal artery intimal flap.

Methods: A 40 year old Caucasian male with ESRD secondary to Alports, underwent a living unrelated renal transplant with post operative nadir creatinine of 1.93 mg/dL. Seventeen days post-transplant, creatinine rose to 2.72 mg/dL and tacrolimus level was 15.3. Renal transplant ultrasound showed resistive indices (RI) at upper limits of normal, with peak systolic velocities highly variable, ranging from 308 to 500 cm/sec. Interestingly, blood pressure was well controlled. Allograft biopsy was consistent with interstitial nephritis. TMP/SMZ, famotidine were discontinued and Tacrolimus was reduced. Serum creatinine gradually decreased to 1.4 mg/dL. However, four days later, the patient developed diarrhea, dehydration and anuric AKI with creatinine of 5.98 mg/dL. Despite aggressive IV fluid resuscitation, the patient remained anuric and creatinine rose to 9 mg/dL. A renal angiography was performed which revealed a 50-60% eccentric, elliptical narrowing at the renal transplant artery ostium with 20 mm dynamic gradient across an intimal flap. A Herculink Elite® stent was deployed with prompt recovery of renal function, return of urine production, and improvement of creatinine to 1.7mg/dL.

Conclusions: TRAS remains an important reversible cause of acute kidney injury. However, when clinical criteria, including blood pressure, resistive indices, velocities and serum creatinine, are inconsistent, a renal artery intimal flap should be considered. Early diagnosis with angiography and intervention for such lesions can result in salvage of graft function.

PUB706

Histopathological Findings in the Early Diagnosis of Obstructive Uropathy Amaya Caviedes Aramburu, Virgilia Soto, Magdalena Madero. *Nephrology, National Institute of Cardiology, Mexico City, Mexico.*

Background: Obstructive uropathy is a common entity at all ages varying frequency depending on age and gender that is analyzed. In the case of transplant patients it is one of the most common complications with an incidence of 7-14%. In the case of a patient with use of JJ catheters with a lower incidence of 3.6%, but not absent; having urinary fistulas and strictures as the most common causes represented as a whole by 95%.

Methods: 2 cases were selected in the pathology service of post- transplant patients with acute graft dysfunction who despite rejection of discarded data evolution had not been adequate and podoplanin staining was performed and it was positive in lymph ducts.

Results: Two clinical cases with inicial creatinine 4.2 and 9.5 the first presented as an anuric pacient and the second with normal urinary volume. Both had biopsy and where positive for D 241 podoplanin. After biopsy both pacients had JJcatheter nda de final Cr was 1.2 for de fist case and 1.9 for the second.

Conclusions: The use of podoplanin could represent one more tool in the early diagnosis of patients with acute obstruction related to graft dysfunction.

PUB707

Diagnosing Transplant Tolerance By In Vitro Assay of CD4+CD25+T Cells Bruce M. Hall, Catherine Robinson, Karren Plain, Giang Tran, Nirupama Verma, Rochelle Boyd, Masaru Nomura, Suzanne Jean Hodgkinson. *Immune Tolerance Laboratory, UNSW Australia, Sydney, NSW, Australia.*

Background: Transplant tolerance in adults is usually mediated by $CD4^+CD25^+Foxp3^+$Treg, but there is no diagnostic test of the tolerant state. This study compared the reactivity of tolerant and naïve $CD4^+$, $CD4^+CD25^+$ and $CD4^+CD25^-$T cells. As antigen(Ag) specific Treg require Ag stimulation and cytokines to survive, we examined which cytokines enhanced proliferation of Ag specific Treg.

Methods: Specific immune tolerance was induced by a short course of immunosuppression after grafting fully allogeneic PVG heterotopic hearts in DA hosts. Cells from rats with grafts surviving >100 days were assayed. Different Th1 or Th2 cytokines were added to cultures. Cytokine receptor expression was assayed by RT-PCR.

Results: T cells subsets were similar in naïve and tolerant: $CD4^+$(49v42.5%), $CD8^+$(16v15.5%), $CD4^+CD25^+$(6.1v5.6%) and $CD25^+Foxp3^+$(10.9v9.1%). Serial dilution showed proliferation of naïve and tolerant $CD4^+$T cells to PVG was the same as to third party Lewis, and less to self. The response of tolerant $CD4^+CD25^-$T cells was less to PVG than to third party. Tolerant $CD4^+CD25^+$T cells response to PVG was at background and similar to self. Tolerant $CD4^+CD25^+$ cells proliferated to Lewis similar to naïve $CD4^+CD25^+$T cells proliferation to PVG and Lewis but not to self. Proliferation of tolerant $CD4^+CD25^+$ cells was enhanced to PVG, but not Lewis or self, by addition of rIL-5 or interferon-gamma (IFN-g). Tolerant $CD4^+CD25^+$T cells had more expression of the receptor for IFN-gamma (ifng) and IL-5 (il5ra) compared to naïve $CD4^+CD25^+$T cells. After culture with rIL-5, il5ra expression was retained but not ifngr expression. After culture with IFN-g, ifngr expression was retained and il5ra lost.

Conclusions: These findings show the alloAg specific tolerant state was mediated by activated $CD4^+CD25^+$Treg similar to the Ts1 and Ts2 cells that develop after nTreg are cultured with specific alloAg respectively with IL-2 or IL-4. They support our hypothesis that the long-term activation to Ag specific Treg is dependent on late Th1 or Th2 cytokines, respectively IFN-g or IL-5. These in vitro assays may diagnose transplant tolerance.

Allograft Oxalate Nephropathy Sandesh Parajuli,[1] Megan L. Troxell,[1] Donald C. Houghton,[1] Thomas D. Batiuk,[2] William M. Bennett,[2] Eric D. Langewisch,[1] Douglas J. Norman.[1] *[1]Oregon Health and Science Univ, Portland, OR; [2]Legacy Good Samaritan Medical Center, Portland, OR.*

Background: Oxalate nephropathy is a known cause of end stage renal disease. There are relatively limited data about the implications of oxalate nephropathy in kidney transplant recipients except in primary hyperoxaluria. We sought to retrospectively review our local experience with allograft oxalate nephropathy (AON).

Methods: Cases of AON were identified from the OHSU pathology archive, and correlated with clinical data.

Results: Seven cases were identified (3 nephrectomy, 4 biopsy; 2 cases were previously reported: Troxell et al. Am J Transplant. 2013;13:501-9). All patients were adults (age 35-70). Native kidney failure was attributed to diabetes (2), interstitial nephritis (1), hepatorenal syndrome (1), and was undetermined in 3; none had primary hyperoxaluria. Retrospective review identified presumptive gastrointestinal etiologies of oxalosis in 6: gastric bypass or bowel surgery (4, many in distant past), chronic pancreatitis (1), Crohn's (1); at least 5 also had heavy antibiotic exposure. Five patients experienced allograft failure at post transplant intervals of 0 to 36 months (mean 25 months). Oxalate crystals were identified on urinalysis in 3 patients; serum oxalate levels were elevated in 1, normal in the patient with primary non-function, and unavailable in 5. Patient 1 had improved renal function with discontinuation of vitamin C, low oxalate diet and calcium carbonate. Interestingly, patient 3 had delayed graft function and was dialysis dependent for 7 months; while graft function slowly recovered, oxalate was an unanticipated finding on renal biopsy and clinical correlation revealed chronic pancreatitis, leading to dietary modification and increased fluid intake; current glomerular filtration rate is 52.

Conclusions: In our experience, patients with AON historically have poor outcomes; however, early clinicopathologic recognition and intervention to reduce oxaluria may lead to improvement of graft function and prevention of graft failure. Screening and prophylaxis of high risk patients (bariatric surgery, inflammatory bowel disease), with treatment of abnormal urine chemistries, has been instituted at one of the centers.

PUB709

Prolonged DGF Post Transplant with Excellent Long Term Outcome-Patience Is a Virtue Raghavesh Pullalarevu, Keith R. Superdock, Robert L. Benz. *Nephrology, Lankenau Medical Center, LIMR, Wynnewood, PA.*

Background: Delayed graft function (DGF) is defined as the need for dialysis in the first posttransplant week. 5% of kidneys with DGF never function. Risk of DGF is high with extended criteria donor kidneys, cadaveric transplants, and inherent donor disease. The most common cause of DGF are postischemic ATN and acute antibody mediated rejection.

Methods: 71 yo. white male had elective DDKT after being on dialysis for 5 years with ESRD due to HTN. Past medical history included hypothyroidism, Anemia, SHPT. Donor met ECD criteria, having a terminal creatinine of 1.3 and HTN. Warm and cold ischemic times were 11 hr 10 min and 30 min respectively. Time zero biopsy revealed 6 glomeruli with no significant pathologic changes. Patient was euvolemic during surgery and had no apparent intraoperative complications. Kidney function did not recover and the patient remained oliguric. Hemodialysis was continued. Induction therapy was 500mg IV solumedrol intraoperatively and 250mg on POD1. 100mg of IV Dacluzimab was given intraoperatively followed by a second dose on POD 14. Immunosuppression was maintained with tacrolimus, mycophenolate mofetil and prednisone, tapered and maintained at 10mg, po daily. Transplant kidney ultrasound (US) on POD2 and POD7 revealed normal resistive indices. Tacrolimus levels were consistently within the target range of 10-14 ng/ml. Kidney biopsy for nonfunction per protocol performed on POD 17 revealed 17 glomeruli with evidence of mild focal acute cellular rejection and mild acute vascular rejection, however C4d staining was negative. The patient was treated with IV steroids for 3 days and IV ATG for 7 days with documented suppression of CD3 counts.

Results: With time and continued immunosuppressive therapy, urine output improved and dialysis was stopped on POD 96. He is now over 7 and ½ years post transplant with excellent kidney function and a baseline creatinine of 1.5-1.6 mg/dl.

Conclusions: We believe this case represents the longest reported case of DGF with excellent long term kidney function. This case underscores the importance of patience in cases of prolonged DGF and justification for continued immunosuppression while awaiting recovery of renal function.

PUB710

The Effect of Steroid Pulse Therapy in BK Viremia Who Might Have Acute Rejection after Kidney Transplantation Hyosang Kim,[1] Su-Kil Park.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Dept of Surgery, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: Steroid pulse therapy would be necessary for BK viremia patients whose pathologic report argued acute rejection. We investigated the effect of high dose steroid pulse therapy on renal function and BK viral load in renal transplant recipients with BK viremia who might have acute rejection by pathology.

Methods: Study population consisted of 98 kidney transplant recipients with BK viremia (defined as serum BK viral load > $1x10^4$ copies/mL) consecutively detected at least two times from January 1, 2004 to December 31, 2011 at Asan Medical Center.

Results: There are 67 patients (68.3%) who did not receive steroid pulse therapy (G1), 13 (13.2%) with less than 2 grams of methylprednisolone (mPD)(G2), and 18 (18.4%) with more than 2 grams of mPD (G3). Mean follow-up duration was 37.6±19.3 months. The amounts of BK viremia were not different between groups (G1; 6.3±0.9 log copies/mL, G2; 5.6±1.4, G3; 6.6±1.0) at initial diagnosis. After 1 month, BK viral load was still persistent in G3 (6.7±0.8 log copies/mL), while it declined to 5.3±2.6 and 5.1±1.9 in G1 and G2, respectively. The initial renal function (eGFR) were 47.9±26.9 ml/min/1.73m^2 (G1), 35.2±19.4 (G2), and 29.3±8.9 (G3) at diagnosis (p<0.05), and after 1 year, no improvement in steroid therapy group (G1; 52.8±34.9 ml/min/1.73m^2, G2; 39.6±28.2, G3; 27.9±11.4). In Kaplan-Meier analysis for 50% decline of eGFR from baseline, renal function in G3 rapidly deteriorated as compared with others. (p=0.051). There are 67 patients (68.3%) who did not receive steroid pulse therapy, 13 (13.2%) with less than 2 grams of methylprednisolone (mPd), and 18 (18.4%) with more than 2 grams of mPd. Mean follow-up duration was 37.6±19.3 months. The amounts of BK viremia were not different between groups (≥2g; 6.6±1.0 log copies/mL, <2g; 5.6±1.4, No mPd; 6.3±0.9). After 1 month, BK viral load was maintained in mPd≥2g group (6.7±0.8 log copies/mL), while levels of viremia in other groups were declined to 5.1±1.9 and 5.3±2.6, respectively. This difference gradually decreased and disappeared after 3 months persisting for 1 years. Estimated GFRs (eGFR) were 29.3±8.9 ml/min/1.73m^2 (mPd≥2g), 35.2±19.4 (mPd<2g), and 47.9±26.9 (no mPd) when BK viremia was detected. After 1 year, differences of eGFR were sustained (≥2g; 27.9±11.4 ml/min/1.73m^2, <2g; 39.6±28.2, No mPd; 52.8±34.9). However, in Kaplan-Meier analysis for 50% decline of eGFR from baseline, renal function in mPd≥2g group rapidly deteriorated as compared with others. (p=0.051).

Conclusions: In BK viremia patients, high dose of steroid pulse therapy would not be necessary to preserve the long term graft function in spite of argued acute rejection pathologically.

PUB711

Early Acute Graft Pyelonephritis Is an Independent Predictor of Long-Term Kidney Allograft Outcome Eun Jung Kim,[1] Jung-Woo Noh,[1] Ja-Ryong Koo.[2] *[1]Dept of Internal Medicine, Hallym Univ College of Medicine Sacred Heart Hospital, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Hallym Univ College of Medicine Sacred Heart Hospital, Gyeonggi Province, Republic of Korea.*

Background: Urinary tract infection (UTI) is the most common form of bacterial infection encountered in a renal transplant. Although UTI was benign nature, a UTI complicated by acute graft pyelonephritis (AGPN) is associated with acute kidney injury and allograft scarring. However, the influence of AGPN on graft outcome in renal transplant recipients still remains controversial.

Methods: One hundred and thirty two patients with renal transplantations were investigated to evaluate the impact of early-AGPN on graft function between January 2001 and December 2011. Early AGPN was defined as occurring within 6 months after renal transplantation. The changes in eGFR over time were compared between patients with and without early AGPN using a linear mixed model. Moreover, Kaplan-Meier plot and Cox analysis were conducted to evaluate the influence of early-AGPN on renal outcome, a reduction of estimated glomerular filtration rate (eGFR) by 50%.

Results: Among the 132 patients, 18 (13.6%) patients diagnosed with early-AGPN. During the mean follow-up of 70.7 ± 27.5 months, 28 (21.1%) patients reached to renal outcome and renal outcome was significantly higher in early-AGPN group (44.4% versus 17.5%, P = 0.025). Moreover, a liner mixed model revealed that there was a significant difference in the rate of eGFR decline over time between two groups (P < 0.001). Kaplan-Meier analysis also showed that renal event-free survival was significantly lower in the early-AGPN group (P = 0.001). In multivariate Cox regression analysis, early-AGPN was found to be an independent predictor of renal outcome (hazard ratio, 5.18; 95% CI, 1.78 - 15.11; P = 0.003).

Conclusions: This retrospective cohort study showed that early-AGPN on patients with renal transplantation was independently associated with deterioration of kidney allograft. So, this study demonstrates that early-AGPN could be predictor for long-term kidney allograft outcome.

PUB712

The Safety of Lower Doses of Immunosuppressants in Rituximab-Treated Kidney Transplantation Chung Hee Baek, Joon-Seok Kim, Hyosang Kim, Su-Kil Park. *Dept of Internal Medicine, Div of Nephrology, Asan Medical Center, Seoul, Republic of Korea.*

Background: Rituximab, an anti-CD20 antibody, effectively depletes B lymphocytes and is used in ABO-incompatible or HLA-sensitized kidney transplantation(KT). However, it is not clear whether the conventional doses of maintenance immunosuppressants in rituximab-treated KT are appropriate. We studied the safety of lower doses of immunosuppressants in rituximab-treated KT.

Methods: We previously reported the results of retrospective study that showed serious infectious complications were increased in rituximab-treated kidney transplant recipients. In this study, we prospectively evaluated 72 patients who used lower doses of maintenance immunosuppressants (tacrolimus, mycophenolate mofetil (MMF) and methylprednisolone) compared to previous study as a new protocol (group1). Sixty-seven patients of study group in the previous report served as control group (group2).

Results: The doses of MMF (in grams/day) at the following times postoperatively were lower in group1 than in group2: 1month: 0.95±0.241versus 1.26±0.42, p=0.000; 3 months: 0.93±0.30 versus 1.14±0.51, p=0.007; 6 months: 0.94±0.26 versus 1.07±0.50, p=0.095; 1 year: 0.93±0.28 versus 0.88±0.52, p=0.637; 2 years: 1.08±0.20 versus 0.69±0.55, p=0.252). The doses of tacrolimus and methylprednisolone were also significantly lower in group1. Mean follow up time (months) showed no difference (14.89±6.01 versus 12.63±7.59, p=0.053). Total infection occurred more often in group2 (29.2% versus 52.2%, p=0.006). The incidence of CMV infection was also higher in group 2 (2.8% versus 16.4%, p=0.007). One patient of group1 and 2 patients in group2 died of infection. The reduction of maintenance immunosuppressants did not increase the incidence of acute rejection in group1 (4.2% in group1 versus 4.5% in group2, p=1.000). If patients who died with functioning graft were excluded, graft survival was 100% in group 1 and 98.5% in group2 (p=0.482).

Conclusions: Lower doses of maintenance immunosuppressants reduced the incidence of infection without increasing rejection or graft loss and it might be adequate to reduce the doses of maintenance immunosuppressants in rituximab-treated KT.

PUB713

Asymptomatic Caecal Perforation in a Renal Transplant Recipient: Should Sodium Polystyrene Sulfonate (SPS) Be Used for Treating Hyperkalemia? Montish Singla, Sunggeun Lee, Donald I. Baumstein, Roger F. Carbajal Mendoza, Ashok P. Chaudhari. *Dept of Nephrology, Metropolitan Hospital Center, New York, NY.*

Background: We present a case of renal transplant recipient who suffered caecal perforation after single oral dose of SPS (15 grams).

Methods: 50 year old female with history of living related renal transplant in 1997, now CKD stage 4 due to chronic allograft nephropathy, on immunosuppression with cyclosporine and prednisone was admitted for right hip arthroplasty. On post-op day three she had a drop in hematocrit. The etiology of drop in hematocrit was unclear with stable vital signs, mild diffuse abdominal tenderness, absent bowel sounds, which were attributed to paralytic ileus. Laboratory examination was negative for any hemolysis and fecal occult blood testing was negative. So, abdominal CT was obtained which surprisingly revealed caecal perforation. Patient was operated emergently but the cause of intestinal perforation was unclear. A careful review of the chart showed that patient was given one dose of SPS for potassium of 5.8 mg/dL on post-op day one. Subsequently, the colonic pathology confirmed colonic necrosis and presence of SPS crystals in necrotic colonic mucosa. In the ensuing months she developed multiple episodes of acute kidney injury (AKI) due to volume depletion from excessive ileostomy loses. The patient was eventually discharged home four months after the surgery with in situ ileostomy and small bore tunneled internal jugular catheter for fluid administration at home to prevent AKI.

Conclusions: The case underlines the need for physicians and nephrologists to be cognizant about the potential side effects of SPS in CKD and especially renal transplant recipients, even at small doses. The immunosuppressive agents can mask the usual signs and symptoms of intestinal perforation so subtle symptoms like abdominal pain should rise high index of suspicion. Intestinal perforation itself has high morbidity and mortality but with concomitant immunosuppression the morbidity increases several fold as illustrated by our case. SPS should be used with extreme caution in post-op period especially in renal transplant recipients on immunosuppression.

PUB714

Sirolimus Based Dual Immunosuppressive Therapy in Renal Transplant Recipients with Malignancies Joon-Seok Kim, Chung Hee Baek, Hyosang Kim, Su-Kil Park. *Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Seoul, Republic of Korea.*

Background: Sirolimus exhibits both antineoplastic and immunosuppressive effects. Conversion to sirolimus based regimen is considered as a common practice when de novo posttransplant malignancy (dNPTM) is newly diagnosed. We evaluated the effect and safety of low dose sirolimus based dual immunosuppressive regimen in renal transplant recipients with dNPTMs.

Methods: From January 2003 to October 2013, calcineurin inhibitor based triple immunosuppressive regimen was converted to dual regimen consisted of low dose sirolimus and corticosteroid in 11 patients among renal transplant recipients who diagnosed as

dNPTM. The initial dose of sirolimus was 2mg daily, without a loading dose at converson. Subsequently, sirolimus dose was adjusted to maintain whole blood level between 4 and 6 ng/ml.

Results: The median time from transplantation to the diagnosis of dNPTM was 66 (13-151) months with median follow-up period of 25 (3-47) months. At the end of follow-up, median doses of sirolimus and prednisolone were 1 mg/day and 5 mg/day (or equivalent doses of other corticosteroids), respectively. Estimated GFRs by CKD-EPI equation were increased from 68.36±6.75 ml/min/1.73m² to 78.2±6.99 ml/min/1.73m² at last follow-up (p=0.02). Total cholesterol level was significantly increased (Δ 40.36±14.08 mg/dl, p=0.017). When compared as an ordinal scale, there was a tendency to increase proteinuria determined by a semi-quantitative dipstick test without statistical significance (p=0.084). Hemoglobin level, WBC and platelet counts showed no significant difference. Six patients (55%) experienced adverse events, presumably related to sirolimus. One patient needed to stop sirolimus due to nephrotic ranged proteinuria and 3 patients required its dose reduction due to pneumonitis. There was no episode of rejection. At the end of follow-up, 8 patients including 7 patients stayed in remission of cancer were alive, and 3 patients died of cancer related events.

Conclusions: Low dose sirolimus with corticosteroid was effective to maintain renal graft function and relatively well tolerated in renal transplant patients with dNPTMs.

PUB715

Ongoing Atypical Hemolytic-Uremic Syndrome after Second Kidney Transplantation on Eculizumab Therapy: Complete Recovery after Plasma Exchange and Intense Eculizumab Therapy Jorge Alexandre Fares, Carlos Eiji Koga, Andre F.G. Larrubia. *Nephrology, REDE D´ÓR - Hospital Sao Luiz Morumbi, Sao Paulo, Brazil.*

Background: CSM, 42 yrs-old, female, was submitted to a 2nd kidney tx(Ktx), unrelated donor, spouse, 6MM, on last feb. 15th. Genetic analysis revealed C3 and Factor I mutations.

Methods: Patient received meningococcal vaccine, Cipro prophylaxis, and Eculizumab infusions started 30 days before second Ktx: induction phase(900mg-weekly)with the forth dose at the day before Ktx, and a extra dose 24h after and at day 8, and 15, when relapse occurred(day15). Plasma Exchange started on day 20,and Eculizumab 600mg was infused after each session(15 sessions). Imx protocol: Basiliximab 2 doses induction and maintenance, Sodium Mycophenolate, Tac., and St. Daily Hemogram, Haptoglobin, LDH and Reticulocytes count were obtained to monitor Thrombotic Microangiopathy activity.

Results: Serum creatinine was 1.97mg-dl on day3 and 1.69m-dl on day 17. Two Kidney bxs were performed on day 3 and 8, both showing ATN. Pneumonia occurred on day 9, and a Subcutaneous Hematoma after 2nd bx(on day8) occurred before relapse. Labs results when patient relapsed: haptoglobin <36mg-dl[22]; Hb;7.9g-dl;Reticulocytes:19% on day15, and hapto undetectable on day 18,and 19;LDH:602 U-l; Hb;7,4g-dl;tacrolimus level on day16:4,6 ng-ml; Plat.:190.000 mm3. Labs at discharge on day 41: Hapto:81mg-dl;Hb:9,5g-dl; Plat:150,000mm3; LDH:303U-l; WBC:7,060mm3; BUN;15mg-dl; C:0.95mg-dl; TAC:11,1ng-ml. Current labs results on day108: Hb:11,4 g-dl; Hapto:131mg-dl;Plat;269.000mm3; LDH:314;C;1,08; BUN:29.

Conclusions: Despite prophylactic use of Eculizumab, this patient presented overt TMA post-Ktx probably related to surgery, ischemia-reperfusion and infection. The ongoing aHUS after transplant was successfully treated with PE and extra doses of Eculizumab. We therefore recommend that hemolysis biomarkers be monitored in the immediate post-Ktx period in order to detect early activity and prompt intervention be done to achive hematological and kidney function recovery.

Clinical Outcome of BK Virus Associated Nephropathy in Renal Transplant Recipients: Single Center Experience In-Ae Jang,[1] Bum Soon Choi,[1] Cheol Whee Park,[1] Yeong Jin Choi,[2] Chul Woo Yang,[1] Yong-Soo Kim,[1] Byung Ha Chung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Dept of Hospital Pathology, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: BK virus-associated nephropathy (BKVAN) is an important cause of allograft dysfunction in kidney transplant recipients. It has an unfavorable clinical course, and no definite treatment guidelines have yet been established. Here, we report our center's experience with biopsy-proven BKVAN cases and investigate factors associated with its progression.

Methods: Between January 2004 and April 2013, 25 patients with BKVAN were diagnosed by biopsy at Seoul St. Mary's Hospital. Of the 25 patients, 10 were deceased-donor transplant recipients and the remaining 15 were living-donor transplant recipients. Three of the patients underwent retransplantation. The primary immunosuppressant used was cyclosporine in 8 patients and tacrolimus in 17 patients.

Results: BKVAN was observed at a mean duration of 22.8 ± 29.1 months after transplantation. The mean serum creatinine level at biopsy was 2.2 ± 0.7 mg/dL. BKVAN occurred with acute rejection in 8 patients (28%). Immunosuppression modification was performed in 21 patients (84%). In addition, leflunomide and intravenous immunoglobulin were administered to 13 (52%) and 2 patients (8%), respectively. Allograft loss occurred in 5 cases (27.8%) during the follow-up periods of 0.7, 17.1, 21.8, 39.8, and 41.5 months from the BKVAN diagnosis. Advanced stages of BKVAN, increased creatinine levels, and accompanied acute rejection at BKVAN diagnosis increased the risk of allograft failure.

Conclusions: In the present study, the clinical outcomes in patients with biopsy-proven BKVAN were unfavorable, especially in those with advanced-stage BKVAN, poor renal function, and acute allograft rejection.

PUB717

Immunologic and Non-Immunologic Complication of Third Kidney Transplantation Hyunseon Kim, Chul Woo Yang, Byung Ha Chung, Yong-Soo Kim, Cheol Whee Park, Bum Soon Choi. *Transplant research center,Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, Seoul, Korea.*

Background: Patients who undergo repeat kidney transplantations (KT) are considered at high risk of experiencing immunologic and non-immunologic complications. In this study, we aimed to investigate the clinical outcomes including medical and surgical complications in patients who underwent a third KT in our center.

Methods: Between March 1969 and December 2012, 2,110 KT were performed at the Seoul St. Mary's Hospital. Of them, we examined 11 patients who underwent a third KT, and investigated the allograft outcomes and complication rates.

Results: The mean follow-up duration after KT was 151.8 ± 143.2 months. The mean age at KT was 38.2 ± 8.0 years, and 7 patients (63.6%) were men. Nine patients (81.8%) underwent living donor KT (LDKT). A cross-match test yielded positive results in 4 of the 9 patients, and all underwent pre-transplant desensitization therapy. After KT, 3 patients (27.2%) showed delayed graft function. Acute rejection developed in 4 patients (36.4%), and surgical complications required surgical correction developed in 4 patients. Allograft failure developed due to acute rejection (n = 3) or chronic rejection (n = 1) in 4 patients.Allograft survival rates at 1, 5, and 10 years were 81.8%, 42.9%, and 42.9%, respectively; however, allograft survival rate at 5 years was >80% when examining patients who underwent KT only after results of the panel reactive antibody test became available.

Conclusions: Thus, a third KT procedure may be acceptable, although aggressive pretransplant immune monitoring and patient selection may be required to reduce the risks of acute rejection and surgical complications.

PUB718

Incidence and Clinical Significance of De Novo Donor Specific Antibodies Post Kidney Transplantation: The Role of the Primary Disease Sophia Lionaki,[1] Apostolos Pappas,[1] Helen Kapsia,[1] Nikolaos Altanis,[1] Georgios Liapis,[1] Aliki G. Iniotaki,[2] George Zavos,[1] Ioannis Boletis.[1] *[1]Nephrology and Transplantation, Laiko General Hopsital, Athens, Greece; [2]National Tissue Typing Centre, Gennimatas General Hospital, Athens, Greece.*

Background: To explore the impact of the Primary Disease (PD) nature in the incidence of de novo Donor Specific Antibodies (DSA) after Kidney Transplantation (KTx), and their correlation with subsequent Acute Rejection (AR).

Methods: We studied patients who were transplanted between 2005 and 2011. Patients with unknown PD, a history of non-compliance, ABO incompatible KTx and a history of DSA prior to KTx were excluded. Patients were categorized by the PD as following: Group A included patients with glomerulonephritis in the native kidneys, primary or in the setting of autoimmune disease, and group B patients with hypertension, obstructive uropathy, polycystic kidney disease, or congenital hypoplastic kidneys. We estimated the frequency of de novo DSA post KTx in the two groups, and the incidence of AR.

Results: Of the 269 patients with known PD, 38 were excluded. Group A and group B were consisted of 92 and 142 patients respectively.

	Group A	Group B	P value
Recipient age(years)	42.7	43.8	0.537
Donor (deceased)	50.7	57.5	0.366
Donor age (years)	52.2	51.25	0.663
Hemodialysis time (months)	46.25	54.4	0.219
PRA >30%	11.4%	15%	0.486

The frequency of de novo DSA was 10.9% for group A, and 11.8% for group B (p=0.835). The mean time to detection was 20.9 months from KTx. Biopsy proven AR (BPAR) was recorded in 13.45% of the total cohort, during a follow up time of 56.5 months. In group B, detection of de novo DSA was associated with higher rates of BPAR (37.5% versus 8.3%, p=0.002, RR=6.6), compared to the patients of the same group without de novo DSA, while in group A there was no difference in BPAR between the patients with and without de novo DSA.

Conclusions: The incidence of de novo DSA was not different between patients with a PD of autoimmune origin, or not. However, detection of de novo DSA was associated with higher rates of BPAR among patients with a non-autoimmune PD, while in patients with an autoimmune PD the rate of BPAR was not influenced by the development of de novo DSA.

PUB719

A "First-in-Human Study" of Implantation of Neo-Kidney Augment®, an Autologous Selected Renal Cell Population, in Type-2 Diabetic CKD 3-4 Patients Torbjörn Lundgren,[1] Jonas Wadstrom,[1] Pontus Blomberg,[2] Torkel Brismar,[3] Peter Stenvinkel.[4] *[1]Dept of Transplantation Surgery, Karolinska Hospital, Stockholm, Sweden; [2]Vecura at Clinical Research Center, Karolinska Hospital, Stockholm, Sweden; [3]Radiology, Karolinska Univ Hospital, Stockholm, Sweden; [4]Renal Medicine, Karolinska Hospital, Stockholm, Sweden.*

Background: Multiple animal models of CKD have demonstrated that a selected population of therapeutically bioactive renal cells (Selected Renal Cells, SRC) can be effectively delivered to the kidney through intra-parenchymal injection resulting in a decrease in disease progression. Direct injection of SRC has been shown to reduce chronic

infiltration by monocytes/macrophages and T-lymphocytes and attenuate the NFkB response known to drive tissue inflammation and promote tubular cell expansion. We present preliminary results from the first-in-human (FIH) clinical study with NKA.

Methods: 5 male type-2 diabetic pts (64±7 yrs) with CKD stage 3-4 were selected. After evaluation of iohexol clearance, MRI, renal scintigraphy and albumin-creatinine ratio (ACR) pts underwent regular ultrasound guided renal biopsy. Two cores of renal tissue were shipped to Tengion manufacturing plant (NC, U.S.A.) for cell isolation, culture and product preparation. Formulated NKA was shipped back to Karolinska Hospital (range 59-87 days after biopsy) for intracortical injection using a laparoscopic technique.

Results: Implantation of NKA was uneventful in all pts. A postoperative complication was observed in one pt (ileocecal volvulus). Infectious complications were observed in 3 pts during follow-up. Antihypertensive medication has been reduced in 2 pts during the first 6 months post-implantation period. Kidney volume, obtained using 1.5 T MRI, was unchanged on the side of injection, 221±62 mL before and 219±54 mL after 3 months. On the contralateral side the kidney volume was 242±75 mL before and 243±59 mL at 3 months.

Conclusions: Using laparoscopic techniques, NKA was safely implanted in 5 CKD pts in this FIH trial. Complications after implantation seem unrelated to the product. Longer follow-up and larger number of pts is needed to reveal if this novel technique arrest progression of CKD and delay the start of renal replacement therapy.

Renal Transplantation in Elderly Patients - Polish Multicentre Study

Alicja Debska-Slizien,[1] Magdalena Jankowska,[1] Maciej Slupski,[2] Jolanta Malyszko,[3] Jacek S. Malyszko,[3] Monika Zurawska,[1] Andrzej Adamowicz,[2] Zbigniew Wlodarczyk,[2] Michal Mysliwiec,[3] Boleslaw Rutkowski.[1] *[1]Dept of Nephrology, Transplantology and Internal Medicine, Medical Univ, Gdansk, Poland; [2]Surgery and Transplantation, CM UMK, Bydgoszcz, Poland; [3]Dept of Nephrology and Transplantology, Medical Univ, Bialystok, Poland.*

Background: The elderly are the fastest growing population among dialysis patients and on waiting lists for kidney transplantation. We analyzed the results of the renal transplantation in recipients elder than 60 years and their younger pairs receiving graft from the same donor between Jan 1994-Dec 2012 in 3 centres.

Methods: The older renal transplantation (ORT) group included 164(102m, 62f) patients aged from 60 to 81(mean 65±4) years. Their pairs created a younger renal transplantation (YRT) group consisting of 164(104m, 60f) patients aged from 14 to 59 (mean 45±12)years. The groups wew similar in respect to dialysis modality, initial immunosuppression. ORT was on dialysis longer duration of dialysis significantly longer, more ORT suffered from coronary heart disease (40% versus 15%) and DM (18 versus 3%).

Results: ORT and *YRT* did not differ significantly with respect to: graft function estimated 1 year after transplantation (CKD-EPI) (50.7 ml/min versus 54.0 ml/min), but the decline in eGRF was significantly faster in YRT (Δ 12-3; p<0.01). One year patient survival (93.9% *versus* 97.0%),one-year graft survival (90.4% versus 82.3%),one-year death- censored graft survival(93.9% *versus* 85.3%; p=0.0222)and the incidences of delayed graft function and acute rejection were similar in OTR and YTR, respectively. During the observation period patient, graft and death –censored graft survivals were as follow: 85.3% versus 92.6% (p=0.0122); 78% versus 72.6% and 89.6% versus 76.9% (p=0.014) in ORT and YRT, respectively. Significantly more cardiovascular complications and post transplant DM were noticed in ORT (p<0.01) and the leading cause of death during 1 year after transplantation were infection and cardiovascular events, followed by neoplasia in the next years.

Conclusions: Our multicentre results confirm that renal transplantation is a good option of renal replacement therapy in patients older than 60 years.

Can Mg Blood Levels in Renal Transplant Recipients Predict Allograft Outcome?

Tammy Hod, Bhanu K. Patibandla, Anil K. Chandraker. *Transplant Research Center, Brigham and Women's Hospital, Boston, MA.*

Background: Hypomagnesemia has been found to be correlated with higher CNI levels, new onset diabetes after transplantation and also hyperparathyroidism post renal transplantation, a known risk factor for vascular calcifications and nephrocalcinosis. Little, however, is known about the relationship between magnesium (Mg) levels and allograft outcome.

Methods: We conducted a retrospective single-center pilot analysis in order to assess Mg blood levels posttransplant association with allograft outcome.

Results: Subjects had a mean age of 49±15 with 57.5% being male. Patients were divided into 2 groups based on the median Mg level measured bewteen 1-12 months posttransplant. Surprisingly those with median Mg level< 1.7 mg/dL (N = 39) versus median Mg level≥ 1.7 mg/dL (N=37) had lower serum creatinine (Scr) values 3 years posttransplant (mean Scr±SD of 1.35±0.51 and 1.78±0.87 respectively, p = 0.018) and a higher GFR (mean GFR±SD of 54.5±15.86 and 46.5±17.8, p=0.04). In 479 patients the odds of a GFR < 60 ml/min three years after transplant was two-fold higher (OR 2.01 95%CI 1.26- 3.20, p=0.004) in patients with Mg level ≥ 1.7 mg/dL relative to those < 1.7 mg/dL when adjusted for age, gender and race.

Conclusions: Lower Mg levels posttransplant are associated with better long term renal graft outcome despite the known association of hypomagnesemia with diabetes and CNI toxicity. Mg levels may serve as a marker of better renal tubular function.

Table 1: Baseline characteristics of the low Mg group versus the high Mg group

	Mg<1.7 (N=39)	Mg≥1.7 (N=37)	P value
Age	48 (14)	52 (16)	0.303
Males	21 (53.8%)	23 (62.2%)	0.469
Females	18 (46.2%)	14 (37.8%)

Bortezomib Based Regimen in the Treatment of Antibody Mediated Rejection in Kidney Transplant Recipients

Angelito F. Yango, Bernard V. Fischbach, Valerie Tan, Arun Chandrakantan, Jeffrey A. Klein. *Baylor Transplant Service, Baylor All Saints, Fort Worth, TX.*

Background: Bortezomib is an emerging therapy for antibody mediated rejection (AMR). We describe our experience with bortezomib in conjunction with intravenous immunoglobulin (IVIG) and plasmapheresis (PP) in 6 patients with AMR.

Methods: A retrospective review was performed on 6 renal transplant recipients with AMR. Therapy for AMR included serial PP, IVIG (500mg/kg) and bortezomib (1.3mg/m2) on days 1, 4, 8 and 11. DSA were detected at the time of rejection and were monitored serially after treatment.

Results: Between Jan 2011 to Apr 2012, AMR was diagnosed in 6 recipients of DDKTx. Four patients were highly sensitized with PRA of > 90%. All episodes of AMR occurred within 6 months posttransplant. 4 patients received induction therapy using ATG (n=3) and alemtuzumab (n=1). At the time of rejection, 3 patients had de novo class I, 2 had class II and 1 had both class I and class II DSA. The mean pretreatment mean fluorescence intensity (MFI) for DSA class I and class II were 5890 and 9733 respectively. Posttreatment, all patients had a significant reduction in MFI (class I - 1700, class II 1688). This response was sustained up to a mean ff up of 9 months posttreatment with mean MFI for both class I and class II DSA remaining low at 1214 and 671 respectively. Four patients underwent follow up biopsies posttreatment and in all cases, C4d staining converted from positive to negative. Patient and graft survival at 1 year was 100%. Mean creatinine at the time of rejection was 5.7mg/dl. At 12 months, the mean creatinine was significantly lower at 1.14 mg/dl

DSA	Patients					
	1	2	3	4	5	6
Pretreatment MFI	A30-5750	A3 - 3180	DR53 - 17939	A24 - 4303	B45-6441	A24 - 2588
	A31 - 6072	CW5 - 12902				DR4 - 1527
Posttreatment MFI		A3 - 1086	DR53 - 3359	A24 - 261	B45-NEG	A24 - 41
		CW5 - 7115				DR4 - 17
MFI at last follow up (9mo)	A30-1031	A3 - 1000	DR53 - 1308	A24 - 99	B45 - 60	A24 - NEG
	A31- 1374	Cw5 - 5000				DR4 - 35

Conclusions: Bortezombi in addition to PP and IVIG is an effective treatment combination for AMR and achieves a sustained reduction in DSA.

PUB723

Vitamin D Deficiency Is Significantly Associated with Anemia in Patients with End-Stage Renal Disease Chang-Yun Yoon,[1] Hyunwook Kim,[3] Yungly Kim,[1] Eunyoung Lee,[1] Seung Gyu Han,[1] Young Su Joo,[1] Shin-Wook Kang.[1,2] *[1]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Brain Korea 21 PLUS, Severance Biomedical Science Institute, Yonsei Univ, Seoul, Korea; [3]Dept of Internal Medicine, College of Medicine, Wonkwang Univ, Gyoeonggi-do, Korea.*

Background: Recent studies have indicated that vitamin D may affect the efficacy of erythropoiesis through its anti-inflammatory action. Even though both vitamin D deficiency and anemia are prevalent in patients with end-stage renal disease (ESRD), the association between these two factors remains poorly understood. In this study, therefore, we investigated the impact of vitamin D deficiency on anemia in ESRD patients.

Methods: This study included 106 ESRD patients who underwent kidney transplantation at Yonsei University Health System between April 2002 and May 2004. Patients were divided into tertiles according to the levels of 25-hydroxyvitamin D [25(OH) D] (Group 1, <9.35; Group 2, 9.35 to 15.50; Group 3, >15.50 ng/mL). Independent association between vitamin D and hemoglobin (Hb) concentrations was evaluated by multivariate linear regression analysis.

Results: The mean serum 25(OH)D and Hb levels were 13.06±6.31 ng/mL and 9.45±1.76 g/dL, respectively. Hb concentrations showed a significant trend of increase across the 25(OH)D groups (Group 1, 9.0±1.8; Group 2, 9.4±1.7; Group 3, 9.9±1.7 g/dL; P for linear trend=0.047). Multivariate linear regression analysis revealed that serum 25(OH) D levels were independently associated with Hb concentrations after adjustment for sex, age, serum calcium and phosphorus levels, intact parathyroid hormone concentrations, and the use of erythrocyte stimulating agents (per 1 ng/mL increase, β=1.168, 95% confidence interval=0.434 to 1.901, P=0.02).

Conclusions: Vitamin D deficiency was significantly associated with anemia in ESRD patients. Further studies are needed to verify whether vitamin D supplement can improve anemia in this population.

PUB724

Change in Body Mass Index (BMI) After Kidney Transplantation and Long-Term Outcomes Tushar Malavade, Olusegun Famure, Yanhong Li, Joseph Kim. *Div of Nephrology and the Multi-Organ Transplant Program, Toronto General Hospital, Univ Health Network, Toronto, ON, Canada.*

Background: The long-term consequences of weight change over the first year after kidney transplantation remains unclear. We studied the relationship between change (Δ) in BMI over the first year after kidney transplantation with graft and patient outcomes.

Methods: We performed a cohort study of all adult recipients of kidney transplants at our center from 1 Jan 2000 to 31 Dec 2011 to determine if Δ BMI over the first year is associated with total graft failure, death-censored graft failure, and death with graft function. Recipient Δ BMI was categorized as ≤ -5%, -4.9 to - 0.1%, 0 to 4.9% (reference), 5 to 9.9% and ≥ 10%. The association of Δ BMI and graft/patient outcomes was assessed in multivariable Cox proportional hazards models.

Results: A total of 1186 patients were studied during which 91 graft losses and 86 deaths occurred over 5346.4 patient-years of follow-up. Patients with a reduction in their BMI greater than 5% over the first year post-transplant was linked to a significantly elevated relative hazard of total graft failure when compared to the referent group of Δ BMI 0 to 4.9%

Outcomes	Δ BMI at 1 year post-transplantHazard Ratio (95% CI)				
	< -5% (n=175)	-5 to -0.1% (n = 205)	0 to 4.9% (n=300)	5 to 9.9 % (n=227)	> 10 % (n=279)
Total Graft Failure	1.65 (1.06, 2.55)	1.02 (0.64, 1.62)	Reference	0.95 (0.59, 1.53)	0.66 (0.41, 1.08)
Graft Failure	1.21 (0.61, 2.37)	0.95 (0.50, 1.81)	Reference	1.00 (0.52, 1.92)	0.76 (0.41, 1.42)
Death	2.00 (1.09, 3.69)	1.00 (0.51, 1.95)	Reference	0.87 (0.42, 1.79	0.45 (0.20, 1.04)

Table 1: Hazard ratios for graft failure and/or death by Δ BMI categories

An increase in weight over the range studied by 1-year was not associated with the risk of graft loss or death beyond 1-year.

Conclusions: A reduction in BMI more than 5% in the first year after kidney transplant is associated with an increased risk of death and total graft failure whereas weight gain during the same time was not detrimental to long-term outcomes.

PUB725

Daily Fluid Intake and Outcomes in Kidney Recipients: Post-Hoc Analysis from the Randomized ABCAN Trial Marc L. Weber,[1] Danielle M. Berglund,[2] Scott Jackson,[1] Arthur J. Matas,[2] Hassan N. Ibrahim.[1] *[1]Medicine, Univ of Minnesota, Minneapolis, Minnesota; [2]Surgery, Univ of Minnesota, Minneapolis, MN.*

Background: Generous and even excessive fluid intake is routinely recommended to kidney transplant recipients despite minimal evidence to support this practice. We hypothesized that increased fluid intake, ascertained by 24-hour urine volume output, may adversely affect graft outcomes as it would impose an extra work load on a limited number of nephrons.

Methods: Kidney transplant recipients who were randomized to losartan versus placebo in the ABCAN trial (n=153) underwent baseline, five year biopsies and annual iothalamate GFR. Participants were divided into tertiles based on 24-hour urine volume (<1.73 L/day, 1.73-2.56 L/day, and >2.56 L/day) at time of randomization. A multivariate logistic regression model was constructed to evaluate the association between baseline urine volume as a predictor of the primary and secondary outcomes.

Results: Recipients with higher urine volume at randomization had higher urinary sodium and also higher urinary protein. The distribution of diuretic use or CNI based regimens were similar across urinary volume tertiles. Highest urinary volume tertile (>2.56 L/day) did not predict the development of interstitial volume doubling or ESRD from IF/TA (OR=3.21, 95% CI 0.31, 33.40, p=0.33), was modestly associated with interstitial volume doubling or all-cause ESRD (OR=11.34, 95% CI 0.79, 161.96, p=0.07), but was not associated with the conventional endpoint of doubling serum creatinine, all cause ESRD, or death (OR=0.53, 95% CI 0.12, 2.40, p=0.41).

Urinary Volume >2.56 L/day* as a predictor of the primary and secondary endpoints:

Outcome	OR (95% CI)	*p* value
Doubling of Interstitium or ESRD from IF/TA	3.21 (0.31, 33.40)	0.33
Doubling of Interstitium or any ESRD	11.34 (0.79, 161.96)	0.07
Doubling of Serum Creatinine, All Cause ESRD or Death	0.53 (0.12, 2.40)	0.41

*Urine volume compared to reference of UV <1.73 L/day

Conclusions: These results suggest that the current practice of liberal fluid intake may not only be not beneficial but maybe associated with more allograft fibrosis.

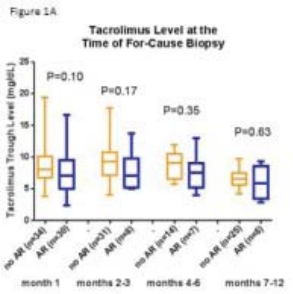
PUB726

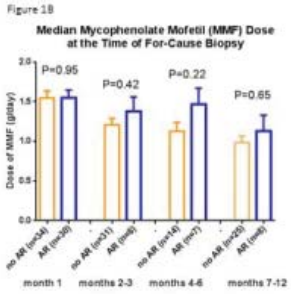
Why Do Allograft Recipients Develop an Episode of Acute Rejection while on Immunosuppressive Therapy? A Single Center Study of 543-Kidney Graft Recipients Sean R. Campbell, John R. Lee, Thangamani Muthukumar, Manikkam Suthanthiran, Darshana Dadhania. *Medicine, New York Presbyterian Hospital, New York, NY.*

Background: Acute rejection (AR) of a kidney transplant, whether it is T cell mediated acute cellular rejection (ACR) or antibody mediated rejection (AMR), is a major cause of graft dysfunction and loss. Why patients on immunosuppressive (IS) therapy develop AR is an unresolved puzzle. Insufficient immunosuppression due to physicians prescribing inadequate amounts of IS drugs and/or patient medication non-adherence is a plausible hypothesis.

Methods: We investigated whether AR diagnosis is associated with: (i) lower tacrolimus trough levels, (ii) lower mycophenolate mofetil (MMF) dosage or (iii) non-adherence. Among 543 patients transplanted between 1/2008 and 12/2010, 157 patients underwent a for-cause allograft biopsy during the first year post-transplantation: 53 patients with AR biopsies, 44 with Tubular Necrosis/Toxicity, 31 with Other findings and 29 with Non-Specific findings.

Results: Figures 1A and 1B illustrates tacrolimus trough levels and MMF dosages were not significantly different between patients with and without AR during the first 12 months. Two of 157 patients had documented non-adherence. Serum anti-HLA donor specific antibodies (DSA) were tested in 135 patients, of which 52 tested positive and 83 tested negative. Mean±SD tacrolimus trough levels were 7.8±3.1 ng/ml and 8.1±2.9 ng/ml (P= 0.67) in the DSA positive and negative groups respectively and mean±SD daily MMF dosage were 1.5±0.51 grams 1.2±0.47 grams (P<0.0001) in the DSA positive and negative groups respectively.





Conclusions: Our data demonstrates that medication non-adherence and IS therapy at the time of a for-cause biopsy fail to explain the development of AR. These results suggest the need for more research on better methods for ascertaining the in-vivo immune status of the graft recipient.

PUB727

Invasive Aspergillosis after Kidney Transplantation: A Case-Control Study

Line Heylen,[1] Johan Andre Maertens,[2] Maarten Naesens,[1] Dirk R. Kuypers,[1] Ben Sprangers.[1] *[1]Nephrology, Univ Hospitals Leuven, Leuven, Belgium; [2]Haematology, Univ Hospitals Leuven, Leuven, Belgium.*

Background: Transplant recipients are among the most significant subgroups of immunosuppressed hosts at risk for invasive aspergillosis (IA). Renal transplantation-specific risk factors for IA have not been defined.

Methods: A retrospective case-control study was performed, including 41 renal transplant recipients with a diagnosis of proven (44%) and probable (56%) IA from 1995 through 2013. The two patients that underwent renal transplantation immediately before and after each case and did not develop IA, were used as control population (n = 82). Variables included were age, gender, duration of hemodialysis before transplantation, smoking habits, chronic lung disease, diabetes mellitus, respiratory function, HLA mismatch, use of basiliximab or antithymocyte globulin, donor and recipient CMV seropositivity and its prophylaxis, and leukopenia. Cox proportional hazard analysis was used to analyze week 12 mortality of the cases with the same covariates, as well as the serum and bronchoalveolar lavage (BAL) galactomannan (GM) index.

Results: The occurrence of leukopenia after kidney transplantation increased the risk of IA among all patients (OR 2.345 (95% CI 1.084-5.071)). 37% had early-onset IA (i.e., occurred during the first 3 months after transplantation). A longer duration of hemodialysis before transplantation and the occurrence of leukopenia after transplantation were risk factors for early-onset IA (OR 1.192 (95% CI 1.006-1.413) and OR 3.346 (95% CI 1.063-10.527), respectively), while donor CMV seropositivity was a risk factor for late-onset IA (i.e., occurred >3 months after transplantation) (OR 3.677 (95% CI 1.388-9.743)). Mortality rate at week 12 after diagnosis was 39%. Disseminated IA, leukopenia at presentation and the height of the serum GM index were associated with an increased risk of death (HR 5.080 (95% CI 1.740-14.830), HR 3.198 (95% CI 1.183-8.649), HR 1.371 (95% CI 1.123-1.674), respectively).

Conclusions: We described for the first time an association between duration of hemodialysis before kidney transplantation and early-onset IA. The serum GM index could predict mortality, whereas the BAL GM index did not.

PUB728

Deflazacort versus Prednisolone: A Study in Renal Transplant Recipients

Richard Savio Fernandes Almeida, Amar Kulkarni, Alan F. Almeida, Jatin P. Kothari, Rasika A. Sirsat. *P.D. Hinduja National Hospital and Medical Research Centre, Mumbai.*

Background: Deflazacort (DEF), a derivative of the old molecule prednisolone(PRD), reported to have a similar efficacy and a more favourable adverse effect profile, has not been evaluated adequately in Indian kidney transplant recipients.The objective of the present study was to compare DEF with PRD with respect to efficacy and safety in kidney transplant recipients.

Methods: Out of 103 archived medical records that were available for review, 60 patients (30 on DEF, 30 on PRD) fulfilled the inclusion criteria. Patients included in the study had been transplanted at least a year before, had received a CNI based immunosuppression (tacrolimus or cyclosporine) along with an anti-proliferative agent (mycophenolic acid or azathioprine) with either DEF or PRD. Retrospective analysis of clinical, biochemical, histological and radiological data was performed. Patients were started on DEF (1.2 mg/kg/day) or PRD (1 mg/kg/day) and were tapered to a maintenance dose of 6 – 12 mg (DEF) and 5 – 10 mg (PRD) by the end of 1 month. For efficacy, interval serum creatinine, graft and patient survival, presence of acute and chronic rejection, were examined. For safety, BMI gain, new-onset diabetes, cataract, cosmetic appearance, dyslipidemia, osteoporosis and post transplantat infections were analysed. Statistical analysis was conducted using Student's t-tests and Fisher's exact test.

Results: The groups were similar in age, sex, pretransplant BMI and HLA mismatches. The patients on DEF were followed up for a period of 3.13±0.93 and those on PRD for 3.46±0.97 years. There was no significant difference between the 2 groups in parameters related to efficacy. However, there was a significant difference in the incidence of steroid facies (p=0.025), new onset diabetes (p=0.036), cataract (p=0.010), osteoporosis (p=0.0001), chest infections (p=0.025) and a percentage increase in BMI over baseline at 180 days (p=0.03) and 1 yr (p=0.02), with those on DEF demonstrating higher levels of safety.

Conclusions: As DEF has a more favourable adverse effect profile, it could be the preferred option in the Indian set-up. However, further research is required to substantiate these findings.

PUB729

Subclinical Cardiac Damage and Its Determinants in a Cohort of Kidney Transplanted Patients

Carlo M. Alfieri,[1] Riccardo Floreani,[1] Maria Meneghini,[1] Anna Regalia,[1] Francesca Zanoni,[1] Simone Vettoretti,[1] Maria Teresa Gandolfo,[1] Maria Daniela Croci,[1] Maria Pia Rastaldi,[2] Piergiorgio Messa.[1] *[1]Nephrology, Dialysis and Kidney Transplantation, Fondazione IRCCS Ca' Granda Ospedale Policlinico, Milan, Italy; [2]Renal research laboratory, Fondazione IRCCS Ca' Granda Ospedale Policlinico, Milan, Italy.*

Background: Left ventricular hypertrophy (LVH) is mostly responsible for the relevant cardiovascular risk in kidney transplanted patients (KTx). The aim of our study was to evaluate: 1) the prevalence of LVH 2) the factors related with left ventricular mass index (LVMI) and 3) those implicated in the increase of LVMI during the 1st year of KTx.

Methods: In 121 pts(M=69) over the 470 transplanted between 2004 and 2013 in our Unit, clinical parameters, blood and urinary samples were collected at 1st(T0) and 12th(T12) month after KTx. In addition, plasmatic levels of FGF-23, Fetuin-A, 25OH-Vitamin D, and Osteoprotegerin (OPG) were assessed. Cardiac parameters were determined by echocardiography: LVMI was indexed at the height$^{2.7}$ and LVH was defined as LVMI>51g/m$^{2.7}$.

Results: At T0,LVMI correlated with age, albumin, FGF-23, SBP, U-Prot-24h and BMI, whereas at T12 it was directly correlated with age, albumin, OPG, FGF-23. In multivariate regression, FGF23 at T0 and albumin at T12 resulted the only parameters associated with LVMI at T0 and at T12 resp. (both p=0.04). LVH was present in 49% of pts at T0 and in 50% at T12, and during the 1styear of KTx, 15% of patients developed LVH,whereas 19% had its regression. Considering the percentage of increase of LVMI in the two time points, in multiple regression LVMI at T0 resulted the only modifiable risk factor associated with LVMI worsening(p=0.001). No influence for immunosuppressive and anti-hypertensive therapy both in general and class-specifically was found as like as for Hb and mineral metabolism parameters.

Conclusions: The prevalence of LVH is relatively high in KTx patients. Nevertheless, in a small portion of them, we observed an improvement of cardiac abnormalities. FGF-23 and albumin seem to influence LVMI. In any case, LVMI at baseline is the only modifiable risk factor able in predicting LVMI increase in the 1st year of KTx.

PUB730

Cinacalcet Use in the Treatment of Hyperparathyroidism in Patients after Renal Transplantation

Nelomi Anandagoda, Tanuja Yalamarti, Mona Wahba. *SW Thames Renal Unit, St. Helier Hospital, Carshalton, Surrey, United Kingdom.*

Background: There are no current guidelines on the use of Cinacalcet in the treatment of hyperparathyroidism in patients following renal transplantation. Thus, evaluation of the effect of Cinacalcet in treatment of hyperparathyroidism after renal transplantation and assessment of potential adverse effects is needed.

Methods: This observational, retrospective, single-centre study collected data from 15 patients with stable renal transplant function and persistent hypercalcaemia. Cinacalcet was commenced at a dose of 30mg/day and up titrated according to corrected calcium levels and serum parathyroid hormone. Serum calcium, phosphate, parathyroid hormone(PTH) and estimated GFR were monitored throughout the study period. All patients were radiologically assessed for parathyroid adenoma with parathyroid SESTAMIBI CT and ultrasound neck.

Results: 26.6% Male, 73.3% Female; Mean Age 59.2years (Range 31y to 75y); Median follow up time 12 months (range 3 months to 48 months); Mean initial serum corrected calcium was 2.83 ±0.13 mmol/L; the mean calcium with treatment was 2.52 ±0.18 mmol/L (p<0.001). Mean initial serum phosphate was 0.75 ±0.24 mmol/L; the mean phosphate with treatment was 0.86 ±0.19 mmol/L (p=0.026). Mean initial serum parathyroid hormone was 51.36 ±53.66 pmol/L; the average PTH with treatment was 36.68 ±26.46 pmol/L (p=0.08). There was no significant change in eGFR pre and post treatment with Cinacalcet. 93.3% of patients had confirmed parathyroid adenoma. Two patients underwent parathyroidectomy with no post-operative complications. The remaining patients were referred for surgery but did not proceed in accordance with patient's wishes. There were no recorded cardiac events, fractures sustained or renal stone disease during the study period.

Conclusions: In this study group, Cinacalcet was safe and effective in treating hypercalcaemia secondary to hyperparathyroidism. Further studies are required with a larger sample size in order to further evaluate the efficacy of this drug in the renal transplant population.

PUB731

Superior Outcomes of Kidney Transplantation Compared with Dialysis in Korea: A Propensity–Matched Analysis of a National Population-Based Cohort Study between 2005 and 2008 Kyung Don Yoo,[1] Clara Tammy Kim,[2] Jeonghwan Lee,[3] Myoung-Hee Kim,[4] Hyunwook Kim,[5] Dong-Ryeol Ryu,[6] Dong Ki Kim,[1] Chun Soo Lim,[1] Yon Su Kim,[1] Jung Pyo Lee.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Korea; [2]School of Public Health, Seoul National Univ, Korea; [3]Internal Medicine, Hallym Univ Hangang Sacred Heart Hospital, Korea; [4]Dental Hygiene, College of Health Science, Eulji Univ, Korea; [5]Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Korea; [6]Internal Medicine, Ewha Womans Univ, Korea.*

Background: Kidney transplantation (KT) can decrease all-cause and cardiovascular mortality. However, the data of KT outcome compared with dialysis was scarce in Asian population. Here, overall survival and cardiovascular outcomes of KT in Korean were compared with those of dialysis using the claim data of the Korea Health Insurance Review and Assessment Service (HIRA).

Methods: Among 35,418 all the incident dialysis patients between 2005 and 2008 in Korea, 1,563 patients who underwent KT were compared with patients maintaining dialysis without before and after 1:1 matching of propensity score. Over-all survival rate and post-transplant Major Adverse Cardiovascular Event (MACE) were traced.

Results: Before matching, dialysis group was older and had more comorbidities. After matching, there were no difference in age, sex, dialysis modalities, and comorbidity. Patient's survival in transplant group was significantly better than in matched-dialysis group by log-rank test (P <0.001). Multivariate analysis also showed that KT significantly decreased risk of death after adjusting for age, sex, and comorbidities (P <0.001, hazard ratio [HR] 0.16, 95% confidence interval [CI] 0.13-0.22). In addition, transplant group showed a better MACE free survival compared with dialysis-maintaining group (P <0.001, HR 0.16, 95% CI 0.13-0.22).

Conclusions: Long-term dialysis had significantly higher cardiovascular mortality and all-cause mortality compared with kidney transplantation in Korean incident dialysis patients. Kidney transplant could be recommended more actively in Korean population.

PUB732

Determinants of Vascular Stiffness in Pediatric Renal Transplant Recipients Michael E. Seifert,[1,2] Lisa de las Fuentes,[2] Nazia Kulsum-Mecci,[2] Victor G. Davila-Roman,[2] Keith A. Hruska.[2] *[1]Southern Illinois Univ; [2]Washington Univ in St. Louis.*

Background: CKD imparts enormous cardiovascular (CV) risk that is only partially improved by renal transplantation. We sought to understand determinants of pulse wave velocity (PWV), a surrogate for vascular stiffness and a biomarker associated with CV risk, in pediatric renal transplant recipients with excellent graft function.

Methods: This prospective cohort of 16 pediatric renal transplant recipients underwent carotid-femoral PWV and pulse wave analysis using applanation tonometry. Circulating biomarkers associated with CV risk were measured at the time of PWV. PWV was transformed to a z-score (PWV-Z) using the LMS method to normalize PWV for gender, age and height. The primary outcome was vascular stiffness, defined *a priori* as a PWV-Z > 1. Secondary outcomes included PWV, peripheral blood pressure (BP), central BP, body mass index (BMI), estimated GFR (Schwartz eGFR), transplant vintage, plasma fibroblast growth factor-23 (FGF23) and plasma phosphorus.

Results: The cohort had a mean age of 15 ± 3.1 years, mean BMI of 23.5 ± 7.8 kg/m^2, mean eGFR of 100 ± 24 ml/min/1.73 m^2, mean PWV of 5.9 ± 1.2 m/s and mean PWV-Z of 1.2 ± 0.9. All had BP < 95th percentile for age/height but 4/16 (25%) were prehypertensive (BP between 90th and 95th percentiles). Vascular stiffness was observed in 9/16 (56%) subjects. Those with vascular stiffness were older and had higher peripheral and central BP within the normal range. Prehypertensive subjects had particularly high PWV-Z (mean 2.1 ± 0.9). BMI, eGFR, transplant vintage, FGF23 and phosphorus were similar in those with versus without vascular stiffness. Using Pearson's correlation PWV-Z was significantly and positively correlated with age (r^2 = 0.610), peripheral SBP and DBP (r^2 = 0.717, 0.662), and central SBP and DBP (r^2 = 0.743, 0.673). PWV-Z did not correlate with other secondary outcomes.

Conclusions: In this modest-sized cohort of pediatric renal transplant recipients, the majority of children had vascular stiffness despite excellent graft function, normal BP and normal BMI. As in the general population, increasing age, peripheral BP and central BP correlated with increasing PWV.

PUB733

Is Polyoma Virus Common Among Middle East Kidney Transplant Recipients? Yousef Boobes, Bassam O. Bernieh, Qutaiba Hussain Daoud, Mohamed Raafat Al Hakim, Hanan Eljack, Mohamed E.O. Ahmed. *Nephrology/Medicine, Tawam Hospital, Al Ain, Abu Dhabi, United Arab Emirates.*

Background: BK viremia and nephritis is an increasing problem in renal transplant recipients. Because there is no safe and effective anti-viral therapy available presently, screening-based prevention and pre-emptive strategy are recommended. Data about its prevalence in Middle East renal transplant recipients are lacking.

Methods: All renal transplant followed in our clinic between 2011 and 2012 (ns116) were screened for the BK virus (BKV) and JC virus (JCV). Quantitative real-time polymerase chain reaction (PCR) for both blood and urine was used. Renal biopsy was performed only in patients with deteriorating renal function associated with positive urine/blood PCR. Patients who showed positive PCR assay were followed-up for at least six months by monitoring serum creatinine level and viral load.

Results: Total number of kidney transplant recipients was 116, 65 (56%) were male, age 51±15 years. Average time on transplantation was 131±61 months. JCV was found in 8% of urine and 1% of plasma specimens (weak positive). While BKV was found in 15% of urine and 2.7% (3 patients) of plasma specimens, two of them had deterioration of kidney function. Renal biopsy confirmed the diagnosis of BK nephropathy in both cases. The three cases were managed by reducing the immunosuppressive treatment with relative stabilization of their kidney function. Cases with stable renal function and positive urine PCR cleared the virus spontaneously during follow-up after minor reduction of the immunosuppressive treatment or without any intervention. None of our patients lost the graft due to BK NP. The immunosuppressive therapy was similar in both PCR positive and negative patients.

Conclusions: These results suggest that polyoma virus is not uncommon in our kidney transplant recipients. Routine screening suggested by KDIGO Guidelines could help minimizing its detrimental effect on graft survival.

PUB734

Characteristics of Immunosuppressant Noncompliance: Experience of One Urban Transplant Center Cheng Chu, Varun Malik, Christopher Bosh Zakhary, Jack Jacob, Mujtaba A. Hasnain, Thet N. Zaw, Heather Rush Lefkowitz. *Nephrology, Newark Beth Israel Medical Center, Newark, NJ.*

Background: Immunosuppressant noncompliance is a major cause of rejection and graft loss. While studies have indentified risk factors for noncompliance, there is a paucity of literature focusing on minorities and indigent populations, the group which historically has the highest rates medication non-adherence.

Methods: A total of 60 questionnaire surveys were distributed and collected at our transplant clinic to all patients post-renal allograft on chronic immunosuppression.

Results: The demographics of our respondents were 65% African American, 68.33% unemployed, and 56.67% Medicaid only patients. 5 out of 60 patients who responded to the survey self-reported some level of immunosuppressant noncompliance. The noncompliant group was associated with African American race(80%), unemployment(80%), and high school education(80%). In addition, a mann-whitney test showed that the depression score is higher in the noncompliant group than the compliant group(U=22.5, p = 0.001, r= 0.47).

Conclusions: The main limitation of our study is the small sample size of the noncompliant group, which can partly be explained by reporting bias, as the percentage of noncompliance nationally is higher. Larger studies are needed to identify and target independent risk factors relevant to our patient population.

PUB735

Role of Cytomegalovirus (CMV) Viremia Monitoring in Kidney Transplant Recepients (KTR) Receiving Basiliximab Induction Dinesh Kumar, Reetesh Sharma, Vijay K. Kher. *Nephrology, Medanta Hospita;, Gurgaon, Haryana, India.*

Background: Prophylactic and preemptive treatment strategies have been employed for Cytomegalovirus (CMV) disease prevention. While these strategies have been well tested in patients receiving thymoglobin, there is paucity of such data in those receiving basiliximab induction.

Methods: This was an observational study of consecutive 19 live donor KTRs (5 females and 14 males) at our center with positive CMV IgG serology in both donor and recipients (D+R+) to evaluate role of preemptive treatment for CMV in patients receiving basiliximab induction (20 mg day 0 and 4). They receivedIV methylprednisolone 500mg on day 0 and maintenance triple immunosuppression with tacrolimus(0.1 mg/kg/day), MMF(1gm twice daily) and prednisolone (40 mg on day 1 and tapered to 5 mg/day at end of 3 to 6 months). None of the patients received CMV prophylaxis. CMV monitoring was done using quantitative nucleic acid PCR test on day 0, week 1, 2, 3, 4, 6, 8, and month 3, 4, 5, 6. CMV infection was defined as persistent viremia with CMV DNA PCR ≥ 2000 copies while CMV disease was defined as fever, leukopenia or organ involvement in addition. Patients with CMV infection were treated with oral valgancyclovir in standard dosage.

Results: Mean recipient and donor age were 45.32 ± 11 and 50.94 ± 9.11 years. CMV infection developed in 1 patient(5.25%) and responded well to valgancyclovir. None of the patients developed CMV disease. At end of follow up, patient and graft survival were 100% and 94.74% respectively and mean serum creatinine was 1.44±1.04 mg/dl. One patient (5.26%) had biopsy proven acute rejection.

Conclusions: Preemptive treatment is an effective and economical strategy as compared to universal prophylaxis for CMV infection in moderate risk (D+R+) KTRs receiving basiliximab induction with maintenance triple immunosuppression of tacrolimus, MMF and prednisolone.

PUB736

High Grade Urothelial Neoplasms, Associated with BK Polyomavirus, Arising in Renal Allografts Daniel J. Kenan, Akanksha Gupta, Harsharan Kaur Singh, Volker Nickeleit. *Pathology and Laboratory Medicine, Univ of North Carolina, Chapel Hill, NC.*

Background: Tumors arising in renal allografts are rare; however, the incidence of urothelial carcinoma is known to be increased at least 3-4 fold in renal transplant patients. Although some renal allograft tumors have been shown to express polyomavirus large T antigen, a causal association between polyomaviruses and human malignancy has never been demonstrated. Here we discuss molecular details of the virus-host interaction that may be related to oncogenesis.

Methods: DNA was isolated from formalin fixed paraffin embedded and frozen tissue sections and submitted for deep sequencing to a read density averaging 10 reads per genomic nucleotide position. The sequences were mapped onto both the human genome as well as a canonical BK polyomavirus sequence. The mapped sequences were used to identify genomic insertion sites, viral break points, and point mutations, insertions and deletions within the viral sequences. These results were compared with related findings published in the literature. Findings were confirmed by PCR analysis. Expression of certain gene products was further analyzed by immunohistochemistry.

Results: A common feature of polyomavirus-related high grade urothelial malignancies is integration of the virus into the genome of the neoplastic cells. This is accompanied by high levels of expression of large T-antigen, without replication of the virus or expression of late viral gene products. There is no evidence of significant amplification of the virus. Upregulation of large T-antigen expression is likely related to rearrangements of the noncoding control region (NCCR), which result in deletion of sequences that down-regulate early gene expression.

Conclusions: BK polyomavirus is associated with high grade malignancies in a variety of clinical settings, including renal transplantation. This may occur in the absence of polyomavirus nephropathy, implying direct involvement of BK polyomavirus in oncogenesis that does not require latent or active infection. Such oncogenesis likely requires upregulation of large T-antigen and may also involve insertional inactivation of human genes at sites of viral integration.

PUB737

The Protective Effect of Cryotherapy Over Surgery in Post-Allograft De Novo Prostate Malignancy Cheng Chu, Varun Malik, Thet N. Zaw. *Nephrology, Newark Beth Israel Medical Center, Newark, NJ.*

Background: Chronic immunosuppression in post-transplant patients have contributed to increasing incidence of de novo malignancy. Immunosuppression reduction have shown to benefit tumor regression in some cancers, however immunosuppression reduction in conjunction with cryotherapy over standard surgical resection in prostate adenocarcinoma have not been well studied.

Methods: Data of 501 renal allograft recipients who developed post-transplant prostate de novo solid tumor was reported for transplants performed between 01/01/2000 and 06/30/2012 by United Network for Organ Sharing. Patients were followed over time for outcomes(i.e. alive with tumor, alive free of tumor, death) after undergoing different sets of treatments(i.e. Observation, surgery, cryotherapy, immunotherapy, radiation) with reduction of immunosuppressant treated as an exposure.

Results: The mean recipient age of renal allograft was 59.8 years and the time to diagnose prostate cancer post-transplantation was 4.2 years. Treatment sets were compared using odds ratio only if they had similar follow-up times. In those patients with immunosuppression reduction, Cryotherapy over surgery showed regression of tumor(OR = 0.21, 95% CI = -3.32 – 0.6, p<.05) while other treatment sets showed maintenance of tumor progression: Immunotherapy over chemotherapy(OR = 7.5; 95% CI = 7.17 – 11.86, p<.05); Radiation over chemotherapy(OR = 3.57; 95% CI = 3.39 – 6.3, p< .05); Radiation over Immunotherapy(OR = 3.57; 95% CI = 3.39 – 6.3; p<.05).

Conclusions: Our results show that in patients who had their immunosuppression regimen reduced, cryotherapy had an protective effect over surgical resection in demonstrating tumor regression. Further studies in this area are needed to elucidate this phenomenon.

PUB738

Long Term Outcomes of Renal Transplant Recipients with prior Plasmapheresis Sapna M. Jairath, Parvathy Madhavan, Amit Basu, Nicole M. Ali, Aditya Kadiyala, Vivek Jayaschandran, Neenu Sukumaran, Navya Voleti, Madhu C. Bhaskaran, Ernesto P. Molmenti. *Renal Transplant Center, NSUH, Manhasset, NY.*

Background: Plasmapheresis (PP) is a treatment modality instituted in patients to reduce risk of and treat antibody mediated rejection. Compared to other immunosuppressive agents, PP may allow for a more intense immunosuppression for a shorter time span, in the initial, crucial period when acute rejection is more likely. While the incidence for acute rejection in Renal Transplant recipients (RTR) remains low, there is limited data on long term outcomes of renal transplant "Recipients who received Pre-transplant Plasmapheresis" (RPTP).

Methods: We reviewed clinical and lab data of RTR who received their transplants from 1/1/2010 to 1/1/2013 at a single center and followed their clinical course till 6/1/2014. We compared the outcomes of RPTP for Donor Specific Antibodies, to that of all RTR in the same period. There were a total of 94 RTR, out of which 17 received PP preceding the transplant. The outcomes, including allograft failure due to recipient death or rejection, in both groups, were considered. Lab parameters including serum creatinine, proteinuria, and acute or chronic rejection on biopsy were recorded. Other variables influencing outcomes such as changes in immunosuppression, infections (BK virus, other major infections like pneumonia and sepsis), noncompliance, and lymphoma were also recorded.

Results: After a period of 18-60 months, RPTP had allograft and recipient survival comparable to overall recipient population. Moreover, BKV infections and acute and chronic rejection were also comparable in both groups. The tabulated representation of the data is shown:

	Total Recipients of Transplant	Pre-transplant Plasmapheresis Recipients(RPTP)
Total Transplant	94	17
Total Allograft Loss (Mortality + Allograft Failure)	16	3
Mortality	11	2
Alive with Failed Allograft	5	1
Acute Rejection	5	3
Chronic Rejection	13	2

Conclusions: Pre-transplant Plasmapheresis may allow comparable allograft and recipient survival in renal transplant candidates with DSA. This may be achieved without unacceptable increase in the rate of opportunistic or severe infections and allograft rejection.

PUB739

Parathyroidectomy for Tertiary Hyperparathyroidism in Kidney Transplant Recipients Zahra Deen,[1] Emad H. Asham,[2] A. Osama Gaber,[2] Dana M. Hong,[2] Luan D. Truong,[2] Sreedhar A. Mandayam,[1] Venkataraman Ramanathan.[1] *[1]Baylor College Of Medicine; [2]Methodist Hospital.*

Background: After kidney transplant, tertiary hyperparathyroidism (ThPT) can cause hypercalcemia and worsen bone disease. While calcimimetic drugs can be potentially useful, their use after transplant is not covered. We present our prevalence data, indications for parathyroidectomy (PTx), and accuracy of sestamibi scan in predicting parathyroid pathology.

Methods: In this retrospective study, we identified transplant recipients who underwent kidney transplant between 2008 and 2013 and who underwent PTx for ThPT at Houston Methodist Hospital. In addition to demographic and clinical information, data collected included serum calcium, phosphorus, Vitamin D and intact PTH (iPTH) levels obtained pre transplant, and at months 1,3,6 and 12 months post-transplantation and also bone density measurement and parathyroid scan.

Results: We identified 26 (2.5%) patients who underwent PTx, among the 1001 patients who underwent kidney transplant at our center, during the 5-year study period. Mean age was 52±12 yrs and 58% were women. The majority (88%) underwent deceased donor transplantation and all patients were on Tacrolimus, Mycophenolate and Prednisone. Prior to surgery, mean calcium and iPTH levels were 10.4±1.3 mg/dl and 508±404 pg/ml, respectively. Median time duration between transplantation and PTx was 482 days (Q1,Q3: 225,909). Indications for PTx included persistent hypercalcemia (42%), significant osteoporosis or worsening osteopenia (35%) or both (15%). Few patients (8%) underwent surgery after failing medical therapy, including calcimimetics. Sestamibi scan, obtained in all patients, showed glandular hyperplasia in 50% and adenoma in 34% of patients. However, surgical pathology showed hypercellular parathyroid tissue in 25 specimens (96%). Only one biopsy showed parathyroid adenoma with thick, fibrous trabecula and calcifications.

Conclusions: In kidney transplant recipients, ThPT is common and in small proportion of cases, it warrants PTx for hypercalcemia and worsening bone disease. Parathyroid hyperplasia is the commonest pathology in these patients. Sestamibi scan is inaccurate in making the distinction between hyperplasia and adenoma.

PUB740

Comorbidity Is Less Prevalent on the Active Kidney Transplantation Waiting List Relative to Inactive Ones Jacek S. Malyszko,[1] Jolanta Malyszko,[1] Andrzej Milkowski,[2] Tomasz Rafal Prystacki,[2] Teresa Rydzynska.[2] *[1]Nephrology, Medical Univ, Bialystok, Poland; [2]Fresenius Medical Care, Poznan, Poland.*

Background: Renal transplant is the best form of treatment for most patients with end-stage renal disease (ESRD). The aim of this study was to examine demographic and comorbidity factors of patients with end-stage renal disease on the kidney transplantation waiting list in regard to their status (active versus temporary disqualified).

Methods: The cross-sectional study was conducted on 270 prevalent patients on the waiting list from 26 dialysis centers in Poland (population of 5500 dialysis patients). They were also 15 peritoneally dialyzed patients.

Results: Patients who had been registered in the cadaver kidney waiting list were aged 49±13 years, median dialysis duration 34 months, median residual renal function was 550 ml, prevalence of hepatitis B and C was below 5%. The primary cause of end-stage renal failure was hypertensie glomerulopathy in 41%, chronic glomerulonephritis in 29% and, diabetic nephropathy in 24%. There were no statistically significant differences except total cholesterol, LDL cholesterol, aspartate aminotransferase and weakly dialysis dose between patients on the active list and temporary disqualified. Clinical status, including cardiovascular status (echocardiography parameters, coronary angiography results) were similar in both groups. Similarly peritoneally dialyzed patients did not differ from those

on hemodialyses, except lower level of protein, albumin, higher fibrinogen and platelet count. When all these parameters were compared with those on dialyses no on the waiting list from a single dialysis unit, dialyzed patients not candidates for transplantation were almost 20 years older, with more comorbidities with diabetes being the most prevalent followed by liver viral infections.

Conclusions: Potential kidney transplant recipients are not typical dialyses patients: they are relatively young, with rather short dialysis vintage, without significant comorbidities. Preemptive transplantation is offered to seldom in this population. Kidney transplantation seems the best option of renal replacement therapy however, minority of dialyzed patients seem suitable for this therapeutic approach.

PUB741

The Role of Systemic Monitoring of Calcineurin Inhibitor (ICN) Concentrations on the Excretory Function of the Transplanted Kidney and Liver Function Marek Kuzniewski, Magdalena Barbara Kaziuk, Wladyslaw Sulowicz. *[1]Dept of Nephrology, Jagiellonian Univ Medical College, Krakow.*

Background: In uncontrolled high concentrations of ICN, acute nephrotoxicity of the transplanted kidney occurs. Such a state presents as rapid decrease of glomerular filtration and liver damage which can be diagnosed by evaluating serum total bilirubin levels and alanine aminotransferase (ALT) concentrations.

Methods: The study included 205 patients with end stage renal disease (ESRD) post kidney transplant (Ktx), 86 females and 120 males between the ages of 18-72 years (mean age- 47 years), treated with ICN. Patients were divided into 4 groups depending upon time post kidney transplant: up to 3 months post transplant, 4-12 months post transplant, 1-5 years post transplant and >5 years after kidney transplant. The patients were under control for a period of 2 years. The hemolytic- uremic syndrome was excluded in the study group. Glomerular filtration rate was evaluated by estimating GFR (eGFR) using the Modification of Diet in Renal Disease fomula (MDRD). Liver function was assessed by measuring serum total bilirubin and ALT levels.

Results: A significant correlation was noted between values of eGFR and ICN concentrations in the study group (p<0,05). Correlations between cyclosporine as well as tacrolimus concentrations with total serum bilirubin are statistically significant (p<0,05). This is essential proof that upholds the existence of an association between high concentractions of cyclosporine and tacrolimus with high levels of total serum bilirubin. Increased levels of ALT significantly correlated with concentractions of cyclosporine A and tacrolimus (p<0,05).

Conclusions: It is essential to systematically monitor ICN concentrations due to their possible future chronic nephrotoxic effect on the function of the transplanted kidney (arteriolopathology). Increased serum total bilirubin and ALAT levels not only represent damage of liver cells but are indirectly indicative of high non- therapeutic concentrations of ICN.

PUB742

Low Dose of Sirolimus Shows No Advantage over Tacrolimus as Immunosuppressive Regimens after Renal Transplantation: A Meta-Analysis Jingyi Zhou, Yan Jiang, Jianghua Chen. *Kidney Center, the First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Tacrolimus as a representative of calcineurin inhibitors (CNIs) has been proved nephrotoxic with long-term use. Replacing tacrolimus with sirolimus after renal transplantation is quite attractive for its potential possibility to avoid side effects and gain better outcomes.

Methods: PubMed, Web of knowledge, Medline and the Cochrane Library were searched. Patient and graft survival, acute rejection and adverse events were evaluated as primary outcomes and glomerular filtration rate (GFR) was an additional surrogate for renal function.

Results: Fifteen studies were included with 2480 patients. Patients in the sirolimus group showed an increased rate of acute rejection within one-year's follow-up 2.02 (95% CI 1.37~2.99, $P < 0.05$) and also a higher risk of adverse events 1.31 (95% CI 1.02~1.68, $P < 0.05$). The incidence of hyperlipidaemia was significantly higher with RR=1.75 (95% CI 1.17~2.61, $P < 0.01$) in the sirolimus group, as well as a significantly higher serum level of triglyceride (MD=74.03, 95% CI 53.89~94.16, $P < 0.01$) and cholesterol (MD = 35.13, 95% CI 21.18~49.08, $P < 0.01$). The other outcomes were insignificantly different between two groups.

Conclusions: This meta-analysis concluded that sirolimus showed no advantage over tacrolimus when used early after transplantation. When used with higher concentrations, the disadvantages may be avoided.

PUB743

Rare Post Transplant Lymphoproliferative Disorder; Long Term Remission with Chemotherapy and Bone Marrow Transplant Madan Bahadur,[1] Keyur K. Dave.[1] *[1]Consultant, Dept of Nephrology, Jaslok Hospital and Research Centre, Mumbai, Maharashtra, India; [2]Fellow in Nephrology, Jaslok Hospital and Research, Mumbai, Maharashtra, India.*

Background: Multifocal Extramedullary Plasmacytoma in post renal transplant recipient is a rare form of post transplant lymphoproliferative disorder (PTLD). Conventionally treatment of PTLDs includes significant reduction in immunosuppression but this can cause rejection or even graft loss. For this refractory rapidly progressive malignancy an aggressive treatment plan was followed.

Methods: A 42 year old, 14 year post transplant patient on Cyclosporine, Azathioprine and Prednisolone, developed rapidly progressive plasmacytoma lesions in pancreas, gums, subcutaneous tissue and near transplant kidney. His lesions responded only partially to immunosuppression reduction and 6 Bortezomib and Dexamethasone chemotherapy cycles. To attain long term remission or cure he was treated with high dose chemotherapy including Melphalan followed by rescue autologous bone marrow stem cell transplant.

Results: Post engraftment, by Day 90 patient achieved complete remission as all PTLD lesions completely disappeared. Patient has remained in complete remission even after 5 years of rigorous follow up with a stable kidney function. His whole body PET CT does not show any malignancy and his creatinine is a stable 1.6 mg % on triple immunosuppression.

Conclusions: We report the first case of long term remission, possible cure, of a rare form of PTLD, multi focal plasmacytoma with high dose chemotherapy and autologous bone marrow transplant. The icing on the cake is a stable renal function 19 years post transplant as immunosuppression was continued. In the review of literature we could find only 4 cases of unifocal post transplant plasma cell dycrasia treated conventionally with varied results. We propose that the same protocol as for multiple myeloma in non transplant setting can be used for this PTLD with rewarding results.

PUB744

Long Term Outcome in a Patient with Post Transplant Epstein Barr Virus Associated Smooth Muscle Tumor Naveed Aslam, Dildar Ahmed Laghari, Seddeg Younis, Nader Mohamed Omran, Muddassar Mahboob, Ramesh Nair, Ebadur Rahman. *Nephrology, Prince Sultan Military Medical CITY, Riyadh, Saudi Arabia.*

Background: Epstein Barr virus associated smooth muscle tumors (EBV+SMT) following solid organ transplantation are rare. This case report discusses use of Valacyclovir and Sirolimus as a successful treatment post surgical removal of multicentric tumors.

Methods: A 40 years old male underwent cadaveric kidney transplantation in 1996. The EBV serostatus was negative both in the donor and the recipient. The patient's immunosuppressive regimen included cyclosporine, mycophenolate mofetil, and prednisolone and induction with anti-thymoglobulin. The baseline creatinine was 80 umol/l (range 70-110). In 2002, due to gradual deterioration of graft function (creatinine 120-130 umol/l), a graft biopsy was performed that showed transplant glomerulopathy. Subsequently, in July 2004, abdominal and chest computed tomography (CT) scan examination was performed following complaint of intermittent epigastric pain of several weeks duration. CT scan showed well-defined masses in mesentery, right lung, and liver. CT scan guided Tru-Cut biopsy taken from the right hepatic mass showed hepatic leiomyoma; a tumor usually associated with EBV infection. Serology for EBV came positive with a high titer of PCR.

Results: Patient underwent surgical removal of the tumors. Post surgically the immunosopressive treatment was changed, from Cyclosporine to Sirolimus with Prednisolone and Valacyclovir; Mycofenolate Mofetil was discontinued. Sirolimus levels were maintained in the range of 4-8 ng/ml. Currently, the patient maintains a stable graft function (creatinine 116 umol/l, proteinuria 0,6 g/day), EBV PCR is still positive with very low titer and follow-up CT did not show any signs of recurrence.

Conclusions: The mTOR pathway plays an important role in regulating cell growth and proliferation and its deregulation is associated with many human cancers. Sirolimus inhibits mTOR and hence could be a potential therapeutic alternative for cancers for which the mTOR pathway is activated. It has been successfully used for the treatment of Kaposi's sarcoma and, in our experience, with EBV+SMT.

PUB745

Renal Graft Survival in Patients with Thymoglobulin Induction Therapy, at the Hospital Centro Medico Nacional De Occidente, Jalisco, Mexico Paloma Arleth Zavalza Camberos, Virginia Ibarra Pedroza, Benjamin Gomez-Navarro, Adriana Banda Lopez. *[1]Nefrologia Y Trasplante, Centro Medico Nacional De Occidente, Imss, Guadalajara, Jalisco, Mexico.*

Background: Induction with Thymoglobulin offers advantages such as reducing the frequency of acute rejection and improved graft function. The objective was to evaluate renal graft function and survival in patients receiving Thymoglobulin induction.

Methods: Retrospective cohort, in the period Jun 2010 to Dec 2013 included patients who has over 15 years of age, who received induction therapy with Thymoglobulin. Excluded patients with graft loss in the 1st week of renal transplantation. Was recorded the dose cumulative mean of Thymoglobulin, and serum creatinine to assess graft function. Kaplan-Meier estimates of freedom from death and graft loss. The frequency of acute rejection-free period it was obtained, and secondarily, freedom from infection- related death and posttrasplant frequency of infections and lymphoproliferative disorders.

Results: 250 patients were included. A 70% received living donor transplants and 30% of deceased donor.

Cumulative dose induction, mean (SD), mg/kg	**4.3 (± 1.5)**
Graft function	**Serum creatinine (mg/dl)**
Basal (at discharge)	0.97 ± 0.46
12 months	1.20 ± 0.90
2 years	1.13 ± 0.82
3 years	1.30 ± 1.10
Acute Rejection at 12 months, n(%)	**24 (9.6)**
3 years of transplant, n.	**98**
Freedom from Acute Rejection	97%
Freedom from infection-related death	96%
Freedom from posttransplant lymphoproliferative disorders	100%

Actual patient and graft survival were 98% (n=250) at 12 months. Kaplan-Meier estimates of freedom from death and graft loss, through 2 years were 98.3% and 97.8% (n=185), respectively, and 96% and 93.9% (n=98), through 3 years.

Conclusions: Induction with Thymoglobulin allowed good graft function and survival. The use of Thymoglobulin as induction agent in our patients at high immunological risk, is safe and associate with excellent patient survival and low rates of acute rejection renal graft survival.

PUB746

Homeostatic Repopulation of CD8$^+$ T-Cells After T-Cell Depletion in a Kidney Allograft Recipient Hajeong Lee, Seung Hee Yang, Yon Su Kim. *Internal Medicine, Seoul National Univ College of Medicine.*

Background: The T-cell depletion for induction therapy leads to clinical tolerance strategy in autoimmune disease and transplantation (TPL), however, that effect of high dose-rejection treatment remains uncertain.

Methods: A 42-year men visited our institution for his delayed graft function after living donor kidney TPL. Although ATG induction therapy was done before TPL, however, he developed acute T-cell mediated rejection type IB. After pulse steroid treatment, he received ATG therapy with a total dose of 13.5 mg/kg. We collected his peripheral blood monocyte before, 2-week, and 6-month after completion of ATG treatment. We used flow cytometry to measure the expression and frequency of T-cell repertoire and compared with those of healthy control.

Results: After ATG treatment, there was greater depletion of CD4$^+$ subsets than CD8$^+$ T-cells within the total T-lympocytes. CD8$^+$ T-cells recovered faster than CD4$^+$ subsets. Among CD8$^+$ T-cells, central memory and naïve T-cells remained depleted until 6months, T_{EM}s (CCR7$^-$CD45RA$^{+/-}$) showed slight drop immediately after ATG, with a return to growth by 6 months. Two-weeks after ATG treatment, homeostatic proliferation was found, leading to the higher expression of Ki-67 and it returned to be stable in 6-months after ATG. Among T_{EM}s, CD45RA$^+$ T_{EM}s more steeply increased than CD45RA$^-$ T_{EM}s. In addition, IL7Rα^{low} T_{EM}s were increased, whereas IL7Rα^{high} T_{EM}s were decreased, which suggested the presence of repetitive antigenic stimulation. Cytotoxic perforin and granzyme B productions were stable persistently in IL7Rα^{low} T_{EM}s. In addition, suppressor T-cells (CD8$^+$CD28$^+$), especially CD27$^+$CD28$^-$ subsets were increased. In case of regulatory T-cells (Tregs), both allogenic Tregs (CD8$^+$CD28$^-$CD56$^+$ and CD8$^+$CD103$^+$ T-cells) were increased after 2-weeks, and only CD8$^+$CD28$^-$CD56$^+$ Tregs remained increased state even after 6-months after ATG. On the contrary, natural Tregs (CD8$^+$CD25$^+$Foxp3$^+$) remained stable.

Conclusions: In this interesting case, we found that T-cell depletion treatment in kidney TPL recipient induced homeostatic repopulation, mainly with expansion of IL7Rα^{low} T_{EM}s, suppressor T-cells and allogenic Tregs, under persistent antigenic stimulation.

PUB747

Thymoglobulin Induction Therapy in Kidney Transplant: Standardizing Dose. Use of 1mg/kg as Initial Dose at the Hospital Centro Medico Nacional de Occidente, Jalisco, Mexico Virginia Ibarra Pedroza, Paloma Arleth Zavalza Camberos, Adriana Banda Lopez, Benjamin Gomez-Navarro. *[1]Nephrology and Transplantation, IMSS, Gdl, Jalisco, Mexico.*

Background: Induction dose of Thymoglobulin modified constantly. In recent years, this has tended to decrease in order to avoid side effects. The purpose was to compare the initial dose in patients receiving thymoglobulin.

Methods: An ambispective cohort of patients with renal transplant, included in the period Jun 2010 to Dec 2013, which has received thymoglobulin induction an initial dose of 1mg/kg and those who received doses above 1.1mg/kg, for 4 days. Evaluating haematological tolerance, dose adjustments, and frequency of acute rejection and rejection-free period. Secondarily, the frequency of infections in the first year after transplantation and the presence of lymphoproliferative disease.

Results: 209 patients were included, divided into 2 groups, those who received initial doses of 1mg/kg (n = 119 patients: 84 received a live donor graft and 36 deceased donor) and those who received doses ≥1.1mg/kg (n= 90; 58 received a live donor graft and 32 deceased donor).

	1mg/kg (n=119)	≥1.1mg/kg (n=90)
Cumulative dose induction, mean (SD), mg/kg	3.5± 0.5	5.1± 0.75
Serum creatinine, mg/dl	0.95 ± 0.31	1.01 ± 0.36
Patients receiving full intended induction dose, n(%)	108 (90.7)	69 (76.6)
Acute Rejection at 12 months, n(%)	10 (8.3)	11 (12.2)
Reported frecuency of infections at 12 months, n(%)	43 (36)	44(49)
Freedom from AR after trasplantation, %	96	94
Freedom from posttransplant lymphoproliferative disorders, %	100	100

Conclusions: The induction dose of Thymoglobulin is different in each hospital, without unifying the standard dose used worldwide. Patients those receiving 1mg/kg, had adequate drug tolerance and no need for adjustments to the starting dose, observed a frequency similar to international registrations acute rejection, a reduction of 13% from infection diseases and no posttransplant lymphoproliferative disorders. An initial dose of 1mg/kg administered for 4 days (cumulative dose of 4mg/kg) is an appropriate dose for our patients.

PUB748

ABO Incompatible Transplantation: A Novel Risk Factor for Post Transplant Erythrocytosis Madan Bahadur, Chandan Laxman Chaudhari, Amjadkhan Mahebubkhan Pathan. *Dept of Nephrology, Jaslok Hospital and Research Centre, Mumbai, Maharashtra, India.*

Background: The incidence of Post transplant Erythrocytosis (PTE) varies from 8% to 22% among published reports.The mechanisms of PTE is unclear and is likely to be multifactorial. We explored this phenomenon in the ABO incompatiable transplant setting.

Methods: This study was carried out to evaluate incidence of PTE in patients undergoing renal transplant at our centre between march 2011 to July 2013. Patients with three consecutive value one week apart of hematocrit above 51% were classified as PTE cases. Patients with graft lost within three months of transplant, those on EPO, with chronic airway disease or a pre transplant hematocrit more than 51% were excluded. Rest of the patients who did not have post transplant erythrocytosis were taken as control. Association with different risk factors, native kidney diseases, immunosuppressives was studied.

Results: During study period out of 150 transplants performed 17 were ABO incompatible and 133 were blood group compatible. PTE was seen in 5/17 in ABO incompatible and 17/133 controls. Total 22 cases of PTE were noted. incidence was 29.41% in incompatible group compared to 12.78% in ABO compatiable transplants. All cases were males. No particular association could be found with any native kidney disease. Out of 5 cases in ABO incompatible group 4 received thymoglobulin as induction and one basiliximab. All cases received rituximab and plasmapheresis prior to surgery.

Conclusions: ABO incompatible transplants differ mainly from routine transplants in more aggressive immunosuppression. In different indications, Rituximab, Basiliximab and Thymogobulin have been used in treatment of autoimmune haemolytic anemias and aplastic anemias. Whether the increased incidence of PTE in ABO incompatible transplants is related to their use or some other mechanisms exist should be matter for future research. Incidentally all PTE cases occurred in patients with stable graft function and in those who had no episodes of rejection.

PUB749

Long Term Outcome of Renal Transplantation in Williams-Beuren Syndrome Parvathy Madhavan, Neenu Sukumaran, Sapna M. Jairath, Aditya Kadiyala, Praveen Kolumam Parameswaran, Nicole M. Ali, Amit Basu, Madhu C. Bhaskaran, Ernesto P. Molmenti. *Renal Transplant Center, North Shore Univ Hospital, Manhasset, NY.*

Background: Williams-Beuren Syndrome (WS) is a genetic disorder caused by mutation in chromosome 7q11.23. Several kidney and urinary tract abnormalities have been reported in WS including bladder diverticula, ectopic or horseshoe kidney, and renal aplasia or hypoplasia. Features of WS like hypertension, hypercalcemia, renal artery stenosis and stenotic abnormalities of abdominal aorta can have adverse effects on the outcome of renal transplant and literature on long term implications of this treatment in WS is scarce.

Methods: A 22 year old, Asian male patient with WS, underwent a deceased donor renal transplant at 5yrs of age, after 5 months on peritoneal dialysis for ESRD. He has been on chronic immunosuppressant therapy with CellCept, cyclosporine and prednisone. His other clinical comorbidities include mild supra valvular aortic stenosis, pulmonary valve stenosis, Wolf Parkinson White Syndrome post ablation and medically controlled hypertension. Physical examination was unremarkable, with the exception of characteristic facial dysmorphia. He has remained normotensive and latest lab values have been within reference ranges. Over the past 8 years, serum creatinine values have ranged from 1.03-1.4mg/dL with insignificant proteinuria and a serum calcium range from 8-10.1mg/dL.

Conclusions: In this patient with WS, the post transplantation clinical course has remained uneventful with normal renal function. His quality of life, post transplant improved and there was no incidence of major complications such as infections due to immunosuppression. In spite of a number of adverse factors that could potentially affect the outcome of the allograft in WS, the successful long term outcome in this transplant recipient, demonstrates that with careful selection and excellent follow up, renal transplant can be considered in this population.

PUB750

Acute Vitamin D2 Administration Does Not Alter Ischemia Tolerance in a Rodent Model of Reversible Myocardial Ischemia Kieran Mccafferty, Conor J. Byrne, Magdi Yaqoob. *William Harvey Research Institute, Queen Mary Univ, London, United Kingdom.*

Background: Vitamin D receptor activation has been associated with many effects beyond bone and mineral metabolism. Vitamin D deficiency is common in patients with CKD and is associated with cardiovascular mortality. Indeed there is evidence to support the role of vitamin D in many of the characteristics of the uremic cardiovascular phenotype: LVH, endothelial dysfunction, arterial stiffness, inflammation and vascular calcification. Chronic administration of vitamin D has been shown to be protective in animal models of both renal and cerebral ischaemia reperfusion injury. It is unknown if acute administration of vitamin D has an effect on subsequent ischemia tolerance.

Methods: Male Wistar rats were given either IP ergocalciferol 100,000IU/kg (n=10) or vehicle (n=10) 24hours before undergoing a reversible LAD ligation model of acute myocardial infarction with 25minutes ischemia and 2h reperfusion. Area at risk was measured using Evans blue and infarct size was measured using NBT and expressed as a % of the AAR.

Results: Acute administration of ergocalciferol lead to a 50% rise in vitamin D2 levels, but had no effects on other biochemical or cardiovascular parameters. Following myocardial IR injury, acute vitamin D2 treatment was not associated with alteration in myocardial infarct size (49.8% v 50.9% p=0.97).

	Vehicle	Ergocalciferol	p Value
Mean Arterial Pressure (mm/Hg)	140 (133-154)	130 (115-151)	0.35
Heart rate (BPM)	430 (420-49)	434 (427-463)	0.46
Calcium (mmol/l)	2.36 (2.33-2.56)	2.38 (2.23-2.57)	0.86
Phosphate (mmol/l)	2.3 (1.78-2.37)	2.32 (1.8-2.39)	0.72
Vitamin D2 (nmol/l)	8 (2.5-9)	12 (7-18)	**0.002**
Total Vitamin D (nmol/l)	28.6 (8.2)	37.7 (10.6)	**0.009**
Area at risk (%)	50.4 (42.9-55.5)	52.1 (45.8-57.1)	0.71
Infarct size (%)	49.8 (30.4-61.2)	50.9 (26.7-62.9)	0.96

Conclusions: Acute administration of vitamin D does not alter myocardial ischemia tolerance. Future studies should examine the effect of chronic vitamin D supplementation on myocardial ischemia tolerance.

PUB751

Decreased Locomotion Is Associated with an Increased Incidence or Worsening of Peripheral Artery Disease in Hemodialysis Patients Manae Harada,[1] Atsuhiko Matsunaga,[1] Yoshifumi Abe,[1] Kei Yoneki,[1] Ryoma Ishikawa,[1] Takaaki Watanabe,[1] Toshiki Kutsuna,[1] Ryota Matsuzawa,[1] Atsushi Yoshida,[2] Naoyoshi Aoyama,[1] Kouju Kamata.[1] *[1]Kitasato Univ, Kanagawa, Sagamihara, Japan; [2]Sagami Junkanki Clinic, Kanagawa, Sagamihara, Japan.*

Background: Hemodialysis (HD) patients are at a higher risk of developing peripheral artery disease (PAD) than the general population. However, factors associated with the incidence or worsening of PAD in HD patients have not been fully elucidated. We performed a prospective and observational study to examine factors associated with changes in Ankle-Brachial Index (ABI) in HD patients.

Methods: A total of 159 Japanese outpatients (age, 64 ± 11.6; male, 59.1%) undergoing maintenance HD three times a week were followed for one year. Age, sex, body mass index, dialysis vintage, history of smoking, comorbid conditions, use of medication (sarpogrelate hydrochloride, cilostazol, clopidogrel and lipid lowering drugs), blood biochemical data (hemoglobin, serum albumin, creatinine, lipid profile, and calcium-phosphate products), and locomotion ability (ambulation and wheelchair use) were obtained from clinical records at baseline. Our analysis divided groups of patients with newly diagnosed PAD (ABI ≥ 1.00 at baseline and ABI ≤ 0.99 at the endpoint) and those without, and patients with progressive PAD (ABI ≤ 0.99 at baseline and a decrease in subsequent ABI ≥ 0.10) and those without, according to changes in ABI during the study period. Multivariable logistic regression analysis, adjusted for baseline clinical variables, was performed to identify factors that predict the incidence or progression of PAD after one year.

Results: During the follow-up period, there were 15 HD patients (9.5%) with newly diagnosed and progressive PAD. Adjusted multivariable logistic regression analysis revealed that the incidence or progression of PAD was significantly associated with locomotion ability (odds ratio [OR], 5.0; 95% confidence interval [CI], 1.0 – 23.7; P = 0.042) and use of medication (OR, 3.0; 95% CI, 1.0 – 9.1; P = 0.049).

Conclusions: These results suggest that decreased locomotion is closely associated with an increased incidence or worsening of PAD in HD patients.

PUB752

End-Stage Renal Disease Associated with Metabolic Syndrome: A Study of Biomarkers Utilizing BioChip Array Profiling Methods Vinod K. Bansal,[1] Debra Hoppensteadt,[2] Daneyal Syed,[2] Schuharazad Abro,[2] Syed Mustafa Ahmed.[2] *[1]Nephrology, Loyola Univ Medical Center; [2]Pathology, Loyola Univ Medical Center.*

Background: Metabolic syndrome (MS) represents a cluster of cardiovascular risk factors which contribute to myocardial infarction and stroke in end stage renal disease (ESRD) patients. Several metabolic biomarkers have been identified and their circulating levels provide a better understanding of the pathogenesis of MS/ESRD. The purpose of this investigation is to profile biomarkers of MS in ESRD patients.

Methods: Plasma samples from 87 patients with ESRD undergoing maintenance hemodialysis and 50 normals were collected prior to a routine session. These samples were profiled for metabolic biomarkers using multiple protein chip bioarray technology. The protein chip array was comprised of several biomarkers of MS. All results were compiled in terms of group means +/- 1 SD (SEM) and statistically analyzed.

Results: In comparison to the normal samples, the ESRD group showed marked increase in circulating levels of all biomarkers. TNFa (47.4 +/- 18.3 *versus* 4.1 +/- 1.1 ng/mL) and IL-6 (7.8 +/- 9.1 *versus* 0.8 +/- 0.4 ng/mL) showed the most pronounced increase. C-peptide (14.5 +/- 4.1 *versus* 2.8 +/- 1.6 ng/mL), leptin (29.7 +/- 29.2 *versus* 5.2 +/- 7.9 ng/mL), resistan (16.1 +/- 6.0 *versus* 2.3 +/- 0.7 ng/mL) and ferritin (274 +/- 57 *versus* 57 +/- 63 ng/mL) showed a 5-fold increase in the ESRD group compared to normal. PAI-1 (5.4 +/- 5.2 *versus* 2.9 +/- 2.5 ng/mL), IL-1a (1.3 +/- 1.7 *versus* 0.35 +/- 0.07 ng/mL) and insulin (32.1 +/- 17.3 *versus* 17.1 +/- 1.7 ng/mL) showed modest increase in the ESRD patients. The increase in all of the MS biomarkers in the ESRD patients were highly significantly elevated, $p<0.05$.

Conclusions: The specific biochip array for MS allows the selective determination of various biomarkers associated with this syndrome in the ESRD patients and normals. Parallel increase in resistan, insulin, C-peptide, and leptin points to the derangement of glucose metabolism in these patients. Increase IL-1a, TNFa, and ferritin suggests the upregulation of an inflammatory process. PAI-1 increase suggests a fibrinolytic deficit. All of these biomarkers stimulate multiple pathways through signal transduction processes.

PUB753

Mechanisms Linking Atherosclerosis and Chronic Kidney Disease: Inflammation and Plaque Microenvironment in an Autopsy Study Miguel Hueso,[1] Juan Torras,[1] Estanis Navarro,[2] Laura De Ramon,[3] Alberto M. Martinez-Castelao,[1] Josep M. Grinyó.[1] *[1]Nephrology, Bellvitge Hospital-IDIBELL, L'Hospitalet, Barcelona, Spain; [2]Laboratori d'Oncología Molecular, IDIBELL, L'Hospitalet, Barcelona, Spain; [3]Laboratori de Nefrología Experimental, IDIBELL, L'Hospitalet, Barcelona, Spain.*

Background: Chronic Kidney Disease (CKD) increases the incidence of atherosclerosis (ATS), an inflammatory disease with a focal distribution in which pathogenesis seem involve the activity of microRNAs (miRNAs). The goal of our study was to detect differences in the CKD-related miRNAome, to gain insights into local factors involved in the onset and progression of atherosclerosis.

Methods: In a case-control studywe compared ATS plaques with normal areas, both obtained from the abdominal aorta of patients with CKD. Lesions were evaluated after hematoxylin-eosin staining, and were classified according to AHA criteria. Inflammation was evaluated by immunohistochemistry as S100, CD3 and NF-kB stainings. miRNA expression in ATS and normal samples was quantified by using Taqman Low Density Arrays (TLDA).

Results: We analyzed 12 paired samples (6 atherosclerotic plaques obtained from abdominal aortas and 6 normal areas from the same patient and vessel) from 6 patients (4 patients with CKD). NF-kB activation was correlated with the severity of the lesions (r=0.53, p=0.004) and with the number of lymphocytes in the intima (r=0.49, p=0.009) and adventitia (r=0.58, p=0.001). ATS plaques showed reduced levels of miR15b (4.86-fold change, p=0.014), miR17 (4.2-fold, p=0.041) and miR106a (4.5-fold, p=0.048). Furthermore, patients with CKD displayed a downregulation of miR125a-5p (3.8-fold, p=0.006).

Conclusions: Aterosclerotic plaques were associated with inflammation and with the dowregulation of miR15b and of the miR17 and miR106a. Interestingly, miR15b suppress the expression of VEGF and angiotensin-2, and promote VSMC proliferation and differentiation in a synthetic phenotype. miR17/106a modulate endothelial function and angiogenesis, and miR125a-5p regulates the differential activation of macrophages promoting alternative activation (M2). Thus, changes in the expression of miR15b, miR17/106a and miR125a-5p may contribute to cardiovascular disease in patients with CKD.

Far-Infrared Therapy Inhibits Renin-Induced Vascular Smooth Muscle Cell Proliferation and Hypertrophy By Blocking the Interaction Betweenpromyelocytic Leukaemia Zinc Finger Protein and (Pro)renin Receptor Yung-Ho Hsu,[1] Tso Hsiao Chen,[2] Cheng-Hsien Chen.[3] *[1]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital,Taipei Medical Univ, New Taipei City, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan; [3]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital,Taipei Medical Univ, New Taipei City, Taiwan.*

Background: High plasma (pro)renin activity is highly associated with chronic hypertension, and indicative of future cardiovascular disease and death. It is widely acknowledged that the (pro)renin receptor (RER) mediates angiotensin (Ang) II-dependent and Ang II-independent effects of (pro)renin. Some studies indicated that far-infrared (FIR) therapy is beneficial for cardiovascular system. In this study, we examined the effect of FIR on renin-induced proliferation and hypertrophy in rat vascular smooth muscle cell (A7r5). Recombinant rat renin significantly increased cell proliferation, and [H]-leucine incorporation, which were attenuated by FIR irradiation. Renin increased extracellular signal-regulated kinase (ERK) 1/2 phosphorylation and the expression of renin receptor (RER) at an early stage in A7r5 cells. FIR irradiation significantly reduced renin-induced ERK1/2 activation and the expression of renin receptor. We found that FIR therapy induced the nuclear translocation of promyelocytic leukaemia zinc finger protein (PLZF) in A7r5 cells, which is independent from thermal effect. There was a physic interaction between PLZF and RER, which was promoted by renin as revealed by immunoprecipitation. FIR irradiation blocked the interaction between PLZF and RER. Fluorescent staining showed that FIR irradiation blocked renin-induced nuclear translocation of RER in smooth muscle cells. PLZF siRNA transfection significantly inhibited renin-induced proliferation and hypertrophy. Renin-induced ERK1/2 activation was also reduced by PLZF siRNA transfection. Our results reveal that FIR irradiation inhibits renin-stimulated smooth muscle cell proliferative and hypertrophic changes by blocking the interaction between PLZF and RER.

MCP-1 and VCAM-1 Overexpression in Response to AGES via RAGE and PKC-β Pathway in a Co-Culture of Monocytes and Endothelial Cells Lisienny C.T. Rempel,[1] Alessandra Becker Finco,[1] Rayana Ariane Pereira Maciel,[1] Bruna Bosquetti,[1] Maíra Barbosa e Reis,[1] Larissa Magalhaes Alvarenga,[1] Roberto Pecoits-Filho,[2] Andréa Marques Stinghen.[1] *[1]Experimental Nephrology Laboratory, UFPR; [2]School of Medicine, PUCPR, Curitiba, Brazil.*

Background: Advanced glycation end products (AGES) induce endothelial dysfunction, a major risk factor for cardiovascular disease in chronic kidney disease (CKD) patients. To explore the underlying mechanisms in the AGES/endothelium interaction via RAGE and PKC-β pathway, we evaluated the expression of monocyte chemoattractant protein-1 (MCP-1) and vascular cell adhesion molecule-1 (VCAM-1), in a co-culture of endothelial cells and monocytes.

Methods: AGES were prepared by albumin glycation and characterized by absorbance and electrophoresis. Cell viability was assessed by MTT. Endothelial cells derived from human umbilical vein (HUVEC), monocytes (U937 cells) and HUVEC + monocytes were treated with AGES (0.2 mg/mL) with or without PKC-β inhibitor in a kinetic of 0, 3 and 6 or 0, 12 and 24h. MCP-1 and VCAM-1 expression was investigated on cell supernatant by ELISA. RAGE expression was evaluated by immunocytochemistry.

Results: There was no significant differences in cell viability after AGES exposure. When HUVEC were exposed to AGES, there was a significant increase in MCP-1 expression after 3 and 6h ($P<0.05$) and VCAM-1 after 24h ($P<0.05$) when compared to control. Moreover, when HUVEC were incubated with AGES and PKC-β inhibitor, there was a significant decrease in MCP-1 ($P<0.005$) and VCAM-1 ($P<0.05$) expression. The same effect was observed when monocytes were exposed to AGES after 6h ($P<0.05$) and PKC-β inhibitor ($P<0.001$). When HUVEC were co-cultured with monocytes, no significant effect after AGES exposure and PKC-β inhibitor treatment was observed. Finally, AGES treatment was able to induce RAGE expression by HUVEC.

Conclusions: This study is the first to demonstrate in three cellular models a regulatory mechanism involved in MCP-1 and VCAM-1 production, mimicking the endothelial dysfunction caused by AGES in the early events of atherosclerosis. We believe that such mechanism could serve as a therapeutic target to reduce the harmful effects of uremic toxicity in CKD patients.

PUB756

The Effect of Sex on Humanin Levels in Healthy Adults and Patients with Uncomplicated Type 1 Diabetes Mellitus Yuliya Lytvyn,[1] Pinchas Cohen,[2] Junxiang Wan,[2] David Cherney.[1] *[1]Div of Nephrology, Univ Health Network, Univ of Toronto, Toronto, ON, Canada; [2]Univ of Southern California School of Medicine, Los Angeles, CA.*

Background: Diabetes mellitus (DM) is associated with a loss of renal and vascular protection observed in women compared with men in a non-diabetic renal disease setting, but the responsible mechanisms are unclear. Recent experimental work in animals has implicated a novel hormone called humanin (HN) as a vasodilatory factor that protects against vascular complications, but the role of HN in humans is unclear. The aim of the present study was to measure sex-related differences in HN levels in men and women with uncomplicated type 1 DM (T1DM) versus healthy controls (HC), as well as the interaction between HN, circulating neurohormones and vascular function.

Methods: Plasma HN, cGMP and aldosterone, blood pressure (BP), glomerular filtration rate and effective renal plasma flow (inulin and paraaminohippurate) were measured in HC (11 men, 10 women) and T1DM (23 men and 18 women) during clamped euglycemia (glucose 4-6 mmol/L).

Results: Plasma HN levels were higher in the T1D group versus HC (969±154 versus 834±214 pg/ml, p=0.006). HN levels were generally lower in HC men versus women but differences (762±154 versus 913±249 pg/ml) were not significant. In contrast, levels in T1DM men were significantly higher compared with T1DM women (1016±139 versus 909±154 pg/ml, p=0.026) and HC men (1016±139 versus 762±154, p<0.0001). In HC men but not women, HN correlated with systolic BP (r=-0.63, p=0.037), but not with renal function, cGMP or aldosterone. HN correlated with plasma cGMP in T1DM men (r=-0.31, p=0.048), but failed to reach significance in T1DM women (r=-0.46, p=0.06). In men and women with T1DM, HN did not correlate with BP, renal function or plasma aldosterone.

Conclusions: HN is higher in T1DM men versus T1DM women and healthy men, and is associated with lower levels of vasodilatory cGMP. Elevated humanin levels in this context likely represent an adaptive response to decreased insulin sensitivity and endothelial dysfunction.Future work should determine the role of HN in the pathogenesis of sex-related vascular function differences in DM.

PUB757

Relationship of Pulse Wave Velocity to Blood-Based Biomarkers in Mexican-Americans Harold M. Szerlip, Raul Vintimilla, Tori Conger, Sid O'bryant. *Internal Medicine, UNTHSC, Fort Worth, TX.*

Background: Pulse wave velocity (PWV), a reflection of "arterial stiffness" is a well-established marker of cardiovascular risk. Aging, metabolic factors, and inflammation lead to the loss of elastin and increase in collagen in the large arteries resulting in loss of aortic elasticity and increased PWV. Being able to identify biomarkers associated the increase in PWV will enable the development of therapeutic strategies to counter this increase.

Methods: The link between PWV and various biomarkers was assessed among 23 participants of the Health and Aging Brain among Latino Elders study. Aorto-femoral PWV was measured using the SphygmoCor® XCEL system. Serum levels of CRP, SAA, sICAM-1 and sVCAM-1 were assayed via electrochemiluminescence using the Meso Scale Discovery multiplex platform. Correlations were assessed via Pearson bivariate correlation coefficients.

Results: There were 12 males and 11 females in the study with an average age of 62.0 (sd=5.6). A total of 44% of the sample had diagnoses of diabetes and 65% hypertension. In the total sample, PWV was not significantly correlated with any biomarkers. However, when split by gender PWV was significantly related to sVCAM-1 among men (r2=0.70, p=0.02), but not other important clinical variables or serum biomarkers: CRP r2=0.36 (p=0.3), SAA r2=0.12 (p=0.7), sICAM-1 r2=0.41 (p=0.2), HDL (r2=-0.40, p=0.2), SBP r2=0.44 (p=0.2), DBP r2=0.41, (p=0.2), HbA1c r2=0.03 (p=0.9), total cholesterol r2=0.1 (p=0.8) or LDL r2=0.14 (p=0.7). Among women, PWV was not significantly related to any variable.

Conclusions: This pilot project supports the link between serum biomarkers of vascular functioning among Mexican American men. sVCAM-1 has been implicated in endothelial cell signaling and atherosclerosis. Although possibly due to small sample size the lack of association of PWV with several markers of inflammation in this cohort is of note. These findings support the notion of the importance of gender in the PWV – biomarker link, which is consistent with other areas of study. This is the first-ever study of the link between PWV and blood-based biomarkers among Mexican Americans and additional work is greatly needed.

PUB758

Acute Inhibition of Oxidative Stress Does Not Overcome Vascular Endothelial Dysfunction and Increased Arterial Stiffness in Patients with Stage 3-4 Chronic Kidney Disease Kristen L. Jablonski, Heather Farmer, Emily Decker, Michel Chonchol. *Univ of Colorado Denver, Aurora, CO.*

Background: Chronic kidney disease (CKD) is characterized by vascular endothelial dysfunction and stiffening of the large elastic arteries. Patients with CKD also exhibit increased systemic oxidative stress; however, oxidative stress at the level of the vasculature is not well described in this population. An acute supraphysiological intravenous infusion of ascorbic acid scavenges superoxide and has been previously used as a physiological tool to acutely reduce vascular dysfunction in various conditions including aging, coronary artery disease, and the metabolic syndrome. We hypothesized that acute inhibition of oxidative stress using this methodology would improve vascular endothelial function and reduce arterial stiffness in patients with moderate-to-severe CKD.

Methods: We assessed vascular endothelial function (using brachial artery flow-mediated dilation [FMD_{BA}]) and arterial stiffness (using aortic pulse-wave velocity [aPWV] and the carotid artery β-stiffness index) in 21 patients (16M/5F; 64±2 years; mean±s.e.) with stage 3-4 CKD (MDRD estimated glomerular filtration rate [eGFR] 35±3 ml/min/1.73 m^2) following an acute infusion of ascorbic acid (priming bolus of 0.06 g kg^{-1} fat free mass [FFM] dissolved in 100 ml of saline infused at 5 ml min^{-1} for 20 min followed by 0.02 g kg^{-1} FFM dissolved in 30 ml of saline administered over 60 min at 0.5 ml min^{-1}) or isovolumic saline (non-randomized cross-over design).

Results: Acute infusion of ascorbic acid failed to improve FMD_{BA} (saline: 3.75±0.65 %, ascorbic acid: 3.76±0.83 %, p=0.99), aPWV (saline: 1017±66 cm/sec, ascorbic acid: 1020±48 cm/sec, p=0.95), or the carotid artery β-stiffness index (saline: 12.7±1.8 AU, ascorbic acid: 13.0±1.1 AU, p=0.75).

Conclusions: Acute inhibition of oxidative stress did not improve vascular endothelial function or decrease arterial stiffness in patients with stage 3-4 CKD. Either vascular oxidative stress does not explain these vascular impairments, or perhaps vascular oxidative stress in moderate-to-severe CKD is too great to be overcome by the scavenging of superoxide.

PUB759

Epoetin Beta Pegol Prevents Vascular Endothelial Dysfunction in Type-2 Diabetic Rats Ken-Ichi Serizawa, Kenji Yogo, Yoshihito Tashiro, Ryohei Kawasaki, Michinori Hirata, Koichi Endo. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Gotemba, Japan.*

Background: Patients with diabetic nephropathy have a high cardiovascular morbidity and mortality, and diabetes is regarded as a major independent risk factor for cardiovascular events, which are mainly caused by endothelial dysfunction. Epoetin beta pegol (continuous erythropoietin receptor activator, C.E.R.A.) is widely used in the treatment of renal anemia. In this study, we examined the effect of C.E.R.A. on endothelial dysfunction in type-2 diabetic rats.

Methods: Male Spontaneously Diabetic Torii (SDT) rats (22 wks old) were used as type-2 diabetic rats. Male Sprague-Dawley (SD) rats were used as age-matched controls. C.E.R.A. (Low, 0.6 μg/kg; High, 1.2 μg/kg) was administered subcutaneously once every 2 wks. After 8 wks, we measured blood pressure by tail-cuff method, collected urine from individual metabolic cages, and sampled blood from the jugular vein. Endothelial function was assessed by flow-mediated dilation (FMD) measured in the femoral arteries of anesthetized rats with an ultrasound system.

Results: In SDT rats, FMD was significantly decreased as compared to SD rats. C.E.R.A. dose-dependently prevented the reduction of FMD in SDT rats (SD, 19.5±1.6%; SDT, 11.3±0.6%; SDT+C.E.R.A. Low, 14.6±2.0%; SDT+C.E.R.A. High, 21.2±3.7%; mean ± S.E., *n*=4-9). C.E.R.A. did not inhibit urinary protein excretion in SDT rats (SD, 7.2±0.6 mg/day; SDT, 67.9±12.0 mg/day; SDT+C.E.R.A. Low, 85.0±27.3 mg/day; SDT+C.E.R.A. High, 87.9±28.4 mg/day). C.E.R.A. increased hemoglobin levels (SD, 14.8±0.4 g/dL; SDT, 15.4±0.4 g/dL; SDT+C.E.R.A. Low, 16.9±0.5 g/dL; SDT+C.E.R.A. High, 17.4±0.3 g/dL). Systolic blood pressure was higher in SDT rats than in SD rats. In addition, SDT rats had lower heart rate and body weight than did SD rats. C.E.R.A. did not influence these parameters.

Conclusions: These results demonstrated that C.E.R.A. prevented endothelial dysfunction as evaluated by FMD in type-2 diabetic rats, and these results are expected to clarify how C.E.R.A. affects endothelial function in patients with diabetic nephropathy.

Assessment of Renal Vascular Alterations in eNOS -/- Mice by Advanced Contrast-Enhanced microCT Technique Daniel S. Perrien,[1,2] Keiko Takahashi,[3] Mohamed A. Saleh,[4] David G. Harrison,[4] Raymond C. Harris,[3] Takamune Takahashi.[3] *[1]Orthopaedic Surgery and Rehabilitation, Vanderbilt Univ, TN; [2]Tennessee Valley Healthcare System, Dept of Veterans Affairs, TN; [3]Nephrology, Vanderbilt Univ, TN; [4]Clinical Pharmacology, Vanderbilt Univ, TN.*

Background: Proper perfusion is critical for kidney function and many renal diseases result from disruption of blood flow. The imaging technique that enables detailed analysis of renal vasculature undoubtedly facilitates our understanding of renal disease. This study explored a novel rigorous method for 3D microCT-based analysis of total and cortical renal vasculature and assessed vascular alterations in eNOS -/- kidneys.

Methods: Wildtype and eNOS -/- mice (8 wks, n=15) were perfused with radiopaque Microfil™ and excised kidneys were imaged with μCT50 (Scanco Medical) at an isotropic voxel-size of 5.0μm. The entire kidney was selected as the initial volume of interest (VOI). A custom algorithm was created to define the cortical VOI as the entire volume within 600 μm of the renal surface. 3D vascular renderings were created using a grey-scale threshold and noise filter. Vessel thickness was analyzed by plotting the distribution of vascular volume at each thickness.

Results: Fractional vascular volume (vascular volume/kidney volume; VV/KV) and vessel number/mm (V.N) were significantly lower in eNOS-/- kidneys ($p<0.05$). Vessel thickness analysis displayed significant reduction in perfusable vessels in eNOS -/- kidneys in the range of 20-40μm, corresponding to arterioles. The cortical analysis of eNOS -/- kidneys showed similar results, significantly lower VV, VV/cortical V, and V.N, with an increase in the distance between vessels, and lower volume of vessels in the range of 20-30 μm (all $p<0.05$, versus WT), though total cortical V was not different. Further, the volume of vessels (40-90 μm) whose size corresponds to glomerulus was also obviously reduced in eNOS -/- kidneys and cortex.

Conclusions: eNOS -/- kidneys have severe defects in vascular perfusion/structure in the fraction of arterioles and glomeruli, which may contribute to their renal pathology. This study demonstrates the power of 3D microCT analysis to assess vascular phenotyping of murine kidney.

PUB761

N-Acetylcysteine as a Potential Strategy to Attenuate the Oxidative Stress Induced by Uremic Serum in the Vascular System Lia S. Nakao,[1] Silvia Daniéle Rodrigues,[1] Clarice K. Fujihara,[3] Roberto Pecoits-Filho.[2] *[1]Basic Pathology, Univ Federal do Parana, Curitiba, PR, Brazil; [2]School of Medicine, Pontificia Univ Catolica do Parana, Curitiba, PR, Brazil; [3]Faculdade de Medicina, Univ de Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Chronic kidney disease (CKD) progression is accompanied by systemic oxidative stress, which contributes to an increase in the risk of cardiovascular diseases. N-acetylcysteine (NAC) is among the most studied antioxidants, but its effects remain controversial.

Methods: Endothelial and smooth muscle cells were challenged with human uremic or nonuremic sera, and the effects of an acute pretreatment (24 h) with 2 mM NAC were evaluated. ROS production, protein oxidation and total GSH/GSSG ratios were measured. Five-sixths nephrectomized or sham-operated rats were orally treated (in the drinking water) with 60 mg/kg/day NAC or not treated for 53 days. Systemic oxidative stress ($E_{h(Cyss/2Cys)}$) was quantified by measuring the plasma cysteine and cystine levels by HPLC and coulometric detection 7 and 60 days after the surgery.

Results: Uremic serum induced increased oxidation of DHE after 3 h incubation, and $DCFH_2$-DA and MitoSOX Red oxidation after 24 h incubation with both cell lines. NADPH oxidase, but not mitochondria, was determined to be the main source of ROS. An increased amount of protein carbonylation was measured after 3 and 24 h incubation. The total GSH/GSSG ratios were decreased along 24 h of treatment with uremic sera. NAC pre-treatment inhibited all the oxidative stress parameters above, likely by supplying cells with GSH. Indeed, total GSH/GSSG ratios increased after NAC incubation. The beneficial effect of NAC was also observed *in vivo*. CKD rats presented a more intense systemic oxidative stress than sham controls. Orally administered NAC attenuated the $E_{h(Cyss/2Cys)}$ in uremic rats by increasing plasma cysteine levels.

Conclusions: The present results indicate that NAC, by preventing GSH depletion in vascular cells exposed to uremic sera, emerges as a facile strategy to prevent uremic toxicity. Early administration of NAC induces a systemic adaptive redox response to buffer the oxidative stress that is associated with uremia.

Association of Vascular Injury Markers with Progressive Chronic Kidney Disease in Type 2 Diabetes Shayan Shirazian, Robert Diep, Ronak Patel, Monika Wadhwani, Candace D. Grant, Joseph Mattana. *Medicine, Winthrop Univ Hospital.*

Background: Albuminuria, the most commonly used biomarker for progressive diabetic renal damage, is in the normal range in up to 50% of patients with type 2 diabetes (T2DM) and stage 3 chronic kidney disease (CKD). The objective of this ongoing pilot study is to determine which vascular injury markers are associated with eGFR decline in patients with T2DM and stage 3 CKD.

Methods: In this cross-sectional study, adults patients were included if they had: 1) T2DM for at least 8-years, 2) stage 3 CKD, 3) normal to moderately increased albuminuria, 4) three prior creatinine values over 4 years. Patients were excluded if they had 1) non-diabetic kidney disease, 2) renal transplant, 3) renal artery stenosis, 4) active malignancy. Circulating endothelial cells (CECs), von willebrand factor, high-sensitivity C-reactive protein (hsCRP), uric acid and morning spot urine-albumin to creatinine ratio (UACR) were measured. Levels of CECs were measured using the CellSearch System (ImmuniconCorp., HuntingdonValley, PA). Average yearly eGFR decline from 2011-2014 was calculated. Subjects were separated into slow and fast eGFR decline groups (cut-off 2 mL/min/1.73m^2/year). Groups were compared using unpaired two-tailed t-tests.

Results: 16 patients were studied. The average age was 75 years, 88% were male, 88% were White and average T2DM duration was 16 years. The average eGFR was 40 mL/min/1.73m^2, UACR was 82 mcg/mg, and the average eGFR decline was 2.6 mL/min/1.73m^2/year. There were 9 patients in the slow and 7 patients in the fast eGFR decline group. There were no statistically significant differences between groups however UACR levels (48 +/- 81 ug/mg versus 120 +/- 109 ug/mg, p 0.18) and hsCRP levels (2.2 +/- 1.8 mg/L versus 6.01 +/- 6.2 mg/L, p= 0.16) were higher in the fast eGFR decline group.

Conclusions: In this ongoing pilot study, hsCRP levels were higher in normal to moderately albuminuric subjects with T2DM and fast eGFR decline. This finding did not reach statistical significance likely because of our small sample size. Future research is needed to determine whether hsCRP can predict progressive eGFR decline in non-albuminuric patients with T2DM and early CKD.

PUB763

The Role of Hypoxia-Inducible Transcription Factors in Determination of Macrophage Phenotypes Enda Patrick Masterson, Catherine Godson, Debra F. Higgins. *Diabetic Complications Research Centre, Conway Institute of Biomedical and Biomolecular Research and School of Medicine, Univ College Dublin, Dublin, Ireland.*

Background: Versatility is a characteristic of macrophages mediating both tissue damage and repair, exemplified by M1 and M2 phenotypes respectively. Understanding how versatility is regulated is important in the context of inflammation. Monocyte-Macrophage recruitment is a feature of responses to tissue hypoxia resulting in accumulation of hypoxia-inducible transcription factors [HIFs]. Different forms of HIF exist (e.g. HIF-1α and HIF-

2α) regulating expression of overlapping and unique target genes. The role of HIF-1α in inflammation is well described, while the role of HIF-2α is relatively unexplored. We hypothesise that HIF-1α drives an M1 pro-inflammatory phenotype and HIF-2α encourages M2 pro-resolution phenotypes.

Methods: Endogenous HIF-1α and HIF-2α protein expression in THP-1 monocytes and macrophages subjected to hypoxia (1% O2) or normoxia (21% O2) was examined using immunoblotting. To determine the effect of over-expressing HIF isoforms on macrophage phenotype, THP-1 cells were transfected with HIF-1α or HIF-2α and subsequently differentiated into macrophages, after which expression of M1 and M2 markers was analysed. The effect of polarization on HIF isoform expression was examined in macrophages polarized into M1 and M2 states by treatment with LPS/ IFNY and IL-4/ IL-13 respectively and subjecting macrophages to either hypoxia or normoxia.

Results: HIF-1α expression was detected in both hypoxic monocytes and macrophages. HIF-2α levels were lost on differentiation of monocytes to macrophages under hypoxia and normoxia. ELISA analysis revealed HIF-1α transfected macrophages had increased levels of MCP-1, an M1 marker and reduced levels of IL-10, an M2 marker. HIF-2α transfected macrophages had significantly decreased levels of MCP-1 ($P < 0.05$). M1 polarized macrophages had increased expression of HIF-1α without detectable HIF-2α expression while M2 polarized macrophages had decreased expression of HIF-1α and regained expression of HIF-2α.

Conclusions: These findings support our hypothesis and highlight the divergent roles of HIF-1α and HIF-2α in inflammation and resolution.

Impairment of Post-Ischemic Angiogenesis in Chronic Kidney Disease in Rats: Underlying Changes in Ischemia-Induced Early Regulation of Gene Expression

Johannes Jacobi,[1] Rafael Heiss,[1] Christoph Daniel,[2] Nada Cordasic,[1] Fabian Fahlbusch,[3] Arif Ekici,[4] Yvonne Riedl,[2] Andrea Hartner,[3] Kerstin U. Amann,[2] Karl F. Hilgers.[1] *[1]Nephrology and Hypertension, Univ of Erlangen-Nürnberg, Erlangen, Germany; [2]Nephropathology, Univ of Erlangen-Nürnberg, Erlangen, Germany; [3]Pediatrics, Univ of Erlangen-Nürnberg, Erlangen, Germany; [4]Human Genetics, Univ of Erlangen-Nürnberg, Erlangen, Germany.*

Background: Ischemia-induced angiogenesis in skeletal muscle of rats with chronic kidney disease (CKD) is impaired which may aggravate peripheral vascular disease. We investigated underlying mechanisms by a systematic comparison of early gene expression in response to ischemia in rats with or without CKD.

Methods: CKD rats underwent 5/6 nephrectomy; controls sham operation. Eight weeks later, ischemia of the right limb was induced by ligation and resection of the femoral artery. Rats were sacrificed 24 h after the onset of ischemia. RNA from Musculus soleus of 4 control and 5 CKD rats (ischemic and non-ischemic sides, respectively, from each rat) was analyzed using 18 Affymetrix GeneChip Rat Genome 230 2.0 Arrays. A 2fold change of gene expression ($p<0.05$) was set as a cutoff. The Ingenuity Pathways Knowledge Base was employed for analysis of functional groups and networks. RT-PCR analysis of selected genes was performed to validate observed changes.

Results: Ischemia up-regulated 266 genes in CKD and 322 genes in control rats (65% overlap) whereas few genes were down-regulated, compared with the respective non-ischemic side. Comparison between the ischemic sides of CKD and control animals revealed down-regulation of 69 genes in CKD; 39 of these genes were also among the ischemia-induced genes in controls. Among the 11 known angiogenesis-related genes which were induced by ischemia but reduced in CKD were VEGF-A, c-MYC, TIMP-1, IL-6 and the chemokines CCL2, CCL7 and CXCL9. Other affected functional groups of genes were leukocyte recruitment and fatty acid metabolism. The differential gene expression of VEGF-A, CCL2 and CCL7 was confirmed by RT-PCR.

Conclusions: Gene expression profiling points to a relatively small number of differentially expressed genes which may underlie impaired post-ischemic angiogenesis in CKD.

Abdominal Aortic Calcification of Hemodialysis Patients and Its Association with Traditional Therapeutic Targets of Bone Disease

Kyriaki Stamatelou,[1] Dimitra Bacharaki,[2] Ioannis Griveas,[3] Stavroula Konstantinidou,[1] Velissarios Ginis,[1] Stamatia Theodorakopoulou,[2] Dimitrios V. Vlahakos.[2] *[1]Kyanous Stavros, Greece; [2]Attikon Hospital, Greece; [3]Nefroiatriki, Greece.*

Background: Vascular calcification (VC) has been implicated in high mortality of dialysis patients. We studied the association of abdominal aorta VC with traditional parameters-targets of diagnosis and treatment of CKD-MBD.

Methods: We studied 79 hemodialysis patients, 51 men, 28 women, 64.2±14.9 years. Diabetes, hypertension, cardiovascular disease and smoking were present at 23, 18, 40.5 and 25.5% respectively. Dialysis vintage was 36.8 months (range 1-228). VC of the abdominal aorta was assessed by Leena Kauppilla score (range 0-24) in lateral abdominal radiographs. Patients were stratified according to the calcification score: Group 1 (grade 0), Group 2 (grade 1-4) and Group 3 (grade 5-22). One-way ANOVA with SPSS was used.

Results: Abdominal aorta calcification was 5.7 (range 0-22). VC score was statistically associated only with dialysis vintage and not with age, sex, smoking, blood Ca^{2+}, P^{+}, iPTH, cholesterol, triglycerides, Ca×P product or use of calcium or non-calcium phosphate binders, calcimimetics or paricalcitol

Patient Groups	Group 1	Group 2	Group 3
Calcification Score	**0**	**1-4**	**5-22**
Patients %	28	25.3	46.7
Age (years)	59±3.8	64.2±4.3	66.2±1.8 NS
Dialysis Vintage (months)	2±0.3	32.5±9	58±12.9 **p<0.05**
Ca^{2+}mg/dl	8.94±1.08	8.86±0.96	9.1±0.14 NS
P^{+}mg/dl	5.78±0.36	6.66±0.29	6.31±0.26 NS
Ca×P	52.63±4.10	59.39±3.94	57.61±2.61 NS
iPTH pg/ml	427.97±102	447±140.29	476.6±82.98 NS

Positive history of cardiovascular events was significantly associated with higher VC score: 7.8±1.33 versus 4.29±0.8, $p<0.05$. When grouping patients according to achievement of KDIGO targets, VC scores were significantly different:PTH<150, 150<PTH<500 and PTH>500pg/ml patient groups had VC scores 3.22±0.54, 5.93±1.41 and 7.87±1.47 respectively, $p<0.05$.

Conclusions: Radiological evaluation of VC was positively associated with dialysis vintage and cardiovascular disease. In our study, achieving PTH was the only CKD-MBD treatment target presenting a difference in terms of VC.

PUB766

A Comparison of Pulse Wave Analysis Results Using Vicorder and SphygmoCor Devices in a Chronic Kidney Disease Cohort

Thilini Nishani Abeygunaratne,[1] Darren Green,[1] Jack Wilkinson,[2] Diana Chiu,[1] Philip A. Kalra.[1] *[1]Salford Vascular Research Group, Univ of Manchester, Manchester, United Kingdom; [2]Dept of Research and Development, Salford Royal Foundation Trust, Salford, United Kingdom.*

Background: Pulse wave analysis (PWA) is a noninvasive measure of vascular stiffness. The Vicorder and SphygmoCor are two devices used to measure PWA, by oscillometry and applanation tonometry respectively. This study compared measurements from both devices undertaken in the same patients to determine whether results from the two devices could be used interchangeably.

Methods: 91 patients with CKD stages 3 to 5 seen in outpatient clinic underwent PWA using both devices. The augmentation pressure (AP) and augmentation index (AIx) from each device were compared using the Bland Altman method.

Results: The mean age was 63.8±12.2 years, eGFR 33.1±15.9mL/min/1.73m², and 57 patients (63%) were male. For AP, mean difference was 1.85mmHg and 95% limits of agreement (LoA) 14.21to17.91 mmHg. The Bland–Altman plot (fig 1A) shows with higher AP values, the Vicorder gives lower measurements. This is formally seen from the regression of the differences in measurements on the means of the measurements (slope=-0.47, $p<0.001$, fig 1B). For AIx, the mean difference was 0.02%, and 95% LoA -19.0%to19.0% (fig 2A). The Bland-Altman plot (fig 2A) shows the Vicorder gives higher measurements for lower values. The expected disagreement is 12.31-0.44a, (fig 2B). These limits are preferred to those in figure 2A, as the latter do not accommodate that the extent to which the Vicorder may over or underestimate AIx compared to SphygmoCor depends on the size of the measurement.

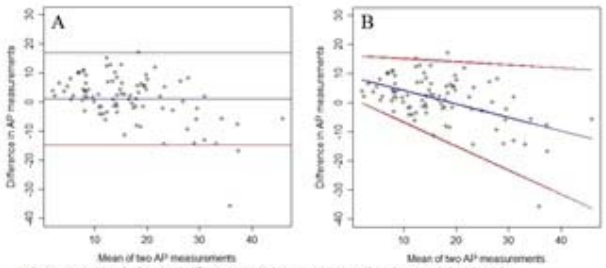

Figure 1. A: Bland-Altman plot for Augmented Pressure (mmHg) and B: regression-based 95% limits of agreement.

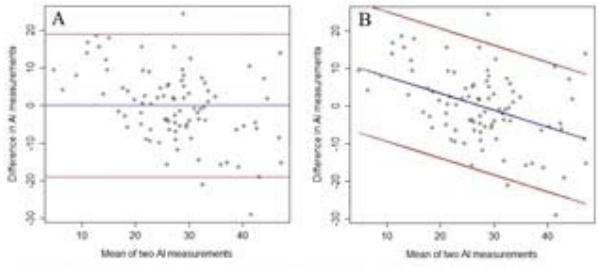

Figure 2. A: Bland-Altman plot for augmented index(%) and B: regression-based 95% limits of agreement.

Conclusions: There is disagreement between the two methods for both AP and AIx. Although the mean difference between AIx was small, the LoA were large, at extremes of measurement. This means that results from the two devices cannot be considered interchangeable.

PUB767

Calcific Uremic Arteriolopathy: A Systemic Vascular Calcification Disorder? Sagar U. Nigwekar,[1] Sean H. Novak,[2] Rosalynn Nazarian,[1] Rajeev Malhotra,[1] Yanchen Zhang,[1] Julia Beth Wenger,[1] Mukesh Harisinghani,[1] Ravi I. Thadhani.[1] *[1]MGH; [2]Mount Auburn Hospital.*

Background: Calcific uremic arteriolopathy (CUA) is considered to be a dermal arteriolar calcification disorder but the extent of calcification involving other vascular beds is unknown. Understanding the overall burden of vascular calcification in CUA may offer mechanistic and therapeutic insights into this devastating disease with unclear pathobiology.

Methods: We conducted a matched case-control study comparing the extent of vascular calcification on CT and mammography in chronic dialysis patients with (cases; n=10) and without CUA (controls; n=10). Skin-biopsy confirmed CUA cases were identified from review of pathology department records and included if they had undergone CT and mammography. Controls were randomly selected from our institutional research database and matched to cases by age, gender, dialysis modality, and dialysis vintage. Calcification on CT and mammography was scored in 5 anatomic vascular distributions (aortic, coronary, visceral, pelvic, and mammary circulations) from 0 (no visible calcification) to 10 (heavy calcification). We also systematically reviewed autopsy records of 8 CUA patients to identify calcification of vascular beds.

Results: The mean age (± standard deviation) was 61 ± 3 years (cases) and 62 ± 2 years (controls). 50% of patients were males, 70% on hemodialysis, and median dialysis vintage was 4.1 years in both cases and controls. Median vascular calcification scores for cases and controls are shown below.

	Aortic	Coronary	Visceral	Pelvic	Mammary
Cases	4	6.5	6	6	9
Controls	3	4	2	3	4

Review of autopsy records identified diffuse mesenteric, pelvic, aortic, coronary, and valvular calcifications in CUA patients.

Conclusions: Dialysis patients with CUA may have a higher calcification burden across multiple vascular beds compared to dialysis patients without CUA suggesting that CUA is a systemic vascular calcification disorder.

PUB768

Relationship of Fetuin-A and Coronary Artery Calcification Score in Patients with Chronic Renal Failure on Maintenance Hemodialysis Ali Abdulmajid Allawi,[1] Mohammed Younus Naji,[2] Jawad Ibrahim Rasheed.[3] *[1]Medicine, Baghdad College of Medicine, Baghdad, Iraq; [2]Medicine, Baghdad Medical City, Baghdad, Iraq; [3]Medicine, Baghdad Teaching Hospital, Baghdad, Iraq.*

Background: In patients on maintenance haemodialysis, serum Fetuin-A levels inversely correlate with the extent and grade of coronary calcification, measured by Coronary artery calcium scoring (CACS) were performed by cardiac CT scan.

Methods: The study was conducted in dialysis department/ Baghdad teaching hospital from February 2013 to the end of March 2014. A total numbers of 60 patients with end stage renal disease already on maintenance hemodialysis and control 30 cases, were examined from both sexes, who already on maintenance hemodialysis, were examined for serum Fetuin A and Coronary artery calcium scoring (CACS) were performed by a 64-slice CT scan. Fetuin A has been tested by quantitative solid phase enzyme immunometric assay (ELISA) designed for the determination of Fetuin A in human serum, using DiaMetra kit.

Results: This case control study that enrolled 60 patients with end stage renal disease already on maintenance hemodialysis were included in the study, 25 males and 35 females and their age range from 15 to 70 years old, with male to female ratio 0.7 :1. There was low serum Fetuin A level in studies patients with chronic renal failure on maintenance hemodialysis with higher coronary artery calcium score 11-400 and >400 as compared to control group, the difference were statistically significant, (p=0.000)

Calcium calicification score	low S. Fetuin A	%	normal S. Fetuin A	%	total No.	%	p value
0-10	6	13	24	54.5	30	33.3	
11-400	25	54.3	7	15.9	32	35.6	
>400	15	32.6	13	29.5	28	31.1	
Total	46	100	44	100	90	100	0.000

Conclusions: Fetuin-A levels is robust marker of vascular calcification in patients with end stage renal failure. Negative relationship between Fetuin-A levels and total coronary artery calcification scores. Fetuin A level is decreased in patients with chronic renal failure with cardiovascular risk factors as male, age older than 55 years, hypertension, diabetes and anemia.

PUB769

Determinants of Therapeutic Success in Sodium Thiosulfate Treated Chronic Kidney Disease Patients with Calciphylaxis Kateri Bourbeau,[2] Chloé Lajoie,[2] Simon Desmeules,[1] Fabrice Mac-Way.[1] *[1]Pharmacy, Hôtel-Dieu de Quebec, QC, Canada; [2]Medicine, Hôtel-Dieu de Quebec, QC, Canada.*

Background: Calciphylaxis is a severe medical condition that affects patients with end-stage renal disease. One-year mortality has been reported to as high as 70% in hemodialysis patients. In the literature, treatment based on a multi-modality approach has been proposed but the optimal therapy remains poorly unknown. In this study, we aimed to evaluate the incidence of calciphylaxis in our center and determine the effects of different treatments approach on the evolution and mortality.

Methods: All patients with chronic kidney disease that were diagnosed with calciphylaxis either clinically or with skin biopsy were included in this retrospective study from l'Hôtel-Dieu de Québec hospital (Québec, Canada). Complete response to treatment was defined as complete lesion healing and partial response as lesion or pain improvement. Univariate analysis was performed to evaluate the role of each different intervention on therapeutic response.

Results: Twelve patients were included in this study. The majority of the lesions were located on the lower limbs. The patients associated comorbidities are consistent with previously reported risk factors for calciphylaxis: diabete (n=11), obesity (n=7), warfarin (n=9) and calcium-based chelators (n=10) treatments. A multi-modality approach was the base of the treatment and included cessation of calcium-based chelators and warfarin, lowering of calcium dialysate, intensification of hemodialysis treatments, variable use of cinacalcet and bisphosphonate. All patients were treated with intravenous sodium thiosulfate. There was a complete lesion healing in 42% of patients, 50% if we add the patients with improved lesion and 100% of our cases had pain improvement. One-year mortality was 25%. No single factor has been found to be associated with positive therapeutic response.

Conclusions: Calciphylaxis is a highly morbid condition if not optimally treated. A multi-modality approach should be encouraged including the use of sodium thiosulfate. The combination of these interventions probably explained the low mortality rate as compared to literature.

PUB770

Osteoprotegerin Is Associated with Vascular Calcification in Peritoneal Dialysis Juan Carlos Ramirez-Sandoval,[1] I. E. Casanova,[1] Jorge A. Villar-Tapia,[1] Enrique Gómez,[2] Cristinoc Cruz,[1] Ricardo Correa-Rotter.[1] *[1]Nephrology and Mineral Metabolism, Inst Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]Physiology of Nutrition, Inst Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.*

Background: Vascular calcification (VC) is associated with cardiovascular mortality. In peritoneal dialysis(PD), VC has been scarcely studied and biomarkers associated to calcification not well characterized. This study aimed to determine the association of osteoprotegerin(OPG), osteopontin(OPN), osteocalcin(OCN), fibroblast growth factor 23(FGF-23), and P clearance with VC.

Methods: The Adragao simple vascular calcification score(SVCS) from pelvis and hand X-rays and Kauppila index(KI), from lateral lumbar X-ray were assessed in 76 adults on PD (43 women, median age 39 yrs, median time on DP 1.4 yrs). OPG, OPN, OCN, and FGF-23 were determined by luminometry.

Results: OPG levels were higher in subjects with increased VC in both indexes (n=22 with SVCS>3; n=19 with KI>7;$p<0.001$). Correlation coefficient between OPG and VC scores were: r=0.49 for SVCS and r=0.51 for KI, (both $p<0.001$). Subjects with VC had significantly lower renal P clearance. In a multiple regression analysis, VC assessed by SVCS was significantly associated with age(r:0.2), DM(r:2.4), BMI(r:0.09), and OPG/100^2(r:0.22); VC assessed by KI was significantly associated with age(r:0.16), time on PD(r:0.54), and OPG/100^2(r:0.08). OCN, OPN, and FGF23 were not associated with VC.

Table. Relations between osteogenic biomarkers and P Clearance(Cl)*,SVCS and KI						
	VSCS ≤3 (n=54)	VSCS >3 (n=22)	p	KI≤7 (n=57)	KI>7 (n=19)	P
OPG, pg/mL	641 (477-998)	1110 (709-1569)	**0.04**	896 (604-1341)	1656 (1118-1850)	**<0.001**
OPN, ng/mL	18 (5-36)	12 (5-29)	0.52	15(5.0-34)	26 (9-40)	0.14
OCN, ng/mL	54 (29-131)	55 (25-91)	0.67	55 (29-116)	42 (21-127)	0.58
FGF-23, ng/mL	1.1 (0.2-9.1)	3.2 (0.4-8.7)	0.22	1.3 (0.3-10.4)	1.7 (0.2-7.0)	0.37
Perit. P Cl, L/wk per 1.73m^2	34 (25-39)	34 (29-43)	0.39	35 (24-42)	33 (26-39)	0.058
Renal P Cl, L/wk per 1.73m^2	12 (0-27)	4 (0-14)	**0.02**	11 (2-35)	6 (0-11)	**0.045**

*Median (interquartile range)

Conclusions: Higher OPG levels showed a consistent association with VC in PD patients.

PUB771

Calcium Level Is an Independent Predictor of Vascular Calcification in Hemodialysis Patients Fellype C. Barreto,[1,2] Andréa Marques Stinghen,[3] Tammy Vernalha Rocha Almeida,[2] Rodrigo Leite Silva,[2] Daniela Veit Barreto.[1,2] *[1]School of Medicine, Pontificia Univ Catolica do Parana, Curitiba, Parana, Brazil; [2]Nephrology, Hospital Santa Casa de Curitiba, Curitiba, Parana, Brazil; [3]Univ Federal do Parana, Curitiba, Parana.*

Background: Vascular calcification (VC) is a common manifestation of chronic kidney disease-mineral bone disorder (CKD-MBD) associated to adverse outcomes in hemodialysis (HD) patients. In this study, we sought to investigate the prevalence and risk factors associated with VC in a cohort of HD patients.

Methods: 81 HD patients (age: 57±14 yrs; 61% males; 40% diabetics; length on HD: 18±8 months) underwent plain X-rays of hands and hips (Adragao score) and laboratory measurements (calcium, phosphate, alkaline phosphatase, 25(OH)vitamin D, iPTH, albumin and lipid profile).

Results: VC was present in 45% of the patients. Patients with VC were older (62±10 versus 53±19 yrs; p=0.002), most of them were diabetics (64%; p=0.01) and had higher calcium levels (9.2±0.9 versus 8.7±0.6 mg/dL; p=0.005) when compared to patients without VC. Interestingly, there was a greater proportion of VC (58%;p=0.04) among patients with calcium levels above the median (8.9 mg/dL). Calcification score was directly associated with age (r=0.27;p=0.01) and calcium levels (r=0.27;p=0.01), and inversely associated with iPTH (r=-0.22;p=0.04), total cholesterol (r=-0.22;p=0.04) and albumin (r=-0.21;p=0.05) levels. Multivariate logistic regression analysis showed that VC was independently associated with calcium (β coefficient= 2.36; p=0.03; 95% CI= 0.393 - 4.771) and diabetes (β coefficient=3.06; p=0.05; 95% CI= 0.566 - 3.903).

Conclusions: VC was highly prevalent in the study population. In addition to traditional risk factors, such as age and diabetes, mineral metabolism derangement, inflammation and altered lipid metabolism may also play a role on VC development. The independent association between VC and calcium gives further support to the recommendation that calcium overload should be avoided and suggests that calcium levels should be kept below the upper limit of the reference range in HD patients.

PUB772

Pelvic Radiograph May Be an Alternative for Coronary Artery CT in Assessing Vascular Calcification in Hemodialysis Patients Daqing Hong, Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: KDIGO (Kidney Disease: Improving Global Outcomes) guidelines recommend that a lateral abdominal radiograph should be performed to assess vascular calcification (VC) in dialysis patients. However, our previous study of 36 hemodialysis patients found that the vascular calcification (VC) in the pelvic radiograph was superior over VC in abdominal radiograph in association with coronary artery calcification (CAC). The objective of this study is to further unravel the story of this finding in a larger sample.

Methods: A total of 117 maintenance hemodialysis patients were enrolled at the Sichuan Provincial People's Hospital between June 2013 and December 2013. Multi-slice spiral computed tomography was taken to detect the CAC. Radiographs of the abdomen, pelvis and hands were evaluated by a radiologist to assess the presence of VC. Predict value of VC in different areas was analyzed using receiver operating characteristic (ROC) curve.

Results: The prevalence of VC in abdominal, pelvic and hands' X-rays was 67.52%, 55.56% and 15.38%, respectively. Area under the ROC curve (AUC) ofabdominal aortic calcification was 0.765 when predicting the presence of CAC, while the AUC of VC observed on pelvis X-ray was 0.711, the AUC of VC observed in all radiograghs (abdomen, pelvis and hands) was 0.771, while the AUC of VC observed on hands X-ray was less than 0.6.When predicting for CACs>100, AUC of abdominal aortic calcification was less than 0.7, while pelvic X-ray, hands' X-ray, total X-rays was 0.735,0.722,0.722, respectively. Predicting for CACs>400, AUC of pelvis X-ray, the total X-rays was 0.719, 0.708, and the AUC of abdominal radiograph was less than 0.7.

Conclusions: Our study demonstrated that the prevalence of VC in different arteries is different. VC presented in pelvic X-rays seemed to be superior over other vascular calcification in predicting coronary artery calcification in hemodialysis patients.

PUB773

Contribution of Hyponatremia (HN) to Hip Fractures (HF): The Under-Reporting of HN and Need to Increase Awareness of Symptomatic HN Sairah Sharif, Mary Joelanny Dominguez, Louis J. Imbriano, Joseph Mattana, John K. Maesaka. *Winthrop Univ Hosptial, Mineola, NY.*

Background: HN is the most common electrolyte abnormality that contributes independently to increased length of stay and mortality. Chronic HN induces significant osteoporosis and even mild HN is associated with impaired cognition, four-fold increase in falls and in the elderly a four-fold increase in bone fractures. These complications of HN are not generally appreciated and HN is thus left untreated. HF are associated with a 25% mortality. We therefore performed a retrospective study on the association between HN and HF.

Methods: We reviewed the medical records of 148 patients admitted to Winthrop-University Hospital with HF between July and Sept, 2013, focusing on demographic information, serum sodium at time of admission and during hospital course, comorbid conditions, falls associated with HF, and inclusion of HN in ICD-9 coding at discharge.

Results: The mean age was 77±SD 16 years, 116 females and 32 males. 16 patients had HN on admission, 15 of whom were females and fell. 15 patients developed HN after admission, of which 5 developed HN post-operatively. The most common co-morbid conditions were hypertension, diabetes and congestive cardiac failure. Out of the 31 HN patients 29 patients were discharged to skilled nursing and rehabilitation facilities and 29 of 31 patients with HN were not included in ICD-9 coding at discharge.

Conclusions: There are enough data to associate HN with significant adverse outcomes and increased morbidity and mortality. HN occurs with equal frequency at admission and as inpatient and contributes to HF which occur more commonly in females. HN is a significant problem that not only contributes to but is possibly induced by HF. However, it's contribution to morbidity and mortality is unappreciated as evidenced by under-reporting in ICD-9 coding in discharge summaries. Efforts are needed to raise awareness of and treat HN to prevent potentially serious complications.

Clinical Evaluation of Patients with Apparently Idiopathic SIADH Alain Soupart,[1,2] Guy Decaux,[2] Michel Coffernils,[1] Irène Nyenyeli,[1] Fabrice Gankam Kengne,[4] Bruno Couturier,[2] Frédéric Vandergheynst,[2] Didier Francois.[3] *[1]Dept of Internal Medicine, Jolimont-Tubize Hospital, Jolimont, Belgium; [2]Dept of Internal Medicine, Erasme Univ Hospital, Bruxelles, Belgium; [3]Dept of Radiology, Jolimont-Tubize Hospital, Belgium; [4]Dept of Nephrology, Erasme Univ Hospital, Belgium.*

Background: Idiopathic SIADH refers to hyponatremia of no obvious cause (± 30% of SIADH). It can be associated with numerous diseases and predate their diagnosis for months and it's incidence increases with aging. The diagnosis workup of idiopathic SIADH is unknown.

Methods: Between 2008 and 2014, 84 successive patients with SIADH lasting for at least 1 month and no obvious cause were enrolled in a prospective study. Inclusion criteria were no specific symptoms/signs, no lab abnormalities pointing toward diagnosis and a normal CXR. All the patients had a brain CT and a FDG-PET.

Results: Underlying disease known to be associated with SIADH was found in 31% of the cases and was intrathoracic in 73% (10 cancer, 7 infections, 3 bronchiectasis), cerebral in 19% (chronic subdural hematoma, normotensive hydrocephaly, intracranial cavernoma, empty sella syndrome, olfactive neuroblastoma), abdominal in 3%, ENT cancer in 3% and 1 NSIAD. Neoplasms were found in 50% of the patients with a high mortality rate (70%). Final diagnosis was made by chest CT in the majority (73%) of the cases. Old ischemic brain lesions were also found in 37% of the patients.

Mean±SD	Total	Negative cases	Positive cases
N	84	58 (69%)	26 (31%)
Age (Range)	70±11 (28-99)	70±14 (51-99)	66±12 (28-84)
Male	53 (63%)	32 (55%)	21 (80%)
SNa (mEq/l)	122±6	120 ±15	122± 6
Duration of Hyponatremia (Months)	37±38	41±35	30±44
Hyponatremia < 12 months	30(35%)	16(28%)	14(53%)
Mortality	20(23%)	9(15%)	11(42%)

Conclusions: In asymptomatic patient with apparently idiopathic SIADH additional investigations can lead to diagnosis of treatable diseases in a significant number of cases. This study shows also that extensive diagnostic procedures are unnecessary and the diagnostic work-up should include only a chest CT scan. In young patients with negative chest CT, brain CT scan can be done. The prognosis of positive cases is poor despite early care.

PUB775

Can Tolvaptan Be Used Safely in the Management of Acute Hyponatremia due to Syndrome of Inappropriate Secretion of Antidiuretic Hormone? David Cucchiari, Manuel Alfredo Podesta', Silvia Santostasi, Paola Arosio, Simona Verdesca, Rosa Pedale, Claudio Angelini, Salvatore Badalamenti. *Nephrology, Humanitas Clinical and Research Center, Rozzano, Milano, Italy.*

Background: Tolvaptan is a selective oral vasopressin V2-receptors antagonist that has great efficacy in the management of the Syndrome of Inappropriate Secretion of AntiDiuretic Hormone (SIADH). However, it is not indicated by international guidelines because of concerns about too rapid increases of serum sodium levels. For this reason, Hypertonic Saline (HS) administration is the treatment of choice, although the quality of evidence supporting this indication is low.

Methods: We present 5 cases of SIADH in which the HS infusion had only partial benefit and led us to consider the off-label administration of Tolvaptan to achieve symptoms remission. The patients were euvolemic. Hypothyroidism and hypocorticism were ruled out while natriuresis was elevated. All these criteria were consistent with SIADH diagnosis.

Results: The treatment was started in every patient at least 12 hours after the beginning of 3% HS infusion. The dose of Tolvaptan was 15 mg for the first three patients and 7.5 mg for the last two ones. We assisted to an immediate increase of sodium levels in all patients, which led to symptoms remission.

Patient #	SIADH Cause	TSH (mUI /L)	ACTH 8am (pg /ml)	Cortisol 8am (mcg /dl)	Glycemia (mg /dl)	Urine Na^+ (meq /L)	Tolvaptan Dose (mg)	Na^+ Basal (meq /L)	Na^+ after HS (meq /L)	Na^+ 24h after Tolvaptan (meq/l)
1	Neoplasm	1.1	29	11	194	111	15	116	123	128
2	Meningitis	0.6	14	13	121	105	15	119	124	136
3	Psychosis	1.3	23	13	155	112	15	114	123	129
4	Neurosurgical	4.1	15	14	181	101	7.5	114	124	131
5	Traumatic	0.1	18	12	147	175	7.5	116	120	135

None of the patients experienced signs of myelinolysis due to rapid correction. However, in patient #2 and #5 we used glucose 5% solution to slow the sodium increase.

Conclusions: In our series, Tolvaptan had great efficacy in increasing sodium levels and achieving symptoms remission in SIADH patients who had an incomplete response to HS infusion. Strict monitoring of serum sodium is essential in order to avoid a too rapid correction that may lead to myelinolysis.

PUB776

Analysis on Body Composition and Related Factors in Maintenance Hemodialysis Patients Yi Yu. *Dept of Blood Purification, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: To measure body composition by body composition monitor (BCM) and analyze related factors in maintenance hemodialysis (MHD) patients.

Methods: We selected 57 MHD patients and measured their body composition and overhydration (OH) by BCM and collected their blood samples. We detected their serum cholesterol, triglyceride, albumin, hemoglobin and creatinine. Then we divided into 2 groups according to the mean value of BMI, fat tissue of unit surface area and muscle tissue of unit surface area, and compared blood biochemical parameters between the 2 groups. According to the difference value between OH measured by BCM and actual ultrafiltration volume, we divided into 2 groups: group A>300ml and group B≤300ml. We recorded the occurrence of adverse reactions on dialysis.

Results: Compared the high and low BMI groups (BMI≥21.68kg/m^2 versus BMI<21.68 kg/m^2), the former's fat tissue of unit body surface area was higher than the latter's (P<0.05). There was a positive correlation between BMI and fat tissue unit surface area (r=0.588, P<0.05), but there was no correlation between BMI and muscle tissue of unit surface area. Compared the groups of high and low fat tissue of unit surface area (≥12.29 kg/m^2 versus <12.29 kg/m^2), the former's cholesterol, triglyceride and hemoglobin were higher than the latter's (P<0.05). There were a positive correlation between fat tissue of unit surface area and cholesterol, triglyceride and hemoglobin (r=0.370, 0.403, 0.405, P<0.05). Compared the groups of high and low muscle tissue of unit surface area (≥22.80 kg/m^2 versus <22.80 kg/m^2), the former's serum creatinine and albumin were higher than the latter's (P<0.05). There were a positive correlation between muscle tissue of unit surface and serum creatinine and albumin (r=0.416, 0.315, P<0.05). We recorded the incidence of adverse reactions of hypotension, nausea and vomiting and convulsion between group A and B on dialysis. The adverse reaction occurrence rate was apparently higher in group A than that in group B. (χ^2=7.402, P<0.05).

Conclusions: In MHD patients, body composition by BCM is an accurate, non-invasive and quick way for assessment of nutritional and overhydration status of MHD patients.

Losartan Improves Renal Function and Pathology in a Rat Model of Type II Diabetic Nephropathy Deborah Widomski, Laura Leys, Kelly Larson, Steve McGaraughty, Zhi Su, Arthur L. Nikkel. *Early Renal Discovery, Abbvie, IL.*

Background: Losartan, a blocker of angiotensin II type I receptor, is an important part of the standard of care for diabetic nephropathy (DN). Obese ZSF-1 rats (bred by crossing female Zucker diabetic fatty rat with male spontaneously hypertensive heart failure rat) display many aspects of the clinical features of human type II DN. The current study was designed to examine the treatment effects of Losartan in ZSF-1 rats as part of the model validation.

Methods: All rats (at 7-10 weeks old) underwent a right uninephrectomy (Unx) surgery and were maintained on a high carbohydrate diet throughout the study. Losartan was dosed orally once a day at 3, 10, and 30 mg/kg, starting 3 weeks post Unx and lasting for 3 months. Blood, 24-hr urine samples, and metabolic parameters were collected once every 2-4 weeks. Blood pressure (BP) was measured by tail cuff. Glomerular filtration rate (GFR) was measured by transdermal clearance of FITC-sinistrin. Kidney collagen content was estimated by Picro Sirius Red (PSR) stain and measuring hydroxyproline.

Results: Compared to lean control rats, ZSF-1 rats showed significant increases in urinary protein excretion rate (UPER), blood lipids and glucose, body weights, food and water intake, and urine output. Systolic BP was slightly decreased by Losartan at 10 and 30 mg/kg. UPER was significantly reduced by Losartan in a dose-dependent manner, with a maximal 41% reduction at week 12 (30 mg/kg). Losartan (30 mg/kg) also reduced blood lipids. Losartan at 3 and 10 mg/kg had little effect on any metabolic parameter, but 30 mg/kg increased blood glucose levels, water intake and urine output. GFR was significantly lower in ZSF-1 rats than lean rats, and all doses of Losartan significantly improved GFR in ZSF-1 rats. Kidney collagen content (PSR stain and hydroxyproline) was significantly increased in ZSF-1 rats (versus lean rats) and reduced by Losartan in a dose-dependent manner.

Conclusions: Those results indicate that Losartan (administered in a treatment/ intervention mode) provided significant renal protection in ZSF-1 rats.

HALT Progression of Polycystic Kidney Disease Trials: Primary Results of a Randomized Trial in Moderately Advanced Stage CKD

Vicente E. Torres,[1] Kaleab Z. Abebe,[2] Arlene B. Chapman,[3] Robert W. Schrier,[4] William E. Braun,[5] Theodore I. Steinman,[6] Franz Winklhofer,[7] Godela M. Brosnahan,[4] Peter G. Czarnecki,[6] Marie C. Hogan,[1] D. Miskulin,[8] Frederic F. Rahbari-Oskoui,[3] Jared J. Grantham,[7] Peter C. Harris,[1] Michael F. Flessner,[9] Charity G. Moore,[2] Ronald D. Perrone.[8] *[1]Mayo, MN; [2]Univ of Pittsburgh, PA; [3]Emory Univ, GA; [4]UCHSC, CO; [5]Cleveland Clinic, OH; [6]BIDMC, MA; [7]KUMC, KS; [8]Tufts, MA; [9]NIH, MD.*

Background: Hypertension in ADPKD develops early and associates with disease progression. The renin-angiotensin-aldosterone system (RAAS) has been implicated in its pathogenesis. Dual RAAS blockade may circumvent compensatory mechanisms that limit the efficacy of ACE-I or ARB monotherapies.

Methods: In a double-blind, placebo-controlled, prospective 5-8 year trial, 486 ADPKD subjects (18-64 yrs-old, eGFR 25-60 ml/min/1.73 m^2)were randomized to an ACE-I (lisinopril) and placebo or to lisinopril and an ARB (telmisartan), titrated to achieve systolic and diastolic BP of 110-130 and 70-80 mmHg, respectively. The composite primary outcome was time to death, ESRD or 50% reduction of baseline eGFR. Secondary outcomes included rates of change of urine aldosterone and albumin excretions, frequency of all-cause and cardiovascular hospitalizations and ADPKD related symptoms, quality of life, and adverse study medication effects.

Results: Lisinopril/placebo or lisinopril/telmisartan lowered urine aldosterone excretion and adequately controlled BP. Estimated GFR declined by 3.91 (95% CI 3.65, 4.17) and 3.87 (95% CI 3.61, 4.14) ml/min/1.73m^2 per yr, respectively. The incidence of primary outcome events (hazard ratio = 1.08, 95% confidence interval [CI], 0.82 to 1.42), rate of eGFR decline and frequency of other secondary outcomes, hyperkalemia and AKI were similar in both groups.

Conclusions: ACE-I monotherapy is safe and by itself sufficient to achieve BP control in the majority of patients with ADPKD and CKD stage 3. Addition of ARB, although relatively safe, does not alter decline in eGFR or other renal outcomes at this stage of the disease.

HALT Progression of Polycystic Kidney Disease (HALT PKD) Trials: Primary Results of a 2x2 Factorial Trial in Early Stage CKD

Arlene B. Chapman,[1] Kaleab Z. Abebe,[2] Ronald D. Perrone,[3] Vicente E. Torres,[4] William E. Braun,[5] Theodore I. Steinman,[6] Franz Winklhofer,[7] Godela M. Brosnahan,[8] Peter G. Czarnecki,[6] Marie C. Hogan,[4] D. Miskulin,[3] Frederic F. Rahbari-Oskoui,[1] Jared J. Grantham,[7] Peter C. Harris,[4] Michael F. Flessner,[9] Kyongtae Ty Bae,[2] Charity G. Moore,[2] Robert W. Schrier.[8] *[1]Emory Univ; [2]Univ of Pittsburgh; [3]Tufts; [4]Mayo; [5]Cleveland Clinic; [6]Beth Israel Deaconess; [7]Univ of Kansas; [8]Univ of Colorado; [9]NIH, NIDDK.*

Background: In autosomal dominant polycystic kidney disease (ADPKD), hypertension is common, associates with greater total kidney volume (TKV), activation of the renin-angiotensin-aldosterone system (RAAS) and progression to ESRD. The optimal level of blood pressure control and the effects of inhibition of the RAAS on progressive renal disease in ADPKD are unclear.

Methods: In a double-blind, placebo-controlled trial, 558 hypertensive ADPKD subjects age 15-49 years with eGFR greater than 60 ml/min/1.73m^2 were randomized to compare 1) angiotensin converting enzyme inhibitor (lisinopril) versus lisinopril and an angiotensin receptor blocker (telmisartan); and 2) standard (120-130/70-80 mmHg) versus low BP (95-110/60-75 mmHg). The primary outcome was annual percent change in TKV.

Results: Annual percent increase in TKV was significantly less in low versus standard BP (5.6 versus 6.6%/year, P=0.006) with no differences between treatment groups (5.9 versus 6.2%/year, P=NS). The rate of change in eGFR was similar between BP groups with a negative acute (P<0.001) and marginally positive (P=0.050) chronic slope difference. Left ventricular mass index (LVMI) and urine albumin excretion (uAlb) decreased more in low versus standard BP (-1.17 vs. -0.57 gm/m/year, P=0.0002; -3.77 vs. 2.43%/yr, P<0.001). Dizziness and lightheadedness were more common in the low BP group (80.7% versus 69.4%, P<0.003).

Conclusions: In early ADPKD, treatment with the combination of lisinopril/telmisartan did not alter the rate of increase in TKV. However, rigorous BP control conferred a reduced rate of increase in TKV, no overall change in eGFR and greater declines in LVMI and uAlb excretion.

ADVANCE-ON: Long Term Benefits of Intensive Glucose Control for End-Stage Kidney Disease

Vlado Perkovic,[1] Mark E. Cooper,[2] Mark Woodward,[1] John P. Chalmers,[1] Michel Marre,[3] Sophia Zoungas.[1,4] *[1]George Institute for Global Health, Sydney, NSW, Australia; [2]Baker IDI, Melbourne, Victoria, Australia; [3]Hôpital Bichat-Claude Bernard and Univ Paris 7, Paris, France; [4]Monash Univ, Melbourne, Victoria.*

Background: The Action in Diabetes and Vascular Disease: Preterax and Diamicron Modified Release Controlled Evaluation (ADVANCE) trial suggested that intensive glucose control, targeting an HbA1c of < 6.5%, may prevent end-stage kidney disease (ESKD), but the small number of events limited the strength of the conclusions.

Methods: Survivors, previously randomized to intensive or standard glucose control and who completed the trial period, were invited to post-trial follow-up (ADVANCE-ON). Data on ESKD outcomes were collected, defined as the need for dialysis or kidney transplantation.

Results: 8494 of 10261 survivors (84%) at the end of ADVANCE entered post-trial follow-up for a median of 5.4 years and had similar characteristics to the original 11140 trial participants. In-trial differences in HbA1c disappeared by the first post-trial visit. The in-trial reductions in the risk of ESKD (7 vs 20 events, HR 0.35, 95% confidence interval [CI] 0.15- 0.83, p=0.02) persisted after 9.9 years of follow-up in total (29 vs 53 events, HR 0.54, CI 0.34-0.85, p<0.01). Greater benefits were observed in people with an eGFR above 60 mls/min/1.73m^2 at trial baseline (HR 0.29, CI 0.14-0.62) compared to lower levels (HR 0.89, CI 0.49-1.62, p heterogeneity = 0.02), as well as in those with BP levels below 140 mmHg (HR 0.19, CI 0.06-0.55) compared to higher levels (HR 0.77, CI 0.46-1.3, p heterogeneity = 0.01). Effects were similar across randomized BP lowering therapy, sex, age, and race as well as baseline albuminuria stage, BMI and HbA1c (all p heterogeneity >0.1).

Conclusions: Intensive glucose control leads to longer-term reductions in the risk of ESKD. The benefits are greater in people with preserved kidney function and better blood pressure control (ClinicalTrials.Gov ID: NCT00949286).

Renal Efficacy and Safety of Anti-TGF-β1 Therapy in Patients with Diabetic Nephropathy

James R. Voelker,[1] Paul H. Berg,[1] Matthew Sheetz,[1] Kevin L. Duffin,[1] Julia Lewis,[2] Tom Greene,[3] Philippe Zaoui.[4] *[1]Eli Lilly and Co, Indianapolis, IN; [2]Vanderbilt Univ, Nashville, TN; [3]Univ of Utah, Salt Lake City, UT; [4]Clinique Universitaire de Néphrologie, Grenoble, France.*

Background: TGF-β over-activity has been implicated as a key pathogenic factor in diabetic nephropathy (DN). This multi-center, randomized, double-masked, Ph 2 dose-ranging study assessed whether modulating TGF-β1 with a -β1 specific humanized monoclonal neutralizing antibody (LY) was safe and more effective than placebo at slowing renal function loss in patients (Pts) with advanced DN on appropriate and stable renin angiotensin system inhibitor (RASi) treatment (Rx).

Methods: 416 eligible Pts ≥25 years of age with T1 (n= 44) or T2 (n=370) diabetes and a SCr of 1.3 to 3.3 mg/dL for women and 1.5 to 3.5 mg/dL for men (or eGFR 20 to 60 mL/min/1.73m^2), and a 24-hr urine PCR of ≥800 mg/g, were randomized to LY (2, 10 or 50 mg monthly subcutaneously dosing for 12 mo) or placebo with Rx stratified by diabetes type. The primary and secondary efficacy outcomes were mean changes from baseline to 12 mo for the mean of duplicate SCr and 1st AM urine PCR, respectively.

Results: Pt demographics were balanced across groups, including age 62.2±10.2 yrs (mean±SD), 77% men, SCr 2.14±0.61 mg/dL, eGFR 35.46±11.85 mL/min/1.73m^2, urine PCR 3.26±2.51 g/g, BMI 33.9±6.7, HbA1c 7.87±1.74 % and SBP 138.1±13.4 mmHg. The trial was terminated 4 mo early for efficacy futility. Results indicate the predicted SCr change (based on entry criteria) but no apparent LY Rx effect on mean change in SCr (table) or PCR (data not shown). LY appeared safe and well tolerated.

Mean SCr ± SD (mg/dL)	Placebo N=103	2 mg N=105	10 mg N=103	50 mg N=105
Baseline	2.22±0.66	2.15±0.63	2.12±0.71	2.15±0.67
12-mo Endpoint	2.48±0.96	2.49±0.84	2.49±1.12	2.50±1.01
LS* mean change from baseline (SE)	0.38±0.08	0.48±0.08	0.48±0.08	0.55±0.08

* No significant Rx effect demonstrated by repeated measures analysis including fixed effects for Rx, visit, and Rx by visit and baseline value as covariate.

Conclusions: LY added to background RASi Rx appeared safe and well tolerated but did not slow progression of DN.

Randomized Clinical Trial of Ergocalciferol Supplementation in 25 Vitamin D Deficient Hemodialysis Patients

D. Miskulin,[1] Hocine Tighiouart,[1] Karen M. Majchrzak,[2] Richard S. Muther,[3] Toros Kapoian,[2] Doug Johnson,[2] Daniel E. Weiner.[1] *[1]Tufts Medical Center; [2]Dialysis Clinic Inc.; [3]Kidney Assoc of Kansas City.*

Background: Many hemodialysis (HD) patients are vitamin D deficient. The major circulating form of VitD is 25-hydroxyvitamin D (25-VitD), but HD patients are treated primarily with 1,25 $(OH)_2$ VitD (1,25-VitD). The VitD receptor and CYP27B1-hydroxylase are widely expressed suggesting local production and action of 1,25 VitD. Reports have extolled the health benefits of VitD administration.

Methods: In a 6-month, randomized, double-blind, placebo controlled trial, 276 HD patients with 25-VitD levels <30 ng/mL were treated with ergocalciferol or placebo. Therapy consisted of 50,000 IU ergocalciferol weekly X 6m for 25-VitD level <16 ng/mL and 50,000 IU weekly X 3m followed by 50,000 IU monthly X 3m for 25-VitD levels of 16-30 ng/mL. The change in prespecified outcomes of Epogen dose, PTH, Ca, P, CRP, 1,25-VitD dose, cinacalcet dose, and infection rate, between arms was tested using ANCOVA.

Results: Mean age was 61 years and median vintage 3.5 years; 60% were black, 45% women and 46% had diabetes as cause of ESRD. There were no differences in clinical factors between arms at baseline. Mean 25-Vit D levels in the ergocalciferol (n=137) vs. placebo (n=139) group at baseline, 3m and 6m, respectively, were 16.0 vs. 16.9, 41.0 vs. 17.3, and 39.2 vs. 17.5 ng/ml. There was no significant difference in EPO dose, Ca, P, 1,25-VitD dose, CRP level or cinacalect utilization between groups, while PTH levels were significantly higher in those receiving placebo. The rate of all-cause or infection-related hospitalization or in total infections did not differ across groups.

Parameter	Placebo (n=139)		Ergocalciferol (n=137)		p-value ^
	Baseline	Month 6	Baseline	Month 6	
EPO dose, units/week	5400 (2400, 11500)	6100 (2000, 12000)	5800 (2600, 12200)	7000 (2700, 15200)	0.22
PTH pg/mL	475 ± 295	450 ± 239	440 ± 257	505 ± 339	0.01

All-cause hospitalization		140.5 (114.0, 173.1)		111.3 (87.8, 141.2)	0.15
Infectious hospitalization		14.4 (7.5, 27.6)		11.5 (5.5, 24.0)	0.65
Total Infections*		38.3 (25.7, 57.2)		62.2 (45.3, 85.5)	0.06

Results are mean ± standard deviation or median (25th, 75th percentile). Events are per 100 patient-year (95% confidence interval). ^Statistical test of the difference in the change from baseline to 6m between treatment arms. * Includes infectious hospitalization and bacteremia or tissue infection without hospitalization. Where missing, 6 month values are determined using last value carried forward.

Conclusions: Administering ergocalciferol to 25-Vit D deficient HD patients normalizes circulating 25-Vit D levels by 3 months but this did not reduce EPO dose, CRP, PTH, 1,25-VitD dose, cinacalcet use or infection rates.

HI-OR06

Effect of Perioperative Aspirin and Clonidine on Acute Kidney Injury

Amit X. Garg. *POISE-2 Investigators, Western Univ, London, Canada.*

Background: Acute kidney injury, a common complication of the approximate 200 million major non-cardiac surgeries performed each year, is associated with poor outcomes and high healthcare costs. Early promising animal, human, and randomized clinical trial data suggest aspirin (a common anti-platelet agent) or clonidine (a central acting α2-adrenergic agonist), administered in the perioperative period, may reduce the risk of acute kidney injury. However, these effects are uncertain and each intervention has the potential for harm (perioperative bleeding with aspirin and perioperative hypotension with clonidine), which could increase the risk of acute kidney injury. We designed and conducted a substudy of the PeriOperative ISchemia Evaluation-2 (POISE-2) trial to determine whether the risk of acute kidney injury after non-cardiac surgery is altered by aspirin compared to placebo, and clonidine compared to placebo [substudy protocol BMJ Open 2014 Feb 25;4(2):e004886].

Methods: A 2 x 2 factorial randomized, blinded, clinical trial in 6,905 patients undergoing non-cardiac surgery from 88 centres in 22 countries between January 2011 and December 2013. Patients were assigned to take aspirin (200 mg) or placebo 2-4 hours before surgery and then aspirin (100 mg) or placebo daily up to 30 days after surgery, and were assigned to take oral clonidine (0.2 mg) or placebo 2-4 hours before surgery, and then a transdermal clonidine patch (which provided clonidine at 0.2 mg/day) or placebo patch that remained until 72 hours after surgery. Acute kidney injury was primarily defined as an increase in serum creatinine concentration from the preoperative concentration by either of the following criteria: (1) an increase ≥ 26.5 µmol/L (≥ 0.3 mg/dL) within 48 hours of surgery, or (2) an increase ≥50% within 7 days of surgery.

Results: Aspirin (n=3,443) versus placebo (n=3,462) did not alter the risk of acute kidney injury (13.4% versus 12.3%, respectively; adjusted relative risk 1.10 [95% CI, 0.96 to 1.25]). Clonidine (n=3,453) versus placebo (n=3,452) did not alter the risk of acute kidney injury (13.0% versus 12.7%, respectively; adjusted relative risk 1.03 [95% CI, 0.90 to1.18]).Aspirin increased the risk of major bleeding which in post hoc analysis was associated with a greater risk of subsequent acute kidney injury (23.3% when bleeding was present versus 12.3% when bleeding was absent, hazard ratio 2.20 [95% CI, 1.72 to 2.83]).. Similarly, clonidine increased the risk of clinically important hypotension which in post hoc analysis was associated with a greater risk of subsequent acute kidney injury (14.3% when hypotension was present versus 11.8% when hypotension was absent; adjusted hazard ratio 1.34 [95% CI, 1.14 to 1.58]).

Conclusions: Among patients undergoing major non-cardiac surgery, neither aspirin nor clonidine administered perioperatively reduced the risk of acute kidney injury. Trial Registration: NCT01082874

Six-Month Results of the RESCUE Trial: Fluency® Plus Endovascular Stent Graft versus PTA for In-Stent Restenosis

Alexander S. Yevzlin,[1] Ivan D. Maya,[3] Abigail falk.[2] *[1]Univ of Wisconsin; [2]American Access Care; [3]Nephrology Associates of Central Florida.*

Background: The Fluency® Plus Endovascular Stent Graft for In-stent Restenosis (RESCUE) study is a multicenter, randomized, concurrently-controlled study designed to compare the safety and effectiveness of the stent graft to balloon angioplasty (PTA) for treatment of in-stent restenotic lesions in the venous outflow of the Arteriovenous (AV) access circuit.

Methods: 265 patients from 23 U.S. sites were randomized to PTA versus PTA plus placement of the stent graft. The primary study endpoints were superiority of access circuit primary patency (ACPP) through 6 months and safety through 30 days. The secondary endpoint of post-intervention lesion patency (PLP), defined as the interval after the index intervention until the next re-intervention at the original treatment site or until the extremity was abandoned for permanent access, was also hypothesis tested. A 90-day follow-up angiogram assessment of binary restenosis was completed by an independent Core Lab.

Results: The intention-to-treat (ITT) population included 265 randomized patients, of which 244 were evaluated for 30-day safety, and 220 for 6-month effectiveness (111 PTA alone and 109 stent graft). The overall ACPP rate at 6 months was significantly higher in the stent graft group (16.7%) than in the PTA group (3.0%; p<0.001). PLP at 6 months was 65.2% in the stent graft group, and 10.4% in the PTA group (p<0.001). The stent graft groupalso demonstrated a significantly higher PLP rate in the two strata (AV Graft and Fistula). In the AV Graft subgroup, the PLP rate was 57.7% vs. 5.2% (stent graft vs. PTA; p<0.001). In the AVF subgroup, the PLP rate was 72% vs.14.7% (stent graft vs. PTA; p<0.001). The freedom from binary restenosis rate at 90 days was 81% in the stent graft group vs. 25% with PTA alone. The percentage of subjects free from safety events through 30 days was comparable between groups (96.8% PTA; 96.6% stent graft; p = 0.007).

Conclusions: The Fluency® Plus Endovascular Stent Graft is superior to PTA alone for both ACPP and PLP rates through 6 months in the treatment of in-stent restenosis.

Impact of Extended Weekly Hemodialysis Hours on Quality of Life and Clinical Outcomes: The ACTIVE Dialysis Multinational Trial

Meg J. Jardine,[1] Li Zuo,[2] Nicholas A. Gray,[3] Janak Rashme de Zoysa,[4] Christopher T. Chan,[5] Martin P. Gallagher,[1] Alan Cass,[6] Vlado Perkovic.[1] *[1]The George Institute for Global Health, Australia; [2]Peking Univ People's Hospital, China; [3]Nambour General Hospital, Australia; [4]North Shore Hospital, Auckland, New Zealand; [5]Univ Health Network, Toronto, Canada; [6]The Menzies Institute, Darwin, Australia.*

Background: Observational studies suggest a relationship between increased dialysis hours and better clinical outcomes. We aimed to assess the impact of extended weekly dialysis hours on quality of life (QOL) and clinical outcomes.

Methods: Participants were randomised to extended (target ≥24 hrs weekly) or standard (target 12-15 hrs) dialysis hours for 12 months. The primary outcome was the difference in change in QOL between baseline and 12 months assessed using EQ-5D (potential score 0-1) in the two groups. Secondary outcomes included access events and other clinical and safety outcomes.

Results: Among 200 participants, mean age was 52 (standard deviation 1.2) years, baseline dialysis hours 13.9 (2.7) hrs/week and most were male (69.5%). At study end, achieved mean weekly hours were 22.1 (4.3) in the extended group compared with 14.2 (4.0) in the standard group. QOL was similar in both groups at study end adjusted for baseline (mean difference in EQ5D 0.038 [-0.03, 0.11] p=0.27). Systolic blood pressure at study end was not different, although those randomised to extended dialysis were receiving fewer blood pressure lowering agents (mean difference -0.35 agents [-0.62, -0.08] p=0.01). Randomisation to extended hours was associated with higher haemoglobin, lower potassium and lower phosphate levels during followup (respective differences 3.51g/l [0.21, 6.81] p=0.037; -0.28mmol/l [-0.43, -0.14] p=0.0001; -0.17mmol/l [-0.27, -0.06] p=0.002). There were 5 deaths in the extended arm, and 2 in the standard arm. The numbers of patients with adverse vascular access events were similar in the two arms.

Conclusions: Extending weekly dialysis hours for 12 months did not improve quality of life, but was associated with improvement in some laboratory parameters and reduced blood pressure medication requirement. (Trial registration: NCT00649298)

ACT-AKI: A Phase 2 Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial of AC607 for the Treatment of Acute Kidney Injury in Cardiac Surgery Subjects Madhav Swaminathan,[1] David Mazer,[2] Glenn M. Chertow,[3] David G. Warnock,[4] Viken Paragamian,[5] Robert M. Brenner.[5] *[1]Anesthesiology, Duke Univ, Durham, NC; [2]Anesthesiology, Univ of Toronto, Toronto, Canada; [3]Medicine, Stanford Univ, Stanford, CA; [4]Medicine, Univ of Alabama, Birmingham, AL; [5]AlloCure Inc., Burlington, MA.*

Background: Acute kidney injury (AKI) is common condition and there is no effective treatment. Pre-clinical studies have shown that mesenchymal stem cells (MSC) both prevent and facilitate recovery from established AKI. AlloCure has developed a proprietary process to isolate and expand allogeneic human MSC (AC607), which was well tolerated and associated with low rates of AKI in a phase 1 trial. A phase 2 trial was conducted to determine if AC607 reduced time to kidney recovery compared to placebo after cardiac surgery.

Methods: Subjects undergoing cardiac surgery with cardiopulmonary bypass (CPB) with AKI defined by a creatinine rise ≥ 0.5 mg/dL ≤ 48 hours after CPB were randomized 1:1 in a double-blind manner to receive an intra-arterial dose of 2 x 10E6 cells/kg AC607 or placebo. Endpoints were time to kidney recovery (return of creatinine to pre-surgical baseline – primary, assessed using a Cox proportional hazards model), and all-cause mortality and need for dialysis within 30 and 90 days (secondary).

Results: A total of156 subjects were randomized in 21 centers in North America to either AC607 (n=77) or placebo (n=79), while 10 in the treatment and 11 in the control arm were randomized but not dosed. Mean age (SD) was 66.6 (11.4) years, 26% were female, and 85% were Caucasian. Mean weight was 91kg (21.2), 44% had diabetes, 84% had hypertension, and 42% had congestive heart failure. Mean baseline creatinine was 1.4 (0.6) mg/dL and mean eGFR was 61 (24) mL/min. There were no differences between AC607 and placebo with regard to median time to kidney recovery (15 vs. 12 days; p=0.32); all-cause mortality (6 vs. 5) and dialysis (7 vs. 5) during the follow up period.

Conclusions: In this phase 2 trial of subjects with early AKI following cardiac surgery, treatment with AC607 did not improve the time to complete kidney recovery, mortality or the need for dialysis.

Levofloxacin for BK Virus Prophylaxis in Kidney Transplantation John S. Gill,[1] Atul Humar,[2] Dean Fergusson,[3] Olwyn Johnston,[1] Andrew A. House,[4] Joseph Kim,[2] Tim Ramsay,[3] Michaël Chassé,[3] Xiaoli L Pang,[5] Jeffrey S. Zaltzman,[2] Sandra M. Cockfield,[5] Marcelo Cantarovich,[6] Martin Karpinski,[7] Louise Lebel,[3] Greg A. Knoll.[8] *[1]UBC, Canada; [2]U of Toronto, Canada; [3]OHRI, Canada; [4]Western, Canada; [5]U of Alberta, Canada; [6]McGill, Canada; [7]U of Mannitoba, Canada; [8]U of Ottawa, Canada.*

Background: Improvement in immunosuppression has led to a dramatic reduction in acute rejection after kidney transplantation. The trade-off of more potent immunosuppression has been the emergence of BK virus infection which can lead to allograft dysfunction with a very high risk of transplant failure. There are currently no therapies to prevent or treat BK virus infection. Quinolone antibiotics have been shown to have antiviral properties against BK virus but efficacy at preventing this infection has not been shown in prospective controlled studies.

Methods: We conducted a multicenter, double-blind, placebo-controlled randomized trial comparing a 3-month course of the quinolone antibiotic, levofloxacin, to placebo in kidney transplant recipients to reduce the risk of BK viruria in 11 Canadian kidney transplant centers. The primary outcome of the study was the time to occurrence of BK viruria within the first year post-transplantation.

Results: 154 patients were included in the study (76 in the levofloxacin group, 78 in the placebo group). The primary outcome of BK viruria occurred in 22 patients (29%) in the levofloxacin group and in 26 patients (33.3%) in the placebo group (Hazard Ratio: 0.91; 95% CI 0.51 to 1.63; P=0.58). There was no difference between the two groups in regards of other clinical events, including BK viral titers, occurrence of BK viremia, death, transplant failure or acute rejection. There was an increased risk of infections with isolates resistant to quinolones in the levofloxacin group versus placebo (58.3% versus 33.3%, RR 1.75; 95% CI 1.01 to 2.98) as well as an increased risk of tendonitis (RR 6.16; 95% CI 1.01 to 38.5).

Conclusions: A 3-month course of levofloxacin early post-transplantation did not prevent BK viruria in kidney transplant recipients. This intervention may however increase the risk of adverse events such as bacterial resistance and tendonitis.

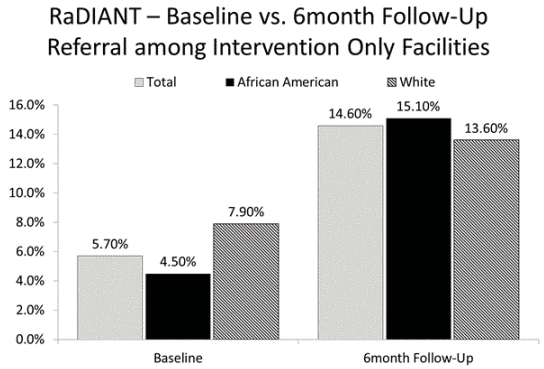
A Randomized Multicomponent Intervention to Reduce Disparities in Transplant Referral: Interim Results from the RaDIANT Community Study Rachel E. Patzer,[1] Leighann Sauls,[2] Jennifer C. Gander,[1] M. Ahinee Amamoo,[2] Laura Plantinga,[1] Debra D. Evans,[2] Eric M. Gibney,[3] Laura L. Mulloy,[4] Stephen O. Pastan.[1] *[1]Emory Univ, Atlanta, GA; [2]Southeastern Kidney Council, Raleigh, NC; [3]Piedmont Hospital, Atlanta, GA; [4]Georgia Regents Univ, Augusta, GA.*

Background: The Reducing Disparities In Access to kidNey Transplantation (RaDIANT) Community Study is a dialysis facility-level randomized clinical trial developed by the Southeastern Kidney Transplant Coalition to test the effectiveness of a multicomponent intervention to reduce racial disparities and improve kidney transplant (KTx) referral in Georgia, which has the lowest KTx rate in the U.S.

Methods: In 2013, 134 dialysis facilities were randomized to receive either "usual" KTx education (n=67) or a multicomponent intervention conducted by ESRD Network 6 and coalition partners consisting of KTx education and engagement activities for dialysis facility leadership, staff, and patients (n=67). We report 6-month pre- to post-data among intervention facilities only.

Results: At baseline (June-December 2012), the proportion of ESRD patients referred for KTx among intervention facilities was 5.5% (4.7% for AA vs. 7.9% for whites). After 6 months of intervention activities, KTx referral more than doubled (14.6%) among patients in the 67 intervention facilities and tripled (15.5%) among AA patients. A total of 56 (83.5%) intervention facilities improved KTx referral in the 6-month study period. Among the 26 dialysis facilities that had an AA vs. white racial disparity in KTx referral at baseline, 65.4% eliminated racial disparity in referral by 6 months.



Conclusions: Interim data from intervention facilities in the RaDIANT Study suggests that a large, randomized, quality improvement program among dialysis facilities in GA may improve equity in KTx access. Availability of control data at 12 months will allow assessment of the effectiveness of the intervention.

Envarsus XR (Once-Daily MeltDose Tacrolimus Tablets) Shows Continued Dose Reduction and Similar Efficacy and Safety vs. Prograf (Twice-Daily Tacrolimus Capsules) at Two-Years: Results of a Phase 3, Double-Blind, Randomized Study in *De Novo* Kidney Transplant Patients Lionel Rostaing,[1] Suphamai Bunnapradist.[2] *[1]Hôpital de Rangueil, Toulouse, France; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Envarsus XR is a once-daily tacrolimus (Tac) tablet formulation that has increased bioavailability, lower C_{max}, less fluctuation between C_{max} and trough, and more rapid achievement of therapeutic Tac blood levels, with a ~30 lower dose, compared to twice-daily Tac capsules (Prograf).

Methods: Presented are 2-year results from a randomized trial of Envarsus XR vs. Prograf in 543 (Envarsus XR, n=268; Prograf, n=275) *de novo* kidney transplant recipients (KTR).

Results: Consistent with 1-year results, Envarsus XR was noninferior to Prograf, with the treatment failure (biopsy-proven acute rejection [BPAR], graft loss, death, or lost-to-follow-up] difference (95% CI) well below the 10% noninferiority margin (-4.14% [-11.38%, +3.17%]). The overall incidence of treatment failure within 24 months was, Envarsus XR: 23.1%; Prograf: 27.3%. In the immediate post-transplant period, target troughs were more rapidly attained for Envarsus XR vs. Prograf; consistent with 1-year results, at 2 years, the mean total daily dose (TDD) for Envarsus XR was 24% lower vs. Prograf, with similar troughs. Renal function was comparable between the groups over the 2 year study. The proportion of KTR with adverse events (AEs) was: Envarsus XR, 98.1%; Prograf, 97.8%; the proportion of KTR with serious AEs was: Envarsus XR, 61.9%; Prograf, 67.3%.

Conclusions: Envarsus XR showed noninferiority vs. Prograf with lower TDD of Envarsus XR. Renal function and AEs were similar between the 2 groups. With once-daily dosing and improved pharmacokinetics, Envarsus XR may offer a preferable option to twice-daily immediate-release Tac formulations.

Urgent-Start Peritoneal Dialysis versus Urgent-Start Hemodialysis: A Multicenter Clinical Trial Arshia Ghaffari,[1] Steven M. Brunelli,[2] Michelle Cassin,[2] Martin J. Schreiber.[3] *[1]Div of Nephrology, Univ of Southern California, Los Angeles, CA; [2]DaVita Clinical Research; [3]DaVita Healthcare Partners.*

Background: Peritoneal dialysis (PD) is rarely offered to patients presenting with advanced chronic kidney disease that require urgent initiation of dialysis. Several recent reports have described the feasibility of urgent-start peritoneal dialysis (USPD), a modality whereby patients are started on low-volume, recumbent PD soon after catheter placement. While clinical outcomes for USPD have been reported to be similar to urgent initiation of hemodialysis via a central venous catheter (HD-CVC), the reports are limited by small size and lack of comparable control groups.

Methods: This is a multi-center, propensity-matched, observational study comparing hospitalizations, infections and mortality in patients that started dialysis urgently either via a protocol-driven USPD program or traditional HD-CVC from multiple dialysis clinics between April 2012 and May 2014. Each USPD patient was 1:1 matched with an HD-CVC patient. Outcomes were compared by Poisson regression models and reported as incident rate ratios (IRR) with 95% confidence intervals (CI).

Results: 690 USPD patients met criteria to be included in the study. Of these 376 were successfully matched to HD-CVC controls. The median duration of followup was 179 days. Compared to matched patients who initiated HD via a CVC, USPD patients had 51% lower mortality (IRR 0.49; 95% CI, 0.29-0.84; $P = 0.009$), 39% lower rate of hospitalization (IRR 0.61; 95% CI, 0.49-0.77; $P < 0.001$) and 42% lower rate of all-cause infections (IRR 0.58: 95% CI, 0.39-0.87; $P = 0.008$). In the USPD group, majority of infections represented peritonitis with a rate of 1 infection every 60 months, whereas all infections in the HD-CVC group represented blood stream infections with a rate of 1 infection every 34 months.

Conclusions: This multi-center large cohort study demonstrates USPD provides superior clinical outcomes as compared to urgent HD with CVC with regards to mortality, hospitalizations and infectious complications. USPD should be more widely implemented to allow more of unplanned ESRD patients the option of starting PD while optimizing outcomes.

SA-PO1095

Standard versus Accelerated Initiation of Renal Replacement Therapy in Acute Kidney Injury Ron Wald,[1] Neill Adhikari,[2] Karen L. Pope,[1] Orla M Smith,[1] Matthew A Weir,[3] Sean M. Bagshaw.[4] *[1]St. Michael's Hospital; [2]Sunnybrook Health Sciences Centre; [3]London Health Sciences Centre; [4]Univ of Alberta Hospital.*

Background: In patients with severe AKI but no urgent indication for renal replacement therapy (RRT), the optimal time to commence RRT is controversial. While starting RRT pre-emptively may have benefits, this approach may also expose patients to unnecessary RRT.

Methods: We conducted a 12-centre open-label pilot RCT of critically ill adults with severe AKI (two of: doubling of creatinine; urine output <6 mL/kg over 12 hrs; blood neutrophil gelatinase-associated lipocalin ≥400 ng/mL), potassium ≤5.5 mmol/L, bicarbonate ≥15 mmol/L, and central venous pressure ≥8 mmHg. Exclusion criteria included eGFR <30 mL/min, presence of creatinine doubling for >48 hrs, or clinicians' belief that either immediate RRT initiation or deferral was mandated. Patients were randomized to **accelerated** (≤12 hrs from eligibility) or **standard** (if potassium >6 mmol/L, bicarbonate <10 mmol/L, CHF, or clinician judgment) RRT initiation. Outcomes were adherence to protocol-defined time limits for RRT initiation (primary), proportion of eligible patients enrolled and followed to 90 days, and safety (secondary).

Results: We enrolled 100/131 (76%) fully eligible patients.

Baseline characteristic	Accelerated RRT (n=48)	Standard RRT (n=52)
Age, y; mean (SD)	62.2 (11.9)	63.9 (13.6)
Sepsis; n (%)	26 (54)	30 (58)
SOFA score; mean (SD)	13.3 (2.5)	12.8 (3.0)
24-hr urine output, mL; median (IQR)	355 (196-528)	434 (214-735)
Ventilated; n (%)	45 (94)	48 (92)
Vasopressor; n (%)	42 (82)	43 (83)
Creatinine, μmol/L; mean (SD)	305 (111)	293 (214)

45/48 (94%) patients in the accelerated arm commenced RRT ≤12 hours after eligibility [median 7.4 (IQR 6.1-9.6) hrs]. In the standard RRT arm, 33 patients started RRT >12 hours after eligibility (median 31.6 (IQR 22.8-59.5) hrs); 19 patients did not receive RRT (6 died, 13 recovered kidney function). All patients were followed to Day 90. No safety signal was evident.

Conclusions: A RCT of accelerated vs standard timing of RRT initiation among critically ill patients with AKI is feasible. These results are informing the design of a large-scale definitive effectiveness RCT.

SA-PO1096

The Utility of Photoplethysmographic Measures of Cardiovascular Stress to Detect Intradialytic Hypotension D. Miskulin,[1] Klemens B. Meyer,[1] Mary kay Deck,[2] Anne M Brumfield,[2] Rajat Deo,[3] John E. Moran.[2,4] *[1]Tufts Medical Center; [2]Intelomed; [3]Univ Pennsylvania; [4]Stanford Univ.*

Background: The incidence of intradialytic hypotension (IDH) is high, despite the development of various monitoring technologies. This prospective trial evaluated the IDH detection accuracy of an algorithm that assesses cardiovascular (CV) stress via continuously measured pulse wave amplitude (PWA) and pulse rate (PR) (CVInsight, Intelomed, Wexford, PA).

Methods: 48 patients (12 controls; 36 with IDH in ≥5 HD treatments (tx) in past 2 months) were monitored with CVInsight (CVI) over 2 tx(1 long and 1 short interdialytic interval). Relative plasma volume (RPV) was also measured via Crit-Line III® (Fresenius, Kaysville, UT). Staff and patients were blinded to device parameters. BP, interventions, and symptoms were recorded by a study coordinator. Patients concurrently wore a Holter monitor. IDH was defined as 1) a drop in SBP to <90 mm Hg, 2) intervention for IDH, or 3) IDH symptoms. Crit-Line was considered positive if ΔRPV exceeded -8%/hour or -15%/tx. A positive test by CVI required defined changes in PWA and PR. Device accuracy for identifying IDH was assessed using ROC analysis.

Results: IDH occurred in 52 of the 96 monitored tx. CVI detected IDH with a sensitivity of 75% and specificity of 36%. Crit-Line yielded lower sensitivity but higher specificity (24%, 68%). False positive alerts that impacted CVI specificity occurred with cardiac arrhythmia and sleep.

	BP Event		INTERVENTION Event		SYMPTOM Event	
	CVI	CL	CVI	CL	CVI	CL
Sensitivity	83	29	73	16	71	21
Specificity	38	73	32	66	31	69

Conclusions: Photoplethysmographic assessment of CV stress is a sensitive indicator of IDH events. Many apparent false positive alerts are related to serious but otherwise unrecognized events, including cardiac arrhythmia and sleep disordered breathing. CVInsight allows better assessment of patient risk, identifies clinically important changes in CV status, and may assist titration of therapy to optimize fluid management.

SA-PO1097

The Beta-Blocker to LOwer CArdiovascular Dialysis Events (BLOCADE) Feasibility Study: A Randomized Controlled Trial of Carvedilol versus Placebo in Patients Receiving Dialysis Matthew Allan Roberts.[1,2] *[1]Eastern Health Clinical School, Monash Univ, Australia; [2]For the BLOCADE Feasibility Study Group and Australasian Kidney Trials Network.*

Background: Beta-blocking agents (BBA) reduce mortality from cardiovascular disease (CVD) in patients not requiring dialysis. The potential benefits and harm of BBA in dialysis patients are not known. We aimed to determine the feasibility of a large-scale randomized controlled trial (LSRCT) to address this uncertainty.

Methods: We recruited patients who had received peritoneal dialysis (PD) or hemodialysis (HD) for ≥3 months and were aged ≥50 years or aged ≥18 years with co-morbid diabetes or CVD, from 11 sites in Australia and New Zealand. After a 6-week run-in with the BBA carvedilol, we randomized participants 1:1 to carvedilol or placebo, titrated to the maximum tolerated dose and maintained for 12 months. The primary outcome was the proportion (95% confidence interval) of participants who tolerated carvedilol 6.25mg b.d. in the run-in. Other outcomes were proportions randomized who withdrew before 12 months and the incidence of intra-dialytic hypotension (IDH) measured at specific times.

Results: Of 1443 patients screened, 354 were eligible, 91 consented to participate and 72 (55 HD, 17 PD) entered run-in. The primary outcome was achieved by 49 [68% (57-79)] of 72 run-in participants; completers and non-completers did not differ by baseline characteristics. Current BBA use was the primary reason 13% of screened patients did not

Underline represents presenting author/disclosure.

participate; only 9 (13%) run-in participants had coronary disease and none had heart failure. Post randomization, 10 of 26 (38%) allocated carvedilol and 4 of 23 (17%) allocated placebo withdrew (p=0.10); median dose achieved was 25mg b.d. for both groups. The incidence of IDH was 0.07 events/session with carvedilol versus 0.02 events/session with placebo (P=0.14) in the 2 weeks following an increase in dose and 0.04 versus 0.03, respectively, on a stable dose (p=0.67).

Conclusions: Any LSRCT of BBA versus placebo in dialysis patients must allow that approximately 1/3 of patients will not tolerate the lowest effective BBA dose, a small proportion of screened patients will participate, and patients withdraw at all stages.

Migalastat and Enzyme Replacement Therapy Have Comparable Effects on Renal Function in Fabry Disease: Phase 3 Study Results

Kathleen M. Nicholls,[1] Daniel G. Bichet,[2] Roberto Giugliani,[3] Derralynn A. Hughes,[4] Raphael Schiffmann,[5] William Wilcox,[6] Nina Skuban,[7] Jasmine L. Rutecki,[7] Julie Yu,[7] Jeff Castelli,[7] John R. Kirk,[7] Elfrida R Benjamin,[7] Jay Barth.[7] *[1]Royal Melbourne Hosp., Australia; [2]Hôpital du Sacré-Coeur Univ Montreal, Canada; [3]Med. Gen. Service, Brazil; [4]Univ College London, United Kingdom; [5]Baylor Res.Inst.; [6]Emory Univ School Med.; [7]Amicus Therap..*

Background: To compare the efficacy and safety of oral migalastat with IV enzyme replacement therapies (ERTs) for Fabry disease (FD).

Methods: The co-primary endpoints were mean annualized changes in estimated glomerular filtration rate ($eGFR_{CKD\text{-}EPI}$) and measured GFR ($mGFR_{iohexol}$) assessed for migalastat and ERT over 18 mo. LS means and 95% CIs were calculated using an ANCOVA model.Median values were also calculated.Comparability of migalastat and ERT was pre-specified based on:≥50% overlap of 95% CIs for the annualized change in GFR, and mean changes within 2.2 mL/min/1.73 m^2/yr. Plasma lyso-Gb_3 (FD biomarker) was assessed over 18 mo.Patients were randomized 1.5:1 to switch to migalastat or remain on ERT.

Results: The study enrolled 60 patients (26m/34f), 56 with amenable mutations based on a validated *in vitro* assay, and 52 of whom also had ≥6 month GFR assessments.

	Overlap of 95% CI (means)	Difference between Migalastat and ERT (means)	Mean Values ± SEM		Median Values	
			Migalastat (n=34)	ERT (n = 18)	Migalastat (n=34)	ERT (n = 18)
$eGFR_{CKD\text{-}EPI}$	100%	+0.63	-0.40±0.93	-1.03±1.29	-1.29	-0.87
$mGFR_{iohexol}$	100%	-1.11	-4.35±1.64	-3.24±2.27	-3.23	-3.57

Levels of plasma lyso-Gb_3 remained low and stable in patients with amenable mutations who continued on ERT and those who switched from ERT to migalastat.In a composite endpoint (renal, cardiac, and cerebrovascular events), event frequency observed on migalastat was 29% compared to 44%on ERT. Migalastat was generally safe, well-tolerated.

Conclusions: Annualized changes in GFR were comparable for migalastat and ERT over 18 mo for amenable mutations. Plasma lyso-GB_3 levels remained stable following switch from ERT to migalastat. This study demonstrates that oral migalastat was comparable to ERT on renal function and an important biomarker of FD.

SA-PO1099

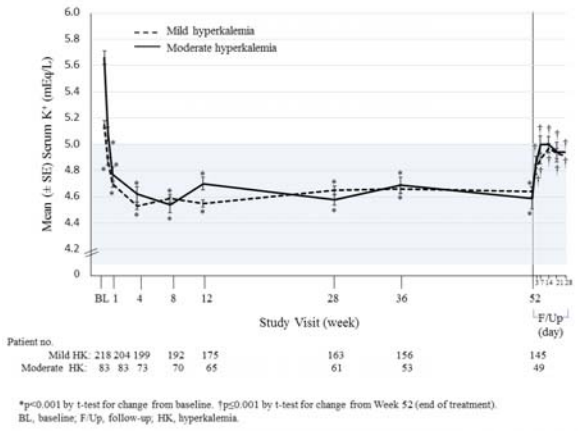
Effect of Patiromer on Hyperkalemia in Patients with Diabetic Nephropathy: Results of a 1-Year Randomized Trial

George L. Bakris,[1] Bertram Pitt,[2] Martha Mayo,[3] Dahlia Garza,[3] Yuri Stasiv,[3] Lance Berman,[3] David A. Bushinsky.[4] *[1]Univ of Chicago, Chicago, IL; [2]Univ of Michigan, Ann Arbor, MI; [3]Relypsa, Redwood City, CA; [4]Univ of Rochester, Rochester, NY.*

Background: Hyperkalemia (HK) is common in patients (pts) with CKD and often limits use of RAAS inhibitors (RAASi). Available K^+-binding resins are poorly tolerated and can cause colonic necrosis. We report results of a 52-week trial evaluating HK treatment in CKD pts on RAASi.

Methods: Multicenter, open-label trial of 306 pts with CKD, T2DM, HTN and serum K^+ (s-K^+) >5.0 mEq/L; pts randomized to patiromer starting doses by baseline s-K^+: K^+ >5.0-5.5 mEq/L (4.2, 8.4 or 12.6 g BID) mild HK (n=222); and K^+ >5.5-<6.0 mEq/L (8.4, 12.6 or 16.8 g BID) moderate HK (n=84). Patiromer was titrated to achieve and maintain normal s-K^+. All pts were on RAASi. A parallel lines ANCOVA model assessed s-K^+ changes from baseline.

Results: Reductions in s-K^+ (p<0.001) were observed at 48 hr in mild and moderate HK groups from respective baseline means (±SE) of 5.2±0.02 and 5.7±0.04 mEq/L, with similar effects across dose groups. Mean s-K^+ was controlled (≤5.0 mEq/L) at 48 hr (mild HK) and Wk 1 (moderate HK) and maintained for 52 wks.



*p<0.001 by t-test for change from baseline. †p≤0.001 by t-test for change from Week 52 (end of treatment).
BL, baseline; F/Up, follow-up; HK, hyperkalemia.

The % of pts with s-K^+ 3.8-5.0 mEq/L at visits between Wk 12-52 ranged from 77-95% for mild and moderate HK pts. Stopping drug at Wk 52 led to a rise in s-K^+. eGFR (baseline 42.5±17.7 mL/min/1.73m^2; Δ +1.8±16.3 mL/min/1.72m^2) and albuminuria (baseline 995±1641 mg/g; Δ -27±1422 mg/g) were unchanged over 52 wks. The most common GI side effect was constipation (6%, none severe); only 2 pts discontinued as a result. Thirteen (4%) pts had serum Mg <1.2 mg/dL (CTCAE grade 2; none <1.0 mg/dL).

Conclusions: Patiromer reduced and maintained control of s-K^+ for up to 1 yr in diabetic CKD pts on RAASi. Renal function was stable and patiromer was well tolerated.

ZS-9 Effectively Reduces Potassium Levels in Hyperkalemic Diabetic Patients Who Have Both Renal Impairment and a History of Heart Failure

David K. Packham,[1] Simon D. Roger,[1] Mohamed A. El-Shahawy,[1] Wajeh Y. Qunibi,[1] Henrik S. Rasmussen,[2] Bhupinder Singh,[2] Alex Yang,[2] Philip T. Lavin,[2] Adrian Covic.[3] *[1]ZS003 Study Group, Coppell, TX; [2]ZS Pharma, Inc., Coppell, TX; [3]Grigore T. Popa U Med Pharm, Iasi, Romania.*

Background: Level 1A clinical evidence supports the routine use of angiotensin-converting enzyme inhibitors (ACEi) or angiotensin-receptor blockers (ARB) in patients with heart failure (HF), diabetes mellitus (DM) and chronic kidney disease (CKD). Despite this, hyperkalemia (HK) remains a major hurdle for initiation and/or continuation of these cardiorenal protective agents. We previously reported the results of a randomized, placebo-controlled trial of sodium zirconium cyclosilicate (ZS-9), a nonabsorbed inorganic crystal, in a large (N=753) cohort of patients with HK (potassium [K^+] 5.0-6.5 mEq/L; Ash et al. ASN 2013).

Methods: Here we report the results in 98 patients from the initial trial who concurrently had DM, HF and CKD (eGFR<60 mL/min/1.73m^2) as probable indications for ACEi or ARB therapy. Patients were treated with ZS-9 5g or 10g (n=62) or placebo (n=36) TID for 48h, followed by QD (12 days) in those who attained normokalemia (K^+ 3.5-4.9 mEq/L).

Results: Results: Mean baseline K^+ was 5.3 mEq/L in the ZS-9 group and 5.4 mEq/L in the placebo group. After 48h, mean K^+ declined by 0.67 mEq/L in the 62 treated patients, compared with a mean of 0.24 mEq/L in patients on placebo (p<0.0001). In the 12-day extended phase, ZS-9-treated patients who continued treatment with ZS-9 remained normokalemic (mean K^+ 4.6 mEq/L), whereas those switched to placebo returned to hyperkalemia (mean K^+, 5.1 mEq/L; p<0.05). Importantly, 24% of the 98 participants were not receiving ACEi or ARB before or during the trial, despite having multiple clinical indications for their therapy and only 31%were receiving maximal recommended dose. Patients who were receiving ACEi or ARB and those who were not had a similar fall in serum K^+ on ZS-9.

Conclusions: ZS-9 at 5 and 10g doses facilitates use of ACEi or ARB in patients who are likely to benefit most from these cardiorenal protective agents. Our results suggest that ZS-9 may enable optimal treatment of these clinical conditions, leading to improved clinical outcomes.

Empagliflozin Reduces Blood Pressure and Markers of Arterial Stiffness and Vascular Resistance in Type 2 Diabetes

Robert Chilton,[1] Ilkka T. Tikkanen,[2] Christopher Paul Cannon,[3] Susanne Crowe,[4] Thomas Hach,[4] Hans-Juergen Woerle,[4] Uli Christian Broedl,[4] Odd Erik Johansen.[5] *[1]Univ of Texas Health Science Center, San Antonio, TX; [2]Helsinki Univ Central Hospital and Minerva Institute for Medical Research, Helsinki, Finland; [3]Harvard Clinical Research Institute, Boston, MA; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [5]Boehringer Ingelheim Norway KS, Asker, Norway.*

Background: We aimed to assess the vascular effects of empagliflozin (EMPA) beyond reducing systolic blood pressure (SBP) and diastolic BP (DBP) in two cohorts of patients with type 2 diabetes.

Underline represents presenting author/disclosure.

Methods: Cohort 1 comprised 823 patients with hypertension from a 12-week ambulatory BP monitoring (ABPM) randomized trial (mean [SD] age 60.2 [9.0] yrs, HbA1c 7.9 [0.7] %, BMI 32.6 [5.1] kg/m^2). Cohort 2 comprised 2476 patients from four 24-week phase III randomized trials (age 55.6 [10.2] yrs, HbA1c 8.0 [0.9] %, BMI 28.7 [5.5] kg/m^2). Changes in HbA1c, SBP, DBP, pulse pressure (PP; SBP-DBP), a marker of conduit vessel stiffening, mean arterial pressure (MAP), reflecting cardiac output multiplied by vascular resistance (MAP = ([2 x DBP]+SBP)/3), and heart rate (HR) were assessed. Ambulatory arterial stiffness index (AASI), derived from 24h ABPM recordings, was assessed in cohort 1.

Results: In cohort 1/cohort 2, EMPA significantly reduced HbA1c relative to placebo (mean [SE] difference: -0.64% [0.04]/-0.65% [0.03], respectively; both p<0.001) and reduced SBP/DBP, PP and MAP without increases in mean HR (Table). AASI reduction was of borderline significance.

Table. Impact on BP, MAP, PP, AASI and HR in cohort 1 and 2 of treatment with empagliflozin (EMPA) and placebo (PBO).

	Cohort 1: 12-week 24h ABPM phase III trial (FAS[A], n=823) (24h ABPM recordings)		Cohort 2: Four pooled 24-week phase III trials (FAS[B], n=2476) (seated office recordings)	
	PBO (n=271)	EMPA 10/25 mg (n=552)	PBO (n=825)	EMPA 10/25 mg (n=1651)

PBO-corrected change from BL (SE)	N/A	-0.016 (0.008) (p=0.059)	N/A	N/A
Heart rate				
HR baseline (SE), bpm	77.6 (0.6)	75.8 (0.4)	74.3 (0.3)	74.1 (0.2)
PBO-corrected change from BL (SE), mmHg	N/A	-0.6 (0.5) (p=0.208)	N/A	-0.8 (0.3)*

[A]: all randomized and treated patients who had a baseline HbA1c value and a baseline mean 24-h SBP value; [B]: all randomized and treated patients who had a baseline HbA1c value; all data mean (SE). P-values for adjusted means based on ANCOVA with last observation carried forward imputation. Values on rescue medication were excluded from analysis. *p<0.05; **p<0.01; ***p<0.001 (all vs PBO). FAS – full analysis set; BL – baseline, ABPM – ambulatory blood pressure monitoring.

Conclusions: EMPA had favorable effects on BP, arterial stiffness and vascular resistance which are intermediate markers of CV risk. The EMPA-REG OUTCOME™ trial (NCT01131676) will evaluate whether these benefits will translate into CV risk reduction.

Ferric Citrate Safely Controls Phosphorus, Delivers Iron, and Reduces IV Iron/ESA in ESRD: A 48-Week Clinical Trial

Julia Lewis,[1] Kausik Umanath,[2] Mohammed Sika,[1] Mark Koury,[1] Peale Chuang,[3] Gerald Schulman,[1] Robert M. Niecestro,[4] Tom Greene,[5] Jamie P. Dwyer,[1] The Collaborative study group.[6]
[1]Vanderbilt Med Ctr; [2]Henry Ford Hosp; [3]Metrolina Neph; [4]Indep Consultant; [5]Univ Utah; [6]Collab Study Grp.

Background: Ferric citrate (FC) controls phosphorus (P),↑ iron stores, and ↓ IV Iron/ESA use while maintaining hgb over 52 wks with demonstrated safety. This trial NCT01554982 extends observations for 48 wks more.

Methods: Subjects from the pivotal FC RCT randomized to FC could enroll at 35 US sites. 1º outcome was safety (labs and AEs). 2º outcomes were P control, iron stores, IV Iron/ESA use, and Hgb. Labs were obtained at local dialysis units.

Results: 168 of 177 eligible subjects enrolled. 78.6% had a lag between the RCT and this trial. 166 received FC. 125 (75.3%) completed study. Commonest reason for study d/c was AE, incl kidney txpl and death. Age was 55.1±11.1y; 62.0% male; 62.0% black. Pill count was 7.9/day.

	BL	Wk 12	Wk 24	Wk 36	Wk 48
P, mg/dL	5.7±1.7	5.3±1.3*	5.2±1.4*	5.2±1.4*	5.2±1.3*
Ferritin, ng/mL	710±385	785±438*	848±445*	866±482*	821±412*
TSAT, %	32.4±13.5	37.7±16.8*	36.8±15.8*	39.5±18.4*	40.3±19.1*
IV Iron Use**, mg/d	NA	1.48±3.45	0.94±2.55	1.18±3.06	0.72±2.15
ESA Use**, U/d	NA	893±1247	837±1429	759±1054	699±936
Hgb, g/dL	11.1±1.4	11.3±1.4	11.1±1.4	11.1±1.3	11.3±1.4
Ca, mg/dL	9.1±1.5	9.1±0.8	9.1±0.9	8.9±0.9	9.0±0.8
PTH, pg/mL	466±352	507±320	523±344	468±231	455±330

*p<0.05, compared to baseline
**Mean use for each 12-wk period; Wk12 represents first 12wks (baseline) use

Both ferritin and TSAT↑ during 12-24 wks, then plateaued. 59.0% required *no* IV iron over 48wks; 85.1% required *no* IV Iron from Wk36-48. 85.5% had a TEAE. 6 died (3.6%). 44.0% had a GI TEAE, mostly N/V/D/stool color. 8 (4.8%) had GI TEAE that led to FC d/c. 45.2% had SAE. 10.8% had Cardiac, 5.4% GI, and 18.1% Infection SAEs, similar to prior results. No SAEs were FC related. No Δs in AST/ALT/Bili. No subject had LFT>3×ULN. Aluminum was similar over 48wks. No other significant Δs in labs.

Conclusions: FC continued to control P over 100 wks. In those reexposed to FC after a lag, FC↑ iron stores and ↓ IV iron/ESA use. Both TSAT and ferritin plateaued suggesting physiologic iron regulation. AE profile now over 100 wks was similar to the RCT's active control group. FC was associated with continued ↓ need for IV Iron/ESA while maintaining Hgb. Thus, FC is an effective P binder that↑ iron stores and ↓ IV iron/ESA use, with acceptable safety over 100 wks.

Safety and Efficacy of Modified-Release Calcifediol for Secondary Hyperparathyroidism in Patients with Stage 3 or 4 CKD and Vitamin D Insufficiency

Stuart M. Sprague,[1] Shaukat Ali,[2] Roberto Mangoo-Karim,[3] Paul W. Crawford,[4] Pablo E. Pergola,[5] Laurel Sindelar,[6] Stephen A Strugnell,[6] Joel Z. Melnick,[6] Jay A. White,[6] Martin P. Petkovich,[6] Charles W. Bishop.[6]
[1]NorthShore Univ Health System-Univ of Chicago, Evanston, IL; [2]Four Rivers Clinical Research, Paducah, KY; [3]South Texas Kidney Specialists, McAllen, TX; [4]Research by Design, Evergreen Park, IL; [5]Clinical Advancement Center, San Antonio, TX; [6]OPKO Health, Miami, FL.

Background: Vitamin D is often inadequate for controlling secondary hyperparathyroidism (SHPT) in patients with stage 3 or 4 CKD, probably due to inconsistent correction of vitamin D insufficiency (VDI). Orally administered modified-release calcifediol (MRC) was evaluated as a more effective alternative.

Methods: Two identical, randomized, double-blind, placebo-controlled trials were conducted in patients with SHPT (>85 pg/mL), stage 3 or 4 CKD and VDI (serum 25D of 10-29 ng/mL). The trials enrolled 429 subjects from 77 US sites, stratified by CKD stage and randomized 2:1 to receive MRC or placebo for 26 weeks. On completion, subjects could elect 26 more weeks of MRC treatment in an ongoing open-label extension trial. MRC dosing started at 30 µg/d and increased, as needed to lower iPTH, to 60 µg/d after 12 weeks. Efficacy endpoints were differences in response rates between treatment groups; the 1º response was a mean 30% decrease in plasma iPTH and a 2º response was a mean serum 25D of >30 ng/mL at end-of-treatment. Safety analyses included changes in serum calcium (Ca) and phosphorus, urine Ca/creatinine and adverse events.

Results: A total of 364 (85%) subjects completed the trials. Efficacy response rates for MRC vs. placebo treatment were 96 vs. 6% for serum 25D and 39 vs. 9% for plasma iPTH at 26 weeks, rising to 55% at 52 weeks (p<0.001). Response rates were similar in CKD stages 3 and 4. Safety and tolerability were comparable in both treatment groups. Mean serum Ca and P rose 0.1-0.2 mg/dL in both groups.

Conclusions: MRC effectively and safely manages SHPT in patients with stage 3 or 4 CKD by gradually correcting vitamin D insufficiency.

SA-PO1104

Phase III Study of ASP1585 (Bixalomer) - Randomized, Double-Blind, Placebo-Controlled Study in Chronic Kidney Disease Patients with Hyperphosphatemia Not on Dialysis

Tadao Akizawa,[1] Hideki Origasa,[2] Chisato Kameoka,[3] Junko Tsukada,[3] Kentarou Kuroishi,[3] Yusuke Yamaguchi.[3]
[1]Dept of Nephrology, Showa Univ School of Medicine, Tokyo, Japan; [2]Div of Biostatistics and Clinical Epidemiology, Univ of Toyama School of Medicine, Toyama, Japan; [3]Astellas Pharma Inc., Tokyo, Japan.

Background: ASP1585 is a non-absorbable polymer that decreases serum phosphorus (Pi) levels by binding phosphate in the gastrointestinal (GI) tract. The efficacy and safety of ASP1585 versus placebo were compared for controlling hyperphosphatemia in chronic kidney disease (CKD) patients not on dialysis.

Methods: This was a phase III, randomized, double-blind, placebo-controlled multi-center study conducted in Japan. The primary endpoint was change from baseline in serum Pi level at the end of treatment (EOT). Secondary endpoints included the achievement rate of the target range of serum Pi level (2.5 ≤, < 4.6 mg/dL). Dosing of ASP1585 was started at 1500 mg/day and adjusted to 7500 mg/day maximum depending on the serum Pi level. Treatment continued up to 12 weeks.

Results: Overall 163 patients were randomized to either the ASP1585 group or placebo group (81 and 82 patients, respectively).In the primary endpoint, ASP1585 showed a statistically significant difference compared with placebo in adjusted mean +/- SE change from baseline in the serum Pi level (mg/dL) (-0.98 +/- 0.15, p < 0.001, Table1). The achievement rates of the target Pi range at the EOT were 57.5% in the ASP1585 group and 23.5% in the placebo group (p < 0.001). Incidences of adverse events (AEs) and GI AEs were comparable between ASP1585 and placebo groups.

Underline represents presenting author/disclosure.

	Placebo (N=81)	ASP1585 (N=80)
Adjusted Mean Change from Baseline (SE) [mg/dL]	0.20 (0.10)	-0.78 (0.10)
Difference with Placebo in Adjusted Mean Change from Baseline (SE) [mg/dL]	-	-0.98 (0.15)
95% CI	-	(-1.27, -0.69)
p-value	-	<0.001

Table1: Result for primary efficacy variable (FAS)

Conclusions: ASP1585 was effective in decreasing serum Pi level, while showing a well-tolerated safety profile compared to placebo. These findings indicated the clinical benefits of ASP1585 as a treatment for hyperphosphatemia in CKD patients not on dialysis.

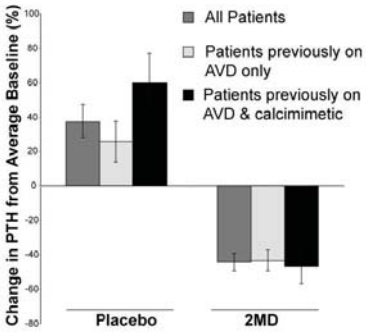
2MD, a New Treatment for Secondary Hyperparathyroidism

Hector F. Deluca. *On Behalf of Phase 2 Study Sponsor and PI's, Deltanoid Pharmaceuticals, Inc., Madison, WI.*

Background: Secondary hyperparathyroidism (SHPT) has been successfully managed with the use of active vitamin D analogs (AVDs) alone, or with the addition of a calcimimetic (CM). However, both classes of compounds have drawbacks. Hypercalcemia is of concern when AVDs are used, while CMs can cause hypocalcemia and have compliance issues because of nausea and vomiting. A novel, highly potent AVD (2-methylene-19-nor-(20S)-1α,25-dihydroxyvitamin D_3, 2MD or DP001) specifically targets the parathyroid glands and bone and is being developed for the treatment of SHPT in patients on hemodialysis.

Methods: A Phase 2B, double-blind, placebo-controlled clinical trial was conducted in 62 Stage 5 patients previously maintained on a commercially available AVD or AVD plus a calcimimetic (NCT01922843). Following a washout period, patients were randomized to receive either placebo (n=28) or 2MD (n=34) softgel capsules orally 3X/week after dialysis for 12 weeks. Serum calcium, parathyroid hormone (PTH), and phosphorus levels were monitored weekly.

Results: 2MD, at doses ranging from 220-770 ng 3X/week, was effective at reducing serum PTH levels in 80% of patients, including those previously requiring an AVD and a calcimimetic. In patients previously treated with a calcimimetic, all but one on DP001 had calcium values in the normal range. Serum phosphorus levels were not affected by 2MD.



Conclusions: 2MD is safe and effective in the management of secondary hyperparathyroidism in renal failure patients on dialysis regardless of whether or not they previously required a calcimimetic together with an AVD.

SA-PO1106

Iron Isomaltoside 1000 (Monofer®) Compared to Oral Iron Sulphate in Patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD)

Philip A. Kalra,[1] Sunil Bhandari,[2] Lars L. Thomsen.[3] *[1]Salford Royal NHS Foundation Trust, Manchester, United Kingdom; [2]Hull and East Yorkshire NHS Trust, Hull, United Kingdom; [3]Pharmacosmos, Holbaek, Denmark.*

Background: Iron deficiency anemia is common in patients with CKD, and is often treated with iron. This study compared the efficacy and safety of intravenous (IV) iron isomaltoside 1000 and oral iron sulphate in patients with NDD-CKD.

Methods: The trial was a phase III open-label, comparative, multi-center, non-inferiority trial conducted in 351 NDD-CKD patients, randomized 2:1 to either IV iron isomaltoside 1000 (group A) or iron sulphate administered as 100 mg elemental oral iron b.i.d. (200 mg daily) for 8 weeks (group B). The patients in group A were equally divided into A1: IV infusion of max 1000 mg single doses over 15 min once weekly and A2: IV bolus injections of 500 mg administered over 2 min once weekly until full replacement dose is achieved (92% of patients in A1 gained full replacement in one visit). Calculation of iron need was according to a modified Ganzoni formula (target Hb13 g/dL, iron stores 500 mg). The primary objective was to demonstrate non-inferiority and the primary endpoint was change in Hb concentrations from baseline to week 4.

Results: Iron isomaltoside 1000 showed not only non-inferiority at week 4 ($p<0.0001$) compared to oral iron but a sustained superior increase in Hb from week 3 until the end of the study at week 8 ($p=0.008$, at week 3). This difference in effect increased week by week. The Hb response was more pronounced with IV replacement doses ≥1000 mg. Ferritin and transferrin saturation concentrations were also significantly increased. Adverse drug reactions (ADRs) were observed in 10.5% in group A and 10.3% in group B and no dose relationship was found. 0.85% of the subjects experienced serious ADRs in both groups. The frequency of a phosphate < 2 mg/dL was 2.2 % vs 1.7 % in groups A and B respectively. More subjects treated with iron sulphate withdrew from the study due to adverse events (4.2% B versus 1.3% A).

Conclusions: Iron isomaltoside 1000 was more efficacious than oral iron sulphate for increase in hemoglobin and proved to be well-tolerated at the tested dose levels in NDD-CKD patients.

In-Hospital, Electronic Alerts for Acute Kidney Injury: A Randomized, Controlled Trial

Francis Perry Wilson,[1] Michael G. Shashaty,[2] Peter P. Reese,[2] Yevgeniy Gitelman,[2] Yuliya Borovskiy,[2] Harold I. Feldman,[2] Susan Ellenberg,[2] Barry D. Fuchs.[2] *[1]Nephrology, Yale School of Medicine; [2]Perelman School of Medicine at the Univ of Pennsylvania.*

Background: Small increases in creatinine are associated with adverse clinical outcomes, but may go unnoticed by clinicians. We evaluated the efficacy of an automated AKI alert system in a randomized trial.

Methods: Starting 7/2013, all patients at the Hospital of the Univ of Pennsylvania (HUP) with AKI as defined by the KDIGO creatinine criteria were identified by a computerized algorithm. Exclusion criteria were age <18, end-stage kidney disease, prior randomization, and presenting creatinine >4.0. Under a waiver of informed consent, patients were randomized 1:1 to usual care (UC) (no alert) or to an electronic alert. Randomization was stratified by medical versus surgical admission and ICU status. For patients randomized to the alerts, the primary provider and unit pharmacist received an automated text-page informing them of the AKI. The primary outcome, a rank-based composite of maximum relative change in serum creatinine, inpatient dialysis, and inpatient death, was assessed 7 days after randomization.

Results: 2393 consecutive patients with AKI were randomized. Baseline characteristics were similar in the two groups. The mean (SD) age was 60.4 (16.3) years, 27.0% of patients were Black, 42.3% were admitted to surgical services, and 30.2% were in intensive care at randomization. The mean (SD) baseline creatinine was 1.10 (0.73) mg/dl while the mean (SD) creatinine at randomization was 1.55 (0.84) mg/dl. At 7 days, the median (IQR) relative increase in creatinine was 0 (0–18%) in the alert group and 0.6 (0–17.5%) in the UC group ($p=0.88$). Seven-day mortality was 5.9% in the alert group vs 5.1% in the UC group ($p=0.40$). The seven-day dialysis incidence was 7.2% in the alert group and 5.9% in the UC group ($p=0.18$). Overall, the rank-based outcome was no different between the groups ($p=0.12$).

Conclusions: In this large trial, alerting providers to the presence of AKI did not significantly improve clinical endpoints. Further studies to identify higher-risk AKI patient subsets which might benefit from alerts paired with targeted interventions may be valuable.

A Randomized Trial of Home Video Monitoring by an Interprofessional Care Team on Outcomes in Patients with Chronic Kidney Disease

Areef Ishani,[1,2] Juleen Christopher,[1] Deirdre A. Palmer,[1] Sara Otterness,[1] Barbara Clothier,[1] Sean Nugent,[1] David Nelson,[1] Mark E. Rosenberg.[1,2] *[1]Minneapolis VA Health Care System, Minneapolis, MN; [2]Dept of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Chronic kidney disease (CKD) is common and is associated with poor patient outcomes. Interprofessional case management has been demonstrated to improve surrogate outcomes in non-CKD populations. The purpose of our study was to determine if an interprofessional team using remote video monitoring of patients with CKD reduced a composite outcome of death, hospitalization, emergency department (ED) visits, or admission to a skilled nursing facility (SNF) compared with usual care.

Methods: We randomly assigned 601 veterans with an eGFR<60mL/min/1.73m^2 to an intervention (n=451) consisting of a remote video monitoring device (touch screen computer, BP cuff, scale, webcam, and glucometer) and care by an interprofessional team (nephrologist, nurse practitioner, nurses, pharmD, psychologist, social worker, and dietician) managing acute and chronic diseases, or to usual care (n=150).

Results: Baseline characteristics of the overall study group were: mean age 75.1±8.1 years, male 98.5%, Caucasian 97.3%, and mean eGFR 37±9 mL/min/1.73m^2. At 1 year, 70 (46.2%) patients in the usual care group and 208 (46.7%) patients in the intervention group experienced the primary composite outcome ($p=0.90$). Results were not altered in multivariable analysis (HR = 1.02, 95% CI=0.77, 1.34). There was also no difference between groups among the components of the primary outcome (Table 1).

Underline represents presenting author/disclosure.

Table 1: Study Group Outcome Rates and Hazard Ratios for Time to Event					
Outcome	Intervention	Usual Care	Hazard Ratio	95% CI	p-value[1]
Primary	208 (46.2%)	70 (46.7%)	0.98	(0.75, 1.29)	0.90
Mortality	13 (2.9%)	3 (2.0%)	1.46	(0.42, 5.11)	0.56
Hospitalization	134 (29.8%)	40 (26.7%)	1.15	(0.80, 1.63)	0.45
ED Visit	164 (36.4%)	58 (38.7%)	0.92	(0.68, 1.24)	0.58
SNF Admission	18 (4.0%)	2 (1.3%)	3.07	(0.71, 13.2)	0.13
[1] Wald Chi Square for Testing HR					

Conclusions: Our intervention of remote monitoring and care by an interprofessional team did not improve health outcomes in patients with moderate to severe CKD compared to usual care.

Stent Treatment in Atherosclerotic Renal Artery Stenosis: Kidney Function and Clinical Events Katherine R. Tuttle, Lance D. Dworkin, Barbara A. Greco, William L. Henrich, Michael Steffes, Kenneth A. Jamerson, Joseph I. Shapiro, Karol M Pencina, Joseph Massaro, Donald Cutlip, Sheldon W. Tobe, Timothy P, Murphy, Christopher J. Cooper, Ralph B D'Agostino. *CORAL, Study Group.*

Background: The study purpose was to determine effects of revascularization by stenting on kidney function and clinical events in the Cardiovascular Outcomes in Renal Atherosclerotic Lesions (CORAL) clinical trial.

Methods: Participants with atherosclerotic renal artery stenosis (ARAS) >60% and systolic hypertension on ≥2 drugs or stage ≥3 chronic kidney disease (CKD) received medical therapy: renin-angiotensin system (RAS) inhibition; statin; target-driven control of blood pressure (BP), LDL cholesterol, and glycemia (diabetic subgroup); anti-platelet agents; smoking cessation education. They were randomized to treatment by stenting and medical therapy or medical therapy alone. The main outcome for the kidney function substudy was estimated glomerular filtration rate (eGFR, creatinine-cystatin C CKD-EPI). CKD events (death, end-stage renal disease, >30% eGFR loss) and cardiovascular disease (CVD) events (death, stroke, myocardial infarction, heart failure) were assessed. Variables were chosen stepwise in generalized estimating equation (eGFR) and pooled Cox proportional hazards (events) models.

Results: eGFR was 59±24 and 53±22ml/min/1.73m^2 (mean±SD) at baseline and 4 years (n=931). CKD and CVD events occurred in 19% (n=175) and 22% (n=207), respectively. No differences between treatment groups were detected for eGFR or events. Participants were followed for 43 (31-55) months (median, IQ range). Baseline predictors of eGFR over time were age, urine albumin-to-creatinine ratio (UACR), systolic BP, diabetes (all inverse); and male sex, total cholesterol, HDL cholesterol. For CKD events, baseline predictors included UACR, systolic BP, HDL cholesterol (inverse). For CVD events, baseline predictors included age, UACR, eGFR (inverse), bilateral ARAS, prior CVD.

Conclusions: Stent treatment did not improve eGFR or reduce CKD or CVD events in CORAL participants receiving RAS inhibition-based medical therapy. Predictors of kidney function and clinical events were traditional risk factors and characteristics.
