Case Description: We present a case of a 26 year old pregnant female (G1P0) who presents at 23 wks of gestation with acute right sided flank pain for 1 day with no other associated symptoms such as fever or dysuria.Her past medical and obstetric histories were unremarkable.Her physical exam revealed right CVA tenderness.She was admitted with impression of pyelonephritis and started on antibiotics. Imaging included renal ultrasound, CT and MRI which revealed right forniceal rupture and fluid in the retroperitoneum with no evidence of nephrolithiasis.Initial aspiration of the fluid returned a sterile culture.She improved symptomatically and was discharged home.Four days later, the patient returned again with right flank pain.Repeat imaging revealed an urinoma measuring 17.5 cm.A nephrostomy tube and surgical drain were placed which decreased the size of the urinoma. She improved symptomatically and discharged home with a nephrostomy tube.Throughout this period,her renal function was preserved.She is currently being followed as an outpatient with planned nephrostomy tube changes every 4-6 weeks until her delivery.

Discussion: Pyeloureteral dilatation is a physiological process occurring in pregnancy. The right side is more affected due to relationship of right ureter to the less distensible right iliac artery and right ovarian blood vessels.This begins at 20 weeks of gestation and is continued until delivery; dilatation resolves in almost half of them within 2 days of delivery. Due to these changes, patients in rare instances have increased intrarenal pressures that lead to pelvic rupture.Risk factors include:nephrolithiasis, pyelonephritis, hamartomas and instrumentation.Few improve with symptomatic management;others require intervention with nephrostomy tube and drainage of urinoma.Monitoring and changing of nephrostomy every 4-6 weeks is recommended. Outcomes are favorable if there are no associated features of infection or tumors in pregnancy.A multidisciplinary approach involving urology,interventional radiology,obstetrics and nephrology is recommended.

Successful Chemotherapy against Invasive Hydatidiform Mole in a Patient with ESRD Tomoaki Onoue, Hideki Inoue, Yuichiro Izumi, Yushi Nakayama, Kenichiro Kitamura, Masashi Mukoyama. *Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Introduction: Invasive hydatidiform mole (IHM) is a rare disease and standard chemotherapy has not been established for the patients with ESRD. This is the first report of successful chemotherapy against IHM in a patient undergoing peritoneal dialysis (PD).

Case Description: A 42-year-old female patient with ESRD undergoing PD for 4 years was diagnosed as invasive hydatidiform mole. Methotrexate and actinomycin D, which are widely used for chemotherapy against IHM, are not recommended to treat patients with ESRD. Since there are several case reports of etoposide chemotherapy against small-cell lung cancer for the patients with ESRD, we chose etoposide as single-agent chemotherapy. One course of therapy was monthly intravenous administration of etoposide with 50mg/m^2 on days 1, 3 and 5. On the days of chemotherapy, the patient received 4 hr hemodialysis after the administration of the agent. Between each chemotherapy course, PD was followed as usual. Serum human chorionic gonadotropin (hCG) was monitored as a marker of IHM. We observed three consecutive negative levels of serum hCG by 10 courses of treatment and completed the therapy after 14 courses (figure1, 2). No severe side effect and recurrence occurred during the observation period.

Discussion: We succeeded in the treatment of IHM in a patient with ESRD using our regimen, which could contribute to the advancement of chemotherapy for the patient with ESRD.

Recurrent Pyroglutamic Acidosis Related to Therapeutic Acetominophen Hazem M. Alhourani,[1] Lekha K. George,[1] Barry M. Wall,[1,2] Aneel Kumar.[1] *[1]UTHSC, Memphis, TN; [2]VAMC, Memphis, TN.*

Introduction: Pyroglutamic acid (PGA), also known as 5-oxoproline, is an intermediate in glutathione metabolism. Elevated anion gap metabolic acidosis due to PGA has been described as a rare complication of the use of therapeutic doses of acetaminophen in adult patients.

Case Description: 36-year-old African-American female with past history of chronic pancreatitis and alcohol abuse presented with nausea, vomiting, and poor oral intake for 3 days. She took 3-4 tablets of oxycodone/acetaminophen daily for months. She had normal vital signs and general examination was unremarkable, except for cachexia and mild respiratory distress. Laboratory: sodium 133 meq/L, potassium 3.5 meq/L, HCO3 3.0 meq/L, chloride 100 meq/L, albumin 3.9 g/dL, anion gap 30 meq/L, glucose 100 mg/dL, BUN 25mg/dL, creatinine 1.0 mg/dL. ABG revealed pH 7.1, PCO2 16 mmHg, PO2 85 mmHg. Serum osmolarity 280 mosm/kg and calculated osmolar gap was 2.0. Serum ketones, L-lactic acid, D-lactic acid, ethylene glycol, methanol, salicylate, liver function tests and acetaminophen came back negative or normal. Urinary organic acid screen was positive for PGA with value of 20 mmol/mmol creatinine Patient was treated with isotonic sodium bicarbonate intravenously, and the anion gap acidosis resolved over 2 days- serum HCO3 normalized to 25 meq/L, and plasma anion gap to 5 meq/L. On further questioning, she reported two additional hospitalizations in the past month with similar presentations of high anion gap metabolic acidosis of unknown etiology. After changing pain medications to oxycodone, acidosis did not recur during 6 months of follow up.

Discussion: In adults, acquired causes of PGA from acetaminophen use are typically associated with conditions leading to acquired glutathione deficiency. Risk factors include female gender, chronic acetaminophen use, alcohol abuse, chronic liver disease, and malnutrition. PGA should be considered in at risk adult patients with unexplained anion gap metabolic acidosis despite normal acetaminophen levels.

SA-PO633

Non Uremic Calciphylaxis with Pseudoxanthoma Elasticum Maria Saleem Khan, Basel Taha, Robenson Jean Marie, Salem Almaani, Alejandro Diez, Udayan Y. Bhatt. *The Ohio State Univ Medical Center.*

Introduction: Non-uremic calciphylaxis(NUC) is an uncommon condition associated with high mortality. Pseudoxanthoma elasticum(PXE) is a rare systemic genetic disorder caused by mutation in ABCC6 gene leading to abnormal elastic tissue structure in multiple systems. We describe a case exhibiting NUC with coexisting histologic changes of PXE. To our knowledge this is the second reported case of NUC with overlying histologic features of PXE.

Case Description: A 33 y/o white female with PMH of alcoholic cirrhosis, hypothyroidism and heparin induced thrombocytopenia on warfarin presented with

worsening jaundice, abdominal distention, lower extremity edema and skin lesions. Physical Exam was remarkable for jaundice, ascites, peripheral edema and tender purpuric plaques on bilateral thighs and right calf.

Labs: WBC:11.0K/uL, Hgb:9.7g/dL, BUN 6 mg/dl, Cr 0.59mg/dL, ALT 8U/L, AST 41U/L, Alk Phos 188U/L, T.Bili 9.8mg/dL, Alb 2.5g/dL, INR 3.8, Ca 7.7mg/dL, Phos 2.4mg/dL and PTH 24.8pg/mL. MELD:30. EGD showed non–bleeding varices and gastritis. Imaging of the liver was consistent with cirrhosis without evidence for hepatocellular carcinoma. Biopsy of the skin lesions were compatible with NUC with histologic changes of PXE. Treatment with cinacalcet or sodium thiosulfate is equivocal hence she was treated conservatively with local wound care. We believe the cause of NUC in this patient is alcoholic liver disease. The patient is being considered for orthoptopic liver transplantation.

Discussion: Both NUC and PXE are rare diseases and require multidisciplinary approach for management. Given the paucity of cases, treatment guidelines are lacking. Nephrologists are often consulted in the management of the disease given the recognized experience with treating uremic calciphylaxis. The main intervention remains education to keep lesions clean and dry to prevent life threatening infections.

SA-PO634

Thyrotoxic Periodic Paralysis in a Hispanic Male Rakesh Kilari, Anuradha Wadhwa, Shirin Amlani Poonja. *Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Periodic paralysis (PP), as manifested by episodes of painless muscle weakness can occur in association with hypokalemia. While most cases of PP are hereditary(autosomal dominant), sporadic cases of hypokalemic PP have been described in association with hyperthyroidism, mostly in Asian population. Here, we present a rare case of thyrotoxic hypokalemic PP in a Hispanic male.

Case Description: A 23 year old Hispanic male with no known medical conditions presented with severe muscle weakness for one day. Weakness initially started in his legs and then progressed to his arms to a point where he was unable to move. Prior to admission, he had been training for army boot camp with rigorous exercise for several weeks and lost 30 lbs during this time. Patient denied any over the counter medication use. Family history was significant for hyperthyroidism in mother. Exam revealed decreased motor strength (proximal>distal), fine tremors and diminished deep tendon reflexes. Admission labwork was significant for hypokalemia (1.4 mmol/L), mild hypophosphatemia/hypomagnesemia and mildly elevated CPK. EKG showed sinus tachycardia, with prolonged QTc and U waves. Urine potassium was low. Treatment with 80 mEq of potassium chloride resulted in rapid resolution of the hypokalemia and weakness. Further work up revealed an undetectable TSH, elevated free T4 at 4.7ng/dL(normal 0.8-1.7) and elevated free T3 at 1315 pg/dL(normal 230-420).

Discussion: Thyrotoxic PP is an often overlooked diagnosis, especially in the western countries. The diagnosis must be considered in any individual who presents with relatively quick onset (usually ascending) paralysis, hypokalemia and hyperthyroid state. These attacks are usually precipitated by strenuous exercise, high carbohydrate meals or stress. Patients may also present with life threatening arrhythmias secondary to hypokalemia. Almost all patients show prompt response to potassium replacement and/or non selective beta blockers such as propranolol. This case highlights that even though most cases have been described in Asians, this rare diagnosis must be considered in Hispanic population with similar clinical presentation and that hypokalemic PP may be the initial presentation of hyperthyroidism.

SA-PO635

Pregnant Filipino with Thyrotoxic Periodic Paralysis: A Case Report Floravil M. Mabras, Brian Michael I. Cabral. *Dept of Medicine, Philippine General Hospital, Manila, Philippines.*

Introduction: Thyrotoxic periodic paralysis (TPP) is a rare complication of hyperthyroidism characterized by acute onset of severe hypokalemia and profound proximal muscle weakness. Ninety percent of all cases reported in the literature were constituted by men of Oriental Asian descent, but rarely among women. It is also not well known that hypophosphatemia, hypomagnesemia and hypocalcemia are also present in TTP.

Case Description: This 35-year-old pregnant Filipino on her 2nd trimester (G7P6, 6006) was admitted for acute lower leg weakness. She had six similar episodes in the past two months which resolved spontaneously over 24 hours. On admission, blood pressure was 130/90, tachycardic with irregular heart rate. Physical examination revealed icteric sclera, diffuse thyromegaly, 3/5 motor strength in lower extremities. In the ER, her initial labs showed thyroid stimulating hormone of <0.005 IU/ml, free thyroxine of 32 pM, hypokalemia at 2.2 mEqs/L, hypomagnesemia at 0.36 mmol/L, hypocalcemia at 1.9 mmol/L and hypophosphatemia of 0.61 mmol/L, urine potassium of 18 mEq/L, urine sodium of 77 mEq/L and normal acid-base status. She was diagnosed as having TTP associated with diffuse toxic goiter in storm. She received propylthiouracil (600mg/day), propranolol (80mg/day), potassium iodide, 80 mEqs of intravenous potassium chloride (KCl) during the first twelve hours, then oral KCl (120mEqs/day). Serial measurements of serum potassium showed a steady return to normal values (3.6 mEqs) within four hours.

Discussion: TTP is predominantly a disease of males, the male to female ratio ranges from 17:1 to 70:1 despite the fact that hyperthyroidism is more common in females. It is ten times more frequent in the Asian population because of presence of HLA-DRw8. Patients with TTP have significantly higher Na-K-ATPase pump number and activity leading to a shift of potassium into the cells. Hyperthyroidism increases renal excretion of magnesium, increased shift of phosphate into cells and hypercalciuria. This case demonstrates a classical presentation of TTP in a female which resolved quickly with a course of non-selective beta blocker, anti-thyroid drugs and supportive potassium chloride correction.

SA-PO636

Thrombotic Microangiopathy and Acute Renal Injury as Complication of Guillain-Barré Syndrome: A Case Report Mariana Pin Andrade, Jonatas Dantas, Beatriz Seves Holanda, Cristiane B. Dias, Luis Yu, Lectícia Jorge, Viktoria Woronik. *Div of Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Introduction: Thrombotic microangiopathy and acute renal injure after malignant hypertension due to autonomic dysfunction can be a rare complication of Guillain-Barré syndrome. This syndrome is believed to result from an aberrant immune response that attacks nerve tissue. This response may be triggered by surgery, immunizations or infections. The most common form of the disease, acute inflammatory demyelinating polyradiculoneuropathy, presents as progressive motor weakness.

Case Description: We describe a case of female patient, 38-years-old, who was admitted to the hospital with status epilepticus, hypertension (BP 266/194 mmHg) and fundus alterations (cotton-wool spots). In recovery, she had been areflexic.Nerve conduction studies confirmed the clinical diagnosis of Guillain-Barré syndrome and laboratory findings showed a severe acute kidney injury and hemolytic anemia pattern of thrombotic microangiopathy: serum creatinine was 7,2mg/dL, BUN 77mg/dL (eGFR 8mL/min/1,73m2), hemoglobin 6g/dL, haptoglobin < 10mg/dL (30-200), lactate dehydrogenase 2964U/L, schizocytes 12,6%, reticulocyte 0,86% (0,5-2,7%), indirect bilirubin 1,3 mg/dL (0,1-0,6) and platelets 9000; Urinalysis: leucocytes :+100, erytrocites +100, protein >1g/dL. Serology and rheumatologic tests were negative.She was treated with antihypertensive and antiseizure medications and intravenous immune globulin with complete resolution of her autonomic symptoms and improvement in her weakness. She remained on dialysis for 1 month.In the end of the treatment, the patient recovered renal function and the anemia: serum creatinine 1,0mg/dL; hemoglobin 12,5g/dL, without evidence of haemolysis, and urinalysis was normalized.

Discussion: Guillain-Barré syndrome may result in autonomic dysfunction about two thirds of cases, and usually presenting with hypotension. In the literature, there are few cases described with malignant hypertension. We present a rare case of Guillam-barre syndrome with malignant hypertension and hypertensive encephalopathy as the first manifestation.

SA-PO637

Hypertension with Bevacizumab and Regorafenib: Treat, but with Caution Akshita Narra, Gaurav Alreja, Ruchir D. Trivedi. *Div of Nephrology, Univ of Connecticut, CT.*

Introduction: Angiogenesis inhibitors, which are increasingly used in advanced stage solid tumors primarily target vascular endothelial growth factor (VEGF) or its receptors. Hypertension is a well recognized dose-dependent side effect attributable to VEGF inhibition. The knowledge of common side effects of various VEGF inhibitors, particularly the underlying mechanisms of VEGF inhibition is essential for appropriate interventions.

Case Description: A 61-year-old Caucasian male with hypertension was diagnosed with stage II colon adenocarcinoma. He underwent partial colectomy and three years later had recurrence of metastatic disease. Several chemotherapy regimens: FOLFOX, capecitabine, FOLFIRI, and cetuximab were attempted with incomplete response. Subsequently, bevacizumab was initiated for advanced disease. His blood pressure(BP) at that time was well controlled(124/78) on metoprolol succinate. As the disease continued to progress, he was switched to regorafenib. After 1.5 cycles of treatment, his BP was persistently elevated above 160/90mmHg. His creatinine remained at baseline and urine studies revealed mild proteinuria. Amlodipine 10mg and losartan 50mg were sequentially added for effective BP control. His cycle-4 of regorafenib was interrupted due to vascular access complication; he then presented with pre-syncope and had BP of 90/60 mmHg. Lab data revealed acute kidney injury necessitating de-escalation of his antihypertensive regimen. After resuming regorafenib, his BP was again elevated warranting initiation of antihypertensive regimen. His BP was monitored closely with cautious use of reduced doses of antihypertensives during off-cycle of regorafenib.

Discussion: Multikinase inhibitors cause broad-spectrum VEGF inhibition as opposed to bevacizumab, which only binds to circulating VEGF which may explain the difference in

magnitude of BP elevation. Regorafenib through VEGF receptor-3 inhibition, also effects pressure natriuresis potentially contributing to higher BP elevation. Hypertension is on-target side effect hence improves with cessation of treatment. This report underscores the importance of close follow up and cautious use of antihypertensives for VEGF induced hypertension during on and off-cycles.

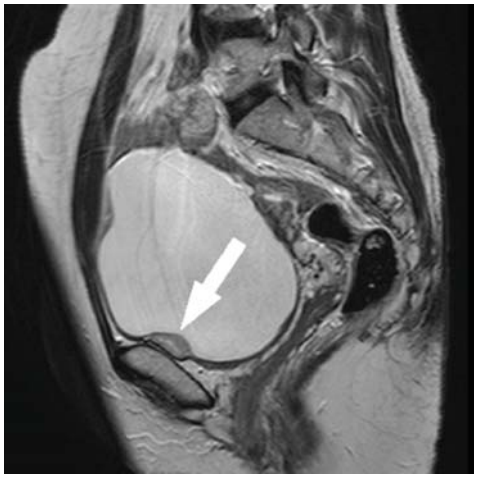
"Avoiding" Hypertension Kainat Shahid,[1] Jordan Weinstein,[2] Catherine J. Streutker,[3] Errol Colak,[4] Jeffrey Perl,[2] Kenneth Pace,[5] Hyangsoon Shin,[2] Marc B. Goldstein.[2] *[1]Dept of Nephrology, Univ Health Network, Toronto, ON, Canada; [2]Dept of Nephrology, St. Michael's Hospital, Toronto, ON, Canada; [3]Dept of Pathology, St. Michael's Hospital, Toronto, ON, Canada; [4]Dept of Medical Imaging, St. Michael's Hospital, Toronto, ON, Canada; [5]Dept of Urology, St. Michael's Hospital, Toronto, ON, Canada.*

Introduction: Paragangliomas of the bladder are rare causes of bladder tumors. We present a case of a bladder paraganglioma highlighting the diagnostic and management challenges of these neuroendocrine tumors.

Case Description: A 53 year old Korean female presented with isolated episodes of hypertension, palpitations and diaphoresis post voiding. Urine metanephrines and catelchoamines collected immediately after the episodes were normal on two occasions. Meta-Iodobenzylguanidine (MIBG) scan did not localize for any pheochromocytoma. Pelvic ultrasound revealed no bladder pathology. MRI revealed a brightly enhancing bladder wall lesion on T2-weighted images.



An extramucosal bladder mass was confirmed on cystoscopy. The patient was started on phenoxybenzamine in advance of an uneventful laparoscopic excision of the perivesical mass. Pathology revealed positive chromogranin staining, confirming a paraganglioma. Post-operative course was challenged with prolonged hypotension managed by high sodium intake. Given an association between false-negative MIBG scan and *succinate dehydrogenase* mutations, which carry higher malignant risk, a referral is being made for genetic testing. As malignancy risk is difficult to determine on a histologic basis, she is subject to yearly symptomatic monitoring and imaging as indicated.

Discussion: The case is unique due to the clinical presentation of a functionally active tumor with negative functional testing. It highlights the diagnostic challenges in these rare tumors, and underscores the adage that the key to a diagnosis is in the history.

SA-PO639

The Pickering Syndrome; a Reason to Stent Renal Artery Stenosis Vikyath Prakash, Vijay Lapsia. *Nephrology, Ichan School of Medicine at Mount Sinai, New York, NY.*

Introduction: In 1988 Pickering reported a series of 11 hypertensive patients with bilateral renal artery stenosis (RAS) presenting with acute pulmonary edema that resolved with renal artery revascularization. The recently published CORAL study, a randomized controlled trial (NEJM 2014), showed no benefit of stenting RAS over medical therapy, thereby questioning the use of revascularization in general. However, a large proportion of patients in CORAL had low risk disease and there may still be clinical situations when revascularization is appropriate.

Case Description: A 90 year old woman was admitted with 4 weeks of increasing lower extremity edema and dyspnea on exertion. She was hypertensive and had bibasilar crackles with elevated jugular venous pressure. The chest x-ray revealed central pulmonary congestion and a cardiac echocardiogram showed preserved biventricular systolic function. Her creatinine had increased from 0.9 to 3.1mg/dl in the span of 5 weeks with decreasing urine output. The urinary sediment was bland with no red/white blood cells, casts, or proteinuria to suggest intrinsic renal disease. Shortly after admission the patient became anuric requiring emergent hemodialysis for hyperkalemia and shortness of breath. A renal doppler ultrasound revealed bilateral RAS 80-99%. Within 24 hours of stenting the right renal artery (left was completely occluded) the urine output increased to over 2.5L/day, shortness of breath resolved, dialysis was discontinued and the patient was discharged dialysis free.

Discussion: This case illustrates the benefit to renal artery stenting in selected patients with Pickering Syndrome. Although multiple case reports have demonstrated similar results in the past, with the publication of CORAL it becomes even more critical for nephrologists to identify the limitations of the study and differentiate those patients who may benefit from revascrualization. Prompt recognition and intervention with stenting of high risk presentations like Pickering Syndrome, refractory heart failure, and otherwise unexplained progressive renal insufficiency may lead to tangible outcomes like the discontinuation of hemodialysis in this patient.

SA-PO640

Interest of Diffusion-Weighted Magnetic Resonance Imaging in IgG4-Related Renal Disease Detection and Follow-Up Joelle L. Nortier,[1] Anwar A. Hamade,[1] Agnieszka Anna Pozdzik.[1] *[1]Nephrology, Erasme Hospital, ULB, Brussels, Belgium; [2]Nephrology, Tenon Hospital, Paris, France.*

Introduction: Tubulointerstitial nephritis (TIN) is a manifestation of IgG4-related diseases, a condition characterized by infiltration of target organs by IgG4+ plasma cells and severe fibrosis. Cortico-sensitivity is one of the diagnostic criteria but the treatment of steroid-resistant and-dependent forms is not well defined.

Case Description: We present one case of 47-years-old patient with IgG4-related NTI followed for 72 months. He complained of fatigue and recurrent postprandial abdominal pain. With the exception of elevated levels of gamma-glutamyl transferase (GGT), transaminases and IgG4, kidney function remained normal (serum creatinine ≤ 0,9 mg/dL). After 2 cures of methylprednisolone (2010-2011) azathioprine was associated in 2012. Due to the cortico-dependence and persistence of bilateral focal renal lesions detected by diffusion-weighted magnetic resonance imaging (DW-MRI), Rituximab (RTX) was given (2x376 mg/m^2/15 days) in 2013. Before the first injection, positron emission tomography (PET) showed metabolic hyperactivity corresponding to axillary and abdominal aorta lymph nodes but not in the kidney. After 4 months of RTX, the patient became asymptomatic. All biological alterations disappeared. PET showed a decrease in metabolic activity at extrarenal lesions described above. A dramatic regression of bilateral renal lesions was noted by DW-MRI: the apparent diffusion coefficient has almost doubled (0,776 versus 1,111x10^{-3} mm^2/sec) and the volume of renal lesions was reduced by 50%, never observed under other treatments.

Discussion: Our observations demonstrate: (1) clinical, biological and radiological efficacy of rituximab in steroid-dependent form of IgG4- related TIN and (2) the interest of DW-MRI as non-nephrotoxic radiological and PET complementary approach not only in monitoring the effectiveness of immunosuppression but also in the early detection of renal involvement during IgG4-related disease.

SA-PO641

A Tale of Two Rare Renal Diseases in the Same Patient Krishna K.R. Manda,[1] Steven P. Lamontagne,[2] Curtis Brasseur,[2] Konstantin Abramov.[1] *[1]Univ of Massachusetts, Worcester, MA; [2]Berkshire Medical Center, Pittsfield, MA.*

Introduction: We report probably the first case of Renal Replacement Lipomatosis (RRL) and Nephrogenic Systemic Fibrosis (NSF) occurring in the same patient.

Case Description: Our patient is a 68 y/o man with significant history of diabetes, CKD stage 3-4, hypertension and peripheral vascular disease. For evaluation of PVD, he had multiple MRA studies in 2007 which led to development of extensive fibrotic skin plaques- gadolinium induced NSF. Around the same time his renal function worsened to end stage and was started on hemodialysis. CT abdomen/pelvis in 2008 showed evidence of RRL in the left kidney which progressed to involve both the kidneys on a CT done in 2012.

Discussion: NSF is a systemic fibrotic disorder which occurs exclusively in patients with kidney failure. The pathogenesis of NSF is not fully understood. Exaggerated tissue fibrosis is thought to be due to activation of the transforming growth factor beta-1 pathway and an increase in circulating fibrocytes. Inciting event may be the tissue deposition of gadolinium which is poorly soluble, highly toxic, and can form precipitates with anions. RRL is a rare disorder in which a massive fatty tissue proliferation occurs within the renal sinus, hilum and perirenal region. It is an advanced form of renal sinus lipomatosis and accompanied by renal stone disease in about 70% of cases. Pathophysiology is not fully understood and it is suggested that an inciting event triggers a process of hydronephrosis and chronic inflammation that results in parenchymal atrophy and fibrofatty replacement. RRL can simulate renal malignancies like angiomyolipoma, liposarcoma. It is interesting to note that our patient never had renal calculi. We highlight the strengthening association between gadolinium exposure in patients with advanced kidney dysfunction and NSF, and the importance of awareness for the potential toxicity of gadolinium in this patient population. Both NSF and RRL are rare conditions, but the similar proposed pathogenesis of chronic inflammation and their coexistence in this one patient raises the question as to whether the two processes are linked. Further research is required to delineate this.

SA-PO642

Unexplained Pain Does Not Equal Drug Seeking Oksana I. Nimkevych, Rose Paccione, Zohreh S. Soltani, Kimberly Cox Fremin. *Section of Nephrology and Hypertension, LSUHSC, New Orleans, LA.*

Introduction: Loin pain hematuria syndrome is a rare diagnosis that occurs amongst young adults. For this reason their pain often dismissed and patients are regarded as drug seeking without the appropriate diagnosis being made.

Case Description: A 22 year old female presents with hematuria and flank pain. She has recurrent bouts of sharp bilateral lower back and flank pain every 3 days. It extends

around to the front of her abdomen. She notes gross blood in her urine daily. Her past medical history is significant for frequent urinary tract infections. Her works up included kidney ultrasound, numerous CT scans, cystoscopies, pyelograms and cystourethrograms, a nuclear renal perfusion scan with normal results. There is no contributory family history. Physical exam is unremarkable. Urinalysis reveals numerous dysmorphic RBCs and no proteinuria. Rheumatoid factor, C3, C4, C-ANCA, P-ANCA, ANA, anti-GBM were negative. Renal biopsy shows thin basement membrane, preserved foot processes, tubules containing numerous red blood cells, negative immunofluorescent stain and no electron dense deposits which are consistent with thin glomerular basement membrane (GBM). Constellation of GBM, hematuria and unexplained chronic flank pain directs us to the diagnosis of loin pain hematuria syndrome.

Discussion: Loin pain hematuria syndrome was first discovered in 1967 and there are now approximately two hundred cases documented in the literature. It is most often seen in young women in their twenties. It is characterized by combination of hematuria with recurrent flank pain that may be constant or intermittent. The etiology of the pain is poorly understood. There is some evidence to suggest that it may be associated with glomerular basement membrane defects. Kidney biopsy in these patients has shown red blood cells in the tubules, suggesting glomerular damage. Once the tubules become blocked this can increase pressure inside the kidney and result in capsular stretch which may cause the pain in these patients. Treatment consists primarily of pain management. There is some evidence to suggest that ACE inhibitor or ARB therapy may reduce the frequency or severity of the pain.

SA-PO643

A Falsely High Blood Creatinine Caused by a Model Aviation Fuel Intoxication Philippe Lachance, Fabrice Mac-Way. *Nephrology, Univ Laval, Québec, QC, Canada.*

Introduction: In many centres, determination of serum creatinine still relies on the Jaffe reaction. However, there are many products that are known to interfere with this reaction and could lead to erroneous level of serum creatinine. We report the case of a man who accidentally ingested nitromethane and presented with a significantly raised serum creatinine when measured by the Jaffe reaction.

Case Description: A 59-year-old man was admitted to the ICU after an accidental ingestion of 250 mL of "Nitrogaz", a product containing 80 % of methanol and 20 % of nitromethane. In the hour after ingestion, the patient felt dizzy, but did not vomit. He did not take any relevant medications and was not known to have a renal disease. On presentation, the serum sent for analysis by the Jaffe reaction showed a creatinine of 940 µmol/L (10,6 mg/dL) but corresponded to 70 µmol/L (0,79 mg/dL) when measured by the enzymatic method. The rest of blood tests were unremarkable except for methanolemia of 12,6 mmol/L. Hemodialysis was performed until methanolemia was undetectable. The patient was discharged from hospital 6 days after admission.

Discussion: Nitromethane is an industrial solvent. Evidence from monkey studies suggest a peak serum concentration at 24 hours and near complete elimination after 3 days. Pharmacokinetic of nitromethane in human is poorly known but it seems to be mainly eliminated by the kidneys. Acute poisoning in humans rarely results in serious toxicity and comes mostly from model fuel ingestion which also contains methanol. Nitromethane intoxication has rarely been reported in the literature and the majority of these cases describe a falsely elevated level of serum creatinine. In these few reports, it has been shown that the nitromethane was indeed the interference product in the Jaffe reaction. Nitromethane is a rare cause of intoxication but a must known product for all nephrologists because of its interaction with measurement of creatinine level. The right recognition of this interaction will allow the avoidance of additional unnecessary tests for high creatinine level.

SA-PO644

Assessment of Knowledge and Perception about Peritoneal Dialysis by in Center Hemodialysis Health Care Workers Ann Mancini,[1] Catherine Firanek,[1] Mary Gellens,[1] Lucy Barker Todd,[1] Ann Robar,[2] Sara L. Garza,[3] Karen Lattrel,[4] James A. Sloand.[1] *[1]Baxter Healthcare, Deerfield, IL; [2]Satellite Healthcare, San Jose, CA; [3]US Renal Care, Plano, TX; [4]Greenfield Health Systems, Detroit, MI.*

Background: Home dialysis use is <10% in the U.S. Most patients begin dialysis in in-center hemodialysis (ICHD) facilities. Medicare mandates all patients must receive modality education. The knowledge and attitudes of ICHD staff may influence modality education.

Methods: A validated online survey was used to assess knowledge of literature-based clinical outcomes and attitudes of responders about home dialysis. Nursing directors of 4 dialysis chains sent a 10 minute survey to 580 dialysis health care workers. Survey dates were 2/24/24 - 4/18/14.

Results: 275 surveys were returned (response rate 47%). In-center hemodialysis (ICHD) nurses, acute hemodialysis (HD) nurses and technicians provided 35% of the responses; peritoneal dialysis (PD) nurses, dieticians, social workers, administrators, managers, and others the remaining 65%. Below are statistically different responses between the groups.

	ICHD RNs, Acute HD RNs and Technicians (35%)	Other Dialysis Staff (65%)
Perceived benefits: PD vs. HD		
Avoiding temporary vascular access w/PD	49%	74%
Preservation of Residual renal function (RRF)	45%	74%
Less risk of infection	13%	26%
Better survival with PD	32%	53%
Perceptions re: Infectious Complications		
Greater risk of infection: PD vs. HD	55%	24%
Patients with peritonitis are likely to be septic	55%	30%
Perceptions of Obstacles to start PD		
Home set up/environment	57%	36%
Automated PD is a complex therapy to learn and self-administer	43%	13%
Lack of physician belief in PD	19%	41%

Conclusions: ICHD staff have misperceptions of PD that contrast with evidence-based findings and those of home-based dialysis staff. Key misperceptions include: avoiding temporary vascular access, preservation of RRF and risk of sepsis. ICHD staff also thinks PD is complex and requires extensive home set up. These misperceptions/beliefs may impact ICHD patient modality education and selection.

Learning Preferences in Renal Physiology: Results of a Q-Sort Survey Needs Assessment John K. Roberts, Alisa Nagler, Ruediger W. Lehrich. *Dept of Medicine, Duke Univ Medical Center, Durham, NC.*

Background: Interest in nephrology has reached an all-time low. A better understanding of medical students' opinions and preferences could reverse this trend. While planning for the re-design of a renal physiology course for first-year medical students, the authors used a Q-Sort survey to assess the students' attitudes and learning preferences to guide curricular change.

Methods: We invited first-year medical students to take a Q-Sort survey at the start of renal physiology. Students ranked statements on a scale from -4 (strongly disagree) to +4 (strongly agree) according to their understanding of renal physiology, interest in nephrology, learning styles, course characteristics, and perceived clinical relevance of renal physiology. By-person factor analysis was then performed to identify statistically different viewpoints among the students.

Results: Factor analysis revealed four statistically different viewpoints. In three of the viewpoints, the students valued learning about the kidney, but differed in how they preferred to learn: the Readers avoid lecture and prefer using a textbook or notes; the Social Auditory learners prefer attending lectures and working with peers; and the Visual learners prefer diagrams and online videos. The fourth factor represented a small group of predestined students with a strong bias against renal physiology and nephrology. (see Figure 1)

Conclusions: The major viewpoints among first-year medical students are defined by preferences for different learning styles rather than attitudes towards renal physiology or interest in nephrology. However, there are some predestined students who have a strong predisposition against nephrology. A curriculum that caters to a diversity of learning styles may impact learning and nephrology interest in students taking renal physiology.

Simulation-Based-Mastery-Learning for Temporary Hemodialysis Catheter Insertion at the Canadian Society of Nephrology Annual Meeting: A Before-After Study James J. Paparello,[1] Edward G. Clark,[2] Cedric A.W. Edwards,[2] Michael Schachter,[3] Rory F. McQuillan,[4] Diane Wayne,[1] Jeffrey H. Barsuk.[1] *[1]Dept of Medicine/Nephrology, Northwestern Univ Feinberg School of Medicine, Chicago, IL; [2]Dept of Medicine/Nephrology, The Ottawa Hospital - Riverside Campus, Ottawa, ON, Canada; [3]Dept of Medicine/Nephrology, Univ of British Columbia, Vancouver, BC, Canada; [4]Dept of Medicine/Nephrology, Univ of Toronto, Toronto, ON, Canada.*

Background: Simulation-based-mastery-learning (SBML) is an effective technique for teaching the insertion of temporary, non-tunneled hemodialysis catheters (NTHDCs). We sought to determine if SBML training for NTHDC insertion could be effective in training nephrology trainees at the annual meeting of the Canadian Society of Nephrology.

Methods: Trainees were surveyed regarding demographics, prior experience and procedural self-confidence. They underwent a baseline assessment of their NTHDC insertion skills using a patient simulator and ultrasound machine. Iinsertion skills were assessed using a 28-item checklist. Participants then had a training session that included a didactic presentation and 2 hours of deliberate practice. On the following day, they underwent repeat assessment using the same 28-item checklist (post-testing). All participants were required to meet or exceed a minimum passing score (MPS) of 79% checklist items correct.

Results: Twenty-two individuals participated in the training. None of the 22 met or exceeded the MPS at baseline assessment (mean checklist score of 15.5/28 [SD=7.2]). Seventeen of 22 participants took part in post-testing and improved their scores (mean of 26.9/28 [SD=1.1; $p < 0.001$]). All 17 met or exceeded the MPS on their first attempt. Participants strongly agreed that SBML-training for NTHDC insertion was beneficial and should be incorporated into nephrology fellowship training.

Conclusions: Although most participants reported having previously inserted NTHDCs in clinical practice, they did not perform well on a simulated procedure. This study establishes that SBML-training for NTHDC insertion in the setting of a medical conference is feasible and effective.

SA-PO647

Validating the Self-Audit Chart Review Method through Verification of Data Accuracy in a Nephrology Fellowship Program Will M. Schouten,[1] Suzanne M. Norby.[1,2] *[1]Dept of Internal Medicine, Mayo Clinic, Rochester, MN; [2]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Self-audit of continuity clinic (CC) patient charts is a method used to assess the Practice-Based Learning and Improvement competency in our nephrology training program and to evaluate how nephrology fellows manage patients with chronic kidney disease (CKD). However, the accuracy of data collection had not been systematically evaluated to determine the validity of this assessment tool. The purpose of this study was to determine if self-audits yield accurate data in a nephrology fellow CC practice setting.

Methods: Each of 11 nephrology fellows was assigned to review medical records of 10 consecutive non-dialysis patients with CKD stage 4 or 5 whom they had evaluated in CC. Data were abstracted from laboratory results and visit notes: blood pressure measurement (BP) recorded in the designated field; diagnosis of diabetes mellitus and, if diabetic, whether the patient was taking an ACEI or ARB; serum bicarbonate level and, if low, whether the patient was on bicarbonate supplementation; and documentation of end-stage renal disease (ESRD) treatment options discussion. Abstraction of the same data was then performed by the program director (PD).

Results: Of 106 patient records reviewed, 8 did not meet criteria and were excluded. 453 data points were collected from 98 records. Overall, 95% of fellow data points agreed with review by the PD. Individual fellow accuracy ranged from 83-100%. Accuracy did not differ by level of training: 94% for 1st year fellows, 98% for 2nd year fellows, and 95% for 3rd year fellows. Overall accuracy by category was 91% for recorded BP, 96% for diabetes diagnosis, 99% for bicarbonate level, and 97% for discussion of ESRD treatment options. For data points requiring an if-then decision, abstraction was 89% accurate for administration of supplemental bicarbonate if the level was low and 93% for ACEI or ARB use in patients with diabetes.

Conclusions: The self-audit chart review method appears to be a valid assessment tool, yielding reasonably accurate results unaffected by year of training.

SA-PO648

Comfort with Computer Technology in Patients with Chronic Kidney Disease Gordana Obradovic,[1] Andrea Lynn Berger,[2] Christina Yule,[2] Steven D. Weisbord,[3] Jamie Alton Green.[1,2] *[1]Nephrology, Geisinger Medical Center, Danville, PA; [2]Center for Health Research, Geisinger Medical Center, Danville, PA; [3]Renal Section, VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: Computer-based tools have the capacity to engage patients in their care and improve self-management, however their use depends upon adequate computer literacy by patients. We sought to assess comfort with and use of computer technology among patients with chronic kidney disease (CKD).

Methods: We administered an investigator-designed survey to adult patients with non-dialysis dependent CKD stages 3-5 in rural Pennsylvania. The survey included questions about internet usage, comfort with computer based tools, and use of electronic health portals.

Results: There were 84 participants. Average age was 71, 57% were male, 96% were white, 53% had a less than or equal to high school level of education, 68% were retired, and 33% had an income less than $25,000. Almost half (47%) reported that they had not used the internet in the preceding 12 months. Only 58% were comfortable using a traditional computer with a mouse, 10% using a cell phone with internet access (smart phone), and 17% using an iPad or touchscreen computer. Nearly one-third (32%) stated that they were not comfortable using any of the above. Forty-two percent were active users of an electronic health portal. Reasons for non-use of a health portal included: lack of internet access (39%), not interested (32%), not sure how it works (11%), and lack of a computer (7%). Forty-three percent allowed someone else to access their health information through a health portal.

Conclusions: Despite the increased reliance on computer technology in health care, many patients with CKD are not comfortable with computer-based tools. These findings may help inform the development of 'technology sensitive' self-management interventions in this patient population.

SA-PO649

Comprehensive Assessment of Health Literacy in Patients with Chronic Kidney Disease Using the Health Literacy Skills Instrument Short Form Gordana Obradovic,[1] Andrea Lynn Berger,[2] Christina Yule,[2] Steven D. Weisbord,[3] Jamie Alton Green.[1,2] *[1]Nephrology, Geisinger Medical Center, Danville, PA; [2]Center for Health Research, Geisinger Medical Center, Danville, PA; [3]Renal Section, VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: Many health literacy screening tools use reading skills as a proxy measure of overall health literacy. However, adequate health literacy requires additional skills including the ability to interpret numbers, listen effectively, and navigate the health care system. We sought to comprehensively assess health literacy in CKD patients using a short, skills-based instrument that measures multiple health literacy domains.

Methods: We assessed health literacy in patients with CKD stages 3-5 not on dialysis using the Health Literacy Skills Instrument-Short Form (HLSI-SF), a 10-item screening tool that measures four domains of health literacy: print literacy (reading and writing), numeracy skills, oral literacy (listening), and information seeking (navigation of internet and facilities). Results are categorized as adequate (7-10 correct) and inadequate (0-6 correct) health literacy.

Results: There were 84 participants. Mean age was 71, 57% were male, 96% were white, and 53% had a high school or lower level of education. Fifty-one patients (61%) had inadequate health literacy. Only 11 (13%) were able to calculate the percent daily value of saturated fat from a nutrition label (numeracy), 43 (51%) were able to identify the appropriate timing of a medication from a chart (print literacy), 43 (51%) were able to select the correct number to press after listening to a telephone recording (oral literacy), and 43 (51%) were able to calculate the amount of calories burned during activity using an interactive web calculator (internet navigation).

Conclusions: When using a skills-based instrument, the prevalence of inadequate health literacy in patients with CKD is high. These findings should inform the development and assessment of targeted interventions to alleviate the challenges faced by patients with CKD who have inadequate health literacy.

SA-PO650

Structured Quality Improvement Curriculum Leads to Increased Productivity of Fellows Laura J. Maursetter. *Div of Nephrology, Dept of Medicine, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Quality improvement (QI) looks at a problem through a lens that is different from that of basic science or clinical research. Its mission is not scientific discovery but, rather, improvements in the efficiency, safety or effectiveness of healthcare delivery. As organizations and individuals are more commonly being measured on quality, it is critical for graduating fellows to have a working understanding of the QI process and the contribution it can have on practice. The aim of this project was to create and deliver a QI curriculum to multiple fellowship programs over the course of the year to increase the number and quality of QI projects that these fellows created.

Methods: The curriculum was developed around the FADE model (Focus, Analyze, Develop, Execute, Evaluate). Five meetings were established among 6 fellowship groups. Fellows met for 20 minutes of didactics and 40 minutes of project discussion at each of the five sessions to develop and implement a QI project. The projects were vetted across the groups for improvement suggestions and then presented at a department-wide event.

Results: 35 fellows and 12 faculty mentors participated in at least one of the sessions. Projects were created by groups ranging from 1-6 fellows. There were 16 projects across the 6 participating divisions with at least 1 project in each division. In the Division of Nephrology, the number of projects created increased from 0 to 3 projects per year over the 2 years the curriculum as been in place. Projects ranged from mechanisms to avoid PICC line placement in CKD stage 4-5 to measuring the efficiency of care impact pre-clinic preparation had on the osteoporosis clinic. This year 10 posters were presented at the end of the year with 1 project, thus far, submitted for publication.

Conclusions: A structured QI curriculum increased the number of QI projects generated. Including fellows from various divisions in the process and discussions allows for common problems to be identified and improved with further-reaching impact. Analysis of participant survey data will help to determine how to improve the process to enhance learning and productivity for the future.

SA-PO651

Medical Trainees' Knowledge of Contrast Use in Chronic Dialysis Patients Rahmat Balogun, Chinmay P. Patel, Shital Gandhi, Hitesh H. Shah, Kenar D. Jhaveri. *Nephrology and Radiology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.*

Background: The knowledge related to IV radiocontrast use in ESRD patients among residents at our two large tertiary hospitals is not known. Hence, to gain a better insight in medical trainees' knowledge on this subject, we conducted an online survey at our institution.

Methods: We first reviewed the literature to gain knowledge related to the use of contrast agents in ESRD patients. An anonymous online survey was subsequently created. Trainees were presented with 4 clinical case scenarios to determine their knowledge on this subject. The survey was internally validated by 3 independent nephrologists that were not a part of this study. The survey was subsequently distributed to all internal medicine, emergency medicine, surgery and radiology residents at two large tertiary centers.

Results: 94 medical trainees responded to the survey (33% response rate). 95% of the residents were trained in U.S. medical schools. Nearly half (47.9%) of the respondents were internal medicine residents, while the remaining respondents were emergency medicine (21.3%), radiology (18.1%), and surgical (12.7%) residents. Over one-third of the respondents were PGY1. Question related to the timing of dialysis following IV contrast use was incorrectly answered by nearly 24.1% of the respondents. 10.1% of the residents incorrectly suggested that N-acetylcysteine should be given to ESRD patients to prevent radiocontrast nephropathy. Over one-fifths (22.7%) of the respondents were unaware of the risks of developing NSF following gadolinium based contrast use in ESRD patients. As compared to all responding trainees, radiology residents performed better on the survey.

Conclusions: While most responding trainees were knowledgeable regarding the appropriate use and risks of IV iodinated radiocontrast material in ESRD patients, a significant percentage were not aware of the risk of developing NSF following gadolinium based contrast material use in this patient group. A significant number of trainees were also not aware of the timing of dialysis following IV contrast use. Measures to enhance medical trainees' knowledge related to iodinated and gadolinium contrast use in ESRD patients are needed.

SA-PO652

Quality Improvement Process and Fellow Education Improves Referral Rates for Transplant and Dialysis Access Anuj Regmi,[1,2] N. Stanley Nahman,[1,2] Usman Afzal,[1,2] Noble Iwuagwu,[1,2] John Jason White.[1,2] *[1]Nephrology, Charlie Norwood VAMC, Augusta, GA; [2]Nephrology, Georgia Regents Univ, Augusta, GA.*

Background: Important functions of any chronic kidney disease (CKD) clinic are timely referrals for renal transplantation and dialysis access. However, the optimal timing of referral is debatable, and the reasons for low referral rates are not well understood.

Methods: As part of an on-going quality assurance initiative (QAI) in our CKD Clinic at the Charlie Norwood VA Medical Center, we evaluated all patients seen by nephrology fellows between January 1, 2013 and April 30, 2013 (4 months) (Phase 1) and assessed referral patterns for renal transplantation and dialysis. We focused on CKD 4 and CKD 5. At the conclusion of Phase I, the results were reviewed in a combined session with fellows and faculty. The need for early referral was emphasized and plans for second audit defined. We subsequently evaluated referral patterns for all patients seen between August 1, 2013 and November 30, 2013 (4 months) (Phase 2). Lastly, we assessed referral rates for eGFR < 20 ml/min/1.73m2 and documented reasons for non referral.

Results: The results are summarized in the table. Following the intervention, there was a general increase in referral rates for access, but there was a limited effect on transplant referral. Reasons for non referral in 24 patients included: advanced age/dementia (n = 5); acute malignancy (n = 4); patient refusal (n = 3); unstable psychiatric disorder (n = 1); and unknown (n = 10).

Percent of patients referred for transplant or access (N)		
Referral	Phase 1 (349)	Phase 2 (361)
Transplant		
CKD 4	9% (67)	25% (49)
eGFR < 20	32%(37)	50%(26)
CKD 5	50% (18)	67% (15)
Access		
CKD 4	21%	11%
eGFR < 20	59%	55%
CKD 5	72%	73%

Conclusions: Rates of referral for transplantation and dialysis access placement may be improved by chart audits. Furthermore, the reasons for non-referral may be due to complicating medical problems but patient refusal is also an issue. Addressing issues of non referral may help increase the rate of referral for transplant and vascular access in advanced CKD.

SA-PO653

Preparing Nephrology Fellows for Difficult Conversations in the Critically Ill Patient with Acute Kidney Injury: The Use of Simulation-Based Communication Skills Training Yusra R. Cheema,[1] Kathy Johnson Neely,[2] Paul J. Hutchison,[3] Cybele Ghossein.[1] *[1]Nephrology, Northwestern Univ, Chicago, IL; [2]Hospital Medicine, Northwestern Univ, Chicago, IL; [3]Pulmonary, Northwestern Univ, Chicago, IL.*

Background: Nephrology fellows spend a significant amount of time caring for the critically-ill that suffer acute kidney injury (AKI), many of whom are started on continuous renal replacement therapy (CRRT) despite a low likelihood of surviving to discharge from the intensive-care unit (ICU). Surveys demonstrate that many nephrology fellows feel unprepared to have conversations regarding withholding or withdrawal of renal replacement therapy in these situations and yet, few programs have addressed communication skills training. Here we describe our experience using didactic sessions followed by simulated patient encounters to prepare nephrology fellows for difficult discussions in critically-ill patients with AKI.

Methods: All 7 nephrology fellows at Northwestern University during the 2013-14 academic year underwent this training as part of a quality improvement initiative. All fellows attended a 1-hour didactic session on useful communication strategies in end-of-life situations. Each fellow then practiced these skills with a standardized patient and received feedback. All fellows completed both pre- and post-encounter questionnaires using a 5-point Likert scale to assess the experience.

Results: All fellows reported an improvement in both knowledge and skills required to lead a successful discussion with a surrogate decision-maker regarding initiation of CRRT. Additionally, 100% of fellows would recommend this type of simulation-based palliative care education.

Statements	% Responding as Good or Excellent (score of 4 or 5)	
	Pre	Post
I would assess my knowledge base to successfully lead such a discussion as..	0	85.7
I would assess my skill set to successfully lead such a discussion as..	14.2	100

Conclusions: At our institution, simulation training with standardized patient encounters served as an effective tool to prepare nephrology fellows to lead difficult end-of-life conversations regarding CRRT initiation in critically-ill patients with AKI.

SA-PO654

Journal Publications of U.S. Adult Nephrology Fellowship Training Program Directors Hitesh H. Shah, Aditya Kadiyala. *Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Publication in peer-reviewed journals can be considered as one measure of scholarly activity among academicians. Peer-reviewed journal publications (PR-JPs) of U.S. adult nephrology fellowship training program directors (N-TPDs) are not known.

Methods: A PubMed search for journal publications was conducted for a period of 3 years (7/2011 to 6/2014) for N-TPDs serving in academic year 2013-14. Publications were categorized as follows: basic science research (BSR), prospective clinical study (PCS), retrospective or cross sectional clinical study (R/CCS), clinical outcomes research (COR), randomized clinical trial (RCT), meta-analysis (MA), educational research (ER), case report/series (CR/S), review article (RA), editorial (E) and letter to editor (LT-E). Data was analyzed in June 2014 for 145 N-TPDs.

Results: 33 (22.8%) N-TPDs had no PR-JP in the last 3 years. While 35.8% had ≤3 publications, 15.2% had ≥10 publications. We identified 664 PR-JPs by N-TPDs over the past 3 years, out of which 19.1% publications had an N-TPD as the primary author (PA), 29.2% had an N-TPD as a corresponding author (CA) and 15.1% had an N-TPD as both the primary and CA. 39% were clinical research (PCS, R/CCS, COR, RCT, MA) related publications. The remaining publications were as follows: RA-22.7%, CR/S-16%, BSR-9.3%, E-7.4%, LT-E-2.9%, and ER-2.7%. While 37.1% of N-TPDs had at least one PR-JP as a PA over the past 3 years, 46.2% had at least one publication as CA and 32.4% had at least one as primary and CA. In the last 3 years, 49.7% of the N-TPDs had authored at least one clinical research publication, 17.2% had a BSR publication, while 7.5% had an ER publication. When analyzed by gender, 41 female N-TPDs had a mean of 4.9 publications in past 3 years as compared to 104 male N-TPDs who had a mean of 4.4 publications with no statistically significant difference between means ($p = 0.63$).

Conclusions: Nearly one in four N-TPDs had no PR-JP over the last 3 years. Nearly half N-TPDs were CA on at least one publication over the last 3 years. Half of the PR-JPs were either clinical research, BSR or ER related publications. The ER category had the least publications. Male N-TPDs were as likely to publish as female N-TPDs.

SA-PO655

Telenephrology May Improve Rural Primary Care Provider (PCP) Satisfaction and Medical Care within Veterans Affairs Raimund H. Pichler,[1] Lauren Beste,[2] Maureen Germani,[1] Michael F. Chang,[3] Bessie A. Young.[1] *[1]Div of Nephrology, Renal Dialysis Unit S-1111, Veterans Administration Puget Sound Health Care System, Seattle, WA; [2]Div of Gastroenterology, S-111 GI, Veterans Administration Puget Sound Health Care System, Seattle, WA; [3]Div of Gastroenterology, Portland VA Medical Center, Portland, OR.*

Background: PCPs practicing in rural areas have more difficulty accessing specialty care for their patients. Rural PCPs also have been shown to report professional isolation, lack of access to professional development and decreased educational opportunities. As part of the Veterans Affairs (VA) Specialty Care Access Network-Extension for Community Health Outcomes (SCAN-ECHO) we launched a provider-to-provider Nephrology telemedicine consultation service to provide mentoring for PCPs to treat mostly rural Veterans with renal disease.

Methods: We conducted an e-mail survey of VA-based PCPs (n=13) in the rural Pacific Northwest, who attended a longitudinal Nephrology telemedicine program. We used a validated survey to assess provider measures.

Results: Most PCPs felt that the program increased their knowledge and competencies (100%), improved the quality of care for their patients (95%) and was useful in treating patients not discussed in the program (85%). The vast majority of providers felt that their participation was rewarding (85%). Almost half of the PCPs (46%) stated that they were using the Nephrology knowledge gained from the program in their daily practice. 62% of PCPs felt more integrated into a clinical team. The majority of PCPs felt that Renal SCAN ECHO increased their overall job satisfaction (70%) and 92% stated that they would recommend the program to a colleague. Almost half (46%) of the providers felt that their participation decreased traditional Nephrology consults.

Conclusions: A renal provider-to-provider Nephrology telemedicine service can be a rewarding experience that improves provider self reported knowledge, job satisfaction and quality of nephrology care in more rural areas. Future research is needed to study the effect of such an intervention on patient outcomes.

Funding: Veterans Affairs Support

SA-PO656

Nephropathology Education during Fellowship: A U.S. Nephrology Fellowship Training Program Directors' Survey Kenar D. Jhaveri,[1] Surya V. Seshan,[2] Rimda Wanchoo,[1] Hitesh H. Shah.[1] *[1]Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY; [2]Pathology, Weill Cornell Medical Center, New York Presbyterian Hospital, New York, NY.*

Background: Nephropathology (NephPath) education is an important component of nephrology fellowship curriculum. To gain a greater insight into NephPath education offered to fellows during fellowship training in the U.S., we conducted this study.

Methods: An anonymous online survey was created and subsequently distributed to all U.S. adult nephrology fellowship training program directors (N-TPDs) in May 2014.

Results: So far, 36 N-TPDs have responded to our survey (25% response rate). Over half (56%) of the respondents' institution had a renal pathology division at their institution. Nearly one-fifth programs did not have an "in-house" nephropathologist (N-Path) and performed <50 kidney biopsies/year. Kidney biopsies in these programs were read by either an affiliated academic center N-Path or by N-Path working in a private setting. Over half (52%) of the programs with "in-house" N-Path had weekly NephPath conferences. Majority (80%) of the programs with no "in-house" N-Path had monthly conferences. 11% sent their fellows to other institutions to attend NephPath conferences. Measures to enhance NephPath education included: dedicated renal pathology elective (46%), send fellows to attend NephPath conferences at national meetings (46%) or dedicated NephPath courses (20%), web-based teaching (20%), and didactic lectures from invited N-Path(s) (14%). While 63% programs felt that their fellows were receiving adequate NephPath education at their institution, another 34% felt that they could do better. "No in-house N-Path" (11%), "not enough kidney biopsies" and "lack of resources" were some of the reasons for inadequate NephPath education for fellows.

Conclusions: Programs with N-Path within their institution were more likely to have frequent NephPath conferences as compared to the programs that did not. While majority of N-TPDs felt that they provided adequate NephPath experience to fellows, nearly one-third felt that they could do better. Novel methods to enhance NephPath experience such as web-based learning or videoconferencing can be considered by training programs.

SA-PO657

Trends of Education Research Abstract Presentations and Publication Rates at ASN Kidney Week 2008-2013 Kenar D. Jhaveri,[1] Rimda Wanchoo,[1] Laura J. Maursetter,[2] Hitesh H. Shah.[1] *[1]Nephrology, Hofstra NSLIJ School of Medicine, Great Neck, NY; [2]Univ of Wisconsin School of Medicine, Madison, WI.*

Background: Since the inception of the educational research category at the ASN Kidney Week (KW) in 2008, the number and types of research abstracts accepted for presentation at ASN KW from 2008 to 2013 is not known. Peer-reviewed journal publication of educational research abstracts at ASN KW is also not known.

Methods: All accepted educational research abstracts from 2008-2013 were reviewed and further categorized into one of the 4 sub-categories: medical trainee (MTE) related educational research, patient education (PE) related research, social media (SoM) and faculty development (FD). To determine the peer-reviewed journal publication rate of these abstracts, a literature (PubMed) search was performed.

Results: A total of 145 abstracts were presented in the educational research category in this time period. ASN KW 2013 had the highest number of abstracts in this category with a total of 35. Over the previous six ASN KW meetings, 48% were MTE related. The remaining abstracts were PE (33%), FD (13%) and SoM (5.5%) related. Of the 145 abstracts, 29% were survey-based studies. So far, 30 (21%) out of the 145 abstracts have been published as papers in peer-reviewed journal. Of those that were published, 13 (45%) were survey based, 2 were RCTs, 2 propensity matched pair analysis, 1 historical control comparison and 1 time controlled trial. While 47% of the published articles were MTE related papers, 23% were PE, 17% were FD and the rest were SoM related educational research papers. Overall, abstracts were more likely to be published if they were SoM related(50%), followed by FD (27%) and then MTE related(20%).

Conclusions: Based on our study, interest in conducting nephrology educational research is increasing among the training community. However, so far, only one-fifth of the educational research abstracts that have been presented at ASN KW have been published as peer-reviewed journals papers. Of those that were published, majority were survey based and MTE related. Reasons for this low publication rate is not known. Training in medical education research might increase quality of abstracts and publication rates.

SA-PO658

Narrative Medicine Reflective Writing in the Dialysis Unit Kenar D. Jhaveri, Elizabeth J. Berger, Hitesh H. Shah, Tomoko Ouchi, Heidi Mandel, Barbara R. Hirsch, Nancy Farber, Mindy B. Nelkin, Michael T. Murn, Alice Fornari. *North Shore LIJ Health System, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.*

Background: Narrative medicine(NM) is being used to enhance professionalism, humanism and ultimately patient care in other areas of medicine. To assess NM utility, a pilot intervention using narrative reflection was developed and implemented with staff members in a single center dialysis unit.

Methods: A NM program was developed for our dialysis staff. Nephrologists, fellows, dietitians, social workers, nurses, technicians, and unit receptionists participated in the study. The 60 minute session began with 5 minutes of silent writing in response to a prompt (visual or words). The expressive writing was subsequently shared among the small group of participants. The skilled NM facilitators guided discussion and where appropriate, connected the writings to their role in patient care. Sessions were conducted twice a week for 3 months. Curriculum development and monitoring of the project's progress took place via monthly teleconferences and emails among the facilitators, with a documented "dialogue" for evaluation purposes.

Results: A total of 24 sessions were conducted. Each session included discussions that were around reflected thoughts of fatigue, death, and work life balance. The overarching goal to bring NM to a patient care team within a dialysis unit was achieved. A wordle image produced themes such as "appreciation, mindfulness, fathers, mothers, love, staff and protection" as examples. The participants self-reported that these sessions were enjoyable and seemed to benefit from the opportunity to reflect. They identified the need for continued support of this kind as desirable, as this is largely unfulfilled in the course of traditional medical rounds in dialysis units.

Conclusions: A pilot program using NM demonstrated preliminary promise as a tool for staff to discuss the humanistic aspect of patient care, work-life balance in a safe manner. Using the knowledge gained from this pilot in organizing such a unit based program, a future larger study with dialysis staff can include pre and post interventions to measure impact of NM sessions specific to humanism and burnout.

SA-PO659

A Latin American Online Continuing Medical Education Course for the Nephrology Community Francisco Gonzalez-Martinez,[1] Oscar A. Noboa,[1] Gustavo Cristian Greloni,[2] Irene L. Noronha,[3] Almerinda Ribeiro,[4] Alvaro Margolis,[5] Leticia Lorier,[5] Ricardo Silvariño,[1] Sofia Garcia,[5] Antonio Lopez,[5] Juan M. Fernández-Cean.[6] *[1]Nephrology, Univ de la República, Uruguay; [2]Nephrology, Hospital Italiano, Argentina; [3]Nephrology, Univ de San Paulo, Brazil; [4]Nephrology, Univ Estadual de Campinas, Brazil; [5]Evimed, Uruguay; [6]SARI, Uruguay.*

Background: In 2013, the Latin American Society for Nephrology and Hypertension (SLANH) and the Latin American and Caribbean Transplantation Society (STALYC), with support from Evimed, implemented a CME course for Latin American nephrologists. We summarize the design, implementation and results of this course.

Methods: The topic was Immunopathology in native and transplanted kidneys. Evimed provided for the educational, technological and logistics support. The course was given in Spanish and Portuguese. The activities included a distance education seven-week asynchronous on-line modality with multiple educational strategies. Thirty hours of study workload was estimated to complete the course.

Results: There were 612 participants (about 7% of the Latin American nephrology community): 498 physicians coming from 18 countries who registered for the course, 59 experts and tutors and 55 observers; 85% of attendees were nephrologists, 11% were residents. Ninety-six percent of registrants (n=479) accessed the online campus, and 92% of them (n=442) participated in the course. Of this last figure, 51% received a certificate of completion (n=226) and 29% a certificate of participation (n=128). Sixty-five percent of registrants participated in the case discussions. Eighty-six percent were very satisfied, 13% were satisfied, 1% was neutral, and none were dissatisfied or very dissatisfied. Lack of time to devote to the course was the main limitation expressed (62% of participants who answered this question), while Internet access or difficulties in the use of technology were

considered by 12 and 6% of participants, respectively. There was a significant increase in knowledge between before and after the course: The grade increased from 64 to 83%.

Conclusions: Technology-enabled education demonstrated good potential to become an instrument for Latin American nephrologists.

SA-PO660

An Educational Intervention on Communication of Prognosis by Renal Fellows Jennifer S. Scherer, Evgenia Litrivis. *Dept of Geriatrics and Palliative Medicine, Icahn School of Medicine at Mount Sinai, NYC, NY.*

Background: Nephrology trainees report being poorly mentored and unprepared to discuss end-of-life issues. We conducted a study to assess renal fellows' preparedness for communicating prognosis and to examine the effects of an educational intervention.

Methods: Fellows from 3 institutions were provided surveys that inquired about communication skills, mentorship, barriers, and knowledge of prognostic tools. Answers were on scale of 1-10. Fellows attended a 15 minute didactic on prognostication and were resurveyed 6 weeks later. Results were compared with a t-test. Study was IRB exempt.

Results: Pre-survey: n=12; Average age: 31.2 years; 66.7% male, 58.3% 2nd year fellows. Post-survey: n=5

	Fellows Pre-Intervention (n=12)	Fellows Post-Intervention (n=5)	Change	t-test p-value
Rank of frequency of discussions of prognosis with patients (average)	5.67	6.60	+0.93	0.52
Rank of frequency of incorporation of prognosis into treatment decision-making (average)	5.67	6.50	+0.83	0.56
Level of Preparedness (average)	5.09	5.29	+0.20	0.91
Frequency of observation by Attendings (average)	4.08	3.25	-0.83	0.58
Frequency of fellows asking for observation (average)	2.42	1.50	-0.92	0.52

Baseline scores were low. There was a non-significant increase in comfort and use of prognosis, with a downward trend in mentorship. 16.7% knew of prognostic tools before the intervention, 100% after. 66.7% found the didactic helpful. 100% felt there should be an increase in communication training during fellowship. Barriers identified were time constraints, inability to explore patients' values, lack of training, and clinical uncertainty.

Conclusions: This study identifies barriers to trainees' use and learning of communication skills. Communication training is taught most effectively through observed feedback, yet our data shows that fellows are not receiving this education. Limitations include the low return of surveys and the short time for the didactic. Strengths are the multi-institution participation and the identification that fellows would like more training in these skills. Future directions include partnership with palliative care departments to provide effective communication education and mentorship.

SA-PO661

NephMadness 2014, a Social Media Campaign to Promote Nephrology Education and Interest Joel Topf,[1] Matthew A. Sparks,[2] Edgar V. Lerma,[3] Warren L. Kupin,[4] Kenar D. Jhaveri.[5] *[1]Medicine, St. John Hospital/Providence, Detroit, MI; [2]Medicine, Duke, Durham, NC; [3]Medicine, Univ of Illinois, Chicago, IL; [4]Medicine, Univ of Miami, Miami, FL; [5]Medicine, Hofstra North Shore, New Hyde Park, NY.*

Background: We created an online homage to the Men's College Basketball Tournament to teach about 8 areas of nephrology. The teaching was integrated into a game where participants tried to predict winners of head-to-head match-ups between nephrology concepts. The authors provided editorial content to provide context and background to guide participants as well as rationale to explain the winners of each match-up.

Methods: The tournament was announced and hosted on the blog eAJKD.com. Signing up for the contest and predicting the winners was done via a third-party site designed to host similar contests. Twitter, blog posts, and e-mails were used to publicize the contest and educational material. We registered the hashtag #NephMadness in order to track Twitter discussions about the contest. We also tracked web site traffic.

Results: The contest was composed of 64 nephrology concepts, distributed across 8 subjects. The 8 core subjects were: toxins, hypertension, dialysis, regeneration, AKI, electrolytes, kidney stones and biologics. Detailed, evidence-based, referenced descriptions, for each concept were published to the blog by select content experts. Concurrent with the Men's College Basketball Tournament, the field of 64 concepts was narrowed in a progressive elimination pattern until a single winner remained. The contest attracted 273 entries. 160 were from doctors or medical students (93 from U.S. medical schools, 68 from international schools). Participants came from 23 countries however 79% were from the U.S. We tracked 1,448 tweets from 160 unique accounts, providing 1.9 million impressions on Twitter using the hashtag #NephMadness.

Conclusions: The social media campaign was successful in attracting people to interact and learn about nephrology. Traffic to the website, the blog of the AJKD, was the highest in its history by a wide margin. Increased employement of social media and educational games could provide a unique portal for improving medical education.

SA-PO662

Inter-Rater Reliability of the Inter-Professional Collaborator Assessment Rubric (ICAR) during Haemodialysis Simulation Maury N. Pinsk,[1,2] Andrew Reid.[3] *[1]Pedaitrics, Univ of Alberta, Edmonton, AB, Canada; [2]Pediatric Nephrology, Stollery Children's Hospital, Edmonton, AB, Canada; [3]ESIM Provincial Simulation Centre, Alberta Health Services, Edmonton, AB, Canada.*

Background: Haemodialysis is a multidisciplinary therapy that involves interaction between physicians and nursing staff. Postgraduate programs excel at teaching the medical expert roles of dialysis, but the interaction on multidisciplinary teams is less effectively assessed, and even less frequently taught. To meet the objectives of competency based learning and assessment, we built a high fidelity haemodialysis simulator for the purpose of training physicians on rare and life threatening dialysis complications, noting that the simulation offers an opportunity to assess multidisciplinary communication. The ICAR is a validated instrument for assessing team dynamics. We piloted this instrument during haemodialysis simulation to assess inter-rater reliability (IRR) and content validity of each instrument item.

Methods: Fifteen consenting adult and paediatric trainees participated in five simulations using a nursing confederate. A physician and a nurse observing the simulation exercises scored the 31-item ICAR independently. Scores for each item during each of the simulations were compared using kappa statistics for IRR, and items were identified with moderate agreement ($0.4 \leq k < 0.7$), weak agreement ($0 \leq k < 0.4$), and no agreement ($k < 0$).

Results: The 31-item ICAR instrument was assessed as cumbersome to use due to its length. Three items pertaining to patient interactions were deemed not applicable in the context of the scenarios where the patient is in crisis and non-communicative. Six items had moderate IRR and three items had low IRR. Twenty-two items did not perform reliably in the simulation environment.

Conclusions: We developed a high fidelity simulator for haemodialysis, and devised an abbreviated ICAR assessment tool that is applicable and reliable in assessment of inter-professional interactions. Scoring by a multidisciplinary team supports content validity to the use of ICAR in haemodialysis simulation. The shortened form is less cumbersome to use than the full length instrument, but requires prospective assessment of usability.

Funding: Clinical Revenue Support

SA-PO663

Are We Losing Important Patient-Doctor Interaction with Increasingly Online Clinics? Rauri A. Clark,[1] Anna Murray,[1] Mary McHugh,[1] John Andrew Sayer,[2] Iain Moore.[1] *[1]Renal Unit, City Hospitals Sunderland, United Kingdom; [2]Inst of Human Genetics, Newcastle Univ, United Kingdom.*

Background: Our study was prompted by patient reaction to increased computer use in clinic for documentation, blood work and investigations. After consultation nursing colleagues received comments from patients such as, "The doctor spent more time looking at the computer screen than me". We investigated whether this was accurate.

Methods: We asked: 1. Do we spend more time looking at the computer than the patient? 2. Do online clinic records have a detrimental effect on patient time? 3. Does computer screen position affect contact time? We studied nephrology clinics performed by the same nephrologist in 1 week, splitting clinics into 2 groups based on whether online records were part of the consultation. Two timers were used, 1 recording patient contact time, the other computer contact time. Patient contact time was defined as writing notes, examining and talking to the patient. Computer contact time was defined as time spent looking at the screen, searching for information and order entry. The angle between the patient, doctor and computer was calculated.

Results: Online record use increased computer time to the detriment of patient time by a mean 1.4 minutes per consultation. 1. At no point in consultation did the doctor spend longer looking at the computer than the patient. In online clinics, 30.2% of time was spent looking at the screen. 2. Patient contact time for clinics with online records was reduced by 20.6%. 3. There was no common positioning of the computer screen at clinic; screen position did not affect patient contact time. Angle of computer from patient ranged 54 to 135 degrees.

Conclusions: We highlight a problem with increasing online records and patient satisfaction in healthcare. Perceptions of how long the doctor spends on the computer did not correlate with actual time spent. However, perceptions need investigation. We are in danger of alienating patients by 'ignoring' them at clinic in favour of a screen. Research needs to be done into the best positioning of the computer for optimum patient contact and satisfaction. We must maintain a patient-centred approach and adjust practice to electronic records.

SA-PO664

The Association of Health Literacy with Patient Understanding of Kidney Test Results Through an Online Health Portal Stefanie L. Puher,[1] Andrea Lynn Berger,[2] Maria C. Bermudez,[1] Alex R. Chang,[1,2] William DiFilippo,[1] Jamie Alton Green.[1,2] *[1]Nephrology, Geisinger Medical Center, Danville, PA; [2]Center for Health Research, Geisinger Medical Center, Danville, PA.*

Background: The use of online health portals has the potential to increase patient engagement in care; however, little is known about the use of online health portals by patients with low health literacy and how well they understand electronic health information.

Methods: We administered an investigator-designed survey about patient understanding of kidney test results through an online health portal to patients with chronic kidney disease (CKD) stages 3-5 who attended at least 1 nephrology clinic, were active portal users, and had viewed test results online. The survey consisted of 29 knowledge questions based on published educational content. Health literacy was assessed using the Brief Health Literacy Screen (BHLS), a validated 3-item self-reported screening instrument.

Results: Out of 1,957 patients sent the survey, 512 completed the survey. The mean age was 66 ±11, 50% were male, 97% were white, 43% had a high school or lower level of education, and 17% had low health literacy. Patients with low health literacy had poorer understanding of their kidney test results (average test score 57.4% versus 64.3%, p<0.001), even when adjusting for age, gender, educational level, number of nephrology visits, CKD stage, use of educational resources, and number of portal logons in past 30 days. Compared with patients with adequate health literacy, patients with low health literacy who viewed their test results online were more likely to report that they need help understanding their test results (p<0.001) and are not sure what to do with the information (p<0.001).

Conclusions: A significant number of kidney patients with low health literacy are seeking use of online health portals to better manage their health. Despite this, patients with low health literacy may have difficulty understanding their test results online and may need tailored educational content and tools to maximize their involvement in care.

SA-PO665

Intensive Education to Chronic Kidney Disease Patients: Benefits on Glomerular Filtration Rate Decline Mario Prieto Velasco1, Benjamin De Leon Gomez, Jose Edgardo Gonzalez Arregoces, Igor Romaniouk Jakovler, Elena Astudillo, Jorge Estifan Kasabji, Aranzazu Sastre, Cristina Lucas. *Nephrology, Complejo Asistencial Univ León, León, Spain.*

Background: We implemented a program for intensive CKD patients education to educate and motivate the patients (MDRD < 20 ml/m) to take part in the therapeutic decisions and treatment election.

Methods: Patients with a MDRD < 20 ml/min are offered to be included in the program, voluntarily, from a pre-dialysis clinic. Educational methodology: multidisciplinary pedagogical group education. The multidisciplinary team is formed by nephrologist, nurses, pharmacist, nutritionist, psychologist, physiotherapist, social service, mentor patients and others, who teaches in 90 minutes sessions every two weeks, after hours, 3 topics related to the disease in every session. The group is composed by 10 CKD patients and one relative/patient. Throughout 8 sessions, twice a year.

Results: > 60 patients enrolled. Evaluation using a satisfaction survey was made (9,6 over 10). Initial-final knowledge survey (initial score of 6,9± 1,18 point and final 9,3 ± 0,23 points; p=0,004). Anxiety state survey at the beginning and at the end of the course (40% of the patients with less anxiety, 36% same as at the beginning and 24% more anxious toward the end). The mean loss of GFR in comparison with the control group, without intervention was 0,28 ± 0,27 ml/month versus 0,62 ± 0,6 ml/month; p=0,009). Renal Replacement Therapies (RRT) elected by patients were HD 45,7%, PD 40% and 13,4% transplant.

Conclusions: The "CKD School" is highly satisfactory for the patient, it helps to improve the knowledge about the disease, it might reduce the anxiety and it reduces the ratio of GFR loss. It also helps to improve transplantation as well as home therapies as first RRT. And might help, to the medical and non-medical staff to have a wider view of the problem, and a more satisfactory work.

SA-PO666

Parent-Child Dyads Preferred Platforms to Learn about Chronic Kidney Disease Ali Annaim,[1] Sarah Elizabeth Cohen,[1] Jessica L. Ryan,[1] Anthony Viera,[2] Rebecca M. Ferris,[3] Sofia Ocegueda,[1] Maria E. Ferris.[1] *[1]UNC Kidney Center, Univ of North Carolina Chapel Hill, Chapel Hill, NC; [2]Dept of Family Medicine, UNC School of Medicine, Chapel Hill, NC; [3]Student, Amercian Univ, Washington DC.*

Background: Chronic Kidney Disease (CKD) is a condition that places a large degree of responsibility on patients and parents/caregivers because of the need to manage several medications, diet and complex medical procedures.

Methods: We performed focused interviews with children and adolescents who have CKD and their parents/caregivers at the University of North Carolina Kidney Center Pediatric Nephrology Clinic. We asked these parent-child dyads to identify their preferred sources of information to learn about CKD. Informed consent or assent was obtained, and the twice reviewed recording transcriptions were analyzed qualitatively using the Atlas T.i software.

Results: We enrolled 22 parents/caregivers (9 fathers and 13 mothers) and their children. The children's characteristics were: mean age 14 (±3) years; 23% Hispanic; 27% Caucasian; 50% African-American; 36% had private insurance; 45% were males. Their disease characteristics were: mean CKD stage 3 (range 2-5); 23% transplant; mean age at diagnosis was 9 (± 5 years); mean percentage life with disease was 38% (±32%); and the mean number of medications was 8 (±4). The most common themes cited by parents and their children are depicted in Table 1.

Themes	Parent	Child
Preferred source of information	Provider (96%), Internet (68%)	Provider (91%), Internet (36%), Parents (41%)
Response to diagnosis	Shock, feeling overwhelmed	Shock and Fear
Strategies to manage condition	Habit and Instinct	Pillboxes, alarms, Schedules

Conclusions: Providers are the preferred source of information about CKD for parents of children with CKD, followed by the internet. For children with CKD, their providers, followed by their parents are the preferred sources of information on their disease. While the parents found themselves in a sense of crisis when their child was diagnosed with CKD, the children found themselves relying on the parents for information and understanding of their situation.

SA-PO667

Shared Decision-Making and Dialysis Modality Selection in Adult Patients Living with Chronic Kidney Disease Ana Paula Rossi,[1] Fahima Nasreen,[1] Anna C. Cloutier,[2] Paul K. Han,[2] Robert Zimmerman.[1] *[1]Nephrology, Maine Medical Center, Portland, ME; [2]Center for Outcomes Research and Evaluation, Portland, ME.*

Background: For most patients with chronic kidney disease (CKD), the mode of dialysis is a preference-sensitive decision. Decision aids (DA) have been created to facilitate informed preference-sensitive decisions. The goal of this study was to determine the efficacy of a DA in improving informed decision making about dialysis modality in CKD patients.

Methods: Single center randomized controlled trial of patients with CKD stage IV/V randomized to DA or standard care (SC). At baseline and after receiving the allocated intervention in the DA arm, or six months later in the SC arm, participants completed surveys assessing several primary outcomes: CKD and dialysis-specific knowledge (14-item questionnaire), decisional conflict, and preparation for decision-making (PDM). Pre-post differences in outcome variables were compared using x^2 test and t-tests.

Results: Of 55 randomized patients, 28 completed the study (14 subjects per arm). Participants were 52% male, had a mean age of 67.2 years, eGFR of 18.4 mls/min/1.73m^2, and duration of nephrology care of 7.4 years. At baseline the percent of correct answers in the knowledge questionnaire was 64.3% for the SC and 61.4% for the DA arm (p=.7). At follow-up knowledge score improved by 20.7% in the DA arm but only by 7.9% in the UC arm (p=.05). There were no differences in the overall decision conflict scale (DCS); however, scores in the informed subscale of the DCS were marginally better in the DA arm (mean score 9.5 ±19.3 for DA versus 25.8 ±34.5 for UC; p=.1; [0–100 scale, 0 = feels extremely informed, 100 = feels extremely uninformed]). Patients in the DA arm also demonstrated high scores on the PDM scale, and reported that the DA was quite effective in preparing them for dialysis selection (mean score 77.7 ±20.9; 0–100 scale, higher scores indicate higher perceived level of PDM).

Conclusions: A dialysis-specific DA was efficacious in improving CKD patients' knowledge about their disease and dialysis options. Further testing is needed to determine if this intervention will help CKD patients make better informed decisions about dialysis modality.

Funding: Private Foundation Support

SA-PO668

An Educational Project to Improve Living Kidney Donor Transplant Rates Marie A. Sosa, Paula Ann Bigwood, Jahan Montague, Ellen Wells. *Nephrology, UMass Memorial Health Care, Worcester, MA.*

Background: Living kidney donor transplant (LDKT) is the optimal treatment for individuals with End Stage Renal disease (ESRD). Despite the benefits of LDKT, living donor transplant rates remain stagnant. Prior research points toward inadequate education of potential recipients as an obstacle to undergoing LDKT. We developed an educational program to help patients with ESRD improve their knowledge and identify barriers to LDKT and learn strategies to communicate their need.

Methods: The UMass Memorial Health Center (UMMHC) transplant department's database was used to identify 30 ESRD patients on the waiting list for Kidney transplant. Using a previously validated survey, we measured barriers to living kidney donation in our patient population. We then conducted a 90 minute 1:1 educational session with each patient which included information about the benefits of living kidney donation as well as communication tools that can assist in finding a living kidney donor. We recorded the number of living donor referrals, evaluations, and transplants pre and post intervention.

Results: The pre education survey identified several barriers to LKDT: knowledge deficit, fear, guilt, and lack of opportunity of having family and friends who could potentially donate a kidney. The educational curriculum was effective in improving knowledge regarding risks of donation and how to ask someone to donate a kidney. Post education, 73% of the participants knew how to ask someone to donate a kidney compared to pre education 40%. Donor referrals improved in the six months of the project; 158 donor referrals compared to the previous six months 117. Seven study subjects were successful at recruiting donors. Of the 7 subjects who recruited a donor, 3 have potential donors being evaluated, and 1 subject has undergone LDKT. LKDTs improved from 8 in FY 2013 compared to YTD 2014 (17).

Conclusions: An educational program that addresses risks of donation and how to communicate the need for a LDKT is effective in improving the ability of ESRD patients to recruit potenital donors. This project's results demonstrate an improvement in living donor referrals. A longer term follow up is needed to assess an impact in LDKT Rates.

SA-PO669

A Medical Student Web-Based Curriculum for Renal Pathology; Development, Optimization, and Assessment of the Teaching Tool

Vanesa Bijol,[1,3] Cathryn J. Byrne-Dugan,[1,3] Melanie P. Hoenig.[2,3] *[1]Pathology, Brigham and Women's Hospital, Boston, MA; [2]Internal Medicine, Div of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: The concept of the "flipped classroom" has gained increasing popularity in recent years. The need for new and exciting curricula is particularly important for renal pathophysiology, as nearly 80% of surveyed medical students report that renal pathophysiology courses are too complex, lack relevance, or are simply uninteresting. This early discouragement may contribute to the dramatic decline in career interest for nephrology that has become evident in recent years. Our goal was to promote active learning by adding web-based learning tools to the already existing renal pathology curriculum in our renal pathophysiology course.

Methods: The online renal pathology curriculum consisted of an open access online textbook, short web-based concept videos, and an online quiz system. At the end of the course, we assessed students' performance on the final examination and administered general course evaluation and an additional survey through SurveyMonkey™ to assess utilization and satisfaction with the curriculum. Quantitative analysis of the tool use was available for the quiz system.

Results: 82.6% of the students used the quiz system. The greatest usage frequency was on the day before the final exam. Students repeated interactive and more challenging quizzes more often. Although the pathophysiology portion was not represented in the quiz, students who used the pathology quiz had comparable results in both pathology and pathophysiology portions of the final exam. Students that did not use the pathology quiz did equally worse in both pathology and pathophysiology on the final exam. The quizzes and concept videos were evaluated as very useful learning tools by 82.5% and 51.6% of student survey responders, respectively. 89.0%, thought the quiz improved their experience with kidney pathology in this course.

Conclusions: Online renal pathology learning tools with interactive features, especially quizzes, are very well received by students and show beneficial impact on the learning experience.

SA-PO670

The Nephrology Fellows Clinical Experience Project: A Pilot Study

Sairah Sharif, Shanza Mujeeb, Nobuyuki (Bill) Miyawaki, Shayan Shirazian, Joseph Mattana. *Winthrop Univ Hosptial, Mineola, NY.*

Background: Despite the emphasis on using clinical experience as a basis for graduate medical education, little is known regarding the frequency with which specific diagnostic entities are seen by nephrology fellows nor the special cognitive challenges they pose. We carried out this pilot study to begin to assess nephrology fellow clinical experience, with the aim of eventually using this information to facilitate patient-centered education and experiential learning.

Methods: Patients from the inpatient and outpatient setting who had a nephrology consult done were included in the study. Data included demographics, admission diagnosis (for inpatients), comorbid conditions, the reason for the renal consult, and the presumed/confirmed renal diagnosis by the fellow and supervising attending nephrologist.

Results: For the inpatient sample (n=300), acute kidney injury (AKI), fluid and electrolyte abnormalities, chronic kidney disease (CKD), ESRD on dialysis, renal transplant status and hypertension (HTN) were common entities seen in contrast to pregnancy-related disorders and vasculitis. Sixty cases were determined to be especially challenging from a diagnostic and or therapeutic perspective. For the outpatient setting (n=50), conditions seen included stage 3 and 4 CKD, glomerulonephritis and nephrotic syndrome, fluid electrolyte disorders, kidney transplant status and hypertensive disorders among others. Our fellowship program has an intervention to promote post-hospital discharge follow up of patients who had AKI by the same fellow who saw them in the hospital. Of note, this accounted for 11% of patients seen.

Conclusions: These pilot results from our ongoing study reveal a rich spectrum of fellow clinical experience and suggest that it is amenable to quantitative assessment. By developing a more comprehensive portfolio of nephrology fellow clinical experience this may help program directors restructure their curriculum, especially to incorporate new experiential learning approaches as well as to develop supplemental learning venues for those clinical experiences which occur at a low frequency and/or pose unique challenges.

SA-PO671

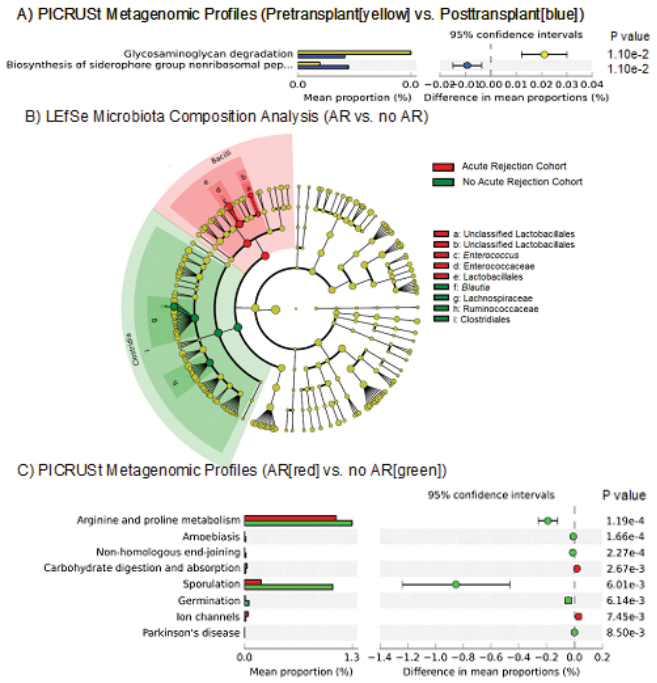
Characterization of the Gut Microbiota and Its Predicted Metagenomics in Kidney Graft Recipients

John R. Lee,[1] Thangamani Muthukumar,[1] Darshana Dadhania,[1] Lilan Ling,[2] Eric Pamer,[2] Manikkam Suthanthiran.[1] *[1]Medicine, Weill Cornell Medical College, New York, NY; [2]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Immunosuppressive therapy, in a similar fashion to antibiotics, has the potential to perturb gut microbial community structure and composition. Such alterations, however, have not been well characterized in recipients of renal allografts.

Methods: We prospectively enrolled 26 kidney transplant recipients and collected 85 sequential fecal specimens during the first 3 months of transplantation. We characterized the microbiota in the 85 fecal specimens by PCR amplification of the 16S rRNA V4-V5 variable region and deep sequencing of the amplified PCR product using the Illumina MiSeq platform. We utilized the PICRUSt tool to predict the metagenomic profiles and we investigated whether the fecal microbiota or metagenomic profiles change after kidney transplantation and whether these were associated with a biopsy confirmed acute rejection.

Results: The relative density of Proteobacteria was higher in the 2 week post-transplant fecal specimens compared to matched pre-transplant specimens (N=5, P=0.04, Wilcoxon Signed Rank test). PICRUSt revealed distinct metagenomic KEGG pathways that were different from pre-transplant and post-transplant fecal specimens (Figure 1A, Paired t test). The patients who developed acute rejection (AR, n=3) had significantly different microbial composition than those who did not (No AR, n=23) by linear discriminant effect size (LEfSe) method (red indicating higher taxon abundance in AR patients; green indicating higher taxon abundance in patients without AR) (Figure 1B). Several distinct metagenomic KEGG 3 pathways were associated with AR (Figure 1C, Welch's t test).



Conclusions: We identified significant alterations in the gut microbiota and the predicted metagenomes after kidney transplantation.

SA-PO672

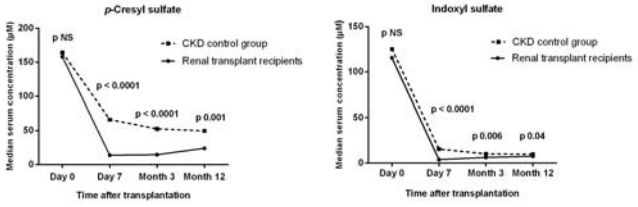
The Impact of Renal Transplantation on Microbiota Derived Uremic Retention Solutes

Ruben Poesen, Katrien De Vusser, Pieter Evenepoel, Dirk R. Kuypers, Maarten Naesens, Bjorn Meijers. *Nephrology, Univ Hospitals Leuven, Belgium.*

Background: The gut microbiota contributes substantially to uremic retention solutes accumulating in CKD. p-Cresyl sulfate and indoxyl sulfate are representatives of this group of solutes and associate with adverse outcome. Although it can be expected that serum levels of these metabolites decrease after renal transplantation, this has not been studied to date. In addition, whether serum levels of p-cresyl sulfate and indoxyl sulfate in renal transplant patients are quantitatively different than in regular CKD patients is unknown.

Methods: A cohort of 51 CKD patients was prospectively followed from time of transplantation to 12 months post transplantation. Serum levels of p-cresyl sulfate and indoxyl sulfate were determined at time of transplantation, day 7, month 3 and month 12 post transplantation. At each time point, serum levels were compared with CKD patients matched for age, gender, BMI, diabetes, dialysis modality/vintage at time of transplantation or renal function at other time points, and biochemistry.

Results: Serum levels of p-cresyl sulfate and indoxyl sulfate substantially decreased after renal transplantation ($P < 0.0001$). When compared to CKD control patients, serum levels of both solutes were still significantly lower in renal allograft recipients at each time point (Figure 1). Additional analyses demonstrated lower urinary excretion rates of microbial metabolites in renal transplant patients ($P < 0.0001$).



Conclusions: Microbiota derived uremic retention solutes substantially decrease after renal transplantation. In addition, serum levels of these solutes are lower when compared to regular CKD patients, suggesting an influence of renal transplantation or

immunosuppressive drugs on gut microbial metabolism. Whether these metabolites are also associated with adverse outcome in renal transplant patients needs further investigation.

Funding: Government Support - Non-U.S.

SA-PO673

Molecular Features of Primary and Secondary Focal Segmental Glomerulosclerosis After Renal Transplantation Michelle L. Lubetzky,[1] Valeria Mas,[2] Enver Akalin.[1] *[1]Nephrology, Montefiore Medical Center, Bronx, NY; [2]Translational Genomics Transplant Laboratory, U of Virginia.*

Background: The intragraft gene expression profiles of focal segmental glomerulosclerosis (FSGS) after renal transplant (KTx) have not been described.

Methods: All for-cause renal allograft biopsies with a diagnosis of FSGS were studied using Affymetrix HuGene 1.0 ST expression arrays and compared to normal KTx biopsies. Patients were divided into 3 groups: Stable allograft function (n=11), primary/recurrent FSGS (n=6) who either had a diagnosis of FSGS in the first 3 months after KTx and/or collapsing FSGS on biopsy and secondary FSGS (n=11) who had a diagnosis of FSGS more than 1 year after KTx.

Results: A total of 272 probe sets were differentially expressed in primary/recurrent FSGS biopsies (FDR ≤ 0.05). Top canonical pathways included dendritic cell maturation, granulocyte adhesion and diapedesis, TREM1 signaling and role of macrophages, fibroblasts and endothelial cells ($p<0.01$). Analysis of upstream regulators showed activation of lypopolysacharide, interferon gamma (IFN), tumor necrosis factor (TNF), interleukin1B, toll-like receptor (TLR)-4, CSF2 ($p<0.01$). A total of 467 probe sets were differentially expressed in secondary FSGS biopsies (FDR≤ 0.05). Top canonical pathways included dendritic cell maturation, altered T and B cell signaling, CD28, and iCOS-iCOSL signaling in helper T cells, and T cell receptor and PKCθ signaling in T lymphocytes, and PI3K signaling in B lymphocytes. Analysis of upstream regulators showed TNF activation, including lymphocyte activation, cell movement of lymphocytes and mononuclear cells. When comparing overlapping probe sets between the two groups, 82 were common to both analyses, 190 were unique to secondary FSGS, and 384 were unique to primary FSGS. In context of the overall analysis, it appears that these unique genes demonstrate innate immune response is critical for primary/collapsing FSGS while cellular/adaptive immune response is more involved in secondary/late FSGS.

Conclusions: Molecular analysis of biopsies with FSGS revealed significant immune activation, more specifically an innate immune response in primary FSGS as compared to an adaptive response in secondary FSGS.

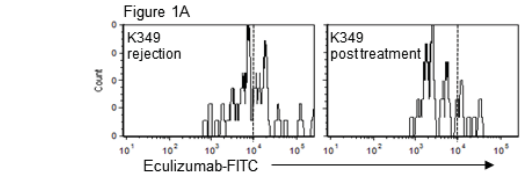
SA-PO674

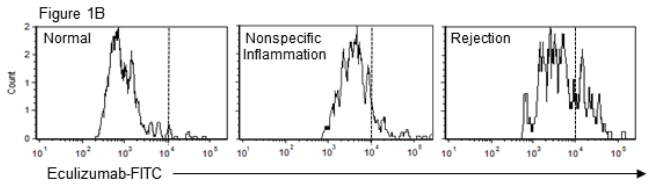
Eculizumab Binding to Human Renal Microvascular Endothelial Cells: Identifying New Therapeutic Targets in Kidney Biopsies Kimberly A. Muczynski, Nicolae Leca, Niamh Kieran, Arthur E. Anderson, Susan K. Anderson. *Univ of Washington, Seattle, WA.*

Background: Complement inhibition agents, such as eculizumab, offer a new approach to treating inflammatory kidney disease. The contribution of complement to different renal pathologic conditions and the therapeutic applications of complement inhibition remain unclear. We investigated eculizumab epitope binding in human kidney biopsies using our cytometry-cytokine detection protocol.

Methods: A direct FITC conjugate of eculizumab was made for use in multicolor flow cytometry. Human Ig-FITC was used as an isotype control. Renal biopsy samples were prepared for cytometry according to our previously reported protocol.

Results: Renal microvascular endothelial cells (RMEC), defined as HLA-DR+, CD34+, CD45-, bound eculizumab under conditions of acute cellular rejection and the level of binding was less following treatment (Figure 1A). RMEC from transplanted kidneys with non-specific inflammation showed a slight shift in eculizumab binding histograms toward the positive direction, but not to the extent of rejecting kidneys (Figure 1B, normal versus nonspecific, p = 0.04; normal versus rejection, p = 0.03).





RMEC from a patient treated with eculizumab for C3 glomerulopathy had minimal eculizumab binding detected with the assay. Tubular cells (defined as CD324+, CD326+, CD45-, HLA-DR-) from native and transplanted kidneys under a variety of conditions consistently showed 8-10% of the population expressed the eculizumab epitope. Eculizumab binding to tubular cells did not differ with pathology.

Conclusions: Our preliminary results of eculizumab binding to RMEC show correlation with renal pathology and may provide a surrogate marker for therapeutic applications of complement inhibition.

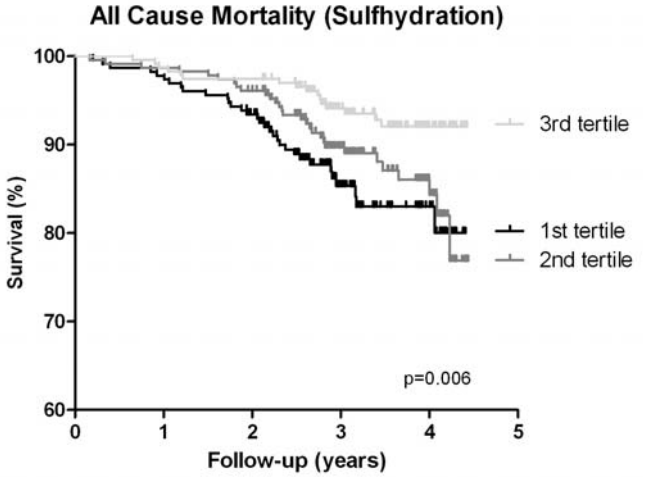
Sulfhydration Is Associated with Patient and Graft Survival in Renal Transplant Recipients Anne-Roos S. Frenay,[1] Martin H. De Borst,[2] Matthias Bachtler,[3] Charlotte A. Keyzer,[2] Else Van den Berg,[2] Stephan J.L. Bakker,[2] Harry Van Goor,[1] Andreas Pasch.[3] *[1]Pathology and Medical Biology, Univ Medical Center Groningen, Netherlands; [2]Nephrology, Univ Medical Center Groningen, Netherlands; [3]Nephrology, Hypertension and Clinical Pharmacology, Univ Hospital Bern, Inselspital, Switzerland.*

Background: Urinary H_2S metabolites beneficially associate with survival in renal transplant recipients (RTR; van den Berg et al. JASN 2014). Protective effects of H_2S can be mediated through sulfhydration (SH): post-translational modification of reactive cysteine residues of targeted proteins, which modulates protein function. We prospectively investigated whether SH is favorably associated with patient and graft survival in RTR.

Methods: Serum SH (corrected for total protein [g]) was quantified in 697 stable outpatient RTR (57% male, 53±13 yr), with a functioning graft for ≥1 yr; transplant vintage 5.4 [1.9-12.1] (median[IQR]) yr. Determinants of SH were evaluated with multivariate linear regression models. Associations between SH and mortality or graft failure risk were assessed with multivariabele Cox regression analyses.

Results: SH (mean 1.83±0.67 μM/g) correlated with the serum and urinary H_2S metabolite thiosulfate ($p<0.01$). In multivariate models, eGFR and serum albumin were positively associated with SH. Male gender, serum cholesterol and calcineurin inhibitor or sirolimus use were inversely associated with SH (model $R^2=0.26$). During follow-up (3.1 [2.7-3.9] yr) 79 (11%) patients died and 45 (7%) patients developed graft failure. SH was inversely associated with all-cause mortality (HR 0.63 [95% CI 0.49-0.82]) and graft failure (HR 0.45 [0.32-0.63]), both $p<0.001$ per SD increase and independent of Framingham risk factors and eGFR.



Conclusions: Increased SH is associated with an improved patient and graft survival in RTR. SH modification may improve long-term outcomes post KTx.

SA-PO676

Comparable Renal Function in De Novo Kidney Transplantation with Prolonged-Release Tacrolimus + MMF/Sirolimus: Initial Results from the ADHERE Study Oleg Rummo,[1] Mario Carmellini,[2] Lionel Rostaing,[3] Rainer Oberbauer,[4] Maarten H.L. Christiaans,[5] Frank Lehner.[6] *[1]RSPC for Organ and Tissue Transplantation, Belarus; [2]Univ of Siena, Italy; [3]Toulouse Univ Hospital, France; [4]Medical Univ of Vienna, Austria; [5]Maastricht Univ Medical Centre, Netherlands; [6]Hannover Medical School, Germany.*

Background: ADHERE: 52-week, Phase IV, randomized, open-label study to investigate renal function with once-daily, prolonged-release tacrolimus (QD) + MMF/sirolimus.

Methods: All patients received tacrolimus QD (initial dose: 0.2mg/kg/day) + MMF (Days 0–27). Patients were randomized on Day 28: tacrolimus QD + MMF (Arm 1) or tacrolimus QD (reduced dose from Day 42) + sirolimus (1mg/day) (Arm 2). Steroids were administered throughout. Target trough levels: Day 0–14: 10–15ng/mL; Day 15–41: 8–12ng/mL; Day 42–365 (Arm 1): 6–10ng/mL; Day 42–365 (Arm 2): 4–5ng/mL. Primary endpoint (full-analysis set; FAS): measured GFR (mGFR; iohexol clearance) at Week 52. Secondary endpoints (intent to treat; ITT) included: Kaplan–Meier analyses of composite efficacy failure (defined as graft loss/early patient withdrawal), patient death, and biopsy-confirmed acute rejection (BCAR).

Results: ITT: 362, 368 in Arms 1–2; 730 randomized. FAS: 287, 282 in Arms 1–2. Baseline characteristics were comparable. Tacrolimus trough levels were comparable until Day 42 and remained lower in Arm 2 after dose reduction. At Week 52, mean (SD) trough levels were: 7.11ng/mL (2.27) and 5.17ng/mL (1.78) in Arms 1–2. mGFR at Week 52 was 40.7 versus 41.8mL/min/1.73m² for Arm 1 versus 2 (1.02; –1.39 to 3.44; p=0.405). Secondary endpoints are presented in the table. A higher incidence of patients in Arm 2 discontinued due to adverse events (AEs).

%	Arm 1 (n=362)	Arm 2 (n=368)	P value Wilcoxon–Gehan
Composite efficacy failure	11.5	18.2	0.0024
- Graft loss	2.9	2.2	0.6757
- Early patient withdrawal	5.2	14.4	<0.001
Patient death	1.1	0.3	0.1769
BCAR (post-randomization)	4.3	3.6	0.8916

Conclusions: Comparable mGFR, incidence of graft loss, mortality and BCAR were reported with tacrolimus QD + MMF/sirolimus at Week 52. A higher incidence of patients discontinued from the tacrolimus QD + sirolimus arm due to AEs.

Funding: Pharmaceutical Company Support - The ADHERE study was sponsored by Astellas Pharma Europe Ltd. Editorial assistance was provided by iS Health and funded by Astellas Pharma Europe Ltd.

SA-PO677

Serum Levels of Soluble Klotho Are a Promising Marker of Graft Function After Kidney Transplantation Makoto Tsujita,[1] Tomoki Kosugi,[2] Waichi Sato,[2] Shoichi Maruyama,[2] Yoshihiko Watarai.[1] *[1]Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan; [2]Nephrology, Nagoya Univ School of Medicine, Japan.*

Background: Fibroblast growth factor 23 (FGF23) is known to predict graft function after kidney transplantation, but the roles of Klotho and vitamin D still remains unknown. The aim of this study is to identify whether serum Klotho and vitamin D are predictive markers of graft function.

Methods: Consecutive 46 patients were enrolled in this retrospective obsevational study at our hospital. Serum FGF23, soluble Klotho levels and 25-hydroxyvitamin D (25-OHD) levels, estimated glomerular filtration (eGFR), and other clinical parameters at 1 year and eGFR at 3 year after kidney transplantation were measured.

Results: Patients' characteristics and clinical data were shown in Table 1.

Age (years)	51.8±11.6
Gender (male/female)	31 / 15
DMN / non DMN	9 / 39
Systoric blood pressure (mmHg)	127.0±11.5
Diastoric blood pressure (mmHg)	77.5±7.7
Corrected Calcium (mg/dl)	9.6±0.7
Phosphorus (mg/dl)	3.4±0.4
iPTH (pg/ml)	110.0±133.3
T-cho (mg/dl)	189.7±28.98
TG (mg/dl)	122.5±65.6
HDL (mg/ml)	62.8±19.4
LDL-C (mg/ml)	96.0±17.3
Klotho (pg/ml)	535.9±171.6
FGF23 (pg/ml)	60.1±21.1
25-OHD (ng/ml)	7.7±4.4
eGFR at 1 year (ml/min/1.73m2)	43.0±12.8
eGFR at 3 year (ml/min/1.73m2)	43.2±14.3
Use of Cycrosporine / tacrolimus (n)	27 / 19
Use of mycophenolate mofetil (n)	45
Use of ARB (n)	33
Use of statin (n)	25

Serum soluble Klotho (pg/ml), FGF23 (pg/ml) and 25-OHD (ng/ml) levels were 535.9±171.6, 60.1±21.1, 7.7±4.4 respectively. ΔeGFR (eGFR at 3 year - eGFR at 1 year) (ml/min/1.73m²) values were 0.1±5.6. Serum soluble Klotho levels were associated with ΔeGFR (r = 0.38 *P* =0.008). Serum soluble Klotho / FGF23 ratio values were also associated withΔeGFR (r = 0.32 *P* =0.03), but serum FGF23 and 25-OHD levels were not associated (r = 0.04 *P* =0.80, r = 0.01 *P* =0.94 respectively).

Conclusions: Serum levels of soluble Klotho might be a promising marker of graft function after kidney transplantation, compared to FGF-23 and 25-OHD.

SA-PO678

Prediction of Calcium and Phosphorus Disorders in the Early Stage After Kidney Transplantationon on the Basis of Pretransplant Fibroblast Growth Factor 23 Levels Makoto Tsujita, Yoshihiko Watarai. *Transplant Surgery, Nagoya Daini Red Cross Hospital, Aichi, Japan.*

Background: Hypercalcemia and hypophosphatemia are common complications of kidney transplantation. Previous studies have shown that pretransplant full-length fibroblast growth factor (FGF) 23 levels predict phosphorus (Pi) metabolism after kidney transplantation; however, it remains unknown whether they are predictive of post-transplant calcium (Ca) metabolism.

Methods: Seventy-one consecutive patients were enrolled in this study at Nagoya Daini Red Cross Hospital, Japan, from 2012. Parameters of corrected Ca and Pi metabolism, including FGF23 and intact parathyroid hormone (iPTH) levels, were measured before (pre) and 6 months (6m) after kidney transplantation.

Results: Patients' characteristics and clinical parameters of this study are shown in Table 1.

Age (years)	50.6±12.7
Gender (male/female)	35 / 36
DMN (diabetic nephropathy) / non DMN	33 / 38
PEKT (preemptive kidney transplantation) / non PEKT	35 / 36
cCa pre (mg/dL)	9.1±0.8
Pi pre (mg/dL)	5.5±1.0
iPTH pre (pg/dL)	260.9±19.2
cCa 6m (mg/dL)	9.8±0.6
Pi 6m (mg/dL)	3.4±0.6
iPTH 6m (pg/dL)	102.9±51.7
FGF23 pre (pg/dL)	7350.9 (793.7, 7411.5)
Ln FGF23 pre	3.4±0.7
Duration of dialysis (months)	26.5
Use of VDRA (oral)	28
Use of VDRA (iv)	5
Use of Pi binder	18
Use of Ca-containing Pi binders	24
Use of cinacalcet	6

Table 2 shows the results of this study.

Table 2 (a)
Pretransplant risk factors associated with serum Ca levels at 6 months after kidney transplantation

Ca	Coefficient	SE	t	R^2	P-value
Univariate					
age	0.01	0.006	1.81	0.05	0.08
gender (female)	0.01	0.006	1.81	0.05	0.08
DMN	−0.3	0.14	−2.2	0.07	<0.05
PEKT	0.54	0.13	4.22	0.31	<0.001

age	−0.002	0.005	−0.36		0.72
gender (female)	0.08	0.11	0.71		0.48
DMN	−0.19	0.12	−1.54		0.13

Table 2 (b)
Pretransplant risk factors associated with serum Pi levels at 6 months after kidney transplantation

P	Coefficient	SE	t	R^2	P-value
Univariate					
age	−0.003	0.006	−0.41	0.003	0.68
gender (female)	0.25	0.15	1.7	0.04	0.1
DMN	0.112	0.15	0.8	0.009	0.43
PEKT	−0.2	0.15	−1.36	0.03	0.18
cCapre	−0.23	0.09	−2.73	0.1	<0.05
Pipre	−0.14	0.07	−1.99	0.05	0.05
iPTHpre	−0.0001	0.0003	−0.23	0.0008	0.81
LnFGF23	−0.43	0.11	−4.24	0.21	<0.001
multivariate				0.26	
age	0.005	0.006	0.8		0.43
gender (female)	0.25	0.13	1.87		0.07
cCapre	−0.1	0.1	−0.99		0.33

Multivariate linear regression analysis revealed that higher FGF23 levels before transplantation, not iPTH levels, were related to higher Ca levels and lower Pi levels at 6 months after kidney transplantation.

Conclusions: This study suggests that pretransplant FGF23 levels, not iPTH levels, are a strong predictive marker of Ca and Pi disorders after kidney transplantation.

SA-PO679

Urinary Biomarkers of Cell Cycle Arrest and Inflammation for Prediction of Dialysis or Recovery After Kidney Transplantation Timothy J. Pianta,[1] Philip Peake,[1] John W. Pickering,[2] Nicholas Buckley,[1] Zoltan H. Endre.[1] *[1]Prince of Wales Clinical School, Univ of New South Wales, Australia; [2]Medicine, Univ of Otago, New Zealand.*

Background: Prediction of allograft recovery within hours of kidney transplantation is difficult and limits the development of therapeutic strategies. Novel urinary acute kidney injury biomarkers, tissue inhibitor of metalloproteinases-2 (TIMP-2) and insulin-like growth factor-binding protein 7 (IGFBP7) predict AKI but performance in renal transplantation is unknown.

Methods: We studied 81 patients immediately after kidney transplantation. Serial urine concentrations of TIMP-2 and IGFBP7 were measured along with putative inflammatory biomarkers vascular endothelial growth factor (VEGF), macrophage migration inhibitory factor (MIF), monocyte chemotactic protein-1 (MCP-1), trefoil factor 3 (TFF3), and chemokine (C-X-C) ligand-16 (CXCL16). The utility of these biomarkers for prediction of delayed graft function (DGF, dialysis within 7 days) within 1 day of transplantation was assessed.

Results: 23 patients (28%) had DGF. At 4h after kidney reperfusion the areas under the receiver operator characteristic curve (AUC) for VEGF and [TIMP-2]*[IGFBP7] were good (AUCs > 0.80), TIMP-2, IGFBP7, and MIF fair (AUCs 0.70 – 0.79), and for MCP-1, TFF3, and CXCL-16 poor (AUC < 0.60). After adjusting for pre-operative clinical variables, anuria and the creatinine reduction ratio, integrated discrimination improvement analysis showed that only VEGF, TIMP-2, and [TIMP-2]*[IGFBP7] separately enhanced a clinical model for prediction of DGF at 4h. TIMP-2 and [TIMP-2]*[IGFBP7] also enhanced the model at 12h.

Conclusions: The cell cycle arrest marker urinary TIMP2 and the combination biomarker [TIMP-2]*[IGFBP7] predict DGF after kidney transplantation. VEGF appears to provide best discrimination very soon after transplantation. Other putative inflammatory biomarkers, MIF, MCP-1 CXCL16, and TFF3 performed poorly.

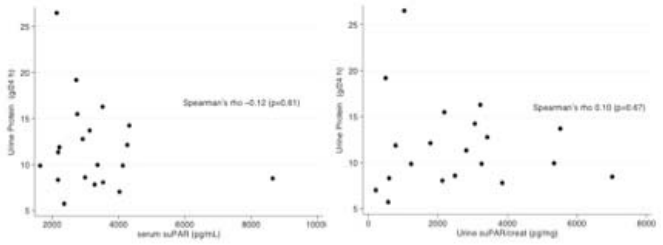
Urinary Soluble Urokinase Receptor (suPAR) Is Not Elevated in Membranous Nephropathy (MN) and Does Not Correlate with Proteinuria

Hatem Amer,[1] Fernando C. Fervenza,[2] Carlos R. Franco-Palacios,[1] Nick Voskoboev,[3] Vesna D. Garovic,[2] Andrew D. Rule,[1] Fernando G. Cosio,[1] John C. Lieske.[2] *[1]William J von Liebig Center for Transplantation and Clinical ReGeneration, Mayo Clinic, Rochester, MN; [2]Div of Nephrology and Hypertension, Mayo Clinic; [3]Dept of Laboratory Medicine, Mayo Clinic.*

Background: Serum suPAR, a proposed marker of FSGS, is elevated in a variety of renal diseases, possibly due to reduced clearance with low GFR. Conversely, elevated urinary suPAR appears more specific to recurrent FSGS. We evaluated the relationships of proteinuria to urine and serum suPAR in MN patients with preserved renal function.

Methods: Urine and serum suPAR were measured in patients with MN and preserved renal function by ELISA. suPAR levels were correlated with proteinuria and compared to levels in pretransplant specimens from patients who experienced post-transplant recurrence FSGS. Data are expressed as mean ± SD, or mean (min-max) or median (25%, 75%).

Results: Age of MN cases (N=20) was 49 ± 13 years; 17 (85%) were male. Serum Cr was 1.49 (0.8-2.3) mg/dL and CrCl 72 (30-156) ml/min. Recurrent FSGS cases (N=5) were similar in age 48±19 years and gender 4 (80%) were male. Serum Cr was higher at 5.8 (3.1-9.9) mg/dl, p <0.01 in FSGS cases.MN compared to FSGS patients had similar proteinuria (10.6 [8.4, 13.9] versus 16.2 [14.8, 20.5] g/24hrs, p=0.12), lower urinary suPAR (2338 [910, 3337] versus 5239 [3141, 5331,] p 0.04), and lower serum suPAR (3058 [2289, 3780] versus 6195 [6137, 7009], p=0.002). In MN patients, serum and urinary suPAR did not correlate with urinary protein see figure 1.



Conclusions: Urine suPAR appears to be uniquely elevated in FSGS patients compared to MN patients despite comparable proteinuria. Thus elevated urinary suPAR could potentially serve as a marker of FSGS recurrence following transplant.

SA-PO681

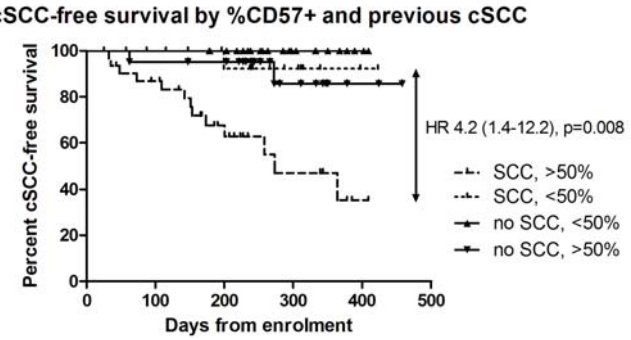
CD57 in CD8 Populations Is a Predictor of Cutaneous Squamous Cell Carcinoma Development in Renal Transplant Recipients

Matthew James Bottomley,[1,2] Paul N. Harden,[1] Kathryn J. Wood.[2] *[1]Oxford Transplant Centre, Oxford Univ Hospitals NHS Trust, Oxford, Oxfordshire, United Kingdom; [2]Nuffield Dept of Surgical Sciences, Univ of Oxford, Oxford, Oxfordshire, United Kingdom.*

Background: Cutaneous squamous cell carcinoma (SCC), the commonest malignancy in renal transplant recipients (RTR), is more aggressive and recurrent than in non-RTR. Identification of high risk RTR may allow targeted screening and intervention. In liver transplantation and non-RTR, higher numbers of CD57-positive cells are associated with increased risk of malignancy.

Methods: We conducted a case-cohort study to identify predictive immunological markers in SCC. 51 RTR with previous SCC were recruited and matched by age, sex and immunosuppression type/duration to 50 RTR without SCC. Follow-up was (median(IQR)) 252 days (190-332));isolated peripheral blood mononuclear cells were analysed using flow cytometry.

Results: During follow-up, 21 further and 2 first SCC occurred in 16 RTR. RTR with >50% CD57-positive CD8+cells were 5.9 times (95% CI: 2.3-15.5) more likely to develop SCC during follow-up than those with <50%. In those with previous SCC, >50% CD57+ was associated with a 4-fold increase in risk (fig 1). Increasing age and clinical risk score (Harwood et al, AJT, 2013) were also associated with SCC development, but on multivariate analysis an increased proportion of CD57+ cells remained independently predictive of malignancy. RTR developing SCC were universally taking azathioprine, which markedly depleted NK cells, in contrast to mycophenolate.



Conclusions: The proportion of CD8+CD57+ cells may augment the power of clinical factors to predict SCC development. Azathioprine may deplete innate anti-tumour responses, compounding this effect. Analysis of CD8 populations may allow identification of a high-risk group for SCC, who would benefit from more intensive dermatological screening and immunosuppression reduction.

Role of Circulating Fibrocytes in Chronic Allograft Dysfunction

Christine M. Ribic, Peter Margetts, Azim S. Gangji. *Medicine, McMaster Univ, Hamilton, ON, Canada.*

Background: Interstitial fibrosis and tubular atrophy (IF/TA) is often described on renal allograft biopsy and the extent of this condition correlates with transplant outcome. Fibrocytes are circulating peripheral blood cells identified by surface progenitor markers (ie CD34) and markers of mesenchymal phenotype (intercellular pro-collagen). The role of fibrocytes in chronic allograft dysfunction has not been previously evaluated.

Methods: This is a single center observational study of patients undergoing a first kidney transplant. Baseline blood was drawn before transplant, 1 month, and 3 months after transplant. Circulating fibrocyte numbers were assessed by flow cytometry. Peripheral blood mononuclear cells were labeled for cell surface CD45 and intercellular collagen I.

Results: Eleven patients have been recruited to this study and followed to 3 months post transplant. There was a significant decline in the circulating fibrocyte count from baseline (pre-transplant) to 3 months post transplant ($5.7x10^9$/L to $1.5x10^9$/L, p=0.039). Patients whose fibrocyte counts decreased between 1 and 3 months post transplant had significantly better renal function (measured by serum creatinine) compared to those whose fibrocytes increased post transplant (3 months creatinine 111 umol/L versus 136 umol/L, p=0.047).

Conclusions: This preliminary study is the first to evaluate circulating fibrocytes post renal transplant. Fibrocytes decreased significantly after transplantation. Increasing fibrocyte counts may predict worse renal function post transplant.

SA-PO683

Renal Transplantation Does Not Result in Complete Restoration of the Endothelial Glycocalyx

Carmen A. Vlahu,[1] Geertrude Struijk,[2] Hans Vink,[3] Frederike J. Bemelman,[1] Ineke Ten Berge.[1] *[1]Dept of Nephrology, Academic Medical Center, Amsterdam, Netherlands; [2]Dept of Internal Medicine, Academic Medical Center, Amsterdam, Netherlands; [3]Cardiovascular Research Inst Maastricht, Maastricht, Netherlands.*

Background: Dialysis patients have impaired glycocalyx barrier properties and increased plasma levels of glycocalyx constituents. It is not known whether renal transplantation leads to restoration of the endothelial glycocalyx (EG). Here, we investigated the state of the EG in renal transplant recipients (RTR) treated with two different immunosuppressive therapies, compared to healthy individuals (HI).

Methods: Investigations were performed in 30 stable RTR (14 receiving cyclosporine (CsA) and 16, everolimus (EVL)) and 19 HI. Plasma levels of the glycocalyx constituents syndecan-1 and hyaluronic acid (HA), and the hyaluronidase activity were measured using ELISA. The state of EG in individual blood vessels was assessed by measuring the perfused boundary region (PBR), which reflects the erythrocyte permeable part of the endothelial surface layer, by Sidestream darkfield (SDF) imaging of the sublingual microvasculature.

Results: GFR was 52.9±19ml/min/1.73m2 in RTR, and similar in CsA and EVL group(p=0.8). Plasma levels of Syndecan-1 and HA were higher in RTR compared to HI (34±20 versus 20±11ng/ml, p=0.02; 51±35 versus 21±11ng/ml, p=0.03), but hyaluronidase activity was not different in the two groups (p=0.1). Patients treated with EVL had higher levels of HA, but not of syndecan-1, and increased hyaluronidase activity compared to the CsA group (75±37 versus 25±10ng/ml, p=0.004; 36±24 versus 31±15ng/ml, p=0.8 and 31±3 versus 27±3U/ml, p=0.03). HA levels in CsA group did not differ from the HI(p=0.2). The PBR was higher in RTR compared to HI (3.3±0.3 versus 2.9±0.5µm, p=0.02) but did not differ between the two therapies (3.1±0.3 versus 3.3±0.4µm, p=0.3).

Conclusions: The high plasma levels of glycocalyx constituents and the increased PBR in the sublingual microvasculature, indicate that RTR have alterations of the endothelial glycocalyx. Since the type of immunosuppressive therapy may influence the state of the endothelial glycocalyx, these data may guide the selection of tailor made immunosuppression in the future.

SA-PO684

Effects of Structured Physical Activity Program on Serum Adipokines and Markers of Inflammation and Heart Disease in Kidney Transplant Recipients Katarzyna Muras, Anna Masajtis Zagajewska, Michal P. Nowicki. *Dept Nephrology, Hypertension and Kidney Transplantation, Medical Univ of Lodz, Lodz, Poland.*

Background: Sedentary behavior typical for patients with chronic kidney disease (CKD) usually persists after kidney transplantation (KTx). Altered adipokine profile and inflammation has been linked to physical inactivity and increased cardiovascular mortality in CKD. We postulated that increased physical activity achieved through individually-tailored program may reverse these changes and improve cardiac function.

Methods: 25 KTx recipients at least 12 months after KTx and 15 age- and eGFR-matched CKD patients were included. Baseline nutritional condition, anthropometry, body composition (impedance spectroscopy), pattern of daily physical activity (SenseWear Armband Pro accelerometer) and serum leptin, adiponectin, NT-proBNP and hsCRP were assessed. Structured program of physical activity was scheduled for each patient. Repeated training and short message service with reminders were provided to participants. All measurements were repeated after 3 months.

Results: Active energy expenditure increased during 3 months of physical activity program in both KTx and CKD patients (from 0.30±0.21 to 0.44±0.30 cal/min, p<0.001 and from 0.30±0.17 to 0.36±0.25 cal/min, p=0.01, respectively). Time spent daily on activities changed similarly (126±87 versus 200±132 and 79±78 versus 129±114 min, respectively, p<0.001). Adipose mass decreased in KTx recipients only (from 40.8±1.6 to 38.5±10.3 kg, p=0.01). Serum leptin decreased in both groups (from 11.5±7.0 to 10.0±5.6, p=0.03 and from 14.1±8.3 to 12.2±6.1 ng/mL, p=0.01, respectively). Serum adiponectin increased in KTx (from 1666±863 to 2015±1133 ng/L, p=0.004) but not in CKD patients (1896±817 and 1905±646 ng/L, respectively). Serum CRP decreased in both groups (in KTx patients from 15.1±5.2 to 14.0±5.6 mg/L, p=0.01 and in CKD patients from 16.5±3.9 to 15.4±4,3 mg/L, p=0.05). NT-proBNP was unchanged in both groups (544±294 versus 537±317 and 514±170 pg/mL versus 512±161 pg/mL, respectively).

Conclusions: Increased physical activity induces beneficial effects on adipokine profile and inflammation but does not seem to affect heart function in kidney transplant recipients.

Funding: Government Support - Non-U.S.

Left Ventricular Hypertrophy and Left Ventricular Systolic Dysfunction Affect Long-Term Outcome in Recipients of Kidney Transplantation Jung Nam An,[1] Hyosang Kim,[2] Jaeseok Yang,[3] Curie Ahn,[3] Yun Kyu Oh,[1] Chun Soo Lim,[1] Su-Kil Park,[2] Yon Su Kim,[4] Jung Pyo Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Asan Medical Center and Univ of Ulsan College of Medicine, Seoul, Republic of Korea; [3]Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea; [4]Dept of Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea.*

Background: Left ventricular hypertrophy (LVH) and left ventricular systolic dysfunction (LVSD) are independent risk factors for cardiac death in both the general population and patients with end-stage renal disease. However, only limited data on echocardiographic prognostic parameters in recipients of kidney transplantation (KT) are available.

Methods: This study was a retrospective review of patients assessed for KT from Jan. 1997 to Jan. 2012. The LVSD was defined by ejection fraction below 50%. The primary and secondary end points were all-cause mortality and graft failure, respectively.

Results: Of 4,650 patients assessed for transplantation, 1,870 had an echocardiography. A total of 231 (12.4%) patients experienced graft failure and 116 (6.2%) died during a mean follow-up of 4.5 years. The recipients with LVH were associated with all-cause mortality (P=0.007) and showed higher occurrence of graft failure (P<0.001). The recipients with LVSD also showed higher all-cause mortality (P=0.045) and graft failure (P=0.004) by Kaplan-Meier method. In a multivariate analysis, increased age (P=0.014), previous history of CV event (P=0.015), post-transplant diabetes (P=0.013) and LVSD (hazard ratio: 2.987, 95% confidence interval: 1.061-8.412; P=0.038) were associated with all-cause mortality. However, none of LVH and LVSD was significantly associated with graft failure in a multivariate analysis.

Conclusions: In patients of KT candidate, easily determined echocardiographic finding of LVSD before KT was independently associated with all-cause mortality after transplantation.

SA-PO686

Kidney Transplantation in Patients with Adenine Phosphoribosyltransferase Deficiency Hrafnhildur L. Runolfsdottir,[1] Runolfur Palsson,[1,2] Inger Maria Agustsdottir,[2] Vidar O. Edvardsson.[1,2] *[1]Univ of Iceland, Reykjavik, Iceland; [2]Landspitali – The National Univ Hospital of Iceland, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase (APRT) deficiency is a rare, hereditary cause of chronic kidney disease, characterized by deposition of 2,8-dihydroxyadenine (DHA) crystals in the renal tubules and interstitium. Treatment with a xanthine dehydrogenase (XDH) inhibitor (allopurinol or febuxostat) prevents progression to end-stage renal disease (ESRD) but limited data exist on the effectiveness of pharmacotherapy in preserving renal allograft function. The aim of this study was to examine the outcome of kidney transplantation in patients with APRT deficiency.

Methods: Included in the study were patients in the APRT Deficiency Registry of the Rare Kidney Stone Consortium who had undergone kidney transplantation. Estimates of glomerular filtration rate (eGFR) were calculated using the MDRD equation. Data are presented as median and range.

Results: Among 51 patients in the Registry, 10 (5 males) of 12 with ESRD underwent 14 kidney transplantation procedures. Eight received one allograft and two patients 2 and 4 grafts, respectively. Age at first kidney transplantation was 44 (15-67) years. Six patients were taking allopurinol in a daily dose of 300 (150-400) mg when they received their first renal allograft, while 4 patients were not prescribed such therapy at the time of first kidney transplantation. At latest follow-up, 1.7 (0.2-8.8) years following kidney transplantation, 6 allografts were still functioning with eGFR of 34 (21-65) mL/min/1.73 m^2 despite a biopsy-proven recurrence of DHA nephropathy in five of these transplants. Four allografts were lost due to disease recurrence 1.3 (0.1-3.4) years post-transplant in untreated patients. Four patients died with a functioning graft.

Conclusions: Long-term renal allograft survival in patients with APRT deficiency is favourable in those receiving XDH inhibitor treatment. Lack of awareness of the disorder and the resultant late institution of appropriate pharmacotherapy is a major contributor to premature graft loss.

Blood Pressure, Graft Survival and Renal Function in Heart Allograft Recipients – The Effect of Intervention Christian Morath,[1] Vedat Schwenger,[1] Peter Schnuelle,[1] Gerhard Opelz,[2] Martin G. Zeier.[1] *[1]Dept of Nephrology, Univ of Heidelberg, Heidelberg, Germany; [2]Transplantation Immunology, Univ of Heidelberg, Heidelberg, Germany.*

Background: Hypertension in non-renal organ transplantant recipients is common. The effect of high blood pressure on the graft survival in heart allograft recpients and on long-term kidney function is unknown. The database of the Collaborative Transplant Study (CTS) provides a high number of heart transplant recipients and their long-term follow-up, including blood pressure and s-creatinine.

Methods: A total of 2853 heart transplant recipients with continuous information on blood pressure, s-creatinine and graft outcome were followed over a time period of 10 years. Systolic blood pressure at year 1 and year 5 was categorized either <140mmHg or >140mmHg. Only patients with normal renal function s-creatinine <1.4mg/dl at year 1 post transplantation were analysed. At year 10 renal function and graft survival were analysed. Altogether four groups were followed: A: bp<140 at year 1 and year 5; B bp>140 at year 1 and <140 at year 5; C: bp <140 at year 1 and >140 at year 5 and bp >140 at year 1 and >140 at year 5.

Results: 10-year graft survival according to group A-D was: A 81.2% (p<0.02 A compared to D), B 80.2% (p n.s. B compared with C), C 76% and D 77%. Normal kidney function, e.g. the relative number of recipients with s-creatinine < 1.4mg/dl was: A 65.2% (p<0.004 A compared to C and D; p n.s. A compared to B), B 58%, C 52.5% and D 42.2%.

Conclusions: Blood pressure control significantly improves heart allograft survival 10 years plus. In addition blood pressure treatment intervention (<140mmHg) between year 1 and 5 (group B) has a significant impact on heart allograft survival and on renal function. More than 60% of patients in group A had normal renal function at year 10. In contrast inadequate blood pressure control (group C and D) resulted in an inferior heart allograft outcome and a reduced relative number of recipients with excellent renal function. Blood pressure and renal functions significanty impact heart allograft survival.

SA-PO688

Relationship of Leptin with Metabolic Syndrome and Hypophosphatemia in Pediatric Kidney Transplant Recipients Kristen Sgambat,[1] Ines Armando,[2] Christy Petyak,[1] Asha Moudgil.[1] *[1]Children's National, Washington DC; [2]Univ of Maryland.*

Background: Leptin, a hormone produced by adiopse tissue, plays a key role in regulation of body weight; recent animal studies suggest it may also influence bone mineral metabolism. A prospective study was conducted to investigate associations of leptin with risk factors for metabolic syndrome (MS) and hypophosphatemia in pediatric kidney transplant (tx) recipients.

Methods: The following parameters were measured at 6 month intervals in children 0-36 months post tx: fasting morning plasma leptin, glucose, HDL, triglycerides (TG), HbA1c%, BMI z score, waist circumference percentile (WC), blood pressure (BP), serum phosphorus and parathyroid hormone (PTH). Children with MS were identified as those meeting ≥ 3 of the following criteria: HbA1c%>5.6 or fasting glucose>100, BP>90th percentile, central obesity (WC≥95th percentile), HDL <5th percentile, TG > 95th percentile. Correlation of leptin with continuous variables was assessed by Spearman's rank correlation. Wilcoxon ranksum was used for comparisons between groups.

Results: Study population consisted of 25 kidney tx recipients age 12.9±0.8 years. One third of the population had central obesity (30%) and MS (33.3%). Leptin levels of children with obesity (39.1±3.4) and MS (28.7±4.7) were higher than those without obesity (8.1±1.8) and MS (11.8±2.4 ng/ml), p=0.0000 and p=0.002 respectively. Leptin positively correlated with BMI z score (rho 0.62, p=0.0000), WC (rho 0.77, p=0.0000), and age (rho 0.4, p=0.001). Leptin negatively correlated with HDL (rho -2.8, p=0.02) and phosphorus (rho -0.45, p=0.001). Leptin did not correlate with time post-tx or PTH. Of those with elevated leptin for sex and tanner stage, 42.1% were hypophosphatemic, while only 10.7% with normal leptin were hypophosphatemic (p=0.01). Mean phosphorus of obese (3.1±0.13) was lower than non-obese (4.02±0.14 mg/dl), p=0.001.

Conclusions: Leptin is a biomarker for obesity and MS in pediatric kidney tx recipients. Elevated leptin levels are associated with hyposphosphatemia but not with PTH levels in this population. Further studies are needed to determine if the stimulation of phosphaturic hormone FGF23 by leptin may play a role in this phenomenon.

Long Term Outcomes of Drug Eluting and Bare Metal Stents as Primary Intervention in Transplant Renal Artery Stenosis Chelsea Estrada, Mersema Abate, Anil John Mani, Frank Darras, Edward P. Nord. *Nephrology, Transplantation, Stony Brook Medicine, Stony Book, NY.*

Background: Transplant renal artery stenosis (TRAS) is a common vascular complication of renal transplantation whose optimal management is uncertain. Little data exists regarding the use of drug eluting stents (DES) in this population.

Methods: This is a prospective study of the targeted deployment of DES for renal artery diameter < 5 mm and bare metal stent (BMS) for renal artery diameter >5 mm as primary treatment of TRAS. The use of DES in small renal arteries is based on prior reports showing restenosis rates up to 50% when BMS are used. Doppler Ultrasound was initially obtained based suspicion for TRAS (rising creatinine or poorly-controlled BP). Positive studies were confirmed by angiogram, and if stenotic, DES and BMS placed accordingly. Patients were started on clopidogrel post-procedure (6 weeks for BMS, 1 year for DES) and lifelong aspirin.

Results: From 3/2008 to 11/2013, 47 patients underwent endovascular intervention (EVI) for TRAS; 23 received DES, 22 received BMS and 2 received both stent types. The primary outcome, ie: resolution of stenosis was achieved in all cases. Secondary outcomes, ie: improvement in BP control and serum creatinine, were evaluated immediately and over time. Patients were followed for 32 ± 21 months, range 3.1-78. At time of EVI, mean serum creatinine was 2.9 ± 1.5 mg/dL, increased from post-transplant nadir of 1.9 ± 0.7 mg/dL, which declined to 2.1 ± 0.9 mg/dL 1 month post procedure and remains 2.1 ± 0.9 mg/dL at last follow up. Mean SBP decreased from 157 ± 19.5 mmHg at EVI to 139 ± 16 mmHg currently, on the same or fewer medications. Eight patients progressed to ESRD and 2 lost to follow-up. Complications were inability to retrieve stent (1), distal edge dissection (1), groin hematoma (2), and transient contrast nephropathy (6). In-stent restenosis occurred in 3 of the DES and in 2 of the BMS groups.

Conclusions: Targeted EVI as primary intervention for TRAS, with DES for vessel < 5mm and BMS for vessel > 5mm, is an effective strategy for blood pressure management and renal function preservation. Use of a DES may offer a lower incidence of in-stent restenosis in renal arteries <5mm.

SA-PO690

Clinical Significance of Pre-Existing Microcalcification in the Iliac Artery in Renal Transplant Recipients Hyeon Seok Hwang,[1] Hye Eun Yoon,[2] Se Young Kim,[1] Suk Young Kim,[1] Chul Woo Yang.[2] *[1]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Daejeon, Korea; [2]Div of Nephrology, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; [3]Convergent Research Consortium for Immunologic Disease, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: The clinical significance of pre-existing microcalcificationin the iliac artery is undetermined in renal transplant recipients.

Methods: We obtained iliac artery segments from 90 transplant recipients at the time of renal transplantation and performed von Kossa staining for microcalcification. The clinical significance of intimal microcalcification was evaluated with allograft survival rate, rate of graft function decline and composite of any cardiovascular event or patient death. Expression of fetuin-A and C-reactive protein (CRP), key regulators of calcification,was also investigated in the iliac artery.

Results: Intimal microcalcification was positive in 48 (53.3%) patients, and its intensity was correlated positively with intimal CRP intensity (P = 0.019). Allograft survival in patients positive for intimal microcalcification was lower than patients who werenegative (P = 0.017). The patients with positivity for both intimal microcalcification and fetuin-A showed lower allograft survival rate than patients with intimal microalcification positivity alone (P = 0.012). The rate of renal graft function decline was significantly steeper in patients positive for intimal microcalcification than in patients who were negative (P = 0.036). In multivariate analysis, positivity for both intimal microcalcification and fetuin-A was an independent predictor for renal graft function decline (β = -10.21; P = 0.011). The intimal microcalcification was not associated with composite-event free survival.

Conclusions: Pre-existing intimal microcalcification in the iliac artery predicts a lower allograft survival rate and rapid decline of allograft function. Positivity of fetuin-A with intimal microcalcificationfurther reduces allograft survival rate and an independent predictor for renal graft function decline.

SA-PO691

Effectiveness of Trunk Fat as a Predictor of Renal Graft Function Using Artificial Neural Networks Catherine Kelley Pantik,[1] Ravi Behara,[2] Donna K. Hathaway,[1] Ann Cashion,[3] Vinaya Rao.[1,4] *[1]College of Nursing, Univ of Tennessee Health Science Center, Memphis, TN; [2]College of Business, Florida Atlantic Univ, Boca Raton, FL; [3]National Inst of Nursing Research, National Insts of Health, Bethesda, MD; [4]Renal Transplant, Methodist Univ Transplant Inst, Memphis, TN.*

Background: There are conflicting reports on the effect of obesity on graft survival. Body Mass Index (BMI) is the most common method used to assess obesity in clinical settings and BMI > 35 is used as exclusion criteria to transplantation. Abdominal fat is highly correlated with worsening renal function. The purpose of this pilot study was to evaluate the usefulness of BMI and percentage of trunk fat in predicting renal graft function at 1year post transplant using artificial neural network (ANN) modeling.

Methods: A hidden layer feed-forward ANN with unsupervised training was developed. The structure was used to develop two models to represent obesity: one model used BMI (N=81) and the other trunk fat percentage at baseline (N=65). Both models were trained with 2/3 of the sample and tested with 1/3 of the sample. The output node represented worsening graft function (serum creatinine (Scr) ≥ 1.5) at 1year post transplant.

Results: When BMI was used as the predictor variable, overall accuracy of prediction was 64%, predicting SCr < 1.5 at 1 year was 57% and predicting SCr ≥ 1.5 was 71%. Trunk fat percentage as a predictor variable resulted in 73% overall accuracy of prediction, predicting SCr < 1.5 was 67%, while predicting SCr ≥ 1.5 at was 80%.

Conclusions: Abdominal fat mass at time of transplant is an important clinical concern. There is a paucity of clinical research on the use of trunk fat v BMI in predicting renal graft function. This pilot study demonstrates trunk fat percentage may be a better predictor of graft function at 1year than BMI. Additional analysis with larger data sets is needed to build model fidelity. The study provides the foundation for additional work using ANN to examine the importance of body mass distribution in predicting long-term renal graft outcomes.

Does Intragraft Gene Expression Vary with the Type of Induction Therapy? Maria Ajaimy,[1] Pilib O Broin,[2] Michelle L. Lubetzky,[1] Yi Bao,[1] Aaron Golden,[2] Enver Akalin.[1] *[1]Einstein/Montefiore Transplant Center; [2]Computational Genomics Facility, Albert/Einstein College of Medicine, Bronx, NY.*

Background: Molecular evidence of allograft injury might precede histopathological findings. We aimed to investigate if the type of induction therapy has an effect on intragraft gene expression profiles of early transplant kidney biopsies.

Methods: We identified 34 near normal clinically indicated biopsy samples taken within 6 months of transplant for gene expression profiling. All patients received induction treatment with either anti-thymocyte globulin, if class I or II panel reactive antibody (PRA) levels > 20% (n=17), or basiliximab, (n=17). The gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: When comparing the two groups, there was no difference in patients demographics between the 2 groups. Although, the mean cold ischemia time was longer (24.6 ±14 versus 18.8 ±11.5 hours, p=0.26) and the delayed graft function was more prevalent (76% versus 50%, p=0.08) in the basiliximab group, the difference was not statistically significant. As expected, median class I 70% (18,100) and II 35% (2,100) PRA levels were higher in anti-thymocyte group compared to basiliximab group class I 0%(0,13) and class II 0%(0,34), respectively. There were no differences in Banff acute allograft injury scores including microvascular inflammation (g, ptc),interstitial inflammation, and chronic injury scores (cg, ct, ci, cv and mm) between the 2 groups. There were no differentially expressed genes between the two groups (Both False discovery rate p<0.05 and fold change >2). Pathogenesis based transcripts showed no difference in the expression of intragraft gene transcripts associated with Cytotoxic T-cells, Regulatory T cells, B cells, Endothelial cells and Interferon-gamma and rejection induced transcripts between the 2 groups. There was also no difference in 12 months serum creatinine levels between the 2 groups.

Conclusions: Although, anti-thymocyte globulin treated patients are immunologically higher risk compared to basiliximab group, there was no difference in intragraft gene expression profiles or Banff allograft injury scores of early kidney biopsies.

SA-PO693

Superior Patient and Graft Survival after Kidney Transplantation in Patients with IgA Nephropathy Aditya Kadiyala, Anna Mathew, Cristina P. Sison, Mala Sachdeva, Steven Fishbane, Kenar D. Jhaveri. *Nephrology, Hofstra-NSLIJ School of Medicine, Great Neck, NY.*

Background: IgA Nephropathy (IgAN) is a common glomerular disease leading to End Stage Renal Disease requiring kidney transplantation. To date, there have been no large studies in the U.S. looking at post-transplant outcomes in patients with IgAN who receive a Kidney transplant.

Methods: Using UNOS/OPTN data, patients > 18 years with first transplant (1/1/1999 to 12/31/2008), and BMI >15 or < 45 were analyzed. 5-year patient survival (PS) and death censored graft survival (DCGS) were compared between patients with IgAN (IgA) and other kidney transplant recipients (non-IgA). Survival curves for PS and DCGS were plotted using Kaplan Meier method. Unadjusted hazard ratios (UHR) and adjusted Hazard ratios (AHR) were calculated using Cox regression analysis. Subgroups of diabetes (DM) and donor type (DT) were also analyzed.

Results: The IgA group (n= 4005) was younger, had more males and Asians compared to the non-IgA group (n=90845). Live donation was more frequent in IgA (47.1% versus 30.2%); DM was more prevalent in non-IgA (31.9% versus 3.9%). Hypertension and BMI were comparable in both groups. IgA had higher unadjusted 5-year DCGS (96.3% versus 87.3%, p<0.001) and PS (88% versus 83.3%, p<0.001). UHR for DCGS (0.77, 95% CI 0.72, 0.83) and PS (0.30, 95% CI 0.27-0.34) were significantly lower in the IgA group (p<0.0001). In the adjusted model for PS there was effect modification by DT. AHR for PS stratified by DT showed significantly lower risk of death in deceased donor IgA (0.54, 95% CI 0.47 to 0.62) and living donor IgA (0.39, 95% CI 0.31 to 0.49) (p<0.05) compared to the non-IgA group. In the adjusted model for DCGS, there was no effect modification by DM or DT. AHR for DCGS was also significantly lower (0.90, 95% CI 0.83 to 0.97) in IgA (p< 0.0075) compared to non-IgA.

Conclusions: This is the first UNOS-based U.S. study of post-transplant outcomes in IgAN. Our study shows that patients with IgAN who receive their first kidney transplant have superior adjusted and unadjusted patient and graft survival compared to other first-time kidney transplant recipients.

SA-PO694

Identification of Risk Factors for BK Infection – A Paired Kidney Analysis

Sobhana Thangaraju, James Dong, Caren L. Rose, Jagbir Gill, John S. Gill. *Univ of British Columbia, Vancouver, Canada.*

Background: BK nephropathy remains an important cause of premature renal allograft failure. It is thought to be primarily related to the intensity of immunosuppression, while the importance of donor and recipient factors remains uncertain.

Methods: Using data from Scientific Registry of Transplant Recipients (SRTR) between 2004 – 2010, we performed a paired kidney analysis in which both kidneys were transplanted from the same deceased donor (n = 21,575) to identify 1) concordance of BK infection – cases where both kidneys were infected, 2) recipient factors for BK infection – using discordant pairs where only one kidney was infected.

Results: Among the 21,575 pairs, 1975 pairs (9%) had discordant infection, while 174 (1%) had concordant infection. Concordant infection was 5-fold higher than would be expected at random. In a multivariate conditional logistic regression model including discordant pairs, the following factors were associated with BK infection: Age < 18 (OR 1.31; 95% CI 1.01-1.54), male gender (OR 1.53; 95% CI 1.32-1.77), HLA MM ≥ 4 (OR 1.80; 95% CI 1.28-2.53), acute rejection (OR 2.75; 95% CI 2.23-3.38), use of T cell depleting antibody (OR 1.22; 95% CI 1.02-1.47). Among recipient pairs, concordant pairs were more likely to have both recipients treated with lymphocyte-depleting antibodies (p<0.001) or tacrolimus (p<0.001), have acute rejection (p<0.001), HLA MM ≥ 4 (p<0.001) and to be from the same center (p=0.001).

Conclusions: We conclude that concordant infection among mate kidneys is higher than would be expected by random chance, suggesting the importance of donor factors. However, similar recipient and treatment factors, as well as the finding that many co-infected kidneys were transplanted at the same center suggest that risk of BK infection may be related primarily to treatment factors, rather than donor factors.

SA-PO695

The Impact of Post-Transplant Urinary Tract Infections on Graft Outcomes in Kidney Transplant Recipients

Xinyun Liang, Olusegun Famure, Yanhong Li, Joseph Kim. *Div of Nephrology and the Multi-Organ Transplant Program, Toronto General Hospital, Univ Health Network, Toronto, ON, Canada.*

Background: Urinary tract infections (UTI) are the most common form of infectious complication in kidney transplant recipients (KTR). However, the impact of UTI on graft outcomes remains poorly understood.

Methods: This retrospective cohort study examined 1,111 KTR from 1 Jan 2000 to 31 Dec 2010 (followed until 31 Dec 2011). A UTI was defined by a positive urine culture (>10^5 CFU/mL) and a urine dipstick positive for leukocytes dated within two days of the positive culture date. Multiple linear regression models were fitted to assess estimated glomerular filtration rate (eGFR) at 1- and 5-years post-transplant. Multivariable Cox proportional hazards models were fitted to examine the association of UTI with first acute rejection, total graft failure, death-censored graft failure, and death with graft function.

Results: There were a total of 196 first acute rejections, 99 graft losses, 90 deaths with graft function, and 189 total graft failures accrued over 5951.8 patient-years of follow-up in this study cohort. In a multiple linear regression model, having at least one UTI episode in the first year post-transplant was significantly associated with a decreased eGFR at 1-year (*b*-2.96 [95% CI: -5.66, -0.26] ml/min) and 5 years (*b* -4.76 [95% CI: -8.47, -1.05]) of follow-up. In multivariable Cox proportional hazards models, the occurrence of a UTI was significantly associated with an elevated relative hazard of total graft failure (HR 1.85 [95% CI: 1.32, 2.60]), death-censored graft failure (HR 1.64 [95% CI: 1.01, 2.67]) and death with graft function (HR 2.14 [95% CI: 1.33, 3.45]). There was not significant association of UTI with time to first acute rejection (HR 1.13 [95% CI: 0.78, 1.64]).

Conclusions: Our results suggest that post-transplant UTI increase the risk of developing adverse outcomes in kidney transplant recipients. The mechanisms by which UTI negatively impact graft and patient longevity, and the prognostic implications of recurrent UTI events, require further study.

SA-PO696

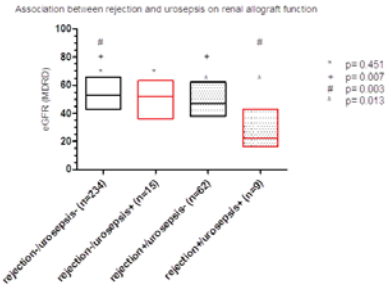
Risk Factors for Urosepsis After Renal Transplantation and Its Impact on the Renal Allograft Function

Ramandeep Singh,[1] Suzanne E. Geerlings,[2] Ineke Ten Berge,[1] Frederike J. Bemelman.[1] *[1]Renal Transplant Unit, Academic Medical Center, Amsterdam, Netherlands; [2]Div of Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands.*

Background: Along with urinary tract infection (UTI), bacteraemia may occur. This is known as urosepsis. The aim of this study is to evaluate the risk factors of urosepsis and its impact on the renal allograft function.

Methods: Retrospective cohort study with adult renal allograft recipient, who had 1 year follow-up after transplantation. Bacteriuria was defined as positive urine culture. Urosepsis was defined as bacteriuria and positive blood culture with the same pathogen. Asymptomatic bacteriuria (ASB) was defined as bacteriuria without symptoms of the urinary tract, fever/malaise. Bacteriuria with these symptoms was defined as UTI. We compared the group with urosepsis to the group without any bacteriuria at all.

Results: In total 431 recipients were analysed. Within 1 year after transplantation; 24 (5.6%) had urosepsis and 298 (69.1%) did not have any bacteriuria at all. The rest had UTI 61(14.2%) or only ASB 48(11.1%). Multivariable analysis showed that only an indwelling urological catheter was associated with the development of urosepsis with OR 13.40 (95%CI=4.43-40.50,p<0.001). Multivariable linear analysis of the renal allograft function at 1 year after transplantation showed significant interaction between urosepsis and acute rejection. In the group without rejection, urosepsis did not impair renal allograft function 1 year after transplantation. However, having experienced both, urosepsis and acute rejection significantly resulted in even greater impairment of the renal allograft function than rejection alone.



Conclusions: The presence of a urological catheter is the greatest risk factor for urosepsis. Having experienced both, acute rejection and urosepsis, is strongly associated with impaired renal allograft function, but urosepsis alone is not.

Herculink Elite® a Cobalt Chromium Alloy Bare Metal Stent Appears to Be Effective for the Treatment of Transplant Renal Artery Stenosis

Siddiq Anwar, Mohammed Abuzar Khan, Ana Paula Rossi, Daniel C. Brennan, Ravkiran Kaur Khurana, Timothy A. Horwedel. *Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Background: Management of transplant renal artery stenosis (TRAS) remains controversial. There is paucity of data regarding timing of intervention, surgical versus endovascular repair (EVR), use of bare metal stent (BMS) versus drug eluting stent (DES), and anticoagulation use post repair.

Methods: Retrospective analysis of 13 consecutive renal transplant recipients(RTR) with a diagnosis of TRAS from 2005-13 in our center

Variables	N=13
Demographic	
Mean age (range) — yr	61 (34-79)

Type — no./total no. (%)	
Bare Metal Stent (Herculink-Elite stent)	11/13 (84.6)
Drug Eluting Stent	2/13 (15.4)
Mean patient follow up post EVR (range) — in months	15.6 (1-27)
Incidence of Herculink-Elite stent restenosis	2/11 (18.2)
Mean time observed for developing HES restenosis (range) — months	6 (3-9)
Post Endovascular Repair	
No. of cases returning to baseline creatinine — no./total no. (%)	12/13 (92.3)
Mean no of months taken for serum creatinine returning to baseline value (range)	4.7 (1-6)
Success post EVR — no./total no. (%)	12/13 (92.3)

Results: Of 13 RTR, 69% where white and 92% received a deceased donor transplant. Mean nadir serum creatinine (SCr) was 1.5mg/dl. Mean time to presentation was 4.5 months post transplantation, with a mean SCr of 3.9mg/dl (Figure 1). 11 RTR received a BMS and 2 a DES. Endovascular repair was immediately successful in 12/13 RTR and there were no procedure related complications. 2 patients with a Herculink Elite® stent required repeat EVR with a DES due to in-stent restenosis (18.2%). All RTR received clopidogrel for at least one month if BMS was used, and nine months for DES. Lastly, they were all placed on lifelong anticoagulation with aspirin (12) or clopidogrel (1).

Conclusions: Herculink Elite® (Abbott Vascular, Santa Clara, CA) BMS are FDA approved for use in TRAS. The cobalt chromium composition allows for thinner stent struts to cause less in-stent restenosis. One advantage of using a BMS is the need for clopidogrel for one month only, which was helpful in 2 of our patients who subsequently required a renal biopsy for unrelated reasons. Endovascular repair is a safe and effective treatment option for TRAS. In our series BMS appear to be an effective option albeit with a risk of in-stent restenosis. Larger controlled studies are required to establish the standard of care for management of transplant renal artery stenosis.

SA-PO698

Evaluation of Long Term Cardiovascular Outcomes in Renal Transplant (RT) Patients Correlated with the Use of Cardioprotective Medications

Sandra Barrow, Federico Calaf, Wadi N. Suki. *Dept of Medicine, Div of Nephrology, Methodist Hospital, Houston, TX.*

Background: Cardiovascular (CV) disease is a leading cause of mortality among RT recipients. Despite that, the use of cardioprotective drugs remains suboptimal. Dawson et al. (2010) evaluated the use of optimal cardioprotective regimen consisting of aspirin (ASA), ACE-I or ARB, and statin in 130 patients. Only 18% of high risk RT patients as defined by prior cardiovascular disease, diabetes or a Framingham risk score exceeding 20%, received optimal treatment. This study evaluates long term CV outcomes of high risk and standard risk RT patients and the correlation of events to the use of cardioprotective drugs.

Methods: 202 renal transplant recipients who transplanted at Houston Methodist Hospital between 9/2005 and 9/2008 were included. Baseline characteristics were recorded, and medication data was obtained at one year after transplant. A retrospective chart review was conducted. Primary end point was a composite of CV death, PCI or CABG, PVD requiring stent or amputation, MI, CHF exacerbation, and TIA/stroke. Chi Square and Students T-Test were used for statistical analysis.

Results: Of the 202 RT patients evaluated, 110 (54.5%) were categorized to standard risk (SR) and 92 (45.5%) to high risk (HR). Optimal treatment was rendered to 14.46% of HR patients and 9.9% of SR patients (p=0.48). Over the course of follow up (average 6.3 years) 7 patients (6%) in SR group reached the primary endpoint (1.1% risk per patient year) compared to 33 patients (35.9%) in the HR group (9.8% risk per patient year) (p<0.000). In the HR group, 41.67% of optimally treated patients had events versus 35% receiving suboptimal treatment (p=0.27). Further analysis of individual drugs also showed no treatment benefit; statin: 34.8% versus 36.1% (p=0.9), ASA: 40.5% versus 28.9% (p=0.28), ACE-I/ARB: 33% versus 37.5% (p=0.7).

Conclusions: Treatment of high risk RT patients with statin, ASA, ACE-I or ARB or the combination of all three did not alter outcomes. At the present time empiric treatment of standard risk patients with cardioprotective drugs is probably not warranted given the low event rate and the lack of effectiveness in the high risk group.

SA-PO699

Renal Transplantation May Improve Baroreflex Function in Patients with Diabetes Mellitus

Dvora Rubinger, Rebecca Backenroth, Michal Dranitzki Elhalel, Dan Sapoznikov. *Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.*

Background: This study was performed to assess the effect of renal transplantation (TX) and of diabetes mellitus (DM) duration on baroreflex function in DM patients with end-stage renal disease.

Methods: Continuous beat-to-beat intervals (IBI) and systolic blood pressure (SBP) were monitored in age-matched controls (C, n=34)), in DM patients on chronic hemodialysis (HD-DM, n=28)) and after renal transplantation (TX-DM), with DM of shorter (≤20 y, n=9) or longer (>20y, n=12) duration.

Results: Mean SBP, IBI variability and baroreflex indices in the low (LF) and high (HF) frequency ranges and slope (median and interquartile ranges) were:

	C	HD-DM	p (vs. C)	TX-DM (≤20y	p (vs. HD-DM)	TX-DM (>20y	p (vs. HD-DM)
Mean SBP (mmHg)	126 (20)	143(37)	0.040	139(22)	NS	120 (36)	NS
sd IBI (ms)	33 (15)	15(11)	0.001	20(16)	NS	11(5)[c]	0.049
%BEI	11.8(14.7)	0.8(3.6)	0.001	1.9 (5.4)	NS	0.2 (0.6)[a]	0.003
Slope (ms/mmHg)	6.53 (4.06)	4.58 (2.68)	0.001	7.07 (6.28)	0.022	3.12 (2.75)[b]	NS
LF IBI (ms^2/Hz)	2327 (3010)	177(756)	0.001	579 (1102)	0.030	93 (211)[a]	NS
HF IBI (ms^2/Hz)	222(243)	84(74)	0.001	78(104)	NS	33(15)[c]	0.001
LF IBI/HF IBI	5.85(3.80)	1.20(2.68)	0.001	4.00 (4.30)	0.004	1.45 (2.93)[c]	NS
LFα (ms/mmHg)	5.05(3.30)	2.53 (2.22)	0.001	4.09 (2.71)	0.028	1.82 (2.33)[b]	NS
HFα (ms/mmHg)	6.12 (5.83)	3.57 (2.25)	0.001	4.98(4.52)	NS	2.40 (1.66)	NS

sdIBI: standard deviation of normal IBI; %BEI: the ratio of SBP ramps followed by ramps in IBI ; Slope: the slope of regression line between IBI and SBP for at least 3 beats; α: the square root of the ratio of average power spectral density of IBI and SBP. DM≤20y vs.>20y,p:[a]0.001;[b]<0.008;[c]<0.05.

In a multiple regression model, baroreflex and variability indices were inversely correlated with DM duration and age and directly correlated with the TX vintage.

Conclusions: 1.Baroreflex indices were significantly impaired in HD-DM; 2.In patients with DM of shorter duration TX was associated with improved heart rate variability and baroreflex function; 3.In contrast, these measurements further deteriorated in those with DM of longer duration. The prognostic value of these findings remains to be determined.

SA-PO700

Predictors for Renal Function Recovery after Orthotopic Liver Transplantation Maria C.C. Andreoli, Nadia K. Guimaraes, Adriano Luiz Ammirati, Thais Nemoto Matsui, Fabiana Dias Carneiro, Ana C.M.S. Ramos, Jose Ben-Hur Ferraz-Neto, Marcio Dias Almeida, Marcelino Souza Durao, Marcelo Costa Batista, Júlio Martins Monte, Virgilio Gonçalves Pereira, Oscar Santos, Bento C. Santos. *Centro de Diálise Einstein, Hospital Israelita Albert Einstein, Sao Paulo - SP, Brazil.*

Background: Renal dysfunction frequently occurs in pre and perioperative period in OLT and in many cases it requires renal replacement therapy (RRT). The rate and timing of renal function recovery (RFR) after OLT are crucial information for transplant program management. We evaluated a sample of stable post-intensive care hemodialysis (HD) patients from a group of 908 adults who were submitted to OLT. We studied the average time of RFR and risk factors for RRT after 90 days post-OLT.

Methods: The Cox proportional hazards model was used to identify factors associated to the relative risk of remaining or not in HD ≥90 days post-OLT.

Results: We analyzed data of 155 patients, 53 (45–60) yo, 64% male, 28% pre-OLT diabetes mellitus, 21% pre-OLT hypertension, 40% virus-related disease, MELD 27 (22-35), 32% creatinine (SCr) at time of listing >1.5mg/dL or on HD, 50% SCr at time of OLT >1.5mg/dL or on HD, 17% acute re-OLT, 18% hepatocellular carcinoma, 14% pre-OLT CVVHDF, 25% pre-OLT intermittent HD, 41% post-OLT CVVHDF; intraoperative transfusion: 2 (0-3)U packet red blood cells, 0 (0-5)U, fresh-frozen plasma (FFP), 22% cryoprecipitate, 30% platelet; 7 (4-14) days in intensive care unit. In a period <90d post-OLT, 118 (76%) patients were removed from RRT and 16 (10%) patients died on HD. During a 1-year follow-up period, a total of 129 (83%) patients were removed from RRT, 19 (12%) patients died on HD, 2 (1%) patients subsequently received a kidney transplant and only 5 (3%) patients were on HD. The median of RFR time was 33 (95%CI 27-39) days. In the multivariate analysis, fulminant hepatic failure (p<0.001), no pre-OLT hypertension (p=0.016), less intraoperative FFP transfusion (p=0.019) and no pre-OLT intermittent HD (p=0.032) were predictors of out of need RRT ≥90d after OLT.

Conclusions: Therefore, a high proportion of OLT patients improves renal function after OLT and pre and intraoperative factors have impact on the probability of this recovery.

SA-PO701

Severe Neutropenia in Children after Renal Transplantation: Incidence, Course and Treatment with Granulocyte Colony Stimulating Factor Rachel Becker-Cohen, Efrat Ben Shalom, Choni Rinat, Sofia Feinstein, Michael Geylis, Yaacov Frishberg. *Shaare Zedek Medical Center, Jerusalem, Israel.*

Background: Infections are an important cause of morbidity and mortality in solid organ transplant recipients. Neutrophils play a crucial role in the initial host defense against bacterial pathogens. Neutropenia is not uncommon after renal transplantation in adults; however, there are scarce published data in children. We conducted a historical cohort study to evaluate the incidence, clinical course and management of severe neutropenia after renal transplantation in children.

Methods: In a single center study we collected clinical and laboratory data on all children (<19 years) who underwent renal transplantation in 2005-2013. All post transplantation blood counts were reviewed, the lowest absolute neutrophil count recorded and correlated with clinical information and laboratory findings.

Results: Of 68 children, 31 (45.6%) had neutropenia <1000/microliter. Fifteen (22%) had severe neutropenia (< 500/ microliter), 2-12 months (mean 4.4) after renal transplantation. Work up for viral infection or malignancy was performed. Initial management included dose decrease/ discontinuation of mycophenolate/ azathioprine, co-trimoxazole and valgancyclovir. Bone marrow aspiration in 4 children revealed normal marrow cellularity in all cases, with myelocyte maturational arrest in 2. Seven children (10.4%) were treated with G-CSF (5 mcg/kg/day), with excellent response in all and no adverse effects. Six children had fever during neutropenia, and were treated with antibiotics. Anti-metabolite was resumed in all patients unless contraindicated, recurrence of neutropenia was seen in 4 patients. Graft function was preserved during and after resolution of neutropenia.

Conclusions: Post-transplant neutropenia in children is common, and mostly occurs in the first few months. Its etiology is probably primarily a result of the combination of immunosuppressive agents and prophylactic treatment of infections in the early post-transplant period. Decreasing immunosuppressive or antimicrobial medications carries the risk of acute rejection or infection. Off –label treatment with G-CSF may present a safe and effective alternative.

SA-PO702

Thrombotic Microangiopathy after Kidney Transplantation: A Case Series Shuang Ying Bao, Surya V. Seshan, Steven Salvatore, Manikkam Suthanthiran, Thangamani Muthukumar. *Weill Cornell Medical College, New York, NY.*

Background: Thrombotic microangiopathy (TMA) in the allograft is a rare but devastating complication after kidney transplantation.

Methods: We reviewed 25 consecutive cases of TMA in the kidney allograft diagnosed at our institution between 2000-2013. We collected their demographic, laboratory and histopathological characteristics as well as outcome. Allograft failure was defined as return to dialysis or a repeat transplant. Follow up time was censored as of 12/31/2013.

Results: The mean (±SD) age was 50±12 years. There were 18 (72%) women, 12 (48%) African-American recipients (48%), and 14 (56%) recipients of deceased donor grafts. The cause of end stage kidney disease was diabetes (20%), chronic glomerulonephritis (16%), hypertension (12%), lupus nephritis (8%), hemolytic uremic syndrome (4%), and others/unknown (40%). Except one, all patients received Thymoglobulin induction and tacrolimus. Patients were diagnosed with TMA at a median of 11 days (range: 4-2030 days) from transplant (Figure).

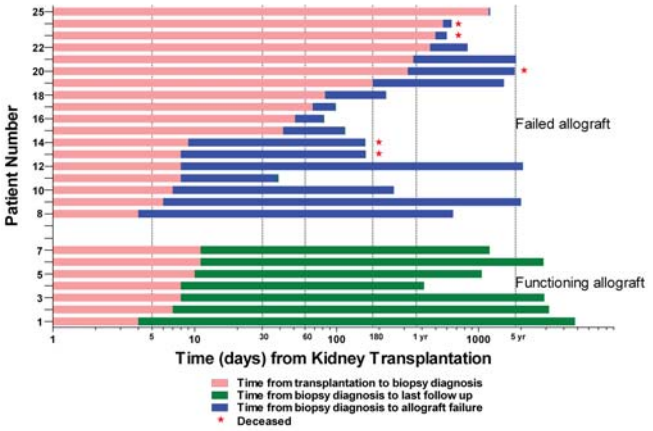

Figure: Time course for the development and outcome of TMA

TMA was renal-limited in 9 of the 16 (56%) patients in whom laboratory data related to hemolysis were available. Concomitant acute rejection was present 16 (64%). Acute antibody mediated rejection was the common (75%) type of acute rejection. Following biopsy diagnosis of TMA, 19 (76%) received pulse steroids, 17 (68%) received plasmapheresis, 13 (52%) received intravenous immunoglobulin and 8 (32%) received rituximab. Tacrolimus was stopped in 13; 5 of these 13 (39%) were started on rapamycin and 6 (46%) were started on cyclosporine. Eighteen patients (72%) had allograft failure during the study period. The median follow up was 8.3 year. The median allograft survival after the diagnosis of TMA was 94 weeks.

Conclusions: Although TMA after kidney transplant portends a poor prognosis, early diagnosis and aggressive therapy appear to improve outcome.

SA-PO703

The Usefulness of Tacrolimus without Basiliximab in Well Matched Living Renal Transplantation in Korea Chung Hee Baek, Joon-Seok Kim, Hyosang Kim, Su-Kil Park. *Dept of Internal Medicine, Div of Nephrology, Asan Medical Center, Seoul, Republic of Korea.*

Background: At the initial investigation, basiliximab was the very effective induction agent with combination of cyclosporine based immunosuppression. From those experiences, basiliximab has been a routine induction therapeutic agent even for well-matched living renal transplantation with tacrolimus based immunosuppression in Korea. As tacrolimus is a different drug from cyclosporine, we studied the usefulness of tacrolimus based immunosuppression without basiliximab in well matched living renal transplantation.

Methods: We prospectively evaluated 22 patients who underwent 1-3 HLA mismatched living donor renal transplants without basiliximab induction therapy between April 2012 and March 2014(group1). They were ABO compatible and T-flow negative transplants and we followed them until April 2014. We used tacrolimus-based triple therapy(tacrolimus, mycophenolate mofetil and methylprednisolone) as maintenance immunosuppressants. Age and sex matched 44 patients who underwent 1-3 HLA mismatched living donor renal transplants with basiliximab induction therapy in the same periods served as a control group(group2).

Results: There was 1 case(4.5%) of infection in group 1 and 9 cases(20.5%) of infection in group 2. Especially, CMV and BKV virus infection was only occurred in group2. Urinary tract infection occurred in 1 patient in group 1, and 2 patients in group2. In addition, 2 cases of pneumonia and 1 case of sepsis were reported only in group2. There was no PCP infection in both groups. Total incidence of infection was not significantly different(p=0.146), but there was a trend of lower incidence of infection in group1. Kidney biopsy was not performed in group1. However, 10 kidney biopsies were performed in group 2, and 1 acute T-cell mediated rejection was reported(p=0.549). Other biopsy results were acute tubular injuries. No mortality or malignancy was reported.

Conclusions: A tacrolimus-based triple drug maintenance immunosuppression without basiliximab might be optimal in well matched living renal transplantation in Korea.

SA-PO704

Correlation of Serum Visfatin and Clinical Outcome in Renal Transplant Recipients Kuo-Hsiung Shu,[1,2] Ming-Ju Wu,[1,2] Cheng-Hsu Chen,[1,3] Chi-Hung Cheng,[1,2] Tung-Min Yu.[1,3] *[1]Dept of Medicine, Div. of Nephrology, Taichung Veterans General Hospital, Taichung, Taiwan; [2]School of Medicine, Chung-Shan Medical Univ, Taichung, Taiwan; [3]School of Medicine, China Medical Univ, Taichung, Taiwan.*

Background: Most of the late graft loss in renal transplant (RTx) recipients can be attributed to chronic antibody-mediated allograft injury elicited by B cells directly against donor-specific antigens. Visfatin is a pre-B cell colony enhancing factor. We hypothesize that visfatin may play a role in the augmentation of B cell colony and facilitate antibody-mediated rejection. Therefore, the aim of the study was to elucidate if serum levels of visfatin might be of clinical relevance in predicting renal allograft outcome.

Methods: RTx recipients were randomly selected for the study. Fasting blood samples were obtained for the assay of visfatin. The participants were prospectively followed up for 3 years. Graft function was assessed by serial change of serum creatinine. Rejection was diagnosed based on clinical judgment and supported by a graft biopsy. Because the serum visfatin levels varied widely, patients were stratified into 3 groups (tertiles). A Chi-square test or Fisher's exact test were used to compare categorical data, while one-way analysis of variance or a Kruskal-Wallis H test were used to compare numeric data.

Results: A total of 158 patients were recruited for the study. There was no statistically significant difference in terms of demographic data or baseline laboratory data in the 3 groups. At the end of follow-up, 7 cases (4.4%) had graft loss and there was no patient mortality. Two (3.8%) graft loss occurred in tertile 1, 3 (5.6%) in tertile 2 and 2 (3.8%) in tertile 3 (p=1.000). Fifteen cases (9.5%) experienced at least one episode of acute rejection while 22 cases (13.9%) were diagnosed as having chronic rejection. The distribution of acute rejection was 7.7% in tertile 1, 16.7% in tertile 2 and 3.8% in tertile 3 (p=0.083). Chronic rejection occurred in 13.5% of tertile 1, 13.0% of tertile 2 and 15.0% of tertile 3 patients (p=0.931).

Conclusions: We conclude that serum visfatin level was not correlated with either graft failure or patient mortality.

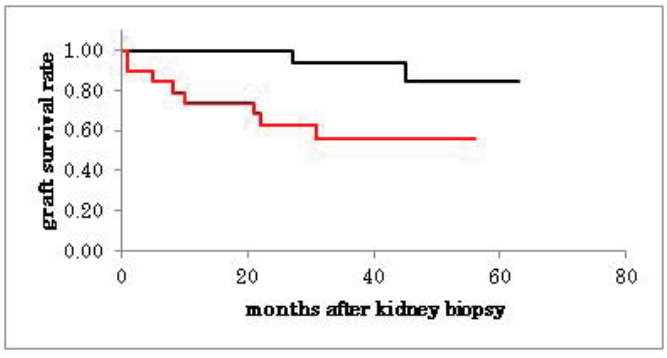
SA-PO705

The Diagnostic and Prognostic Value of Caveolin-1 Immunoreactivity in Peritubular Capirallies in Patients with Chronic Antibody-Mediated Rejection Yasuyuki Nakada, Izumi Yamamoto, Yudo Tanno, Ichiro Ohkido, Keitaro Yokoyama, Hiroyasu Yamamoto, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ of Medicine, Tokyo, Japan.*

Background: The issue of the C4d immunoreactivity in peritubular capillaries (PTCs) was its low sensitivity for the diagnosis of Antibody-Mediated Rejection (ABMR). C4d-negative ABMR was defined in the new version of Banff classification(AJT2014;14:272) and they focused on the expression of endothelial-associated transcripts (ENDATs) (AJT2009;9:2312), which is not available in any center. Our previous report showed that Caveolin-1(CAV-1), which is one of the ENDATs, is a distinct feature of chronic ABMR (AJT2008;8:2627). We investigated the diagnostic and prognostic value of CAV-1 immunoreactivity in PTCs in patients with chronic ABMR.

Methods: To examine the diagnostic and prognostic value of CAV-1 immunoreactivity in PTCs, biopsy samples from cases of chronic ABMRwere double-immunostained for CAV-1 and PAL-E; a marker of peritubular capillary. Twenty-one cases of chronic AMR were compared with 20 cases of interstitial fibrosis and tubular atrophy(IF/TA). The receiver operating characteristic curves (ROC) analysis and kaplan–meier method/log-rank test were applied for the diagnostic and prognostic value of CAV-1 immunoreactivity in PTCs, respectively.

Results: C4d immunoreactivity was positive for 61.9% while CAV-1 for 100% in chronic ABMR. Further, the %CAV-1/PAL-E in PTCs were significantly higher in chronic ABMR compared with IF/TA (71±16% versus 36±14% p<0.001). Area under the ROC curves was 0.93 when we used 55% as a cutoff value (sensitivity, 90.5%, specificity, 95%). Kaplan–meier method showed high %CAV-1/PAL-E (> 55%) was associated with high kidney graft failure (log-rank test, p=0.01. Fig).



Conclusions: The CAV-1 immunoreactivity in PTCs could be a diagnostic and prognostic marker for chronic ABMR.

SA-PO706

Omega-3 Fatty Acids and Risk of Graft Failure and Mortality in Renal Transplant Recipients Ilse Pranger,[1] Michel M. Joosten,[1] Sabita Soedamah-Muthu,[3] Gerjan Navis,[1] Rijk O.B. Gans,[1] Frits A.J. Muskiet,[2] Ido Peter Kema,[2] Stephan J.L. Bakker.[1] *[1]Internal Medicine, UMCG; [2]Laboratory Medicine, UMCG; [3]Human Nutrition, Wageningen Univ.*

Background: Omega-3 fatty acids (O3FA) have been shown to protect against acute rejection in renal transplant recipients (RTR). In the general population (GP), intake of O3FA is associated with survival benefit. Whether O3FA are associated with protection against chronic rejection or survival benefit in RTR is unknown. We examined the association of omega-3 fatty acids with graft failure (GF)and mortality in RTR.

Methods: Intake of O3FA (i.e. marine eicosapentaenoic acid (EPA) and docosahexanoic acid (DHA) and plant α-linolenic acid (ALA) were assessed by validated food-frequency questionnaire. GF was defined as return to dialysis or re-transplantation. Statistical analyses were performed using Cox-regression.

Results: We included 636 RTR (mean age 53 yrs, 57% male). Median intakes of EPA, DHA and ALA were 40, 51 and 128mg/d resp. During 3 yrs of follow-up, 41 developed GF and 67 died. Intake of O3FA was not associated with GF. In age- and sex adjusted analyses, both EPA and DHA tended to be inversely associated with mortality (HR[95%CI]=0.77[0.52-1.14] and 0.80[0.59-1.10] resp. per 100mg difference). ALA was significantly associated with increased mortality (HR=1.06[1.01-1.11], p=0.02). This association remained after adjustment for potential confounders. The highest tertile of ALA intake (>145mg/d) was at ~2-fold mortality risk (1.90[1.07-3.37]) compared to the lowest tertile (<114mg/d).

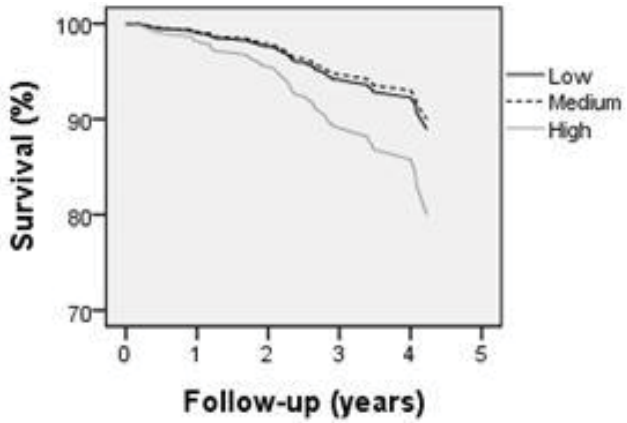


Figure 1: Survival curve for tertiles of ALA intake in RTR.

Conclusions: Intake of EPA and DHA showed trends towards decreased mortality. ALA was associated with increased mortality. The mechanisms of this llatter association might relate to differences in risk factor profile and pathophysiology between RTR and the GP. Further investigation on the long-term effects of O3FA, particularly ALA, in RTR is warranted.

Funding: Government Support - Non-U.S.

Contrast Induced Nephropathy in Renal Allograft Recipients Yuvraj Sharma, Swapna Katipally, Anthony C. Leonard, Rita R. Alloway, E. Steve Woodle, Charuhas V. Thakar, Bassam G. Abu Jawdeh. *Nephrology, Univ of Cincinnati, Cincinnati, OH.*

Background: Contrast induced nephropathy (CIN) is associated with significant increase in mortality and morbidity in patients with native kidneys; however data is limited regarding its impact in renal transplants (txp). We retrospectively studied the incidence of CIN in renal txp, its risk factors and effect on long term outcome including allograft loss or death.

Methods: 135 renal txp recipients undergoing CT scan or cardiac catheterization (Cath) with iso or low osmolar contrast during 2000-2013 at a single institution were identified. CIN was defined as rise in serum creatinine (SCr) by > 0.3 mg/dl or 25% from baseline within 4 days of contrast exposure. After excluding 85 patients who had no SCr within 4 days of contrast; 76 procedures (Cath: n=31; CT: n=45) in 50 patients were analyzed. Risk factors assessed included demographics, comorbid conditions, type/volume of contrast and calcineurin inhibitor use. Bivariate and multivariate analyses were used to assess the risk of CIN. 53% were pre-treated with fluids and 36% with N-acetylcysteine (NAC).

Results: The sample included 50% males, mean age of 53.3 +/- 15.3 years, and mean SCr of 1.46 +/- 0.88 mg/dl (mean +/- sd). Characteristics included DM (32%), HTN (78%), CHF (7%), Live donor recipients (78%), Deceased donor recipients (22%), on Calcineurin inhibitor (83%). CIN was identified in 10 out of 76 procedures (incidence 13.16%). Incidence of CIN following Cath was 12.9% (4 out of 31) and CT was 13.3% (6 out 45). Significant bivariate predictors of CIN were fluids (P=0.05), lower hemoglobin (P=0.03) and lower albumin (P=0.02). In a multivariable model, CIN was predicted by NAC (P=0.03) and lower hemoglobin (P=0.01). CIN was not associated with Calcineurin inhibitors. During long term follow up CIN did not affect renal function, loss of allograft or death.

Conclusions: CIN is common in transplant recipients; and there is room for quality improvement with regards to careful renal function monitoring post contrast. In our study NAC exposure and lower hemoglobin were associated with CIN, although the sample size is small. Randomized studies of CIN in transplant setting are needed.

SA-PO708

Myocardial Perfusion (MIBI) Scanning Has Significant False Positive Results in Detecting Coronary Artery Disease in Patients with Stage 5 Chronic Kidney Disease Freya Baird, Sumith C. Abeygunasekara, Abdelgalil Abdelrahman Ali. *Broomfield Hospital, Essex, United Kingdom.*

Background: Cardiovascular disease is the leading cause of mortality following renal transplantation in patients with chronic kidney disease (CKD), accounting for 40-55% of all deaths (*Briggs, 2001*). This is attributable to both an ageing cohort, other co-morbidities (e.g. diabetes) and a reduction in other post-transplantation complications, such as infection. MIBI scans have been shown to be highly accurate for the detection of coronary artery disease (CAD), with one study [Narin et al, 2012] calculating a high sensitivity (85%), specificity (71%) and positive predicted value (90%) in non-renal patients. However, it has also been shown (*Ammann et al, 2003*) that hypertension and left ventricular hypertrophy, which are both prevalent complications of CKD, significantly increase the incidence of falsely positive MIBI scans. In this study we aim to evaluate the effectiveness of the current screening technique in identifying CAD in patients with stage 5 CKD.

Methods: From January to December 2012 at Broomfield Hospital, all prospective renal transplant patients (stage 5 CKD) who had a positive MIBI scan and subsequently went on to have a coronary angiogram, were reviewed. The outcomes were compared to that of a cohort of cardiac patients (eGFR >60) with positive MIBI scans who also went on to have coronary angiograms.

Results: Of the 11 CKD patients with a positive MIBI scan, only 2 went on to have a significant coronary angiogram requiring intervention (18.8%). This was proportionally fewer compared to the cardiac patient cohort, in which 11 of the 46 patients with a positive MIBI scan had significant coronary stenosis on angiogram (23.9%). (Chi-square 0.166, p = 0.684).

Conclusions: Despite the small patient numbers, our initial findings suggest that there may be a high false positive rate for MIBI scans in CKD patients. A larger cohort of patients across multiple centers would be needed to investigate this further and determine whether use of this scan represents the most efficient and cost-effective pre-operative work-up, or whether these patients should receive a coronary angiogram as a first line investigation.

SA-PO709

A Prospective Study of Renal Transplant Recipients with Acute Clinical and Subclinical Rejection Shan Shan Chen, Rajil B. Mehta, Riyaj A. Kasekar, Puneet Sood, Christine Wu, Nirav A. Shah, Sundaram Hariharan. *Renal-Electrolyte Div, UPMC, Pittsburgh, PA.*

Background: To study the impact of clinical rejection (CR) and subclinical rejection(SCR) on 1 year renal allograft function and to prospectively study acute and chronic histological changes in renal transplant recipients.

Methods: We prospectively followed all patients (n=81) undergoing kidney transplantation at our center from 1/1/2013 to 5/31/2013 with at least 12 months follow up. Protocol biopsies were performed at 3 and 12months post-transplant. The patients were divided into 4 groups based on 3 month protocol biopsy: those with SCR (group1,n=9), without rejection (group2,n=36), with CR (group3,n=10), and without kidney biopsy (group4,n=26). All rejection patients (n=19) were treated per our center's protocol. Serum creatinine was measured at 3,6 and 12 months. Acute and chronic (Banff) composite scores were calculated for the 3 and 12 month biopsies. Data was analyzed using repeat measures ANOVA, T-test and chi square.

Results: Baseline demographics and other variables were not significantly different in the four groups (all p>0.05). Serum creatinine at 3, 6 and 12 months within patients and between four groups was not statistically different (p=0.07 and 0.10). There was no difference in acute and chronic composite scores between 3 and 12 month biopsies among the four groups (all p>0.05).

			Group 1	Group 2	Group 3	Group 4	p value
Demographics		Mean Age (range, year)	27 (23-81)	51 (24-80)	49.6 (31-72)	53.6 (23-78)	>0.05
		Gender (M/F)	7/2	27/9	4/6	16/10	>0.05
		Race (W/AA/ Other)	9/0/0	27/8/1	6/4/0	24/2/0	>0.05
Renal Function	Serum Creatinine (mg/dl)	3month	1.49	1.39	1.71	1.41	0.3
		6month	1.49	1.40	1.66	1.28	0.11
		12month	1.62	1.39	1.84	1.32	0.01
Banff Classification Histological Parameters	Mean Acute Composite Score (i+t+v+g+c4d)	3month	5.44 (n=9)	1.32 (n=34)	3.2 (n=10)	n=0	
		12month	2.75 (n=5)	2.40 (n=22)	3.66 (n=6)	3 (n=7)	
		p value	0.25	0.06	0.52		
	Mean Chronic Composite Score (ct+cv+ci+cg)	3month	2.77 (n=9)	1.41 (n=34)	2.3 (n=10)	n=0	
		12month	3.2 (n=5)	2.52 (n=22)	2.40 (n=6)	1.71 (n=7)	
		p value	0.78	0.08	0.77		

Conclusions: Renal function and histology score (acute and chronic) did not change from 3 months to 12 months post-transplant in patients with CR and SCR.

SA-PO710

CD45, Vimentin and Periostin as Novel Markers of Graft Outcome in a Cohort of Kidney Transplanted Patients Carlo M. Alfieri,[1] Paola Simonini,[1] Anna Regalia,[1] Masami Ikehata,[2] Deborah Mattinzoli,[2] Francesca Zanoni,[1] Christos Chatziantoniou,[3] Maria Pia Rastaldi,[2] Gabriella Moroni,[1] Piergiorgio Messa.[1] *[1]Nephrology, Dialysis and Kidney Transplantation, Fondazione IRCCS Ca' Granda Ospedale Policlinico, Milan, Italy; [2]Renal Research Laboratory, Fondazione IRCCS Ca' Granda Ospedale Policlinico, Milan, Italy; [3]INSERM Joint Research Unit S_702, Tenon Hospital, Paris, France.*

Background: Renal biopsy gives several informations about the prognosis of Kidney Transplantation(KTx). The aim of our study was to evaluate in KTx biopsies: 1)the prevalence of histologic anomalies; 2)the prognostic role of markers of inflammation(CD45), epithelial-mesenchymal transition(Vimentin-VIM) and fibrosis(Periostin (POST)).

Methods: 149 KBx performed on clinical indication in 149 KTx patients (M=83; age 44±14 yr) between 2009 and 2012 were processed for general histology. A mean of 15±4 glomeruli/patient were evaluated. Tubular atrophy (TA), interstitial infiltration (I-Inf) and fibrosis (IF) were defined as absent,mild,moderate, and severe, whereas glomerulosclerosis (GS) as %of glomeruli affected. CD45,VIM and POST tissutal positivity, was quantified as %of positive area. Clinical and biochemical data were collected at the time (T0),12 mths before and after the KBx, whereas FGF-23, osteoprotegerin, fetuin and 25-OH-VITD (VIT D) only at T0.

Results: GS was present in 25±22% glomeruli/biopsy. I-Inf, TA and IF were slight in 18%,21% and 25%, moderate in29%,23% and 27% and severe in 18%,29% and 27% of patients respectively. CD45, VIM and POST were correlated each other. CD45 and VIM were both directly correlated with creatinine and inversely with eGFR and VITD, while POST was inversely related with VitD only. Both VIM and POST were directly related to GS. The 32pts that restarted dialysis(HD+) in the year after KBx, had lower eGFR at T0 and higher positivity for CD45,VIM and POST. CD45 and POST significantly predicted HD+, independently of renal function. POST by ROC-CURVE resulted the best marker inHD+ prediction:(AUC: CD45=0,678;VIM=0,673;POST=0,760).

Conclusions: CD45,VIM and POST,obtained in KTx biopsies, were correlated each other and seem to predict graft outcome. POST and CD45, have prognostic role independently of the renal function.

SA-PO711

Membranous Glomerulopathy After Renal Transplantation Artur Quintiliano Silva,[1] Tainá Veras de Sandes Freitas.[1,2] *[1]Div of Nephrology, Federal Univ of São Paulo – UNIFESP, São Paulo, Brazil; [2]Div of Nephrology, Hospital do Rim e Hipertensao, São Paulo, Brazil.*

Background: Membranous nephropathy (MN) is one of the more common causes of nephrotic syndrome in the adult population, accounting for about 20% of cases. It can be idiopathic (70%-80%) or secondary to various clinical conditions.The incidence of post transplant (pTx) glomerulonephritis in the renal allograft varies widely depending on the criteria of recurrence (pathologic or clinicopathologic) and of the type of glomerular disease in native kidneys.

Methods: We performed a retrospective study of pTx MN in a single transplant center, identifying 36 cases until this moment among 11525 transplants already performed.

Results: Most patients were males (54.5%), 96.7% had hypertension and 36.3% delayed graft function, 21.1% acute cellular rejection, 9.1% diabetes and 51.5% dyslipidemia. The median overall graft survival was 103 months(m) and 106m among those with graft loss (9/33). The median time for detection of the first proteinuria was 48m and of pTx

MN diagnosis was 58m Eleven patients had a secondary cause of MN (HCV, HBV, SLE, neoplasia). Primary recurrence, secondary recurrence, primary "de novo" and secondary "de novo" MN corresponded to 30.3%; 36.36%; 6.1% and 27.3%, respectively. The most common *human leukocyte antigen* (*HLA*) were A2 (54%), B35(37.5%) and DR11 (37.5%). Development of pTX MN was not associated to any immunosuppressive regimen.

Conclusions: In the present study, graft loss was not common throughout follow-up; the onset of proteinuria occurred later than in previous reports (48m versus 10m) and nephrotic syndrome did not correspond to the initial main manifestation (as usually described). Recurrence was diagnosed in 36.4% (a frequency higher than in previous studies), regardless of the immunosuppressive regimen used. Additional analyzes are underway to better define the profile of this group of patients and peculiarities of the of the disease.

Long Term Outcomes of Kidney Transplant Recipients Converting From a Calcineurin-Inhibitor to a mTOR Inhibitor in a Prednisone-Free Regimen

Antonio Alvarado, Opas Traitanon, Lorenzo G. Gallon. *Northwestern Memorial Hospital, Chicago, IL.*

Background: Our center previously described similar clinical outcomes(3 years of follow up) between kidney transplantation recipients converted from Tacrolimus(Tac) to Sirolimus(SRL) in a prednisone free regimen. The current analysis focuses on longer-term outcomes in this population of patients.

Methods: Prospective, randomized single center trial. Patients(N=200) were induced with alemtuzumab and maintained on a prednisone-free regimen with Tac and MMF. At 1 year post transplantation, patients were randomized 2:1 to be converted to SRL(n=135) or continue Tac(n=65). Recipient and donor demographics were similar in both groups. Patients with acute rejection, proteinuria, or death before randomization were excluded from analysis (n=7). Patients lost to follow up or who withdrew consent were also excluded from analysis(n=7). Patient randomized to SRL group but did not undergo conversion were included in the Tac group(n=11).

Results: Of 186 patients (Tac=71, SRL=115) analyzed, 26 experienced death or graft loss (Tac=10, SRL=16). Of the remaining 160 patients(Tac=61,SRL=99), 144 (90%) had greater than 4 years of follow up after transplant. The rates of death, graft loss, and acute rejection were similar between the 2 groups(Table 1). At a mean follow up of 5.41 years in the Tac group and 5.47 years in the SRL group, allograft function (eGFR by MDRD) was not statistically different between the two groups(figure 1).

Table 1

	Tacrolimus (Tac) N= 71		Rapamune (SRL) N=115		
Outcome	n	%	n	%	P Value*
Acute Rejection	5	7.0	13	11.3	0.44
Death	5	7.0	7**	6.1	0.77
Graft loss	5	7.0	10	8.7	0.79

*Fisher's exact test

**One patient with graft loss prior to death

Figure 1

	Prograft(FK) N=61	Rapamune(SRL) N=99	P value*
Unadjusted Mean (SD) GFR in abbreviated MDRD(ml/min per 1.73m2)	61.44(18.54)	66.12(21.19)	0.157
Mean (SD) follow up in months post-randomization	65.20(14.63)	65.69(16.02)	0.846

*Two-tailed, unpaired t-test

Conclusions: After alemtuzumab induction and rapid steroid elimination, conversion from Tac to SRL after transplantation is safe. In addition, renal allograft function is equally maintained in both groups.

SA-PO713

Vitamin D Deficiency Is an Independent Risk Factor of Urinary Tract Infection after Kidney Transplantation

Seung Gyu Han,[1] Young Eun Kwon,[1] Hyunwook Kim,[2] Hyung Jung Oh,[1] Jung Tak Park,[1] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang.[1,3] *[1]Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine, Wonkwang Univ, Gunpo-si, Gyoeonggi-do, Korea; [3]Brain Korea 21 PLUS, Severance Biomedical Science Inst Yonsei Univ, Seoul, Korea.*

Background: Vitamin D deficiency is frequently found in patients with kidney transplantation (KT). Since vitamin D plays indispensable roles in the immune system, there may be an association between vitamin D deficiency and infection in these patients. However, this has not been fully elucidated. This study, therefore, was aimed to investigate the impact of pre-KT vitamin D deficiency on the development of urinary tract infection (UTI) after KT.

Methods: 25-hydroxyvitamin D [25(OH)D] levels were measured in 410 patients within two weeks before KT. Vitamin D deficiency was defined as 25(OH)D < 10 ng/mL. The primary outcome was the occurrence of UTI after KT. Cox proportional hazard analysis was performed to determine the independent association of vitamin D deficiency with UTI.

Results: The mean 25(OH)D levels were 12.8±6.9 ng/mL, and 171 patients (34.4%) were deficient of vitamin D. Vitamin D deficiency was significantly associated with female gender [β = 2.30, 95% confidence interval (CI) = 1.41 to 3.77, P = 0.001], hemoglobin (β = 0.83, 95% CI = 0.72 to 0.95, P = 0.006) and serum albumin concentrations (β = 0.17, 95% CI = 0.10 to 0.30, P <0.001), and the season of KT operation (summer, β = 0.22, 95% CI = 0.11 to 0.42, P <0.001; autumn, β = 0.32, 95% CI = 0.17 to 0.63, P = 0.001, spring as a reference). During a median follow-up duration of 7.1 years, the incidence rates of UTI were significantly higher in patients with vitamin D deficiency compared to those without deficiency [52 (30.4%) versus 40 patients (16.7%), P = 0.001). Moreover, multivariate Cox analysis showed that vitamin D deficiency was a significant independent predictor of UTI after KT (hazard ratio = 1.81, 95% CI = 1.11 to 2.97, P = 0.018).

Conclusions: Vitamin D deficiency was an independent risk factor for UTI after KT, suggesting that determining 25(OH)D levels might be helpful to predict infectious complications after KT.

SA-PO714

Routine Employment of Intraoperative Continuous Renal Replacement Therapy for Liver Transplantation was Safe and Effective

Dhaval Sureja, Kenneth Lau, Gregory Malat, PharmD, Stephen Guy, Karthik M. Ranganna, Alden Michael Doyle. *Transplant Nephrology, Drexel Univ, Philadelphia, PA.*

Background: Liver transplantation is a lengthy and complex procedure during which there are often large shifts in volume, disturbance in sodium - potassium homeostasis, and acid/base physiology that can be difficult to manage. Intraoperative management is more challenging when the patient has severely compromised kidney function. In order to better manage these physiologic variables in the operating room, we instituted a standard policy whereby all patients on dialysis awaiting liver transplant are placed on continuous renal replacement therapy (CRRT) throughout the liver transplant procedure and for at least 24 hours post-operatively. Here in we report our experience with this transplant dialysis protocol.

Methods: We retrospectively examined 8 liver or combined liver and kidney transplant patients from 2010 - 2014, who also received dialysis support in the week prior to receiving their transplant organ(s). Data included electrolytes, volume status, daily input/output, the day of extubation, total blood products received, and blood pressure, from 2 days pre-op to 3 days post-op period.

Results: None of the patients developed hyperkalemia or acidosis. Hyponatremia resolved post operatively which is a common challenge in end stage liver disease patients. Blood pressure was well controlled perioperatively. Patients' volume status better controlled despite receiving on average 40-100 blood products intra-operatively. Four patients were extubated on post op day 1 and two patients on post op day 2. No anticoagulation was required during CRRT to maintain filter and circuit patency.

Conclusions: We found that a protocol that utilized intraoperative CRRT during the liver transplant surgery was safe and effective at maintaining tight sodium, potassium, fluid and acid/base balance despite large peri and intra-operative transfusion and crystalloid fluid requirements. Although we are not able to comment on long term outcomes and its impact on ICU stay or hospitalization length, we submit that this type of CRRT protocol could be utilized by other transplant centers and is worthy of larger, prospective studies.

SA-PO715

Urinary Alpha$_1$-Microglobulin Excretion and Renal Outcome after Kidney Transplantation

Anneke Bech, Judith M. Hoogendijk-van den Akker, Andries Jan Hoitsma, Jack F. Wetzels. *Nephrology, Radboud Univ Medical Center, Nijmegen, Gelderland, Netherlands.*

Background: Although one year survival after kidney transplantation is excellent, renal function deteriorates in many patients within the first decade. Urinary excretion of alpha$_1$-microglobulin (Ua$_1$m) reflects tubulo-interstitial damage and predicts outcome in patients with glomerular diseases. The predictive value of Ua$_1$m in the transplantation setting is unknown.

Methods: In patients who received a renal transplant between 2006 and 2010, Ua$_1$m was measured at 3 and 12 months after kidney transplantation. Ua$_1$m was expressed as mg per 10 mmol creatinine (normal values < 15).

Results: 139 patients were included with a median age of 48 years (IQR 36-58). Median follow-up time after kidney transplantation was 60 months (IQR 48-72). During follow-up 3 patients developed graft failure and 10 patients died. Ua$_1$m-ratio at 12 months was increased in 78% of patients. Increased Ua$_1$m was associated with the type of donor, gender of the recipient, eGFR, albuminuria and rejections (Table1). Ua$_1$m did not predict deterioration of renal function during follow up. Table 1: patient characteristics per quartile of Ua$_1$m at 12 months.

	Q1	Q2	Q3	Q4	P value
Postmortal donor (N,%)	12 (34)	15 (43)	8 (24)	20 (57)	0.03
Gender (M/F)	17/18	18/17	24/10	26/9	0.06
Ua_1m 3 months	17 (12-38)	28 (23-45)	46 (34-63)	79 (53-135)	<0.01
Ua_1m 12 months	10 (6-14)	22 (21-28)	38 (33-43)	75 (55-113)	<0.01
ACR 12 months	15 (5-41)	25 (9-89)	34 (17-117)	60 (17-177)	<0.01
Rejection <12 months (N,%)	6 (17)	7 (20)	8 (24)	15 (43)	0.06
eGFR 12 months	60±15	50±15	47±12	44±12	<0.01
eGFR difference last FU-12 months	2 (-4-7)	0 (-6-9)	1 (-6-5)	1 (-2-9)	0.73

Median values with interquartile ranges for skewed data and mean values with standard deviation for normally distributed data
ACR = albumin/creatinine ratio (mg/10 mmol)
eGFR = MDRD4 (ml/min/1.73m^2)

Conclusions: The majority of kidney transplant patients have elevated Ua_1m at 12 months after transplantation. Ua_1m was associated with factors contributing to kidney injury during or shortly after transplantation but did not predict renal outcome. Our data suggest that an elevated Ua_1m reflects fibrosis and not active tubular cell injury.

SA-PO716

Using Cinacalcet to Treat the Hypophosphatemia of Early Kidney Transplant Maria Coco, Enver Akalin, Daniel G. Glicklich. *Medicine, Montefiore Medical Center, Albert Einstein College of Medicine, Bx, NY.*

Background: Hypophosphatemia is common early after kidney transplantation due to residual hyperparathyroidism. We hypothesized that cinacalcet will normalize phosphorus in early renal transplantation by reducing the effect of PTH on the proximal convoluted tubules, thereby reducing urinary phosphate wasting.

Methods: This was a randomized, double-blinded, placebo controlled trial of cinacalcet start within 3 months of renal transplant in patients with serum phosphorus less than 2 mg/dl and creatinine less than 2 mg/dl and continued for 3 months. Baseline and 3 month creatinine, calcium, phosphorus, Vitamin D, FGF23, Urinary calcium and phosphorus excretion were obtained. Calcium, phosphorus and creatinine were compared 6 months after the drug was stopped. Repletion with phosphorus was allowed if phosphorus remained low.

Results: 36 subjects were randomized blindly by pharmacist. There was no difference in baseline demographics and biochemical parameters between study (CINA) and control (CON) groups. At the end of the 3 month study period, absolute values and percent change in calcium, phosphorus, creatinine, urinary excretion of phosphate and calcium were not different between the groups. Similarly, Calcium and Phosphorus were not different 6 months after the study drug was stopped. Phosphate supplementation tended to be more in control group.

drug	Ca3m(mg/dl)	Ca9m(mg/dl)	phos3m(mg/dl)	phos9m(mg/dl)	UPhos3m(mg/dl)
Con	10.2	10.2	2.6	2.9	0.78
Cina	9.8	10.1	2.9	2.9	1.5

Conclusions: Cinacalcet, given in a placebo-controlled, blinded manner, did not appreciably affect phosphate control in kidney transplant patients with adequate renal function, although phosphate supplementation may have been lower. FGF23 assay is pending: while results will be interesting, it may not have an important role in phosphate control early after kidney transplantation.

Funding: Clinical Revenue Support

SA-PO717

Post Renal Transplant Hypercalcemia Effect on Graft Function and Cinacalcet Use Gaurav Tandon, Sravan Jasti, Rasib Raja. *Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Background: Post renal transplant hypercalcemia is common and is usually due to pre transplant hyperparathyroidism. We perviously reported a high incidence of 70% of post renal transplant hypercalcemia in our study population, mostly because of significantly high pre-transplant parathyroid hormone. In our mean follow up of 9months on the same study population, we attempt to see if post renal transplant hypercalcemia has any effect on allograft function and incidence of Cinacalcet usage.

Methods: 47 patient charts were reviewed for allograft function and Cinacalcet usage for a mean follow up period of 9 months. The patient were divided into two arms. First arm was with patients who had normal post transplant calcium (<10.2 mg/dl) and the second arm consisted of patients with post transplant hypercalcemia. Patient's allograft function and Cinacalcet usage after a mean follow up period of 9 months, in the both the arms were compared.

Results: In our study we found a trend towards worsening graft function but it was not statistically significant with our sample size. In normocalcemic group graft function improved by 20% and in hypercalcemia group graft function worsened by 5%. We observed 125% (pvalue 0.08) increased dosage of Cinacalcet after a mean follow up of 9 months when compared to 1 month post transplant. Pre transplant hyperparathyroidism usually resolves in 6-12 months post transplant. In our study population we found that 45% were still requiring Cinacalcet at 6-12 months at a 125% higher dose.

Conclusions: As it is known hypercalcemia leads to afferent arteriolar vasoconstriction, polyuria, interstitial fibrosis and nephrocalcinosis. Hence it can lead to worsening graft function. Better control of Pre transplant hyperparathyroidism may decrease the incidence of post transplant hypercalcemia and the need for Cinacalcet usage. This will lead to better transplant outcomes and cost. Further large studies with long term follow up are required to validate our findings.

SA-PO718

25OH vitD Supplementation in Kidney Transplantation: A 24 Month Follow Up Ines Aires, Isabel Mesquita, Ana Azevedo, Manuel A. Ferreira, Fernando Barbosa Nolasco. *Nephrology and Transplantation, HCC-CHLC, Lisbon, Portugal.*

Background: Native vitamin D serum levels (25-OH) are reduced in kidney transplant (KTx) patients (pts) and have been associated with chronic kidney disease-mineral and bone disorder (CKD-MBD), neoplasic, immunological and cardiovascular effects.

Methods: We evaluated the effects of 24 months cholecalciferol supplementation (median dose 2664 UI), in 121 KTx pts, 60,4% men, mean age 54.4±13 years, 25% diabetic, mean post KTx follow up:71.5±8.5 months. All pts were naïve to 25-OH vitD therapy but 29.7% were on VDRA. 25% were on ACE/ARB inhibitors, that were unchanged.Pts were supplemented accordingly to basal (T0) calcidiol serum levels (ng/mL): deficiency (<15), insufficiency (15 to 30) and normal (>30). Wilcoxon and Anova tests were used.

Results: At T0, 25-OH levels were 15.9±8.2 ng/mL and 93.4 % pts had lower than normal levels. At T24, 25OH levels increased to 31.2±13.3 with 44.6% pts attaining normal levels(versus 6.6% at T0). Proteinuria and PTH levels were significantly reduced: 0.83±1.2 g/d (T0) to 0.56±1 g/d (T24),p<0.001 and 133.9±85.3 (T0) to 110±102 pg/mL (T24), p<0.001, although phosphorus increased (3,3±0,7 mg/dl versus 3,6±0,8, p<0,005) and calcium decreased (9,8±0,9 mg/dl versus 9,7±1 mg/dl; p>0,05). As expected Pcr increased at T24 from 1.35±0.5 mg/dL to 1.48±0.8 mg/dL, p<0,05, but that did not seem to account for the reduction in proteinuria (r=0,31; p<0,005). Supplementation was well tolerated and no adverse events or acute rejection episodes were reported.There were no differences in the number of hospital admissions, cardiovascular events or neoplasia between pts with normal or insufficient 25OH levels.

Conclusions: Accordingly to our results, vitamin D deficiency is highly prevalent among KTx pts. Oral supplementation with cholecalciferol is efficient and safe in the correction of calcidiol serum levels, leading to reduction in proteinuria and CKD-MBD. In this period it was not associated with CV, infectious or neoplasic risk reduction but the short follow up and the late supplementation may have contributed to these results. Larger and longer randomized controlled studies are needed to address different results.

SA-PO719

Overweight and Fat Mass as an Aggravating for Reduced Bone Mineral Density in Renal Transplant Recipients Ita Pfeferman Heilberg, Alessandra Calábria Baxmann, Aluizio B. Carvalho. *Nephrology Div, Federal Univ of São Paulo, São Paulo, Brazil.*

Background: A high prevalence of overweight has been frequently found after renal transplant. Although a higher body mass index (BMI) has been traditionally associated with higher bone mineral density (BMD), it has been suggested more recently that fat mass may exert a detrimental effect on BMD, possibly mediated through leptin. We aimed to evaluate the impact of obesity and fat mass in non-diabetic renal transplant recipients (RTR).

Methods: A hundred nondiabetic RTR (62M/38F,42±10 years) with serum creatinine <2.0mg/dL and at least 6 months of transplantation were subjected to an anthropometric evaluation and body composition assessment through bioelectrical impedance. A blood sample was drawn for serum biochemical and hormonal determinations, and BMD was assessed by dual-energy x-ray absorptiometry.

Results: We observed overweight (BMI>25kg/m2) in 59% of RTR evaluated up to 165 months after transplant and a significant median weight gain of 5.1 kg. An inadequate distribution of body fat was evidenced in 50% of males and in 58% of females. Sixty (60%) of the patients presented low BMD. Hypovitaminosis D was observed in 65% of them, with levels indicating Insufficiency [25(OH)D< 30 ng/mL] in 53% and Deficiency [25(OH) D<15 ng/mL] in 12%. When we analyzed all factors contributing to both lumbar spine and femoral neck BMD, the univariate linear regression showed significant associations (p=0.001) with female gender, levels of 25(OH)D, weight gain, BMI, body fat, lean mass and serum leptin levels. Finally, the multivariate linear regression analysis showed that serum leptin levels and BMI were the only significant (p=0.001) variables remaining in the model predictive of low BMD, adjusting for immnunosupression and factors related to persistence or de novo CKD-MBD.

Conclusions: The present study showed a high percentage of overweight, body fat and weight gain after Tx combined with a high prevalence of low BMD and hypovitaminosis D. Serum leptin levels and BMI were considered the only independent risk factors for low BMD in these patients, suggesting that excessive fat mass may present an unfavorable impact on bone mass in RTR.

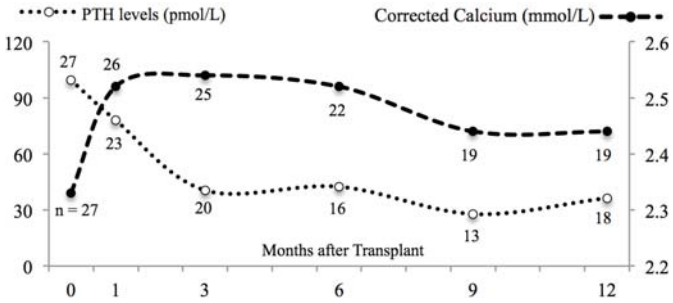
SA-PO720

Cinacalcet in the Management of Persistent Hyperparathyroidism after Renal Transplantation Habib Mawad, Robert Zoël Bell, Sarah Bezzaoucha, Hugues Bouchard, Anne Boucher, Suzon Collette, Jean-Philippe Lafrance, Denis Ouimet, Vincent Pichette, Lynne Senecal, Duy Tran, Michel Vallee. *Nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: Successful renal transplantation (RTX) corrects many abnormalities of ESRD. Nevertheless, hyperparathyroidism (HPT) persists in up to 50% of recipients 1 year after RTX. In such patients, hypercalcemia may occur thereby limiting the use of vitamin D analogues. Parathyroidectomy is hence often required. The aim of our study is to evaluate the use of cinacalcet in the management of persistent HPT.

Methods: In this retrospective study, we conducted a chart review of all patients having been transplanted from 2003 to 2012 and having received cinacalcet up to RTX and/or thereafter. Baseline characteristics as well as evolution of calcemia and PTH levels were collected.

Results: A total of 27 patients were included consisting mainly of middle-aged men. Time spent on dialysis prior to RTX was 5.8±4.3 years. Data was collected up to 3.2±2.5 years after RTX. 6 patients initiated cinacalcet only after RTX. The remaining 21 patients already had cinacalcet at the time of RTX. Cinacalcet was stopped within the first month after RTX in 12 of these patients of which 7 had to restart the treatment. The main reason for restarting cinacalcet was hypercalcemia. At the end of the study only 8 patients had stopped cinacalcet. Length of treatment post-RTX was 26±24 months. Dosage requirements decreased with time although not statistically significant. There were only 3 cases of mild hypocalcemia. PTH decreased during the first 3 months whereas calcium increased.



Conclusions: HPT is a common problem in renal transplant patients and may persist for years. Cinacalcet appears to be a safe and effective treatment. It may serve as a relay to parathyroidectomy or as an alternative. In our study, spontaneous resolution of HPT was uncommon.

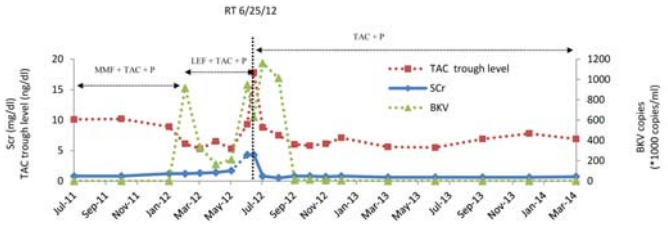
SA-PO721

Kidney Retransplantation for BK Virus Nephropathy Despite Active Viremia without Allograft Nephrectomy Jingbo Huang, Gabriel M. Danovitch, P.T. T. Pham, Suphamai Bunnapradist, Edmund Huang. *Nephrology, UCLA David Geffen School of Medicine, Los Angeles, CA.*

Introduction: Kidney retransplantation (KRT) may be done for patients with previous BK nephropathy (BKN). Whether transplant (TP) nephrectomy and viral clearance are required prior to KRT is unclear.

Case Description: A 65 year-old female with ESRD secondary to polycystic kidney disease received a living unrelated kidney TP with basiliximab induction and tacrolimus (TAC; trough 8-10 ng/ml months 0-3; 6-8 ng/ml thereafter), mycophenolate mofetil (MMF) and prednisone maintenance. She had a baseline creatinine (Scr) of 0.7 mg/dl until 11m post-TP when Scr increased to 1.2 mg/dl. Plasma BK PCR was noted to be 854K copies. Kidney biopsy confirmed BKN by SV40 staining. Leflunomide (LEF) 20 mg twice daily was initiated, MMF was stopped, and TAC trough was targeted at 4-6 ng/ml. 15m post-TP, she developed fulminant hepatic failure, with liver biopsy suggesting drug-induced injury. LEF was stopped. She was thought to have hepatorenal syndrome and initiated hemodialysis (HD). BK PCR increased to 946K copies and IVIG 2 g/kg was given. Due to a clinically deteriorating status, she was listed for liver/kidney TP (SLK). Allograft nephrectomy was considered, but she was deemed too unstable for surgery. 3 days after HD initiation and IVIG, she underwent SLK with active BK viremia. She did not receive antibody induction and was maintained on TAC (trough 4-6 ng/ml) and prednisone alone. She had immediate graft function. She received a 2nd course of IVIG 5 days post-SLK and started on ciprofloxacin. BK PCR was undetectable 3m post-SLK. At 15m follow-up, Scr was 0.6 mg/dl and BK PCR remained undetectable. The trend of BK PCR and TAC level is shown in Figure 1.

Figure 1



Discussion: To our knowledge, this is the first reported case of successful KRT for BKVN in the setting of severe BK viremia without concomitant allograft nephrectomy.

SA-PO722

BK Virus Nephropathy in the Native Kidney Anjali Narain Masand, Jordan Gabriela Nestor, Jeffrey I. Silberzweig, Steven Salvatore. *Dept of Nephrology and Hypertension, New York-Presbyterian/Weill Cornell, New York, NY.*

Introduction: BK virus associated nephropathy (BKVN) is known as an important cause of renal allograft dysfunction after renal transplantation.Case reports suggest that BKVN is not confined to allograft kidneys,and can be seen in the native kidneys of immune-compromised hosts.We present a case of a patient with refractory chronic lymphocytic leukemia and renal dysfunction who had BK virus detected in the serum and histologically confirmed on renal biopsy.

Case Description: The patient was a 72 year-old male with a history of refractory chronic lymphocytic leukemia (CLL) which was diagnosed initially in 1997 when he presented with diffuse lymphadenopathy.He had been treated with numerous chemotherapy protocols and experimental regimens since 2001 when he was treated with Fludarabine and Rituximab.His creatinine level had been mildly elevated since at least 2007, in the range of 1.1-1.5 mg/dL.It reached a peak level of 2.4 mg/dL in June 2013.He had a renal ultrasound at this time which showed no evidence of hydronephrosis and normal echogenicity.He had several urinalyses,none of which showed glycosuria,microscopic hematuria,proteinuria,or pyuria. He had none of the usual risk factors for chronic kidney disease but the various chemotherapy regimens placed him at risk of renal injury.His creatinine remained stable in the range of 1.8-2.4 mg/dL over the course of the next several months.In August 2013 a BK virus level was checked and was found to be elevated at 45,000 cpy/mL.He subsequently underwent a kidney biopsy which showed BK virus associated nephropathy with no direct renal involvement by CLL.He was started on treatment with Ciprofloxacin 400 mg twice daily and Leflunomide 20 mg once daily.Despite this, the patient's renal function did not recover, and hemodialysis was initiated in March 2014.

Discussion: BK virus associated nephropathy of the native kidneys may be under-recognized. Quantitative BK virus DNA is not routinely measured in immune-compromised patients with worsening renal function. A high level of suspicion in immune-compromised patients is required in order to facilitate early diagnosis of BKVN and optimize initiation of antiviral therapy.

SA-PO723

Poor Outcome of Occult Hepatitis C Infection in Kidney Transplant Recipient Alejandra Mena- Gutierrez, Fahd Syed, Sameh R. Abul-Ezz. *Div of Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Identification of Hepatitis C infection (HCV) in kidney transplant candidates relies on the detection of anti-HCV antibody and evaluation of liver function. Patients with End Stage Renal Disease may have an ineffective immune response resulting in negative anti-HCV antibody while HCV-RNA can be detected by polymerase chain reaction (PCR). If not detected before kidney transplantation, further immunosuppression may result in fatal outcome.

Case Description: A 65 years old male with ESRD secondary to IgA nephropathy received a living related kidney transplant from his son. He had no indication of liver disease or high risk behavior. Both the recipient and donor had negative HCV serology and liver function before transplantation. 9 months after transplantation, the recipient had deranged liver function with hyperbilirubinemia. Ultrasound showed cholelithiasis and he underwent laparoscopic cholecystectomy with marked improvement in liver function. He presented few weeks later with worsening liver enzymes, and all serologies for infectious and autoimmune causes were unrevealing. Immunosuppression was decreased and liver function improved again. He returned with severe jaundice and in addition to repeat viral serologies, HCV-RNA by PCR was checked. Levels came back extremely high despite negative anti-HCV antibody. Liver biopsy showed fibrosing cholestatic hepatitis. He progressed rapidly to fulminant hepatitis and was not considered candidate for HCV treatment or transplantation. He shortly died of sepsis. Blood samples from the donor were obtained and did not show evidence of HCV infection by PCR or by antibody testing. The recipient's stored blood samples dated before transplantation were retested for anti-HCV antibody and were confirmed negative.

Discussion: Occult hepatitis C infection with negative anti-HCV antibody can only be detected by HCV-RNA PCR. The devastating outcome of this occult infection indicates the need to test all kidney transplant candidates for HCV-RNA regardless of their HCV antibody status. Patients with negative anti-HCV antibody and positive HCV-RNA PCR should undergo liver biopsy and treatment before considering kidney transplant.

SA-PO724

Abatacept for Rheumatoid Arthritis in a Renal Transplant Recipient with Six-Year Follow-Up Mohamed A. Sheta, Hassan N. Ibrahim, Arthur J. Matas, Aleksandra Kukla. *Renal Diseases and Hypertension, Univ of Minnesota, Minneapolis, MN.*

Introduction: Treatment of autoimmune diseases is challenging in renal transplant patients. Inhibition of T cell co-stimulation pathway has been gaining widespread interest in the treatment of autoimmune diseases and as an Induction/maintenance therapy for renal transplantation. We are presenting a case of de novo membranous glomerulonephritis in kidney transplant recipient secondary to rheumatoid arthritis which responded well to Abatacept, a co-stimulatory inhibitor, while graft function remained stable for a follow up period of Six years.

Case Description: A 69 year-old white male patient,with a history of end stage kidney of unknown etiology received a living donor kidney transplant in 1998 on Cyclosporine,Mycophenolate mofetil(MMF) and low dose Prednisone with serum creatinine (Scr) of 1.5 to1.7 mg/dl.Past medical history includes hypertension, coronary artery disease and gout.in 2008 patient was diagnosed with rheumatoid arthritis (RA).BP 120/70. Positive examination finding were symmetrical arthritis of the PIPs,MCPs and wrists,boutonniere and swan neck deformities, and bilateral leg edema. UA showed 300 mg/dl with no RBCs, Scr of 1.6 mg/dl, and protein to creatinine ratio of 6.8 g/g. Renal graft biopsy showed membranous glomerulopathy (MGN). Methotrexate (MTX) was started, while MMF was discontinued. Scr increased to 3.6 mg/dl. A Repeated renal graft biopsy did not show new findings. MTX was discontinued because of worsening Scr and inadequate clinical response. Patient was started on monthly Abatacept, together with discontinuation of cyclosporine and re-starting MMF and continuation of low dose prednisone. This led to both clinical and laboratory response. Curently Scr is 1.6 and protein creatinine ratio is 0.76 g/g. Abatcept was tolerated well.

Discussion: Abatacept,FDA approved for treatment of RA, was chosen in our patient based on the understanding of the central role of T-cell in both normal immune response to transplanted organ and autoimmune diseases. Adopting this concept in renal transplant patients with autoimmune diseases will lead to less number of immunosuppressive use and, hence, less toxicity.

SA-PO725

Glomerular Disorders in Two Patients with Intestinal Transplant Arwa Nada,[1] Brian Becknell,[1] Peter Baker,[2] Hiren P. Patel.[1] *[1]Div of Nephrology, Nationwide Children's Hospital, Columbus, OH; [2]Div of Pathology, Nationwide Children's Hospital, Columbus, OH.*

Introduction: Prior studies of end stage kidney disease (ESKD) after intestinal transplant (IT) found the incidence of ESKD is up to 3% of children and 21% of adults. ESKD is often attributed to calcineurin inhibitors in children and diabetes and hypertension in adults, but reports of glomerular diseases in this population is rare. To our knowledge this is the first report of the pathological findings of glomerular disease in patients who received IT as children.

Case Description: We report 2 patients with IT for Hirschsprung disease who had kidney biopsy for proteinuria. The age at first IT was 2 and 16 years. Neither patient had diabetes mellitus at the time of the kidney biopsy. Both patients had progressive increase in proteinuria with urine protein/creatinine ratio of 15 mg/mg in the first patient and 30 mg/mg in the second patient at the time of biopsy. The estimated glomerular filtration rate at the time of the biopsy was 55 and 33 ml/min/1.73m^2. Both kidney biopsies showed focal segmental glomerulosclerosis (FSGS) with hyalinosis on light microscopy. Both had positive IgG, IgM, IgA, C3, C1q, C4, and fibrinogen on immunofluorescence. Electron microscopy showed primarily subendothelial deposits in the first patient and a small amount of subepithelial and intramembranous deposits in the second. Both patients had normal serum C3, and C4 complement.

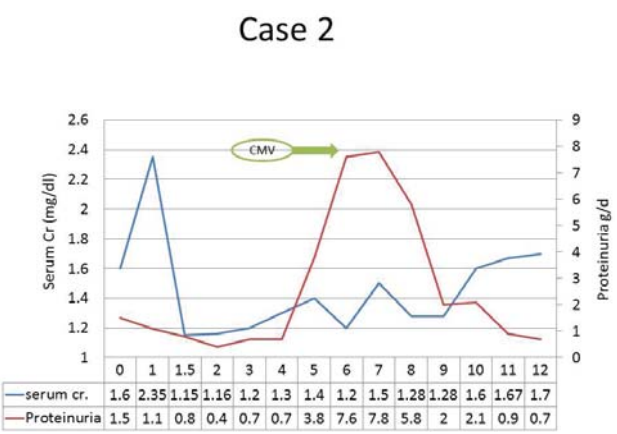
Discussion: We found FSGS with immune deposits in 2 patients with IT who developed proteinuria. This report underscores the importance of obtaining kidney biopsy in patients with IT who develop proteinuria, especially when the proteinuria is out of proportion to what one may expect from drug toxicity. Early screening and identification of underlying kidney disease may allow intervention to prevent or slow the development of ESKD in these children. Studying larger number of patients to further investigate our preliminary findings and develop a better understanding of the cause of ESKD in these patients is warranted.

SA-PO726

CMV Induced Proteinuria in Renal Transplant Recipients Syed J. Sher, Teena Tandon, Muhammad Ahmad Mujtaba, Muhammad S. Yaqub, Tim E. Taber, Asif A. Sharfuddin. *Nephrology/Medicine, Indiana Univ.*

Introduction: CMV is a common infection in kidney transplant recipients in the first year after transplantation. It is unclear if CMV infection in renal transplantation can cause allograft dysfunction with glomerulopathy.

Case Description: Case1. 54 year old CMV seronegative male with ESRD who received a CMV seropositive living kidney transplant and received 6 months of valgancyclovir for CMV prophylaxis. Ten months after his transplant, he developed acute new- onset proteinuria and rising serum creatinine from 1.1 to 1.7mg/dl. He was found to have CMV viremia of 15,000 copies while his proteinuria increased from a baseline of 0.4gm/day tot 2.5g/day. Transplant biopsy showed minimal change disease and was negative for rejection or chronic transplant changes. Treatment was initiated with valgancyclovir and CMV PCR decreased to less than 250 while proteinuria also improved back to 0.5 gms, with the addition of lisinopril. Case 2. 56 year old CMV seropositive male with ESRD who received a CMV seropositive living unrelated kidney transplant with 3 months of valgancyclovir for CMV prophylaxis. Five months after transplant the patient developed CMV disease with viremia of > 500,000 copies along with simultaneous new onset proteinuria rising from baseline 0.7g to 7.6g/day.



Transplant biopsy showed mild lymphocytic tubulitis and patchy foot process effacement of the podocytes. His proteinuria improved to 0.7 gm after his CMV was treated with valgancyclovir, initiation of lisinopril as well as reduction in mycophenolate and temporary use of high dose prednisone therapy. CMV inclusions or positive viral staining was not found in either of the biopsy cases.

Discussion: These 2 cases represent a very rare complication of CMV and clearly show that even in the presence of immunosuppression, and absence of direct visualization of virus in the kidney, glomerular changes can occur in CMV disease.

SA-PO727

Living Donor Transmitted Histoplasmosis in a Kidney Transplant Recipient Nader S. Bahri,[1] Martin L. Mai.[2] *[1]Nephrology, UF, Jacksonville, FL; [2]Transplant, Mayo Clinic, Jacksoville, FL.*

Introduction: Donor transmitted histoplasmosis (histo) post solid organ transplant is rare even in endemic areas. Most cases occur in deceased donor transplant recipients with median time from transplantation to diagnosis of 17 months. We report a case 78 days post living donor kidney transplant.

Case Description: Data was abstracted from an electronic medical record of recipient and donor data with review of medical history,exam,lab, microbiology and diagnostic studies.

A 73 year-old female native of Florida with ESRD due to hypertensive and T2DM nephropathy underwent kidney transplant from a 21 year-old donor. Donor and recipient fungal serologies by EIA were negative preop. Immunosuppression included rabbit antithymoglobin (rATG) induction (high PRA pretransplant) with maintenance tacrolimus, mycophenolate and corticosteroids with excellent kidney function. 14 days postop the recipient developed acute cellular and antibody mediated rejection managed with steroids, rATG, and IVIG and plasma exchange. 64 days later, she presented with high fever for 3 days. Travel history was unremarkable. There was no exposure to pets/birds, sick contacts, or other risk factors for fungal infection.CT scan of chest and abdomen were unremarkable. Kidney biopsy showed no rejection. Blood and urine cultures were negative for 5 days. She subsequently developed altered mental status, respiratory failure and hypotension requiring intensive care unit admission, intubation and blood pressure support. Fungal serologies by EIA were negative as were CMV and EBV PCR of serum. Bronchoalveolar lavage was remarkable for yeast. Peripheral blood smear showed intracellular yeast forms in RBC, prompting bone marrow biopsy and histo urine antigen confirming infection with histo. The donor remained asymptomatic and fungal EIA were negative postop but histo urine antigen was found to be positive.

Discussion: We believe this is the first reported case of living donor transmitted histo in kidney transplant.Donor and recipient fungal screening with EIA pre and post transplant did not identify fungal infection. Screening for histo is only recommended for high risk donors. Early use of urine histoplasma antigen is valuable in identifying acute infection.

SA-PO728

A Rare Case of Ocular Toxoplasmosis That Developed Four Years After Kidney Transplantation Toshinari Fujimoto, Izumi Yamamoto, Masatsugu Nakao, Yudo Tanno, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Takashi Yokoo. *Dept of Internal Medicine, Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

Introduction: Toxoplasmosis is a zoonotic infection caused by Toxoplasma gondii, a ubiquitous obligate intracellular parasite in both humans and warm-blooded animals. Approximately one-third of humans worldwide are estimated to be chronically infected with Toxoplasma gondii. Toxoplasmosis after solid organ transplantation is associated with high morbidity post-transplantation. Here, we report a rare case of ocular toxoplasmosis that had developed 4 years after kidney transplantation.

Case Description: A 39-year-old man had undergone living-related kidney transplantation because of IgA nephropathy. Four years post-transplantation, he revisited our

hospital because of altered visual acuity. We detected significantly high serum toxoplasma IgG antibodies (×40960) and toxoplasma antigen (×2048) using a serum latex agglutination method. Furthermore, using a primer to target the '18S rDNA' area of Toxoplasma gondii DNA (GenBank no. L37415), nested-polymerase chain reaction (PCR) test results of the anterior chamber aqueous humour were positive for Toxoplasma gondii. Consequently, ocular toxoplasmosis was diagnosed and was successfully treated with clindamycin together with pyrimethamine and folinate. After initiation of therapy, his intraocular findings markedly improved, and visual acuity recovered.

Discussion: The diagnosis of ocular toxoplasmosis is difficult when patients are in an immunosuppressive state since IgM antibodies for Toxoplasma gondii do not appear in the blood. The nested-PCR test for the anterior chamber aqueous humour is useful definitive diagnostic method for ocular toxoplasmosis. In addition, ocular toxoplasmosis should be considered in the differential diagnosis of patients with a history of kidney transplantation who present with the altered visual acuity.

SA-PO729

Ileal Tuberculosis Presenting as Fever of Unknown Origin in a Post Renal Transplant Patient Paul L. Cespedes. *Dept of Nephrology, Univ of California at Davis, Sacramento, CA.*

Introduction: Mycobacterium Tuberculosis is a leading infection following renal transplant throughout the world, with reactivation being the most common mode of infection. Prevalence of post transplant TB ranges from 1.5% in the U.S. to up to 15% in Asia. Up to 1/2 of all active TB cases after transplant are disseminated or extra pulmonary. Fever is present in 91% of patients with disseminated TB. The typical time course for TB to develop in post transplant patient is 26 months in patient treated with azathioprine and prednisilone and 11 months if the patient received cyclosporin.

Case Description: Patient is a 71 year old woman with a history of hypertension, Type II diabetes, CVA, CKD stage 5 of unknown etiology who underwent a living unrelated kidney transplant in the Philippines in 2008. Patient was treated with tacrolimus, azathioprine and prednisone initially, with azathioprine slowly tapered off. Patient presented to an outside hospital 2 month prior due to declining health with intermittent fevers, decreased PO intake, abdominal pain, nausea, diarrhea, and weight loss. Patient underwent a workup at the outside facility on 2 separate occasions with no source of fever identified. Patient's family brought the patient to UC Davis for further evaluation.

On presentation, patient had low WBC count and was spiking daily fevers to 38 degrees and 39 degrees. Infectious disease evaluation was unremarkable. A CT abdomen and pelvis showed cecal and terminal ileal wall thickening with aneurysmal dilation of the terminal ileum, consistent with lymphoma or tuberculosis. A CT chest showed numerous peripheral sub centimeter ground glass nodules and right middle lobe 12mm well-circumscribed nodule. A colonoscopy with biopsy was positive for AFB and subsequent sputum samples were positive for AFB as well. Patient was started on 4 drug anti TB regimen of rifabutin, isoniazid, pyrazinamide and ethambutol with resolution of fevers.

Discussion: While post renal transplant TB is not as common an infection in the U.S. as in other parts of the world, TB should be considered in all transplant recipients with fever of unknown origin.

SA-PO730

JC Virus Associated Transplant Nephropathy Ashraf M. Mohammed, Jiries S. Dahu, Bahar Bastani, Alexandra Ileana Voinescu. *Nephrology, St. Louis Univ, St. Louis, MO.*

Introduction: Polyomavirus-associated nephropathy is a known cause of renal graft dysfunction. While the majority of cases are caused by BK virus, very few are linked to JC virus. We report the 9th case of JC-associated nephropathy, 6 yrs post renal transplant.

Case Description: 65 years old male recipient of a deceased donor kidney induced with alemtuzumab and maintained on tacrolimus and sirolimus, presented with asymptomatic allograft dysfunction with no clear cause. Laboratory and radiology evaluation were unremarkable in the setting of therapeutic immunosuppressant levels and absence of BK viremia and viruria. Renal allograft biopsy was unremarkable for any type of rejection; however it revealed mononuclear tubulointerstitial inflammation and nuclear enlargement with granular inclusions of epithelial cells suggestive of PyVAN. Immunohistochemical stain for SV40 was strongly positive. In the absence of BK viruria and viremia, JC virus became the suspected pathogen which was confirmed by serum JC PCR and urine decoy cells. Our patient was treated with reduction of tacrolimus and sirolimus. Due to suboptimal response, tacrolimus was discontinued, leflunomide was added and sirolimus was switched to cyclosporine along with 3 doses of IVIG. JC viremia and renal function has gradually improved and remained stable to date.

Discussion: Our case illustrates the possibility of PyVAN several years post transplant, contrary to the projected time for its occurence within the first 2 years of transplant. It also demonstrates the importance of immunohistochemical staining for polyomavirus in allograft biopsies even in the absence of BK viremia or viruira to avoid diagnostic and therapeutic delays of JC nephropathy. Like previously reported cases, our case shows that JC-associated nephropathy is a unique clinical entity and we suggest testing for JC PCR when BK PCR is negative in a setting of histological evidence for PyVAN and positive SV40 stain. Despite lack of clear guidelines, our patient responded favorably to similar therapeutic protocols currently in place for treating BK nephropathy. Prospective studies are needed to better understand the risk, clinical presentation, diagnostic and therapeutic approaches of JC nephropathy.

SA-PO731

Refractory BK-Virus Induced Nephropathy in the Native Kidneys of a Pediatric Bone Marrow Transplant Recipient Nirupama Gupta, Kiran K. Upadhyay. *Pediatric Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: BK virus-induced nephropathy (BKVN) is a serious complication after renal transplantation; however, BKVN in the native kidneys of immunocompromised patients is not well known. In this report, we describe a child with multi-drug resistant BKVN. To our knowledge, this is the youngest surviving child with refractory BKVN in the native kidneys following complications of bone marrow transplantation(BMT) that led to end stage renal disease.

Case Description: A 10 y.o. African American male was diagnosed with severe aplastic anemia in April 2008. He received an allogeneic BMT in March 2012 with pre-and post-chemo and radiation therapy. By January 2013, he developed severe warm-autoimmune hemolytic anemia and became blood transfusion-dependent. He was treated with multiple courses of IVIG, Rituximab, Eculizumab, Bortezomib and Prednisone for several months along with 11 courses of plasmapheresis without any clinical improvement. His renal function started deteriorating at the same time from a baseline serum creatinine of 0.4mg/dL to 1.4mg/dL. The acute kidney injury (AKI) was initially attributed to pigment nephropathy and chronic renal damage from multiple nephrotoxic medications. His renal function declined (serum creatinine peaked at 4mg/dL) despite aggressive supportive therapy. His serum CMV and EBV titers were negative. The serum and CSF BK viral DNA PCRs were 5 million and 587copies/ml, respectively. The renal biopsy in July 2013 showed intranuclear viral inclusions and positive staining for SV40 T antigen in the tubular epithelial cells. There was extensive interstitial fibrosis and tubular atrophy. Therapy included reduction and discontinuation of immunosuppressive agents along with multiple courses of Leflunomide and Cidofovir; however, this did not reduce the BK viral load. He remains hemodialysis-dependent since September 2013.

Discussion: Although BKVN is more common in renal transplant patients, the use of newer and stronger immunosuppressive medications is increasing the risk of BKVN in non-renal transplant patients. Thus, BKVN should be included in the broad differential of AKI when taking care of such vulnerable patients for a prompt diagnosis and treatment.

SA-PO732

Cytomegalovirus-Induced Thrombotic Microangiopathy after Renal Transplant Treated with Eculizumab Anuja Java, Angelina Edwards, Ana Paula Rossi, Rowena B. Delos Santos, Christina L. Klein, Daniel C. Brennan. *Nephrology, Washington Univ in St. Louis, St. Louis, MO.*

Introduction: De novo thrombotic microangiopathy (TMA) after renal transplant is rare but life-threatening. The insult from ischemia-reperfusion is enhanced by viral infections, immunosuppressive drugs or dysregulated complement activation. Our case provides insight into the pathogenesis and novel treatment of de novo TMA.

Case Description: 75 yo Caucasian woman with ESRD from diabetes received a 4-antigen mismatched, CMV D-R+, DDTx with thymoglobulin induction (5 mg/kg), followed by tacrolimus, azathioprine, and prednisone. Creatinine (Cr) was 1.6 mg/dL but 5 months later 9.2 mg/dL with anuria. Allograft biopsy showed acute TMA without systemic evidence (Hgb 11 g/dL, LDH 214 U/L, Plt 137K/cumm, no schistocytes, ADAMTS13 75%, STEC negative). C4d and DSAs were negative and a diagnosis of aHUS was made. Eculizumab (1200 mg) was given with improvement in urine output. Infectious workup showed CMV viremia (2,582copies/mL) which was treated with valganciclovir (VGCV). Belatacept replaced tacrolimus for possible CNI-induced TMA. Cr improved to 1.8 mg/dL but rose to 6.6 mg/dL 4 months later. Repeat biopsy showed recurrent renal-limited TMA. C4d and DSAs were negative. CMV viremia (unable to quantify) was again noted. VGCV was resumed with clearance of viremia. Belatacept was stopped and eculizumab (1200 mg weekly x 4 doses, then 1200mg q2weeks) restarted. Cr improved to 2.0 mg/dL. 3 months later, testing for complement gene mutations was negative and eculizumab was discontinued. 14 months later, patient has remained stable (Cr 2.0 mg/dL, UP/C 0.1) on azathioprine, prednisone and low-dose VGCV.

Discussion: CMV-related posttransplant TMA has only been reported in 6 cases. Resolution of acute TMA with CMV treatment, recurrence with CMV viremia and the lack of correlation with a CNI in our case supports CMV as cause of the TMA. Eculizumab without plasmapheresis led to prompt improvement in renal function but was discontinued when no genetic cause was identified. This case highlights the beneficial effects of complement inhibitors in acute aHUS and shows that they can be safely discontinued once the inciting etiology is addressed.

SA-PO733

Advanced HIV Infection Leading to Graft Tolerance in a Kidney Transplant Patient Neha Das, Christine M. Durand, Hamid Rabb. *Johns Hopkins Univ.*

Introduction: With effective antiretroviral therapy (ART), patients with ESRD and well controlled HIV infection have excellent survival outcomes with renal transplantation; however, the higher rate of rejection in these patients is not well understood. We present an unusual case of renal allograft tolerance in the absence of immunosuppression in a patient with untreated advanced HIV infection.

Case Description: A 33-year-old male with ESRD due to congenital renal dysplasia underwent live donor kidney transplantation in September 2006. He had immediate graft function. Immunosupressive (IS) therapy included antithymocyte globulin for induction followed by tacrolimus, mycophenolate mofetil, and prednisone. He developed acute tacrolimus toxicity 8 months post-transplant. Serum creatinine (Scr) stabilized at 1.8-2 mg/dl. In May 2008, he was diagnosed with HIV infection. Both recipient and donor had tested

negative for HIV prior to transplant. After the HIV diagnosis, he was lost to follow-up and later self-discontinued IS therapy in September 2009. In November 2013, he presented with focal neurologic deficits. Brain MRI showed multifocal white matter lesions. CSF JC virus PCR was positive. He was diagnosed with progressive multifocal leukoencephalopathy. CD4 count was 232 cells/mm≥ and HIV RNA was 166,832 copies/ml. Scr was 1.7-1.9 mg/dl despite being off IS therapy for over 4 years. He was started on ART. IS therapy was not resumed given his active infection. A week later, he presented with a rise in Scr to 4.2 mg/dl. A transplant renal biopsy showed immune complex-mediated glomerulonephritis and moderate tubular injury without evidence of cellular or humoral rejection. Two months later, Scr improved to 1.9 mg/dl.

Discussion: The lack of allograft rejection despite absence of immunosuppression in this HIV-infected patient was unexpected. We speculate that dysfunction of helper T cell response due to advanced HIV infection resulted in allograft tolerance seen in our patient. Additionally, there is growing evidence suggesting a role of regulatory T and B cells in both allograft tolerance and HIV pathogenesis. A better understanding of the effect of HIV infection on alloimmunity is needed for effective IS therapy for HIV-positive patients with transplants.

SA-PO734

An Unusual Case of a Parasite in a Transplanted Kidney Billy T. Hour, Piangwarin Phaosawasdi, Angelo M. De Mattos. *Div of Nephrology, Univ of California, Davis, Sacramento, CA.*

Introduction: Microsporidia are obligate, spore-forming intracellular organisms that parasitize immunocompromised hosts, such as those who have undergone kidney transplantation. It can infect a variety of organ systems, including respiratory, ocular, GI, GU, and CNS. We describe here a case of microsporidia infection in a kidney transplant patient causing AKI requiring brief hemodialysis (HD) which subsequently improved after albendazole treatment.

Case Description: A 36 year old male s/p kidney transplant was noted to have worsening kidney function about 4 months after transplantation. He presented with fever, diarrhea, and AKI (creat 2.89) with workup negative. Biopsy revealed ATN. One month later he again presented with intermittent fever and AKI (creat 6.3) and biopsy revealed mixed interstitial inflammation with renal tubular abscesses. He was treated for urosepsis and discharged. Several weeks later, patient again presents with intermittent fever with AKI (creat 16.1), biopsy revealed fungus elements with intracellular parasites consistent with microsporidia despite a negative stool stain. He was subsequently started on albendazole 400mg bid but required HD for support and was discharged on HD. After a couple of weeks HD was discontinued due to improved kidney function and repeat biopsy 3 months later revealed only residual microsporidia species. Patient did not require removal of his transplanted kidney and maintains a stable creatinine of around 3.0.

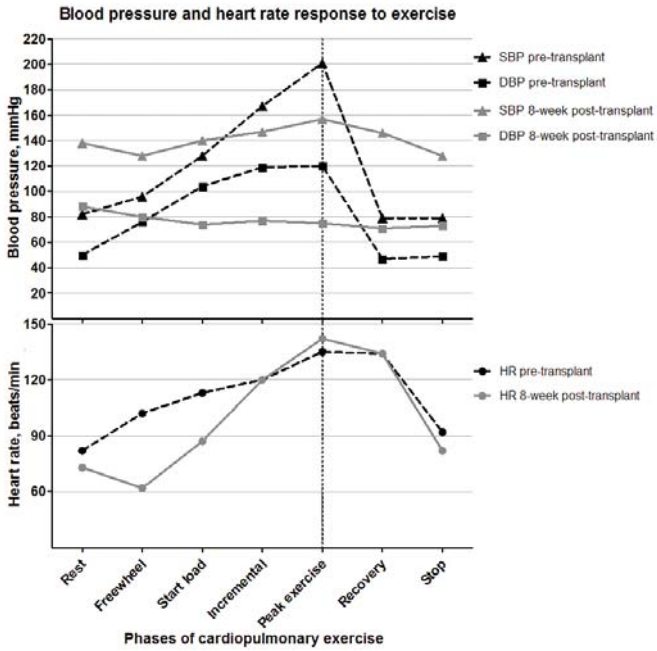
Discussion: Few cases have been described regarding microsporidia in renal transplant recipients. Common symptoms include fever and diarrhea. Diagnosis is made histologically with electron microscopy as confirmation. Treatment is typically with albendazole until stool stain is negative. This case illustrates that microsporidia should be among the differential in kidney transplant recipients with unexplained fever and diarrhea despite a negative stool stain as it can be localized to the transplanted kidney. Therefore, serial biopsies may be required for monitoring and albendazole therapy continued until it is cleared.

SA-PO735

Cardiopulmonary Exercise Triggered an Exaggerated Blood Pressure Response in a Patient with 'Refractory Hypotension' prior to Kidney Transplantation Stephen M.S. Ting,[1] Gordon Mcgregor,[1] Alice Rogan,[1] Nicolas Aldridge,[1] Susan Hewins,[1] Charles E. Weston,[2] Robert Higgins,[1] Daniel Zehnder.[1] *[1]Univ Hospitals Coventry and Warwickshire NHS Trust; [2]Dorset County Hospital NHS Foundation Trust.*

Introduction: Chronic persistent hypotension carries a significant risk of death in patients with ESRD. Such hemodynamic instability would preclude patient from major surgery.

Case Description: A 40-year old female hemodialysis-dependent patient underwent assessment in our center for antibody-incompatible kidney transplantation. A 24 months history of severe hypotension during inter- and intra-dialytic period (<80/50 mmHg) had precluded her from another transplant center. Myocardial perfusion scan and echocardiography were normal. LV ejection fraction was 62%. Aortic pulse wave velocity was preserved at 5.9m/sec. On maximal cardiopulmonary exercise testing (CPET), anaerobic threshold was 10.6ml/min/kg and oxygen consumption at peak exercise was at 73% predicted. Exaggerated rise in systolic (SBP) and diastolic blood pressure (DBP) at maximal load (ΔSBP/ΔDBP=119/70mmHg) was followed by a rapid decline during the recovery phase. Post-operatively, she was vasopressor reliant for 14 days. Eight weeks following transplantation, her resting BP was 124/82. On repeat CPET, SBP rose uniformly but DBP did not rise from baseline (ΔSBP/ΔDBP=19/-13mmHg). The heightened heart rate (HR) in the early phase of exercise was only observed prior to transplant. Cortisol, renin and aldosterone levels at rest were (pre- versus post-transplant) 433 versus 356nmol/l, <9 versus 9mU/l and 515 versus 372pmol/l, respectively.



Discussion: Exercise BP profiling and measures of functional cardiovascular reserve can facilitate the management of such complex case. Severe exercise hypertension could be the result of simultaneous augmentation of cardiac contractility, HR and vascular tone induced by dysregulated catecholamine concentration.

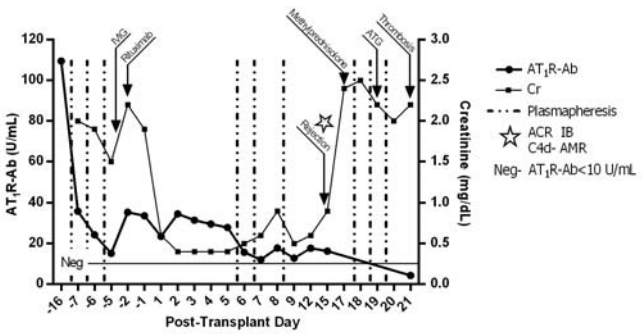
Accelerated Transplant Rejection, Allograft Thrombosis, and Failure with Angiotensin II Type 1 Receptor Antibodies Meghan Pearl, Richard K. Leuchter, Elaine F. Reed, Robert B. Ettenger, Eileen W. Tsai. *Pediatrics, UCLA, Los Angeles, CA.*

Introduction: Angiotensin II type 1 receptor antibodies (AT_1R-Ab) have been associated with vascular injury, antibody mediated rejection (AMR), and allograft (AG) failure. This case illustrates the pro-coagulant effects, accelerated rejection, and early AG loss that can occur with AT_1R-Ab despite desensitization.

Case Description: A 7yo M with ESRD secondary to posterior urethral valves lost his first renal transplant (tx) from chronic C4d+ AMR with HLA donor specific antibodies (DSA). To avoid preformed HLA antibodies (Ab) (cPRA 71%), his re-tx was a paired exchange 3/6 match. Endothelial cell crossmatch and MHC class I related chain A Ab were screened and negative, but, his AT_1R-Ab were 110U/mL (normal <10U/ml). A hypercoagulablity work-up was otherwise negative. Pre-tx desensitization with 3 days (d) of plasmapheresis (pp), IVIG, and rituximab reduced his titer to 34U/mL. He was induced with thymoglobulin (ATG), and maintained on a steroid based regimen with FK and MMF. Mild HTN (130/90) post-tx day (PTD) 3 resolved with losartan. Due to mild decline in AG function and persistent AT_1R-Ab 28U/mL, pp was performed PTD 6-9 with improvement in function and titer. PTD 15 he developed AG tenderness, fever, Cr to 2.5mg/dL, and AT_1R-Ab to 17U/ml. DSA were negative and biopsy revealed ACR IB and C4d- AMR. Cr and oliguria improved with treatment; however, he acutely developed increased pain and anuria. MR angiogram revealed renal artery thrombosis with AG loss PTD 21.



Discussion: We report the first pediatric case of AT_1R-Ab with accelerated rejection and renal artery thrombosis. We avoided tx through DSA, as DSA and AT_1R-Ab have been linked to accelerated AMR.[1] Adjunctive therapies to desensitization, such as anticoagulation, for AT_1R-Ab require further investigation. 1.Kelsch, R.et al. 'Accelerated Kidney Transplant Rejection' *Transplantation, 2011.*

IgG-Kappa Light Chain Crystalline Plasma Cell Inclusions in a Transplant Kidney Biopsy Vanessa Moreno,[1] Laura R. Kidd,[1] Rupinder Chatha,[2] William F. Glass.[1] *[1]Pathology and Laboratory Medicine, The Univ of Texas - Health Science Center, Houston, TX; [2]Nephrology, Houston Nephrology Group, Cypress, TX.*

Introduction: Intracellular immunoglobulin crystals within lymphoid cells and plasma cells are uncommon but well-documented in B-cell lymphoproliferative disorders (plasmacytoma, multiple myeloma, chronic lymphocytic leukemia, lymphoplasmacytic lymphoma, mucosa-associated lymphoid tissue lymphomas and high-grade lymphomas); but rarely occur in reactive plasmacytic infiltrates.

Case Description: A 65 year-old male with hepatitis C and status post-renal transplantation (2007) underwent kidney biopsy due to acute renal failure with elevated BUN (52 mg/dl) and Cr (2.6 mg/dl). He also presented with anemia (Hgb 7.9 g/dl), thrombocytopenia (26,000/uL), hypoalbuminemia (2.7 g/dl), and increased beta-2 microglobulin (14.1 mg/dl). SPEP and UPEP showed elevated free kappa and lambda-light chains, but kappa/lambda ratio was normal. Calcium levels were normal. The kidney biopsy showed no evidence of T-cell or antibody mediated rejection. However, focal medullary interstitial infiltrates rich in lymphocytes and polyclonal plasma cells were present. In addition, numerous eosinophilic, rectangular to rhomboid-shaped crystals were seen in the cytoplasm of plasma cells and in the interstitium which were accentuated in H&E-sections by fluorescence microcopy with the Texas red filter. The crystals were positive for IgG and kappa-light chain, but negative for IgA, IgM, and lambda-light chain. By electron microscopy, plasma cells contained intracytoplasmic rectangular to rhomboid-shaped crystals with parallel linear fine-structure (14nm repeat) within rough endoplasmic reticulum.

Discussion: The presence within a polyclonal lymphoplasmacytic infiltrate of a plasma cell subset containing monoclonal, IgG-kappa crystals has not been previously reported in native or renal allograft biopsies. While early plasma cell dyscrasia is not entirely ruled out, the overall polyclonal plasma cell population and mixed inflammatory infiltrate favors a reactive process. This conclusion is supported by reports of similar findings in *Helicobacter*-associated gastritis, osteoarthritis and bilateral papillary conjunctivitis.

SA-PO738

Takotsubo Cardiomyopathy after Simultaneous Liver–Kidney Transplantation Ekamol Tantisattamo, Sundus A. Lodhi. *Renal Div, Emory Univ.*

Introduction: Takotsubo cardiomyopathy (TC) is a rare cardiac complication of severe stress situation. Postoperative period especially after transplantation involving several immunosuppressive medications may increases risk of TC. We report a case of simultaneous liver–kidney (SLT) transplant recipient with new onset acute decompensated heart failure (ADHF) from TC.

Case Description: A 56 year-old woman with end stage liver disease secondary to non-alcoholic steatohepatitis and α-1 antitrypsin deficiency and end stage renal disease from hepatorenal syndrome requiring hemodialysis underwent SLK with basiliximab induction. Maintenance immunosuppression was with tacrolimus, mycophenolate mofetil, and prednisone. Postoperative course was complicated by delayed graft function requiring continuous renal replacement therapy (CRRT). On postoperative day 3, she developed cardiogenic shock. EKG showed sinus tachycardia without ST segment change. Troponin-I rose to 1.42 ng/mL. Transthoracic echocardiogram (TTE) showed decreased ejection fraction (EF) of 25% with basal hypokinesis and mid and apical akinesis (Figure1). Preoperative cardiac catheterization revealed normal coronary arteries and a normal EF. Her clinical condition was improved with inotropes and careful fluid management by CRRRT, which were subsequently discontinued once her renal function improved. Followup TTE one month late showed normalized EF (Figure1). She was discharged with normal liver function and serum creatinine of 1.53 mg/dL on postoperative day 15.

Discussion: TC is a rare but reversible cardiac complication after stress situation such posttransplantation. It should be considered as part of the differential diagnoses of new onset cardiomyopathy in post-organ transplantation, particulary if there is documented absence of significant coronary artery disease. Early diagnosis and treatment can normalize cardiac function and avoid morbidity and mortality.

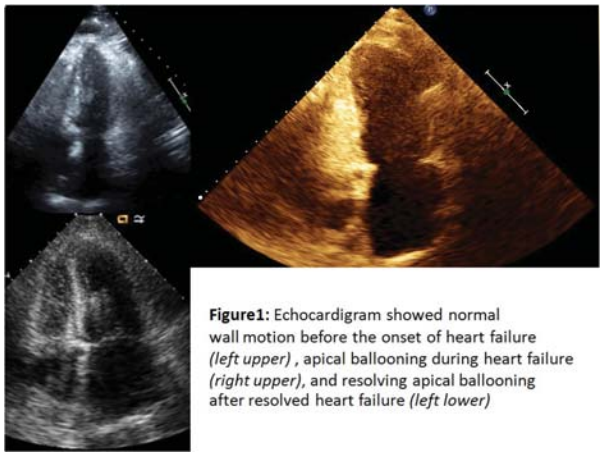

Figure1: Echocardigram showed normal wall motion before the onset of heart failure *(left upper)* , apical ballooning during heart failure *(right upper)*, and resolving apical ballooning after resolved heart failure *(left lower)*

SA-PO739

Late Onset Cerebral Toxoplasmosis in a Kidney Transplant Recipient Ekamol Tantisattamo,[1] Michael J. Connor,[2] John Doran.[1] *[1]Renal Div; [2]Div of Pulmonary, Allergy, and Critical Care Medicine, Emory Univ.*

Introduction: Opportunistic infection usually occurs during the first 6 months post-kidney transplantation when the immunity is intensely suppressed. *Toxoplama gondii* infection commonly presents in the first 3 months. We report a case of cerebral toxoplasmosis 8 years post-kidney transplantation.

Case Description: A 63 year-old woman with history of ESRD underwent deceased donor kidney transplantation with thymoglobulin induction 8 years ago. Immunosuppressive medications were tacrolimus 3 mg twice a day, mycophenolate mofetil (MMF) 500 mg twice a day, and prednisone 7.5 mg daily. She presented with left-sided weakness for 2 days. Head CT scan showed a large area of edema in the right frontal lobe with right to left shift. Brain MRI revealed a ring-enhancing mass in the right frontal lobe (Figure1). She underwent right frontal craniotomy for resection of the mass. Pathology revealed necrotizing cerebritis. Focal bradyzoite cysts and tachyzoite forms of toxoplasma were present and immunostain confirmed toxoplasmosis. She received 6-weeks of pyrimethamine, leucovorin and sulfadiazine (switched to clindamycin due to hyperkalemia), followed by lifelong prophylaxis. MMF was discontinued and tacrolimus dose was decreased to 2 mg twice a day. One week later, low dose MMF 250 mg twice a day was restarted and target tacrolimus trough level was decreased to 3-5 ng/ml. Renal function was stable during the admission with serum creatinine of 1.8 – 2 mg/dl. She was discharged on hospital day 28 to rehabilitation center with persistent left weakness, dysarthria and cognitive deficits.

Discussion: Cerebral toxoplasmosis has a poor prognosis if not promptly treated, so high index of suspicion and early tissue diagnosis are warranted even in late post-kidney transplantation in order to avoid treatment delays and lessen morbidity and mortality.

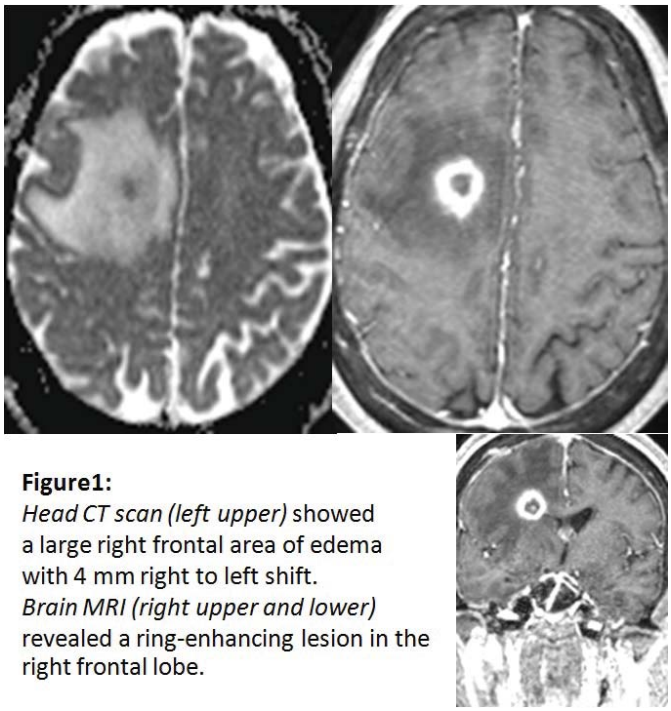

Figure1:
Head CT scan (left upper) showed a large right frontal area of edema with 4 mm right to left shift.
Brain MRI (right upper and lower) revealed a ring-enhancing lesion in the right frontal lobe.

SA-PO740

Foscarnet-Induced Crystal Nephrotoxicity in a Kidney Transplant Recipient Ekamol Tantisattamo,[1] Thomas E. Rogers,[2] Alton Brad Farris,[2] Sundus A. Lodhi.[1] *[1]Renal Div; [2]Dept of Pathology, Emory Univ.*

Introduction: Foscarnet is the treatment of choice for ganciclovir-resistant cytomegalovirus (CMV) infection. Renal injury from crystalline nephropathy is a serious side effect and can challenge the treatment of CMV disease.

Case Description: A 38-year-old CMV seronegative man with ESRD underwent kidney transplantation with a CMV seropositive deceased donor. He was on valganciclovir 450 mg daily for CMV prophylaxis. Six weeks post transplant, he developed primary CMV infection with serum PCR of 4800 IU/mL. Maintenance immunosuppression was decreased, and valganciclovir was increased to 900 mg bid with subsequent reduction in CMV PCR to 580 IU/mL. Three months post transplant he developed abdominal pain, diarrhea, and CMV PCR elevation to 199,000 IU/mL. Genetic mutation testing of UL97 confirmed ganciclovir-resistant CMV. Foscarnet and normal saline were initiated. CMV PCR decreased to low positive within 1 month. However, serum creatinine (SCr) rose to 2.35 mg/dL from the baseline of 1.1 mg/dL. A kidney allograft biopsy was performed and revealed unstained polarizable crystalline material in the tubules and in the hila of involved glomeruli (Figure1). IV fluid was increased and foscarnet was discontinued. Five months later, SCr improved to 1.5 mg/dL with low positive CMV PCR. Serum CMV PCR initially

rebounded to a peak of 50,000 IU/mL, but he did not have evidence of organ involvement. The viremia was managed with a combination of maribavir and CMV IVIG, ultimately leading to a negative serum CMV PCR.

Discussion: As a successful treatment for ganciclovir-resistant CMV, foscarnet is a highly nephrotoxic medication. Here we present a rarely reported case of crystalline nephropathy in the renal allograft. Medication discontinuation and hydration are the mainstays of treatment. Subsequent treatment of CMV disease requires judicious use of medications.

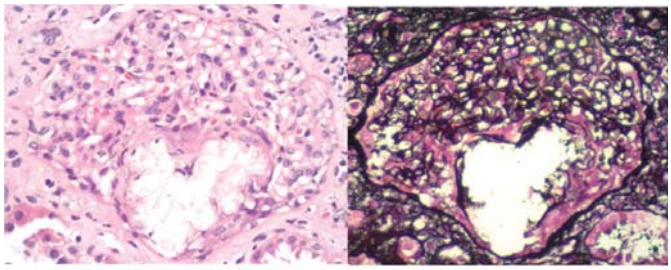

Figure1: A glomerulus has a prominent collection of crystalline material at the hilum (hematoxylin and eosin, left, and Jones silver stain, right, both 400x original magnification).

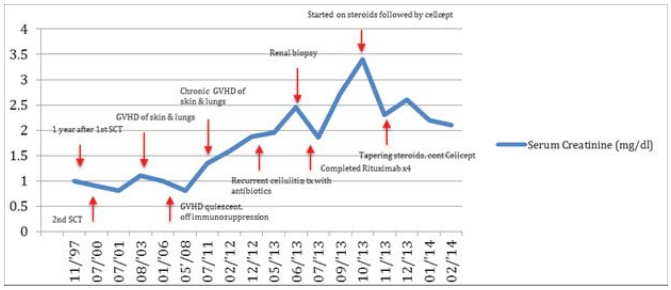
SA-PO741

Thrombotic Microangiopathy of the Kidney in a Hematopetic Stem Cell Transplant Recipient Successfully Treated with Cellcept: A Presumed Graft versus Host Disease of the Kidney Naveed S. Anwar,[1] Maen Abdelrahim,[2] Ala Abudayyeh.[2] *[1]Nephrology, The Univ of Texas Medical School at Houston, Houston, TX; [2]Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: The causes of AKI in HSCT could be due to prerenal, nephrotoxins, engrafment syndrome, veno-occlusive disease of the liver, thrombotic microangiopathy(TMA),and calcineurin inhibitors. A rare late cause of renal dysfunction in allogenic SCT patients is GVHD of the kidney.We will be presenting TMA of the kidney as the first reported case of probable GVHD of the kidney successfully treated with cellcept.

Case Description: A 37-year-old male with a history of chronic myelogenous leukemia underwent allogeneic SCT fourteen years ago. Conditioning regimen included cyclophosphamide and total-body radiation.Post-transplant course was complicated by GVHD of the skin, liver and lungs. He has been off immunsosuppression for over 5 years and his creatinine started to rise from 1.0mg/dl to 1.96mg/dl with proteinuria of 5gm. He underwent a renal biopsy that revealed thrombotic microangiopathy. Initially he was treated with rituximab with a partial response. He later relapsed with creatinine peaked at 3.7mg/dl and proteinuria of 8gm.The patient was initiated on steroids and Cellcept with dramatic improvement in his serum creatinine at 2.0mg/dl and proteinuria at 3gm for the last eight months



Discussion: Recently, nephrotic syndrome occurring in allogeneic SCT patients has been considered to be a possible presentation of chronic GVHD of the kidney. The pathogenesis is yet to be defined, but it has been shown that 52% of patients with HCT-associated membranous nephropathy had active GVHD at the time of diagnosis.This is the first case to report TMA as a presentation of possible kidney GVHD post stem cell transplant successfully treated with cellcept.

SA-PO742

Acute Pyelonephritis of Transplant Kidney with False Positive C4d Staining Mimicking Acute Humoral Rejection Shehpar Khan,[1] Mumnoon Haider,[1] Bruce A. Jones,[2] Jerry Yee,[1] K.K. Venkat.[1] *[1]Div of Nephrology, Henry Ford Hospital; [2]Dept of Pathology, Henry Ford Hospital, Detroit, MI.*

Introduction: Circumferential diffuse (in more than 50% of peritubular capillaries [PTC]) C4d staining is a key diagnostic marker for both Acute Humoral Rejection (A-HR) and Chronic Humoral Rejection (C-HR) of renal allografts. Complement C4 activation in HR generates C4 breakdown products of which C4d has the longest half-life and strongest tissue binding affinity, making it a good marker for C4 activation. We report the occurrence of false positive C4d staining in a patient with allograft pyelonephritis with AKI.

Case Description: A 40 y.o. woman with ADPKD and stage-5 CKD underwent preemptive living unrelated donor (friend) renal transplant (bazliximab induction, tacrolimus/mycophenolate/prednisone maintenance). Nadir serum creatinine (SCr) posttransplant was ~ 2.0 mg/dL. One month after completing six months of trimethoprim-sulfa prophylaxis, fever, oliguria and AKI (SCr 8.43 mg /dL) developed. Urinalysis showed pyuria, hematuria, and positive nitrite test. Allograft biopsy revealed interstitial and tubular wall infiltration ("tubulitis") by PMNs and lymphocytes with many tubular intraluminal PMNs. The C4d immunoperoxidase stain was diffusely positive (90-95% of PTC) with atypical granular PTC wall staining and frequent intraluminal staining. Treatment for A-HR was being considered but positive urine and blood cultures for *Klebsiella pneumoniae* were reported soon after the biopsy. Donor-specific anti-HLA antibody (DSA) was negative. SCr returned to baseline within 1 week with intravenous antibiotic therapy alone and remained between 1.8 and 2.1 mg/dL over the subsequent 7 months. Repeat biopsy 1 month after AKI resolved was negative for C4d.

Discussion: Recovery from severe AKI without added (or change in maintenance) immunosuppression and the negative DSA test confirm that our patient did not have A-HR. Thus, allograft pyelonephritis may cause false and strongly positive C4d staining in PTC, suggestive of A-HR and may result in unnecessary aggressive immunosuppressive therapy. Atypical, granular and intraluminal C4d-PTC staining, in the setting of acute pyelonephritis, should be interpreted with caution.

SA-PO743

Severe Acute Cellular (ACR) and Humoral Rejection (AHR) After Renal Transplant: A Case Report Snigdha Reddy, Jerry Yee, Anita K. Patel. *Div of Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Introduction: Human leukocyte antigen (HLA) donor-specific antibodies (DSA) have been widely associated with poor graft survival. The role of non-HLA antibodies with antigenic targets such as various minor HLA antigens, vascular receptors, adhesion molecules, and intermediate filaments is not clearly understood. We report a case of severe acute cellular and endothelial precursor cell (EPC) antibody-mediated rejection.

Case Description: A 49 year-old immigrant male with end-stage renal disease of unknown etiology with a history of a failed living-related renal transplant underwent a second deceased-donor kidney transplant from a 58 year-old male with a serum creatinine (SCr) of 1.1 mg/dL and a Kidney Donor Profile Index (KDPI) of 70%. The patient received thymoglobulin (TMG) for induction, but developed delayed graft function. The immediate postoperative course was complicated by anuria and revision of the renal artery anastomosis. Allograft biopsy revealed focal infarction. Postoperatively, the urinalysis showed numerous dysmorphic RBCs, cellular casts and urine protein-to-creatinine ratio of 3 g/g. DSA were negative. An intraoperative biopsy on day 11, done during surgery for small bowel obstruction, revealed acute T-cell mediated rejection, Banff 2A, glomerulitis, peritubular capillaritis and endothelialitis. C4d staining was absent. Electron microscopy demonstrated podocyte injury with effacement and endothelial cell detachment from the glomerular basement membrane. In the absence of HLA DSA, the histocompatibility lab flow crossmatch was positive for EPC IgM and IgG antibodies. The patient was treated for severe ACR and AHR with TMG, steroids, and plasma exchanges with intravenous immunoglobulin (IVIG) per institution protocol. His urine output improved and hemodialysis was discontinued as kidney function improved, with a nadir SCr of 1.65 mg/dL.

Discussion: Post-transplant rejection may be mediated by simultaneous ACR and AHR. Investigation for non-HLA antibodies should be carried out when HLA DSA are absent. A better understanding of effector mechanisms between HLA and non HLA antibodies is required to improve targeted therapy.

SA-PO744

Primary Graft Dysfunction Secondary to Early Cell Mediated Rejection after Zero Mismatch Kidney Transplantation Nissreen S. Elfadawy,[1] Gabriela Soledad Diaz,[2] Andres G. Chiesa-Vottero,[1] Emilio D. Poggio,[1] Richard A. Fatica,[1] Saul Nurko,[1] Brian R. Stephany,[1] Stuart M. Flechner,[1] Medhat Askar.[1] *[1]The Kidney Transplant Program, Cleveland Clinic, Cleveland, OH; [2]Unidad de Inmunología e Histocompatibilidad, Hospital Durand, Buenos Aires, Argentina.*

Introduction: We report on a primary graft dysfunction and early acute cell mediated graft rejection (ACR) in a highly sensitized recipient after receiving a zero mismatch (0MM) kidney transplantation.

Case Description: The recipient is a 40-year-old male, with end stage renal disease secondary to IgA nephropathy with previous 2 failed transplants. He subsequently presented with high level of HLA allsonsitization including multiple HLA-DP antibodies (cPRA=100%). The third allograft was a deceased donor (DD) 0MM graft for all HLA including DP (he was allele level mismatch at DQB1) with negative DSA and flow cytometry crossmatch. Donor was a 27-year-old; the implant biopsy showed no sclerosis and normal architecture of the allograft. Despite initially diuresing graft immediately after revascularization alongside induction with IL2-RB and maintenance immunosuppression with Tac/MMF/pred, the patient remained anuric, and he required dialysis on postoperative day 1 (POD1) due to hyperkalemia. Graft biopsy was done on POD9 which showed ACR BANFF grade 2A. The peritubular capillaries stained negative for C4d, and DSA were negative. Combination therapy consisting of antithymoglobulin (ATG), plasmapheresis and intravenous immunoglobulin (IVIG) failed to improve the graft function. Graft biopsy was repeated on POD50 and showed chronic active T-call mediated rejection. Another cycle of ATG was given. By 3.5 months post-transplant, he had no clinical signs of graft recovery, and remained dialysis dependent.

Discussion: This case is the first to report primary graft dysfunction and evidence of cell mediated rejection in a high sensitized patient after 0MM kidney transplantation. Our findings lend support to the notion that highly sensitized kidney transplant candidates are

at increased risk of cell mediated rejection and graft loss even in the context of 0MM DD kidney transplantation, and in the settings of prospective negative DSA and flow crossmatch.

SA-PO745

High-Dose Chemotherapy-Induced Severe Thrombotic Microangiopathy (TMA) in an Autologous Stem Cell Transplant (SCT) Recipient for Post-Renal Transplant B Cell Lymphoma:Critiical Therapeutic Role of Plasma Exchanges (PE) and Eculizumab Despite No Tumor Recurrence or Mutations in the Complement Pathway Proteins (CPP) Usman Z. Bhutta,[1] Kai Lau.[1,2] *[1]Nephrology, Univ of Oklahoma, OKC, OK; [2]Medicine, VAMC, OKC, OK.*

Introduction: Differential diagnoses of TMA in renal transplants include calcineurin inhibitor toxicity, radiation, rejection, cancers, sepsis, thrombotic thrombocytopenia purpura, hemolytic uremic syndrome (HUS) and the increasingly recognized mutations in CPP, producing atypical (a) HUS. Recently we cared for a 36-year-old man with post-transplant B cell lymphoma for which he underwent resection, followed by rituximab, high-dose chemotherapy with cytoxan, adriamycin, vincristine and autologous SCT. Despite complete lymphoma remission and full SCT engraftment, a few mon later, he showed persistent and worsening thrombocytopenia, hemolytic anemia and acute allograft failure.

Case Description: History, clinical course and lab findings were reviewed to gain insights in potential pathogenesis and management.

Serum (S) creatinine (cre) rose relentlessly from 1.4 to 2.8 mg%. Renal biopsy showed severe TMA and no antibody-mediated rejection. Donor-specific HLA antibodies were negative. Despite steroid pulses and omitting tacrolimus, S cre steadily rose to peak at 7.5. Platetets (Plt) fell from 156 to 46 k/mm3; Hgb from 11 to 5.6 g%. LDH rose from 287 to 870 U/L. ADAMTS 13 activity was normal. Genetic testing and studies of CCP showed no defects. He received plasma exchanges (7 courses each ~6 sessions in 5 mon) reducing mean LDH by 207 U/L and raising haptoglobin by 26 mg%. Though C3 [71 (nl >85 mg%)] and C4 [8 (nl >13 mg%] were mildly low, his rapidly deterioration forced us to try eculizumab, monoclonal antibodies versus C5. After 11 doses in 5 mon and with extra rituximab, his plt rose to 200 K/mm3, Hgb stabilized at 8.9 g% without transfusion, LDH <500, S cre ~ 5 mg%. He was asymptomatic and able to work full time.

Discussion: By exclusion, we attribute his TMA to high-dose chemotherapy though deemed very rare in autologous (versus allogenic) SCT without prior radiation. Previous reports suggest poor prognosis but our patient illustrates possible sustained remission over time by combining PE and eculizumab.

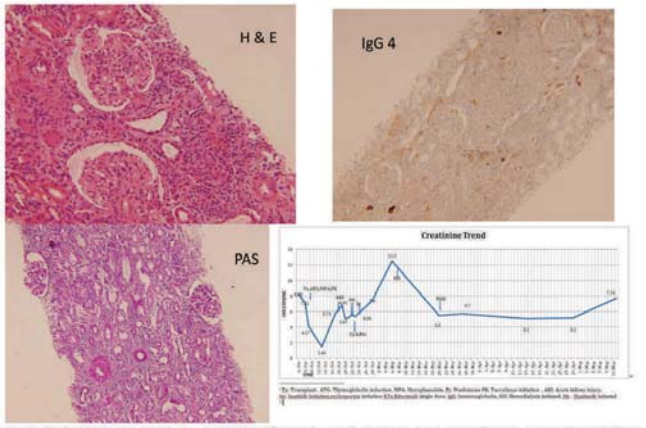
SA-PO746

Novel Use of Masitinib for Recurrent Familial Interstitial Nephritis Post Renal Transplantation Siddiq Anwar, Ravkiran Kaur Khurana, Helen Liapis, Timothy A. Horwedel, Daniel C. Brennan. *Washington Univ School of Medicine.*

Introduction: Recurrence of familial interstitial nephritis(FIN) post kidney transplantation (KT) is previously reported. We report a fulminant course of acute interstitial nephritis(AIN) post KT.

Case Description: 32 yr. white man with FIN underwent his third KT; 0-A,2-B, 1-DR Mismatch deceased donor(DD)KT with thymoglobulin induction, prednisone taper, myfortic 360mgBID, Prograf - aim 5-7ng/L plus Valgancylcovir, Bactrim and fluconazole prophylaxis. Creatinine (SC) was 1.4mg/dl at discharge.Represented week later with SC of 5.2mg/dL needing dialysis (HD). Biopsy showed severe AIN with negative C4d. Bactrim, aspirin +omeprazole were stopped and high dose prednisone commenced + Rituximab given in view of 1 donor specific antibody (B7:MFI 12, 817). We commenced him on Imatinib(Tyrosine kinase inhibitor-TKI). As his insurance would not pay, Masitinib 300mg Qd was commenced 4 weeks after his initial presentation after obtaining on compassionate grounds. As he remained on HD after 5 weeks MB was discontinued



Sample contained about 17 glomeruli, of which none are globally sclerosed and are unremarkable. The tubules show extensive tubular injury. There is mild tubulitis. There is diffuse severe acute interstitial nephritis with eosinophils and focal vague granulomas. There is mild interstitial fibrosis and tubular atrophy. The arteries and arterioles are moderately thickened. Arteriolar hyalinosis is not seen. At least two medium to large sized arteries are present and show no endothelialitis. Peritubular capillaritis is not present. PAS x2 shows minimal tubulitis with the majority of inflammation in the interstitum. The trichrome stain highlights no interstitial fibrosis. The findings show mild tubulitis. IgG4 staining was performed and was negative

His 1st KT from his mother was lost due chronic rejection (CAMR) after 15 yrs and lost his 2nd KT (DD) in 6 months due to AIN. Sister's KT from her eldest brother was lost due to CAMR after 15yrs and lost her 2nd KT(DD) early due to AIN. Brother received KT from his father which has lasted > 15 yrs.

Discussion: We believe recurrence of FIN post KT is autoimmune process that occurs in DDKT due to introduction of foreign antigens however living related KT provides relative protection as the tubular epitope was similar. Recurrence has been reported within weeks to years post KT. TKI have immunomodulating and antifibrotic properties. In this case though ineffective in reversing his inflammatory process it was well tolerated with no untoward events. Further control studies are needed to define its use in kidney diseases. Genetic workup is underway in this family cohort.

SA-PO747

Wunderlich Syndrome in a Transplant Recipient Venkatesh Kumar Ariyamuthu,[1] Tanya Tocharoen Tang,[1] Muhammad Omer,[1] Daniela P. Ladner,[2] Mohammed Javeed Ansari.[1] *[1]Nephrology, Feinberg School of Medicine, Northwestern Univ, Chicago, IL; [2]Surgery, Feinberg School of Medicine, Northwestern Univ, Chicago, IL.*

Introduction: Spontaneous rupture of renal cell cancer (RCC) is rare yet well-recognized entity. Wunderlich syndrome is spontaneous non-traumatic renal hemorrhage and we report one such case in a renal transplant recipient caused by Papillary RCC (PRCC).

Case Description: 54 year old African American male who had been on hemodialysis for 6 years for End Stage Renal Disease secondary to hypertension underwent a deceased donor kidney transplant in 2006 which failed and received another kidney transplant in 2011. He presented with sudden onset right flank and right lower quadrant abdominal pain. Computed tomography of abdomen was initially reported as consistent with a large right retroperitoneal hemorrhage later revised as an intra-renal hematoma. The patient underwent transcatheter embolization of the right native kidney and subsequently underwent exploratory laparotomy with right native nephrectomy due to high clinical suspicion of underlying RCC in light of the dialysis vintage. This suspicion was further heightened by the fact that the patient's hemoglobin was 15 g/dl despite CKD stage 4, which hinted towards paraneoplastic erythrocytosis from RCC. Pathological examination revealed Fuhrman's Grade 1 PRCC, type 1. A CT of chest and PET scan were negative. Immunosuppression was lowered given the malignancy.

Discussion: Wunderlich syndrome is commonly caused by tumors, vasculitis and cysts. Patients may present with the classic Lenk triad, including acute flank or abdominal pain, palpable flank mass, and hypovolemia. CT is 100% sensitive for detection of retroperitoneal hemorrhage and better than ultrasound for identification of an underlying renal mass, however CT can miss underlying tumors because of smaller size of mass, presence of surrounding hematoma and acquired cysts. Incidence of RCC is increased in both ESRD patients and transplant recipients. Erythrocytosis is a presenting feature of RCC. Currently there are no guidelines for screening for RCC in ESRD patients. Our case reiterates the significance of routine screening for RCC in renal transplant recipients.

SA-PO748

Plasmapheresis as Bridging Therapy for Primary Non-Function following Liver Transplantation Anja H. Bienholz,[1] Bartosz Tyczynski,[1] Ali Canbay,[2] Andreas Kribben,[1] Andreas Paul,[3] Fuat H. Saner.[3] *[1]Dept of Nephrology, Univ Hospital Essen, Univ Duisburg-Essen, Essen, Germany; [2]Dept of Gastroenterology and Hepatology, Univ Hospital Essen, Univ Duisburg-Essen, Essen, Germany; [3]Dept of General, Visceral and Transplant Surgery, Univ Hospital Essen, Univ Duisburg-Essen, Essen, Germany.*

Introduction: Primary non-function (PNF) following liver transplantation (LTX) is a rare, but severe complication of unknown cause. The only life-saving therapy consists of a second LTX within a narrow time frame. To bridge the time to organ allocation and to ensure a clinical condition which seems to make a successful LTX feasible is a special difficulty.

Case Description: We report on two 41 and 56 years old patients (pre-operative MELD-Score 11 and 16) with PNF following LTX were plasmapheresis ensured retransplantation.

Initial LTXs were without complications and free of blood product transfusions. Despite ultrasound doppler proofed regular perfusion, both patients developed PNF immediately following surgery with transaminase elevation GOT/GPT >10,000/>7,500 U/l, severe coagulopathy and lactate levels >17 mmol/l. Hemodynamic instability required vasopressors in cumulative concentrations of >5 resp. >1.7 µg/kg/min. Both patients developed anuric acute kidney failure requiring renal replacement therapy. Patients were listed "high urgency" for retransplantation. Lacking further therapeutical options patients received two resp. one plasmapheresis with replacement of plasma volume by 3.4-4.0 l fresh frozen plasma during organ allocation. Besides an adequate treatment of coagulopathy, transaminases were reduced by >50% and lactate levels to <3 mmol/l. Already during treatment demand for vasopressors declined to concentrations of <1,5 und <0,4 µg/kg/min. Plasmapheresis stabilized the clinical conditions of the patients and allowed a second, successful LTX. Histological work-up of both cases indicated massive necrosis (>80%) of the first grafts.

Discussion: Plasmapheresis as bridging therapy for PNF following LTX seems to be an option especially for hemodynamic stabilization during organ allocation for renewed LTX. The underlying mechanisms going beyond plasma infusion are unknown by today.

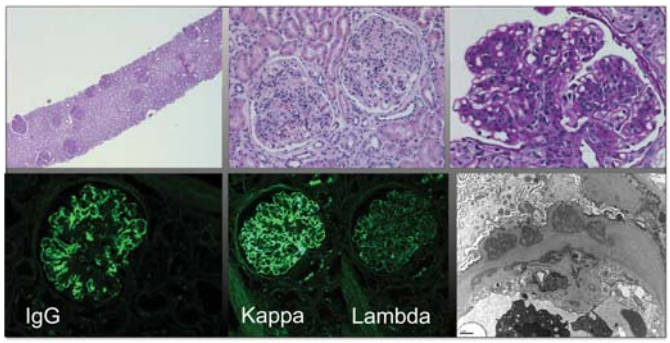
SA-PO749

Proliferative Glomerulonephritis with Monoclonal IgG in Renal Allografts Laith Farah Al-Rabadi, Sandeep Ghai, Joel M. Henderson, Jean M. Francis. *Nephrology, Boston Univ Medical Center.*

Introduction: Various glomerular diseases are associated with the deposition of monoclonal IgG. The differential diagnosis of monoclonal IgG glomerular deposition include type 1 cryoglobulinemia, light and heavy chain deposition disease, and immunotactoid glomerulonephritis. Proliferative GN with monoclonal IgG deposits (PGNMID) is a newly described entity that does not conform to any of those subtypes. It represents a form of proliferative GN with electron-dense deposits localized to the glomeruli and the finding of monoclonal IgG deposits on immunofluorescence. Recurrent and de novo PGNMID in the renal allograft have been described in few case series with total of nine cases reported. Herein, we present the clinical-pathologic features of three cases of recurrent PGNMID in the renal allograft showing the variable course of this disease.

Case Description: The 3 patients did not have any bone marrow involvement and there was no evidence of monoclonal protein in the urine and serum immunofixation studies making disease activity monitoring difficult. Case 1 was treated only conservatively with ACE inhibitors but eventually developed worsening renal function. Patient opted to resume chronic dialysis with no further therapy. Case 2 was complicated with the loss of the graft within the first year after transplant, and case 3 (Biopsy below) is actively being treated with bortezomib in the setting of worsening graft function and nephrotic range proteinuria.



Discussion: PGNMID is becoming a more recognized entity. Evaluating those patients for transplant eligibility has not been previously discussed and may be challenging in the absence of distinct data of remission given that most patients have normal bone marrow biopsy and no monoclonal band on serum and urine testing. Data is scarce in terms of follow up and treatment. Some immunosuppressive medications in the new era of transplant may be promising.

SA-PO750

Secondary Oxalosis: An Under Diagnosed Cause of Delayed Graft Function After Kidney Transplantation Varsha Pathak, Iris J. Lee, Avrum Gillespie, Serban Constantinescu, Mythili Ghanta. *Temple Univ School of Medicine.*

Introduction: Secondary oxalosis is associated with malabsorptive states, ethylene glycol poisoning, and excessive vitamin C ingestion. It can be clinically silent in end stage renal disease patients on dialysis. If left untreated after kidney transplantation, secondary oxalosis can lead to oxalate deposition and allograft loss. Primary renal allograft non-function has also been reported as a consequence of secondary oxalosis. We report a case of secondary oxalosis that contributed to prolonged delayed graft function (DGF).

Case Description: 55-year-old male with ESRD on hemodialysis received a deceased donor kidney from a 50-year-old male with hypertension and stroke. Donation was after cardiac death with terminal Cr of 1.2 mg/dl. Post transplant, the recipient required dialysis. Allograft biopsy ten days after transplant showed minimal tubular injury and no rejection. Second biopsy three weeks after transplant due to ongoing dialysis dependency showed extensive deposition of oxalate crystals in the tubules. Review of recipient history suggested enteric hyperoxalosis secondary to chronic pancreatitis and malabsorption. Therapy with oral calcium carbonate was initiated, along with a strict low oxalate diet and adherence to pancreatic enzyme replacement therapy. Renal allograft function recovered four weeks after transplant. 24 hr urine studies showed hyperoxaluria (50ng/dl) and also hypocitraturia, hypomagnesuria. Repeat biopsy eight weeks post transplant showed decreasing burden of oxalate in biopsy sample. Allograft function stabilized with Cr at 2.4 mg/dl at 6 months.

Discussion: Enteric oxalate nephropathy may lead to allograft dysfunction and should be considered in the differential for DGF in kidney recipients with history of chronic malabsorptive states. This case emphasizes the need to identify potential causes of secondary hyperoxaluria at the time of initial transplant evaluation, which can lead to prevention or early diagnosis post transplantation.

SA-PO751

Successful Transplantation of Deceased Donor Kidneys From an Anuric Dialysis Dependent Donor with Acute Kidney Injury Varsha Pathak, Akshta Pai, Mythili Ghanta, Serban Constantinescu, Iris J. Lee. *Temple Univ School of Medicine.*

Introduction: Kidneys from donors with acute kidney injury (AKI) are often under utilized for transplantation. Despite studies showing comparable outcomes (3-5 year follow-up) to a standard criteria donor kidney, donor AKI remains the second leading cause of organ discard after harvest. Donor features in AKI that lead to center refusal include: 1. Dialysis dependency, 2. Oliguria or anuria, 3. Patients with disseminated intravascular coagulopathy (DIC) and 4. Terminal serum creatinine (Cr) >2.

Case Description: We report two successful kidney transplants from a donor with severe anuric AKI, dialysis dependency and DIC at the time of organ recovery. The donor was a 17 year old white male, with KDPI of 21%, with an admission Cr of 1mg/dl. Procurement biopsies showed moderate to severe acute tubular necrosis with no evidence of interstitial fibrosis or glomerulosclerosis. The organs were perfused after recovery with acceptable pump numbers. Recipient 1 had delayed graft function (DGF) requiring dialysis for 17 days, but achieved stable allograft function with a Cr of 1.4mg/dl at three months. Recipient no 2 had DGF requiring dialysis for 30 days, with recovery of the Cr to 1.5mg/dl at three months.

Discussion: With a growing wait list, increased acceptance of carefully selected kidneys from donors with AKI is needed. Elevated terminal creatinine and dialysis dependency are strong risk factors for kidney discard, however further studies are needed to optimally identify AKI donor features that are associated with safe and favorable outcomes.

SA-PO752

Minimal Change Disease Superimposed on Chronic Calcineurin Inhibitor Nephrotoxicity in a Stem-Cell Transplant Recipient with Chronic Graft versus Host Disease Egbert C. Liquete,[1] Josephus Sanjorjo,[1] Jerry Yee,[1] Nalini Janakiraman,[2] K.K. Venkat.[1] *[1]Nephrology and Hypetension, Henry Ford Hospital, Detroit, MI; [2]Hematology/Oncology, Henry Ford Hospital, Detroit, MI.*

Introduction: Late renal complications in Stem-Cell Transplant Recipient (SCTR) include CKD from Chronic Calcineurin Inhibitor Nephrotoxicity (CNIT) or CNI-related thrombotic microangiopathy and Graft versus Host Disease (GVHD)-related membranous nephropathy or Minimal Change Disease (MCD).

Case Description: We report the rare, simultaneous occurrence of CKD from CNIT and AKI on a background of GVHD-related MCD. A 40 year-old man, an allogenic SCTR for thalassemia intermedia, developed cutaneous Graft versus Host Disease 1 month after SCT. He was treated with tacrolimus, sirolimus and prednisone and developed CKD (serum creatinine [SCr] 1.5 mg/dL) within 1.5 years after treatment. The SCr increased to 2.04 mg/dL 3 years post- transplant; tacrolimus and sirolimus were discontinued, and prednisone was maintained at 15 mg daily. Within 8 weeks, the patient gained 30 lb and developed anasarca, and the SCr increased to 3.28 mg/dL, with a 24-h urine protein of 30 g and serum albumin of 1.2 g/dL. A kidney biopsy revealed nodular afferent arteriolar hyalinosis, 32% glomerular obsolescence, tubular atrophy, interstitial fibrosis, diffuse podocyte fusion, thickened basement membranes, and no glomerular electron dense deposits. Anasarca resolved, SCr declined to 1.52 mg/dL and the urine protein-to-creatinine ratio was 1.5 g/g, following rituximab administration (375mg/m^2/wk× 4) and an increase in prednisone dosage to 30 mg daily.

Discussion: The severe, abrupt appearance of nephrotic range proteinuria and salutary response to rituximab and prednisone supports a diagnosis of MCD. Its rapid development after tacrolimus and sirolimus discontinuation implies that MCD was a manifestation of GVHD, and superimposed on CNIT-induced CKD. This report demonstrates that MCD may be superimposed on CNIT and establishes the efficacy of rituximab treatment in GVHD-related MCD.

SA-PO753

Rapid Recurrence of C3 Glomerulonephritis after Transplantation in Setting of Delayed Graft Function Neetika Garg,[1] Eliyahu V. Khankin,[1] Anne Nicholson-Weller,[2] Christin Rogers,[3] Isaac Ely Stillman,[4] Martha Pavlakis.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center (BIDMC); [2]Immunology, BIDMC; [3]Pharmacy, BIDMC; [4]Pathology, BIDMC.*

Introduction: C3 glomerulonephritis (C3GN) is a recently described entity resulting from dysregulation of the alternate complement pathway (ACP). Recurrence rate is high (up to 67%), typically occurring months to years after transplantation, and frequently leading to graft loss. Here, we describe a patient with C3GN whose disease recurred in the allograft soon after transplantation, in setting of delayed graft function (DGF).

Case Description: 51 year old Caucasian male on hemodialysis (HD) for 4 years underwent deceased donor renal transplantation. Native renal biopsy was consistent with C3GN. Serum was negative for C3 nephritic factor, anti factor H autoantibody, hepatitis C and monoclonal gammopathy. Genetic evaluation revealed mutations in one allele each of CFH and CFI, encoding regulatory complement factors H and I respectively. Immunosuppression regimen consisted of antithymocyte globulin (6 mg/kg), steroids (withdrawal over 6 days), mycophenolate (2 grams/day) and tacrolimus (target trough 10 – 12 ng/mL). Due to acute kidney injury in donor and prolonged cold ischemia time, DGF was not unexpected. However, despite improving urine output over the next two weeks, he remained HD dependent for solute clearance. He had low C3 level (54 mg/dL), normal C4 level and heavy proteinuria (urine protein to creatinine ratio (PCR) 8 to 15). Allograft biopsy on POD 14 was consistent with acute tubular necrosis and recurrent

C3GN. Following booster vaccinations and antibiotic prophylaxis for various encapsulated organisms, treatment with eculizumab was initiated. After his first two doses, he has been able to come off HD with current creatinine of 2.7 mg/dL and urine PCR down to 0.1.

Discussion: To our knowledge, this is the first report of C3GN recurrence soon after transplantation, in a patient with known complement gene mutations. Ischemic reperfusion injury related complement activation contributing to DGF may have played a role. Terminal complement blockade with eculizumab, when used early, may be effective in limiting renal injury from both these processes.

SA-PO754

Renal Recovery of Pediatric Liver Transplant Patients after Prolonged Renal Replacement Therapy Adnan Safdar,[1] Karen Eldin,[2] Ryan Himes,[3] Ayse Akcan Arikan,[1,4] Moreshwar Desai,[4] Michael C. Braun,[1] Poyyapakkam Srivaths.[1] *[1]Renal Section, Texas Children's Hospital; [2]Dept of Pathology, Texas Children's Hospital; [3]Gastroentrology and Liver, Texas Children's Hospital; [4]Critical Care Medicine, Texas Children's Hospital, Houston, TX.*

Introduction: The RIFLE classification for acute kidney injury (AKI) defines end stage renal disease (ESRD) as the persistence of renal failure for greater than 3 months. In pediatrics the impact of prolonged AKI on renal recovery has not been described in detail. We report renal recovery in a case series of pediatric liver transplant recipients (OLT) with AKI who received a renal replacement therapy (RRT) for more than four weeks.

Case Description: This is a retrospective chart review of all patients less than 21 years of age who received OTL at Texas Children's Hospital and developed AKI requiring RRT for more than 30 days, between June 2013 to June 2014.

Five patients were identified during this period. The etiology of their AKI was multifactorial including hypotension, sepsis, capillary leak, hepato-renal syndrome, and multiple nephrotoxic medications. Despite aggressive medical management, they developed significant fluid overload (>15%) with oliguria/anuria requiring RRT. All five were initially treated with continuous venovenus hemodiafiltration (CVVHDF) and later transitioned to intermittent hemodialysis. Renal biopsy in the two patients with AKI for more than 8 weeks was consistent with ATN. All five patients were eventually discharged home without chronic dialysis.

Case	Age (M)	Creatinine on Admission (mg/dL)	Days on RRT	Creatinine on Discharge (mg/dL)	Creatinine at Last Followup (mg/dL)	eGFR (Modified Swartz) ml/min/1.73 m^2
1	9	0.21	31	0.46	0.29	108
2	13	0.20	34	0.29	0.22	142
3	9	0.20	62	0.12	0.12	261
4	4	0.13	81	0.46	0.34	83
5	7	0.13	157	0.99	0.51	55

Discussion: In this case series, all five patients with after OLT who developed loss and/or ESRD per RIFLE, and required RRT for more than four weeks had significant recovery of renal function; none were dialysis dependent. Our data prompts reconsideration of the RIFLE ESRD classification, since recovery was observed even after three months of dialysis.

SA-PO755

Treatment of Recurrent *Clostridium difficile* Infection with Fecal Microbiota Transplantation in a Renal Transplant Recipient Vishwas Raghunath, Michael G. Suranyi, Angela Makris. *Nephrology, Liverpool Hospital, Liverpool, Sydney, New South Wales, Australia.*

Introduction: Clostridium difficile associated diarrhoea can be devastating in solid organ transplant recipients with a strong tendency for recurrence. The novel use of a known therapy - fecal microbiota transplantation has shown promise in recurring and refractory cases, with minimal complications in this susceptible population, as we illustrate in this case of a renal transplant recipient.

Case Description: We report the case of a 62yr deceased donor renal transplant recipient on standard immunosupression, who had multiple hospital admissions either as a result of, or complicated by Clostridium difficult associated diarrhoea. She was treated with multiple courses of specific antibiotics (vancomicin, metronoidazole and rifaximin) but proved to be refractory to medical therapy. She had a total of 20 hospital admissions across the health district in the period from October 2011 to February 2014, resulting in a total of 397 days spent in hospital. She underwent a fecal microbiota transplant, which resulted in resolution of diarrhea, improvement in well being and has kept her out of hospital.

Discussion: Clostridium difficile is more prevalent in immunocompromised patients, resulting in significant patient morbidity and strain of the health care resources. This novel therapy has the potential to decrease hospitalization rates and length of stay in future especially with early application. To date there are only very few reported cases of the use of this therapy in solid organ transplant patients.

SA-PO756

Case of Acquired Pure Red Cell Aplasia with Synthetic Erythropoietin That Resolved after Renal Transplantation Vishwas Raghunath, Michael G. Suranyi, Angela Makris. *Nephrology, Liverpool Hospital, Liverpool, Sydney, New South Wales, Australia.*

Introduction: Pure red cell aplasia is a rare hematological disorder characterized by severe anemia and a striking absence of erythroid precursors in the bone marrow. In the renal population an important cause is synthetic erythropoietin, causing progressive anemia despite escalating doses of erythropoetin.

Case Description: We report a case of darbepoetin induced pure red cell aplasia in a 52-year male with chronic kidney disease presumed secondary to recurrent renal calculi on maintenance dialysis. He developed transfusion dependent anemia while on synthetic erythropoietin therapy. The diagnosis was confirmed with a bone marrow aspirate, which showed absent erythroblasts. He was found to have antibodies to the generic erythropoetin epitope and darbepoetin epitope. The initial anti-erythropoetin alfa antibody level was 25.40 mcg/mL and anti-darbepoetin antibody level was 24.40 mcg/mL (reference positive of >0.25 mcg/mL). He was treated with a series of immunosuppressive medications including prednisolone, cyclophosphamide, intravenous immunoglobulin, mycophenolate and rituximab over a period of 16 months, without success. He required 2-3 units of packed cells per week to maintain his hemoglobin, resulting in iron overload and attempts at intraperitoneal and oral chelation. He underwent a deceased-donor kidney transplantation following which his hemoglobin stabilized. The antibody levels were reduced at 2 weeks and undetectable by 4 weeks post transplantation. He has remained transfusion-free post transplant other than 2 units of packed cells required for severe haemorrhagic adenoviral cystitis at 12 weeks. His current immunosuppressive regimen includes prednisolone, tacrolimus and mycohenolate. He has developed post transplant diabetes but maintains a stable graft function with a creatinine of 103 umol/L.

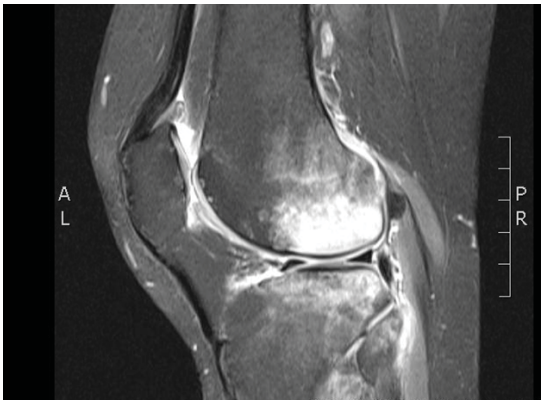
Discussion: The efficacy of immunosuppressive regimen for acquired pure red cell aplasia in end stage kidney disease is suboptimal .We recommend earlier renal transplant to minimize complications of multiple blood transfusions and serial immunosuppression.

SA-PO757

Calcineurin Inhibitor-Induced Pain Syndrome Post-Kidney Transplantation Mohammad Sharif, Thanh Hoang. *Loma Linda Univ Medical Center.*

Introduction: Musculoskeletal pain is a common problem after kidney transplant. It is most often a manifestation of steroid therapy, renal osteodystrophy, hypophosphatemia, gout or avascular necrosis. Here, we present a case of a young female who presented with disabling bone pain post kidney transplant.

Case Description: A 30 year old female with past medical history of hypertension and end stage renal disease secondary to presumed hypertensive nephrosclerosis had a deceased donor kidney transplant (DDKT). She was started and maintained on Tacrolimus, Mycophenolate Mofetil and Prednisone. Ten months post-transplant, she presented with bilateral knee pain. The pain was mainly when she stood up and interfered with her activity. Patient denied any trauma or muscle pain. The pain worsened and involved other joints. Subsequently she became wheelchair bound. Extensive work up was done including: knee x-ray, joint aspiration, serum electrolytes – including phosphate, calcium and magnesium, parathyroid hormone and rheumatological work up. All were negative so knee magnetic resonance imaging was done



It showed extensive bone marrow edema involving distal femur, proximal tibia, and fibula. Therefore, diagnosis of Calcineurin inhibitor-induced pain syndrome (CIPS) was concluded. Tacrolimus was gradually weaned off. Her joint pain slowly improved over time. Interestingly, her grandfather had CIPS when he was taking a Calcineurin inhibitor (CNI) after transplant. This might indicate underlying genetic or familial predisposition to this disease.

Discussion: CIPS is thought to be secondary to hypervascularization, hyperperfusion and hypermetabolism. It is a diagnosis of exclusion. It requires prompt attention from physicians because it is a rare but disabling condition. Management includes reduction or replacement of CNI therapy and administration of calcium-channel blockers to help ameliorate symptoms and improve quality of life.

SA-PO758

Non-HIV Collapsing Glomerulopathy in Living Kidney Transplants: A Case Series Etti Deborah Zeldis,[1] Girish N. Nadkarni,[1] Rebecca L. Kent,[1] Fadi Salem,[1] Ioannis Konstantinidis,[1] Achint Patel,[2] Madhav C. Menon,[1] Michael J. Ross.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]School of Public Health at Mount Sinai.*

Introduction: Collapsing glomerulopathy (CG) is increasingly recognized in non-HIV patients. There have been case-series of CG in allografts in predominantly deceased donor kidney transplants (DDKT). We describe a case series of 8 patients developing CG post living kidney transplant (LKT).

Case Description: We reviewed non-HIV CG cases after LKT from 2005-2013 and abstracted demographic, clinical, laboratory, follow-up and outcome data.We had complete data on 8 patients. The age range was 25-65 years with 5/8 (62.5%) males. Recipient race was African American (AA) (3/8), Caucasian (2/8), Hispanic/Other (3/8), and donor race was AA (2/8), Caucasian (2/8) and Hispanic/Other (4/8). One recipient had a history of FSGS prior to transplant. Four of eight patients were on tacrolimus, and 4/8 were on cyclosporine. Duration from LKT to biopsy varied from 9 months to 15 years (mean 6.25 years). At time of biopsy, the mean urine protein/creatinine ratio was 5.4± 4.6 gms and mean creatinine was 2.3+1 mg/dL. Pathology revealed a mean of 12.6± 5.1 glomeruli per biopsy with 18±11.6% of glomeruli demonstrating collapsing features. One patient underwent plasmapheresis, and one was treated with high dose steroids; both patients progressed to ESRD. Graft failure [defined as End stage renal disease(ESRD)] occurred in 6/8 patients after a mean of 14±(22.3) months post biopsy; 5/6 patients progressed to ESRD within 12 months of diagnosis. Overall graft survival of those who progressed to ESRD was 6.6(+/2.9) years.

Discussion: We describe one of the largest case series of non-HIV CG in LKT. The prognosis remains poor with most patients progressing rapidly to graft loss. Interestingly, the two patients with CG who did not experience graft loss were Caucasian with Caucasian donors. Larger series including multi-institutional registries are needed to elucidate its natural history, identify risk factors for progression, and to determine strategies to improve clinical outcomes.

SA-PO759

Unique Case of Extremely High Tacrolimus Level Nivin Haroon, Atul Singh, Zeenat Yousuf Bhat. *Nephrology, Wayne State, Detroit, MI.*

Introduction: Tacrolimus (Fk) is an effective immunosuppressive agent derived from the fungus Streptomyces tsukubaensisde.Despite being a very potent immunosuppressant, its use is complicated by narrow therapeutic range, significant individual variation in pharmacokinetics and complex and significant drug-drug interactions.We report a case of very high Fk level (>120ng/ml) in a patient who was on antiretroviral medication and Fk.

Case Description: The patient is a 40 year old who underwent a deceased donor renal transplant in 2009.His immunosuppressant regimen includes Fk 0.2mg once a week, Cellcept 500mg twice daily and prednisone 5mg daily.His significant past medical history include human immunodeficiency (HIV) infection diagnosed in 1993 and on combination antiretroviral therapy (cARV) since diagnosis. His regimen included ritonavir 100 mg daily atazanavir 300 mg daily and lamivudine-zidovudine 150 mg in morning and 300 mg in evening.Patient was admitted with significant complaints of head ache,malaise and diarrhea of 3 day duration. His clinical exam was unremarkable including detailed neurologic exam, He did not have any tremors.Lab work showed acute kidney injury with a peak creatinine (Cr) of 2.5 mg/dL from a baseline Cr around 1.4 mg/dL.The FK level was reported as more than 120 mg/dL.Repeat on subsequent days were also reported as more than 120 mg/dl persistently.Despite these patient only complaints was that of his headache. His FK toxicity was attributed to a combination of compounding error from pharmacy and the significant drug interaction with cARV medications keeping the levels higher for over a week.He was treated by withholding FK and cARV medications for that one week duration.His renal function and symptoms of headache improved paralleling the FK levels.

Discussion: To our knowledge there are only a handful of literature on Fk toxicity and treatment of overdose.The highlight of this case report is an extremely high Fk level with negligible clinical outcomes and complete renal recovery despite the postulates of severe central nervous system adverse effects.We also would like to draw attention to the severe drug interaction and the conservative approach to manage such high FK levels.

SA-PO760

Ureteral Herniation into the Inguinal Canal Causing Transplant Obstructive Uropathy Chelsea Estrada, Deepika Eve Slawek, Doris Chan, Frank Darras, Patrick Gerard Lynch, Nand K. Wadhwa. *Nephrology and Transplantation, Stony Brook Medicine, Stony Brook, Ny.*

Introduction: Obstructive uropathy is a reversible cause of allograft dysfunction. Etiology ranges from ureteral clot, ureterolithiasis, ureteral stricture, hematoma or lymphocele. We report a rare case of an inguinal herniation of the transplant ureter leading to acute kidney injury from urinary obstruction.

Case Description: A 44 year old man with ESRD due to HUS received his first kidney transplant in 1976, which failed secondary to chronic allograft nephropathy in 1991. He remained on hemodialysis until 1998 when he received his second deceased donor transplant. He had one episode of acute rejection treated with methylprednisolone in 1999. He was managed by an outside institution and reported a baseline serum creatinine of 2.0 mg/dL which gradually increased to 3.1 mg/dL over the past one year. He recently presented for a routine follow-up visit and he had no complaints. Physical examination revealed BP of 130/84 mmHg, HR 70 beats a minute and temperature of 36.5C. Chest examination was normal. Abdomen was obese, and the left lower quadrant allograft was non-tender. He had no leg edema. Immunosupression included tacrolimus 1 mg twice a day, azathioprine 50 mg daily and prednisone 5 mg daily. His BUN was 70 mg/dL, serum creatinine 3.4 mg/dL, serum potassium of 5.3 mg/dL, WBC 8.9k/mcL, Hgb 13.3g/dL, and platelets 123 k/mcL. Urinalysis showed no protein, blood or cells. Serum tacrolimus level was 4.8 ng/mL. Serum BK virus PCR was negative. A CT scan of the abdomen and pelvis was done due to rising creatinine and revealed hydroureteronephrosis due to herniation of the transplant ureter into the left inguinal canal. He underwent left inguinal hernia repair, ureter repair and re-implantation with stent placement. At outpatient follow-up 1 week later his serum creatinine improved to 1.8 mg/dL.

Discussion: Transplant ureteral herniation into the inguinal canal leading to hydroureteronephrosis and acute kidney injury is rare. Our patient underwent emergent surgical correction with an improvement in his allograft function. Early recognition and prompt intervention of this entity is needed.

SA-PO761

Successful Eculizumab Treatment of Recurrent Atypical Hemolytic Uremic Syndrome after Kidney Transplantation Katherine Garlo,[1] Douglas M. Dressel,[2] John P. Vella.[1] *[1]Div of Nephrology and Transplantation, Maine Medical Center, Tufts Univ School of Medicine, Portland, ME; [2]Dept of Pathology, Maine Medical Center, Tufts Univ School of Medicine, Portland, ME.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare disorder of the alternative pathway of the complement system. Fifty percent of aHUS cases are linked to genetic mutations, 5% to autoimmune disease, and the remainder are incompletely understood.

Case Description: The patient first presented to an outside hospital at age 28 years with aHUS that developed after a first delivery. In spite of treatment with plasma exchange, she required two years of hemodialysis before receiving a living donor kidney transplant. Two years later, she presented to our institution. She was pregnant at 26 weeks gestation with hypertension and proteinuria. After premature delivery, she developed hemolytic anemia, thrombocytopenia, and oliguric kidney injury requiring dialysis.

Lab Test	Patient's Result (Normal range)
Hb	6.5 (11.8-15.8) g/dL
MCV	96 (80-100) fL
Cr	7.1 (0.50 - 1.30) mg/dL
PLTs	89 (140-440) Thou/uL
AST	35 (0-37) U/L
ALT	19 (0-40) U/L
ALK PHOS	70 (39-117) U/L
LDH	975 (94-250) U/L
Hapto	< 20 (25-200) mg/dL
Blood Smear	2+ Schistocytes (none expected)
ADAMTS13	75% (50-160%)

There was no response to plasma exchange, but Eculizumab led to successful resolution of hemolysis and AKI. Three months after therapy was stopped she relapsed and again needed dialysis. At that time, an allograft biopsy revealed thrombotic microangiopathy. Eculizumab was resumed without plasma exchange leading to resolution of aHUS and acute kidney injury. Her baby survived. She remains on maintenance Eculizumab therapy with a Cr of 1.5mg/dl.

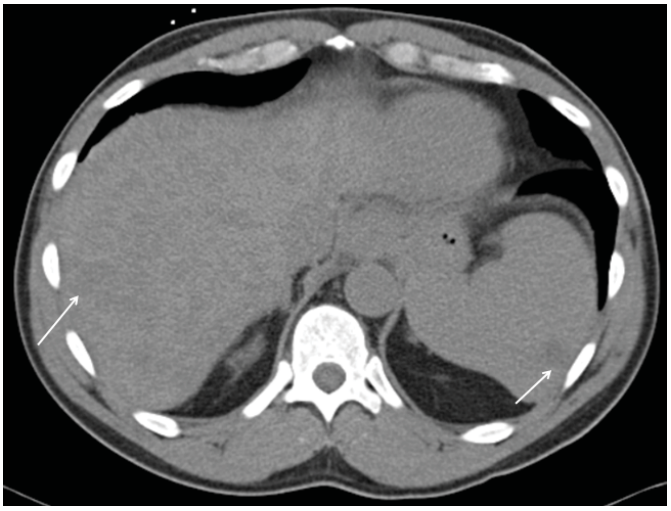
Discussion: Postpartum aHUS is rare but severe disorder with an incidence of 1:25,000 gestations. It usually presents within 48 hours of delivery and is associated with pre-eclampsia, prematurity, and mortality. Many maternal survivors develop ESRD and recurrence after transplantation. Conventional management is often ineffective. Eculizumab is a monoclonal antibody to C5 and suppresses complement amplification. It was FDA approved for treatment of aHUS in 2012.

SA-PO762

Post-Transplant Lymphoproliferative Disorder Presenting as Fever of Unknown Origin Anyeri K. Peguero,[1] Hani Wadei.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Jacksonville, FL; [2]Transplant Nephrology, Mayo Clinic, Jacksonville, FL.*

Introduction: Post-transplant lymphoproliferative disorder (PTLD) is a rare but serious post-transplant complication and can have various presentations. We hereby present a case of PTLD presenting with fever of unknown origin (FUO) in a kidney transplant recipient.

Case Description: 58-year-old African American man received a deceased donor renal transplant with induction immunosuppression consisting of anti-thymocyte globulin (ATG) followed by prednisone, mycophenolate mofetil (MMF) and tacrolimus. At the time of transplant, both donor and recipient tested positive for previous EBV exposure. His post-transplant course was complicated with recurrent rejections requiring parenteral steroids and later ATG. 9 months post-transplant he presented with 2 weeks of pleuritic chest pain, productive cough, fevers, and generalized malaise. He had been treated with azithromycin and later levofloxacin for presumed pneumonia in another institution without remission of his symptoms. Further evaluation showed both blood and urine cultures were negative, chest x-ray failed to show consolidation but he did have transaminitis and detectable plasma EBV PCR. Abdominal CT showed a mottled liver (Figuere 1 left arrow) and a new splenic hypodense lesion (Figure 1 right arrow) but no lymphadenopathy.



Liver biopsy was significant for diffuse large B cell lymphoma which stained positive for CD20 and EBV. MMF and tacrolimus were discontinued and after consultation with oncology; rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (RCHOP) were started. Two weeks later his symptoms resolved and fever disappeared.

Discussion: PTLD can present as fever in up to 50% of cases. This case highlights the importance of considering PTLD in kidney transplant recipients presenting with FUO.

SA-PO763

Regression of Immunoglobulin (IG) Deposits in Renal Amyloidosis after Successful Autologous Stem Cell Transplant (ASCT) Sami Safadi,[1] Ahmed Saad,[1] Nelson Leung,[1] Paul J. Kurtin,[2] Samih H. Nasr.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Introduction: Clinical remission of IG related amyloidosis is achieved with chemotherapy and ASCT. However, the effect on the amyloid kidney mass is unclear. Previous reports showed persistence of deposits in light-chain amyloidosis(AL). In contrast, we present a case of heavy-light-chain amyloidosis(AHL) in which monoclonal IG deposits regressed after successful treatment.

Case Description: A 64 y/o male presented with AHL involving kidney and heart. He had monoclonal IgG-lambda on serum and urine immunofixation. His bone marrow(BM) biopsy showed 10% lambda-restricted plasma cells. His kidney biopsy showed extensive Congo-red positive glomerular amyloid deposits on light microscopy(LM) that were composed of randomly-oriented fibrils on electron microscopy(EM). The amyloid deposits stained for IgG and lambda, but was negative for kappa, IgA and IgM. Laser microdissection/ tandem mass spectrometry(LMD/MS) showed abundant spectra for IgG, lambda, SAP, ApoE. He underwent ASCT. His early course was complicated by ATN requiring transient dialysis. 4 years later, he developed renal failure, and worsened proteinuria. He was still in hematologic remission with no identifiable monoclonal protein in the serum or urine and a negative BM biopsy. A repeat biopsy was done. LM again showed typical Congo red positive glomerular amyloid deposits with fibrillary substructure on EM. One glomerulus had a sclerotic lesion. Surprisingly, the amyloid deposits did not stain for IgG, kappa or lambda on IF. LMD/MS detected SAP and ApoE but not IG heavy or light chains.

Discussion: AHL is an uncommon form of amyloidosis. It is more common in older patients, has less cardiac involvement, better patient, and renal outcomes. In this case, we hypothesize that the patient's worsening renal function is due to secondary FSGS from previous injury. The amyloid deposits on the second biopsy did not stain for IgG, kappa or lambda on IF, which suggests that the amyloid deposits are old. In conclusion, monoclonal IG deposits can regress in amyloidosis after treatment whereas the other structural proteins (SAP and ApoE) do not.

SA-PO764

Recurrent Immunotactoid Glomerulopathy in a Transplanted Kidney Koyal Jain,[1] Akanksha Gupta,[2] Kawan A. Swain,[1] Patrick H. Nachman,[1] Karin A. True.[1] *[1]Nephrology, Univ of North Carolina Kidney Center, Chapel Hill, NC; [2]Nephropathology, Univ of North Carolina, Chapel Hill, NC.*

Introduction: Immunotactoid glomerulopathy (ITG) is found in only 0.06% of native kidney biopsies. It is characterized by Congo-red-negative glomerular deposits of microtubules staining for IgG and complement. It has been commonly associated with lymphoproliferative disorders and cryoglobulinemia. We present a patient with early recurrence of ITG within 9 months after kidney transplantation.

Case Description: Our patient is a 71 year old man with a history of end-stage kidney disease due to ITG 5 years prior to kidney transplantation. Work-up for malignancy at the time of first diagnosis was negative. A kidney biopsy for BK viremia 9 months after transplantation revealed scant polyclonal ITG deposits (Urine Protein/Cr 0.05) along glomerular basement membranes. 3 months later, the patient developed proteinuria (Urine Protein/Cr 5.5). Repeat biopsy demonstrated overt MPGN (membrano-proliferative glomerulonephritis) pattern with immunotactoid deposits. Laboratory data revealed creatinine 1.8 mg/dL (baseline 1.2), low C3 and C4, and rheumatoid factor 119.7 IU/mL. HIV, Hepatitis B/C, ANA, RPR, ANCA, echocardiogram and PET scan were negative. A monoclonal IgG Lambda was detected on serum and urine electrophoresis. Bone marrow biopsy showed monoclonal fixation consistent with monoclonal gammopathy, leading to a diagnosis of "monoclonal gammopathy of renal significance" (MGRS). Treatment for MGRS is being initiated with Cyclophosphamide, Bortezomib and Dexamethasone.

Discussion: ITG has been reported to recur after transplantation in 47-64% of patients. Patients have been treated with a combination of Cyclophosphamide, Rituximab and steroids, with varied outcomes. This case illustrates the clinical emergence of monoclonal gammopathy 6 years after the initial diagnosis of ITG. Clinical vigilance and repeat work up for underlying lymphoproliferative or infectious disorders is therefore warranted.

SA-PO765

An Unusual Case of Renal Failure After Liver Transplantation Amanda K. Hall,[1] Jo Abraham,[1] Monica Patricia Revelo Penafiel,[2] Kalani L. Raphael.[1] *[1]Nephrology and Hypertension, Univ of Utah, Salt Lake, UT; [2]Anatomic Pathology, Univ of Utah, Salt Lake, UT.*

Introduction: A 61 year old woman who received a liver transplant in 2011 for end stage liver disease due to hepatitis C virus(HCV) and hepatocellular carcinoma was evaluated for worsening renal function and nephrotic proteinuria.

Case Description: After transplantation, HCV recurred but was successfully treated with negative viremia. One month prior to nephrology consultation, she had left eye pain, blindness, and serum creatinine of 2.8mg/dL(baseline 1.7mg/dL). She was diagnosed with optic perineuritis and began oral prednisone 60mg daily. Other medications included cyclosporine, lisinopril and furosemide. Urine microscopy showed dysmorphic hematuria. Workup revealed ANCA(1:40) with atypical p-ANCA staining, 5.4 g/g proteinuria, negative cryoglobulins, normal C3 and C4, and negative HCV RNA by PCR. There were 13 glomeruli on renal biopsy;>50% showed membranoproliferative features, 5 cellular crescents, 2 had focal fibrinoid necrosis, and 2 with segmental sclerosis. Immunofluorescence showed granular mesangial and capillary wall staining with C3, IgG, IgA and IgM, and kappa and lambda light chains.

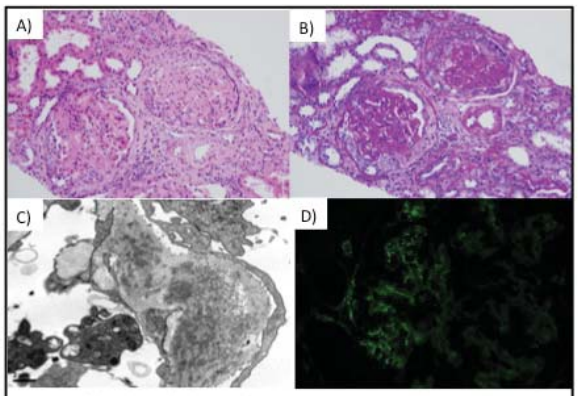


Figure 1: A) The glomeruli show moderate increase in mesangial matrix. The capillary loops appear thickened. Endocapillary proliferation is seen segmentally. B) Segmental cellular crescents. C) The glomerular basement membranes appear thickened with intramembranous electron dense deposits with randomly oriented fibrils measuring 16 to 23 nm in diameter. D) 3+ granular mesangial and capillary wall staining with C3.

Electron microscopy(EM) revealed randomly arranged 16-23nm fibrils. Congo red stain was negative. The diagnosis of crescentic fibrillary glomerulonephritis was made and oral cyclophosphamide was added. Renal function continued to deteriorate and hemodialysis began for refractory volume overload.

Discussion: Fibrillary glomerulonephritis is a rare cause of kidney disease. Pathognomonic findings include randomly arranged fibrils of 12-22nm in size on EM, which are Congo-red negative. It is commonly idiopathic or secondary to malignancy, autoimmune diseases, HIV, or HCV. Like most with fibrillary glomerulonephritis, this patient presented with renal insufficiency that did not respond well to immunosuppression.

SA-PO766

A Rare Case of Tuberculosis in Bilateral Native Polycystic Kidneys following Renal Transplantation Dhaval Sureja, Farhan Zahid, Ahmed Abdulrahman, Dong Heun Lee, Adrianne M. Ortega, Suganthi Soundararajan, Gregory Malat, PharmD, Karthik M. Ranganna, Gary S. Xiao, Alden Michael Doyle. *Nephrology, Drexel Univ, Philadelphia, PA.*

Introduction: The risk of tuberculosis (TB) in dialysis and renal transplant recipients is higher than general population. Clinical presentation of TB in dialysis patients can be atypical and reliance on positive purified protein derivative (PPD) test and chest x-ray (CXR) screening may miss significant extra pulmonary disease as it may require invasive procedure for diagnosis. We report a rare case of extra pulmonary tuberculosis in native bilateral polycystic kidneys in a renal transplant recipient.

Case Description: A 60 year old Cambodian female with history of polycystic kidney disease on peritoneal dialysis, successfully received deceased donor kidney transplant. Six months after transplant, she presented with fever, flank pain and dysuria, and was treated

for E. Coli pyelonephritis. Despite appropriate antibiotics, her fever and back pain recurred. CT scan of abdomen was unremarkable except for stable polycystic kidneys. Patient underwent bilateral native nephrectomy to manage pain and probable recurrent polycystic kidney infections. Intraoperatively, multiple nodules in the peritoneum were discovered. Biopsy revealed caseating granulomas with rare acid fast bacilli which was confirmed as Mycobacterium Tuberculosis by culture. Native kidneys showed tuberculous granulomatous interstitial nephritis. Allograft function was stable. Post operatively, patient was started on anti-tuberculous therapy and remained afebrile. This case presented as disseminated TB likely due to reactivation in the background of BCG vaccination in Cambodia, positive PPD and a negative CXR.

Discussion: Diagnosis in our case was challenging and it underscores the limitations of standard dialysis and pre-transplant testing for TB. It requires low threshold of suspicion with proper screening tests for early diagnosis. Our program has adopted widespread use of direct testing for TB antigens using T-spot and QuantiFERON-TB gold tests. We suggest that the nephrology and transplant communities adopt this improved testing methodology, especially in patients at increased risk of TB.

SA-PO767

Management Issues following Successful Kidney Transplantation for a Patient with Alström Syndrome Dhaval Sureja, Gregory Malat, PharmD, Karthik M. Ranganna, Stephen Guy, Alden Michael Doyle. *Nephrology, Drexel Univ, Philadelphia, PA.*

Introduction: Alström Syndrome is a rare, autosomal recessive disorder affecting less than 1:5,000,000 live births caused by mutation in ALMS1 gene. Alstroöm syndrome is associated with childhood obesity, early onset type II diabetes, retinal degeneration, sensory-neural hearing loss, hypertriglyceridemia, liver dysfunction, dilated cardiomyopathy, and progressive nephropathy with glomerulosclerosis. Although it often results in end-stage kidney disease, there are only few reports of affected patients undergoing successful kidney transplantation.

Case Description: Our patient is a 20 year old male found to have Alstroöm syndrome after being diagnosed with early childhood hypertriglyceridemia and hyperinsulinism. At the age of 14, he was found to have elevated serum creatinine with significant proteinuria. He also has a history of retinal degeneration with photophobia and vision loss, sensory neural hearing loss, hypertension, anemia, and hyperparathyroidism. He received a living related kidney transplant from his mother and is maintained on tacrolimus, mycophenolate mofetil, and low dose prednisone. His post-transplant course has been complicated by severe hypertriglyceridemia, with triglyceride levels of 3000's despite high dose statins, fibrates, and omega-3 fatty acids. He has had persistent liver dysfunction, with moderate transaminitis and elevated alkaline phosphatase levels. He has persistently low platelet counts (80,000). Although his cardiac function has remained stable, it requires regular monitoring as affected patients can develop symptoms at any time during the disease course. He is legally blind and attends a university that caters to the visually impaired. He requires specific arrangements at school including timer system for meds and special attention to his fitness.

Discussion: Alstroöm syndrome is a rare genetic disorder associated with progressive kidney disease that can be successfully treated with kidney transplantation as in our case; however providers who care for these patients should be aware of multiple manifestations of Alstroöm syndrome as they are likely to complicate post-transplant management.

SA-PO768

Use of ACTH Gel (Acthar) as Rescue Therapy for Transplant Glomeruloapthy (TG) in Two Kidney Transplant Recipients: Short and Long Term Follow-Up Maybel M. Tan, Laurel W. Yap, Mariana S. Markell. *Renal Diseases, SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction: Chronic allograft nephropathy (CAN) is a leading cause of allograft failure. TG is a particularly virulent form of CAN. At the present time there is no good treatment once it has been established. Our Center has been using ACTHAR as rescue therapy since 2010. We present long-term follow up of the first patient treated for TG and the clinical course of a second case.

Case Description: Case 1: A 36 year old woman with history of systemic lupus erythematosis, underwent Deceased Donor Renal Transplant in 2013 with baseline creatinine of 1.1, maintained on tacrolimus and prednisone. 10 months post-transplant she developed severe proteinuria despite telmisartan. Kidney biopsy suggested early TG. At initiation of 80mcg twice weekly Acthar, her urine protein was 9.8 gm/l and decreased to 2.8 g/L and 1.4g/l respectively after 2 and 4 months of therapy. Her current creatinine is 1.29 mg/dl. Case 2: A 42 year old woman with a history of medullary cystic disease received a second living related kidney transplant in 2004. In 2010 she developed rapid progression of proteinuria to a peak of 12 gm with albumin 2.9 and cholesterol 350. Transplant biopsy revealed TG. Creatinine was 1.9. Acthar was initiated at 80mcg twice weekly in June 2011 and proteinuria fell to 8 gm by Dec, 5.3 gm by April 2012, and 2.4 gm with normalization of albumin and cholesterol by June 2012. She was tapered to 80mcg once weekly and has refused to stop the medication. Repeat biopsy in 2013 showed no interval change from her previous biopsy. It was negative for C4d staining. She is now 4 years post initiation of treatment with a recent creatinine of 2.8 and proteinuria of 3.7 gm. Her cholesterol is 220mg on Ezetimibe and her albumin is normal.

Discussion: TG carries an ominous prognosis for kidney allograft survival, and is complicated by features of severe nephrotic syndrome. Acthar has been used to treat nephrotic syndrome in native kidneys. We suggest that long term use of Acthar should be considered in patients with transplant glomerulopathy for whom no other therapy is available, based on the efficacy and long term safety of the patients reported here.

SA-PO769

Acute Myeloid Leukemia in a Renal Transplant Patient Deepti S. Moon, Lisa K. Prince. *Nephrology, Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Acute myeloid leukemia is rare post transplant but associated with poor survival. This case highlights importance of high degree of suspicion and early referral for evaluation of leukopenia in renal transplant patient.

Case Description: 58 year old Caucasian male with history of Crohn's disease, autoimmune hepatitis, primary sclerosing cholangitis and is status post liver/renal transplant in October 2012 presents with new onset leukopenia. Patient denied any complaints and ROS was negative. Physical exam was unremarkable. Laboratory tests revealed white blood cell count of 2.3, patient had normal count 4 months before. Patient's mycophenolate mofetil was decreased to 250mg twice a day but no improvement. Patient was evaluated by hematology/oncology and noted on peripheral smear to have blasts. Bone marrow biopsy revealed findings consistent with acute myeloid leukemia. Patient's immunosuppressant regimen was modified to tacrolimus with trough goal 2-3, and prednisone 10mg. He completed induction chemotherapy with idarubicin and cytarabine and is doing well with renal and liver function at baseline.

Discussion: Organ transplant recipients are at 2-fold overall increased risk for cancer with Non Hodgkin's lymphoma, skin cancers, and cancers of the lung, liver, and kidney most common. But leukemia accounted for 2.7% of non-cutaneous tumors in one study, but AML made up 43%. Another study found recipients have standardized incidence ratio of 2.7 for AML. Screening for breast, colon, skin, and cervical cancers is routine part in transplant patient's care, providers need to have high degree of suspicion for myeloid malignancies in appropriate circumstances. Especially with new onset leukopenia when timely referral to hematology/oncology is needed if patient's leukopenia fails to improve. Another contributing factor to development of myeloid disorders is choice of immunosuppressant. Correlation between use of azathioprine has been noted to increase frequency of AML and a study found 60% of kidney transplant patients with AML had received azathioprine as immunosuppressant. Interestingly this patient was placed on MMF and tacrolimus post-transplant, he had been on azathioprine for his Crohn's for 2 years prior to transplantation.

SA-PO770

Thermal Ablation as an Alternative to Traditional Surgical Resection for Renal Cell Carcinoma in a Transplanted Renal Allograft Rajat Lamba, Nandita Singh, Maureen E. Brogan, Anita Kaul. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Renal cell carcinoma in renal transplant recipients is usually in the native kidneys, particularly in patients who have been on dialysis for many years. Renal tumors are rare in the transplanted kidney but when they do occur the treatment options include allograft nephrectomy, partial nephrectomy or more recently reported option of thermal ablation. We are reporting a case of papillary cell carcinoma in the renal allograft that we treated with thermal ablation.

Case Description: A 61 year old female with history of hypertension, right native nephrectomy for renal cell carcinoma 5 years prior, ESRD status post dual pediatric en bloc kidney transplant in the right lower quadrant 18 years ago, with baseline creatinine of 0.6, on tacrolimus and Post Transplant Lymphoproliferative Disorder treated with Rituximab, was found to have a 3.1cm mass in the lateral allograft on an MRI. A biopsy showed fuhrman grade 2 of 4 papillary renal cell carcinoma. Lateral transplant nephrectomy was considered high risk due to the complicated anatomy. Considering the low tumor grade, a CT guided microwave ablation at 140 W for 10 minutes of the lateral transplanted renal mass was performed via per cutaneous route. Post operatively, the patient had severe pain at the ablation site and was noted to have right lower extremity weakness from femoral nerve injury requiring physical therapy. Her creatinine acutely increased post procedure and stabilized at a new baseline of 1.4. She had to be rehospitalized within a week of her discharge for a urine leak from a nephrocutaneous fistula and a urinary tract infection which was treated with intravenous antibiotics and a Foley catheter placement.

Discussion: Thermal ablation has been reported in small case series as a safe and effective nephron sparing treatment in the renal allograft for tumors less than 4cm in diameter, specifically in patients at high surgical risk. While making treatment decision, it should be kept in mind that although transplant nephrectomy is associated with surgical risks, thermal ablation can also lead to complications like femoral nerve damage, acute kidney injury and nephrocutaneous fistula.

SA-PO771

Leukemoid Reaction in Acute Antibody-Mediated Rejection with Thrombotic Microangiopathy Vesh Srivatana,[1] Thangamani Muthukumar,[1] Surya V. Seshan,[2] Choli Hartono.[1] *[1]Dept of Nephrology and Hypertension, Weill Cornell Medical College, New York, NY; [2]Dept of Pathology, Weill Cornell Medical College, New York, NY.*

Introduction: Fever and leukocytosis are common characteristics of systemic infection. However, a predominantly neutrophilic leukemoid reaction occurring in a transplant patient on immunosuppression is rare and may have diagnostic, therapeutic, and prognostic implications.

Case Description: We report a patient with end stage renal disease of unknown etiology who received a one haplotype-matched live-donor kidney transplant. Despite low levels of donor-specific antibodies (DSA), the pre-transplant crossmatch was negative. She received induction therapy with rabbit-antithymocyte globulin. Corticosteroids were rapidly tapered to a daily dose of 20mg of prednisone at 5 days after transplant with maintenance tacrolimus

and mycophenolic acid. The patient's serum creatinine was 1.34mg/dl at discharge. She presented 8 days later with fever, creatinine of 2.13 mg/dl, and white blood cell count (WBC) of 44.4x10(3)/ul with 83% neutrophils and 13% bands. Blood and urine cultures obtained prior to empiric antibiotic coverage were negative. Biopsy of the kidney allograft showed intense peritubular capillary C4d staining with thrombotic microangiopathy (TMA) consistent with acute antibody-mediated rejection (AMR) in the presence of a rising DSA titer. The patient was treated with high-dose corticosteroids, plasmapheresis, and bortezomib which promptly reversed the leukemoid reaction to WBC of 9.3x10(3)/ul. The renal function returned to baseline within 2 weeks and remained stable at one year follow-up.

Discussion: Review of the literature showed that leukocytosis is uncommon during acute rejection. We propose that complement activation on the graft endothelium produced tissue inflammation and ischemic injury. In response to local hypoxia, damaged-associated molecular pattern molecules (DAMPs) are recognized by toll-like receptors (TLR). Both complements and TLRs are capable of recruiting neutrophils, possibly causing the leukemoid reaction in our patient. To our knowledge, this is the first reported case of a leukemoid reaction elicited by AMR and TMA in the modern era of immunosuppression.

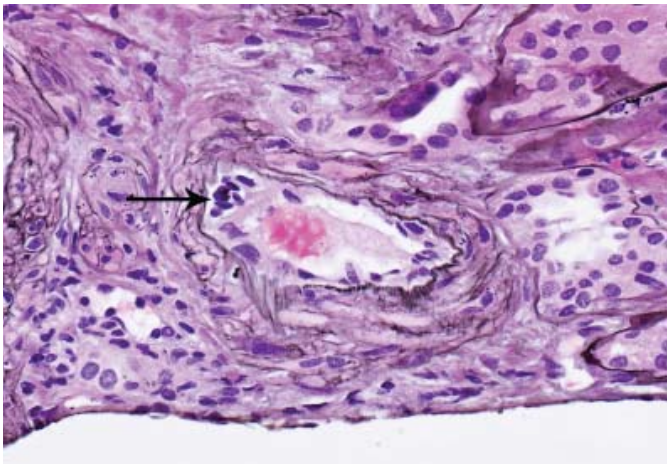
SA-PO772

Isolated V Lesions: Uncertain Prognostic Significance Irfan K. Moinuddin,[1] Machaiah M. Madhrira,[1] Amy Nicole Sussman,[2] Erika R. Bracamonte.[3] *[1]Div of Nephrology, Univ of Arizona Medical Center, Tucson, AZ; [2]Dept of Nephrology, Univ of Arizona at Tucson, Tucson, AZ; [3]Dept of Pathology, Univ of Arizona at Tucson, Tucson, AZ.*

Introduction: Isolated V lesions, in renal transplant patients, are characterized by endothelialitis with minimal tubulitis and interstitial inflammation. The significance of isolated v lesions remains unclear with opinions ranging from no prognostic significance to severe vascular rejection requiring accelerated immunosuppression.

Case Description: We report a case study of isolated v lesion in a 70 year old patient with ESRD due to HTN who received a deceased donor kidney transplant. Postop, patient developed atrial fibrillation and hypotension requiring transient pressors; patient also had to be taken to the OR for repair of a bowel leak. Patient had delayed graft function and oliguria. Patient had abdominal fluid with Cr 18.8 and was taken to OR for repair of urinary leak and biopsy of the transplant kidney.

On kidney biopsy, there is no significant glomerulitis or capillaritis. No segmental sclerosis. There is a mild chronic interstitial inflammatory infiltrate. Rare tubules contain 1-2 lymphocytes per cross section. Two muscular arteries show endotheliitis characterized by small clusters of mononuclear cells beneath the endothelium. No fibrinoid necrosis or transmural inflammation is seen. SV40 stain is negative. Stain for C4d is negative. Banff scoring: i1, t1, g0, v1, ci1, ct1, cg0, cv0, mm1, ah0,c4d0. Patient was not thought to be a candidate for accelerated immunosuppression. Persistent urinary leak lead to placement of nephrostomy tubes with subsequent downtrending of creatinine and good graft function on a regimen of MMF 500mg bid, prednisone 5mg qd, and program 2mg qam and 1.5mg qpm.



Discussion: Isolated V lesion, in this case, did not require accelerated immunosuppression and may not be of prognostic significance. This case points out that other etiologies of DGF such as urinary leak should be sought out and treated before subjecting the patient to the risk of increased immunosuppression.

SA-PO773

Effects of Serum Creatinine Calibration on Estimated Glomerular Filtration Rate and Chronic Kidney Disease Determination in African Americans: The Jackson Heart Study Wei Wang,[1] Michael Griswold,[1] Adolfo Correa,[1] Bessie A. Young,[2] L. Ebony Boulware,[3] Tibor Fulop,[1] Ian H. de Boer,[2] Ronit Katz.[2] *[1]Univ of Mississippi Medical Center, Jackson, MS; [2]Univ of Washington, Sealttle, WA; [3]Duke Univ, Durham, NC.*

Background: The calibration of serum creatinine values to Isotope Dilution Mass Spectroscopy (IDMS) traceable creatinine is essential for valid use of the new Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation to estimate the glomerular filtration rate (GFR).

Methods: For 5,210 participants in the Jackson Heart Study, serum creatinine concentration was measured with a multipoint enzymatic spectrophotometric assay at the baseline study visit (2000-2004). Serum creatinine was re-measured using the Roche enzymatic method, traceable to IDMS in a subset of 206 subjects. The 206 samples were divided into three disjoint sets - training, validation, and test - to select an appropriate calibration model, estimate true errors, and assess performance of the final calibration equation. The selected calibration equation was applied to serum creatinine measurements of all 5,210 subjects to estimate GFR and the prevalence of CKD.

Results: According to the true error estimate among four potential calibration models and justifiable assumption made, the final selected Deming regression model showed a slope of 0.968 (95% CI:0.904, 1.053; $P < 0.001$) and intercept of -0.0248 (95% CI: -0.0862, 0.0366; $P = 0.430$) with $R^2 = 0.9527$. Applying the calibration equation to the unused test set (50 samples), calibrated serum creatinine concentration showed high agreement with actual measurements (concordance correlation coefficient 0.934, 95% CI: 0.894, 0.960). The baseline prevalence of CKD in the Jackson Heart Study (2000-2004) defined by eGFR less than 60 ml/min/1.73 m^2 was 6.30% using calibrated serum creatinine concentrations, compared with 8.29% using non-calibrated serum creatinine values with CKD-EPI equation ($p < 0.001$).

Conclusions: A Deming regression model was generated and validated to calibrate baseline serum creatinine concentrations in the Jackson Heart Study to values traceable to IDMS and accurately estimate the prevalence of CKD.

SA-PO774

Inter-laboratory Variability of Serum Creatinine Assays Despite Assay Calibration Standardization Elizabeth S. Lee, Christine A. White. *Medicine, Queen's Univ, Kingston, ON, Canada.*

Background: Inter-laboratory variation in analyte measurement exist due to differences in assay methods, manufacturers, heterogeneous reference materials and other inherent measurement errors. The aim of this study was to examine the extent of inter-laboratory variability in serum creatinine (sCr) and its impact on GFR estimation in the post-IDMS standardization era.

Methods: Serum samples from 53 ICU patients at Kingston General Hospital, ON, Canada were obtained. Samples were split and an aliquot from each patient was sent to 12 participating laboratories (7 using enzymatic and 5 using Jaffe methods) for sCr measurement. Glucose, total bilirubin and protein were also measured. For each patient, we calculated all labs mean sCr and the mean sCr for both Jaffe and Enzymatic labs. We also determined the all labs mean CKD-EPI eGFR (SD) assuming 65 year old non-African American woman. For each laboratory and patient, we determined the absolute percentage (| (%) difference | from the mean for sCr and eGFR. The overall mean (| (%) difference | and coefficient of variation (COV) were then calculated. This analysis was repeated after stratifying by the median study sCr of 121.4 umol/L.

Results: On average, Jaffe results were 5.8±7.0 umol/L higher than enzymatic results resulting in 2.3±4.7 mL/min/1.73m^2 lower mean eGFR results. Table 1 shows the inter-laboratory variability results. Greater variability is seen at lower sCrs and in the presence of high levels of bilirubin and glucose as evidenced by greater % difference from the mean and higher COV.

	Mean l% difference in sCrl (SD)	Mean % COV	Mean l% difference in eGFRl (SD)	Mean % COV
All (n=53)	4.7±4.3	6.2	4.3±2.8	5.5
sCr (n=27) <121.4umol/L	6.4±5.4	8.5	4.9±3.6	6.4
sCr (n=26) >121.4umol/L	2.9±1.2	3.8	3.8±1.3	5.7

Conclusions: Significant inter-laboratory variability of serum Cr measurement persists despite IDMS-standardization and this results in variability in estimated GFR. Inter-laboratory differences are due in part to the presence of interfering substances. Manufacturers need to improve assay specificity in order to reduce measurement error and variability between labs.

Does the BIS2 Equation Best Predict Mortality in the Elderly?
Muna T. Canales,[1,2] Terri L. Blackwell,[3] Brent C. Taylor,[4] Areef Ishani,[4] Allyson Hart,[5] Cora E. Lewis,[6] Rebecca Beyth,[1,2] Katie L. Stone,[3] Kristine E. Ensrud.[4] *[1]Malcom-Randall VAMC; [2]UF Div of Nephrology, Gainesville, FL; [3]Research Inst, CPMC, San Francisco, CA; [4]Minneapolis VAMC, Minneapolis, MN; [5]HCMC, Minneapolis, MN; [6]UAB, Birmingham, AL.*

Background: Recently a new serum cystatin C and SCr-based eGFR equation, the Berlin Initiative Study-2(BIS2), was developed for the community-dwelling elderly. However, it is unclear whether BIS2 improves prediction of mortality in the elderly when compared with existing equations.

Methods: We conducted a prospective study of 2994 community-dwelling elderly men in the MrOS Sleep Study who had serum cystatin-C and SCr measured at baseline(2003-2005). We used Cox regression and net reclassification improvement(NRI) to compare the ability of BIS2, CKD-EPI$_{cysc,cr}$, CKD-EPI$_{cysc}$ and MDRD in 4 eGFR categories (≥90, 75-89, 60-74, <60) to predict all-cause mortality. For NRI analyses, CKD-EPI$_{cysc,cr}$ was the reference.

Results: Mean age was 76±6y; 91% were white. Mean BMI was 27±4 kg/m^2. Mean follow-up was 7±2y. Mean eGFR(ml/min/1.73m^2) was: CKD-EPI$_{cycscr}$ 70±17, BIS2 62±14, MDRD 73±17, CKD-EPI$_{cysc}$ 68±20. Only 2% had eGFR≥90 by BIS2 eGFR versus MDRD(14%), CKD-EPI$_{cysc}$(15%), CKD-EPI$_{cysc,cr}$(12%). However, 42% had eGFR<60 by BIS2 versus MDRD(22%), CKD-EPI$_{cysc}$(36%), CKD-EPI$_{cysc,cr}$(28%). BIS2 eGFR<60 was associated with a trend for higher mortality versus BIS2 eGFR≥90, after adjustment for age, race, BMI, HTN, DM(HR 1.2, 95%CI[0.6,2.3], p trend 0.007). Results were stronger for CKD-EPI$_{cysc,cr}$<60(HR 1.7, 95%CI[1.2,2.4], p trend<0.001) and CKD-EPI$_{cycs}$<60(HR 1.9, 95%CI[1.4,2.6], p trend<0.001);there was no association for MDRD<60(HR 1.1, 95%CI[0.8,1.3], p trend 0.17). In NRI analyses, both BIS2 and MDRD misclassified more subjects with respect to mortality risk compared to CKD-EPI$_{cysc,cr}$(BIS2 NRI -0.13, 95%CI[-0.17, -0.09], p<0.001; MDRD NRI -0.22, 95%CI[-0.27, -0.17], p<0.001). CKD-EPI$_{cysc}$ correctly classified subjects more often than CKD-EPI$_{cysc,cr}$(NRI 0.05, 95%CI[0.01, 0.08], p=0.02).

Conclusions: In a cohort of elderly community-dwelling men, BIS2 identified a higher proportion as having CKD. However, BIS2 performed somewhat worse with respect to mortality risk prediction than current equations used for clinical and research purposes.

SA-PO776

Comparison of the Japanese, CKD-EPI, and MDRD Study Equations for GFR Estimation in a Multicenter Korean Population
Yong Kyu Lee,[2] Beom Seok Kim,[1] Hoon Young Choi,[3] Sug Kyun Shin,[2] Ho Yung Lee.[1] *[1]Nephrology Div, Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Republic of Korea; [2]Nephrology Div, Dept of Internal Medicine, National Health Inst Corporation, Ilsan Hospital, Goyang, Republic of Korea; [3]Nephrology Div, Dept of Internal Medicine, Kangnam Severance Hospital, Seoul, Republic of Korea.*

Background: A new glomerular filtration rate estimation equation for the Japanese population was proposed using measured inulin clearance. To expand its applicability to other Asian populations, we performed a comparative study of the Korean population.

Methods: Inulin clearance was measured in 166 patients who were selected from seven participating medical centers in Korea. Patient sera and urine were collected, and baseline clinical characteristics were measured to provide an estimated glomerular filtration rate by the Japanese GFR equation using inulin clearance (Japanese 2009 equation), the Modification of Diet in Renal Disease (MDRD) study 2006 equation, and the Chronic Kidney Disease - Epidemiology Collaboration (CKD-EPI) 2009 equation. We compared the equation results to determine which equation best estimated the measured GFR (mGFR).

Results: Accuracy (95% CI) within 30% of mGFR by the Japanese 2009 equation, the CKD-EPI 2009 equation and the MDRD study 2006 equation were 66 (58-72), 51(43-58), and 55 (47-62)%, respectively. Bias (mGFR minus eGFR) were 3.4 22.4, -12.0 22.1, and -9.7 23.8 ml/min/1.73m^2, respectively. The accuracy of the Japanese 2009 equation was significantly better than MDRD study 2006 equation in subjects with mGFR <60 ml/min/1.73m^2 and in total subjects. The bias of the Japanese 2009 equation was significantly smaller compared with other two equations in total subjects. The coefficient (95% CI) for the Japanese 2009 equation, the CKD-EPI 2009 equation, and the MDRD study 2006 equation in Korean subjects were 1.067 (1.014-1.118), 0.847 (0.808-0.886), and 0.858 (0.816-0.901), respectively, indicating significant overestimation of GFR by MDRD study 2006 equation and CKD-EPI 2009 equation. There were no adverse events associated with inulin administration during the study.

Conclusions: The Japanese 2009 equation shows a higher accuracy in estimating GFR in Korean populations.

SA-PO777

Comparison of Estimated Glomerular Filtration Rate By the Chronic Kidney Disease Epidemiology Collaboration Equations with and without Cystatin C for Predicting Clinical Outcomes in Elderly Women
Wai Hon Lim,[1] Germaine Wong.[2] *[1]Dept of Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; [2]School of Public Health, Sydney Univ, Sydney, New South Wales, Australia.*

Background: Reduced estimated glomerular filtration rate (eGFR) using the cystatin-C derived equations might be a better predictor of cardiovascular disease (CVD) mortality compared with the creatinine-derived equations, but this association remains unclear in elderly individuals. The aims of this study were to compare the predictive values of the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI)-creatinine, CKD-EPI-cystatin C and CKD-EPI-creatinine-cystatin C eGFR equations for all-cause mortality and CVD events (hospitalizations±mortality).

Methods: Prospective cohort study of 1165 elderly women aged >70 years. Associations between eGFR and outcomes were examined using Cox regression analysis. Test accuracy of eGFR equations for predicting outcomes was examined using Receiver Operating Characteristic (ROC) analysis and net reclassification improvement (NRI).

Results: Risk of all-cause mortality for every incremental reduction in eGFR determined using CKD-EPI-creatinine, CKD-EPI-cystatin C and the CKD-EPI-creatinine-cystatic C equations was similar. Areas under the ROC curves of CKD-EPI-creatinine, CKD-EPI-cystatin C and CKD-EPI-creatinine-cystatin C equations for all-cause mortality were 0.604 (95%CI 0.561-0.647), 0.606 (95%CI 0.563-0.649; p=0.963) and 0.606 (95%CI 0.563-0.649; p=0.894) respectively. For all-cause mortality, there was no improvement in the reclassification of eGFR categories using the CKD-EPI-cystatin C (NRI -4.1%; p=0.401) and CKD-EPI-creatinine-cystatin C (NRI -1.2%; p=0.748) compared with CKD-EPI-creatinine equation. Similar findings were observed for CVD events.

Conclusions: eGFR derived from CKD-EPI cystatin C and CKD-EPI creatinine-cystatin C equations did not improve the accuracy or predictive ability for clinical events compared to CKD-EPI-creatinine equation in this cohort of elderly women.

Funding: Government Support - Non-U.S.

SA-PO778

Limitations of Creatinine- and Cystatin C-Based GFR Estimation in Assessing CKD Risk in Obese Persons: NHANES 1999-2004
Stephen P. Yang, Deep Sharma, Matthew K. Abramowitz. *Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: Higher BMI has been associated with increasing risk of CKD using GFR estimated by creatinine (eGFR$_{Cr}$) or cystatin C (eGFR$_{CysC}$). However, obesity can affect the accuracy of eGFR$_{Cr}$ and eGFR$_{CysC}$. We investigated the role of body composition in assessing CKD risk in obese persons.

Methods: We identified subjects from the National Health and Nutrition Examination Survey 1999-2004. Lean body mass (LBM) and percent total body fat (%TBF) were measured by dual-energy X-ray absorptiometry. Moderate and severe obesity were defined as 35>BMI≥30 and BMI ≥35, respectively. We defined CKD as eGFR <60 ml/min/1.73m^2 and excluded participants with eGFR <15 ml/min/1.73m^2. Logistic regression models were created to examine the association of obesity with CKD after adjustment for age, sex, and race/ethnicity.

Results: Greater obesity was associated with higher LBM, %TBF, and prevalence of CKD. Moderate and severe obesity were associated with CKD defined by eGFR$_{Cr}$, with odds ratios (OR) of 1.66 (1.17 – 2.34) and 2.05 (1.21 – 3.49), respectively. This association was not seen after further adjusting for LBM (OR 1.24 (0.81 – 1.92) and 1.21 (0.65 – 2.25) in moderate and severe obesity, respectively), but was unchanged after adjustment for %TBF. There was a non-significant trend towards an association of higher %TBF with CKD defined by eGFR$_{Cr}$ (OR per 10% TBF 1.25 (0.98 – 1.61)), which was substantially attenuated after adjusting for LBM (OR 1.03 (0.81 – 1.32)). Moderate and severe obesity were also associated with CKD defined by eGFR$_{CysC}$ (OR 2.28 (1.56 – 3.33) and 4.28 (2.49 – 7.36), respectively). This association was independent of LBM, but was attenuated by adjustment for %TBF (OR 1.66 (1.11 – 2.50) and 2.70 (1.17 – 6.22), respectively).

Conclusions: Obesity is associated with high levels of muscle mass, which can confound the diagnosis of CKD in obese patients. Although eGFR$_{CysC}$ is independent of muscle mass, higher %TBF may result in higher serum cystatin C levels and also confound eGFR$_{CysC}$. Whether this results in overdiagnosis of CKD deserves further study.

Slope Estimates of Glomerular Filtration Rate in a UK Population with Diabetes Mellitus: Assessing Progression of Chronic Kidney Disease in Relation to Modeling for Cardiovascular Outcomes
Claudia S. Cabrera,[1] Alison Lee,[2] Marita Olsson,[1,3] Sergio Eslava.[4] *[1]AstraZeneca R&D, Mölndal, Sweden; [2]AstraZeneca R&D, Macclesfield, United Kingdom; [3]Dept of Mathematical Sciences, Chalmers Univ of Technology, Gothenburg, Sweden; [4]AstraZeneca R&D, Gaithersburg.*

Background: The interaction between type II diabetes mellitus (T2DM) and chronic kidney disease (CKD) on cardiovascular disease (CVD) is not well understood, in part due to a lack of consensus regarding the optimal measure for nephropathy progression in observational studies. We describe CKD progression in a representative UK population.

Methods: Within the Clinical Practice Research Datalink (CPRD), a CKD cohort of adults (≥18 yrs) was selected among prevalent T2DM subjects (Jan 1 1995–Dec 31 2013). CKD was defined by the Chronic Kidney Disease Epi Equation (CKD-EPI) and READ codes. Due to the long and heterogeneous follow-up, computing a single eGFR slope per patient appeared to be imprecise. Instead, multiple slopes were calculated over varied time periods per patient: one slope over the full follow-up period "no-window model", slope for 3 yr windows with an 18 month overlap "3-yr model", and slope for 1 yr windows with a 6 month overlap "1-yr model".

Results: Among 56,671 adults with ≥4 eGFR measures and follow-up ≥1 yr (mean age 69 yrs, 52% women), 22% had >10 yrs prevalent diabetes at Index Date. The follow-up period ranged between 1 and 19.5 yrs [mean (SD), 4.9 (1.8) yrs]. Heart failure was the most prominent CVD outcome. The % per slope type was: no window 5.02% (n=56,671); 3-yr 5.13% (n=51,972); and 1-yr 6.36% (n=32,688). The rate (per 1000 person-yrs) of incident CVD in general was: heart failure 11.5 (95% CI 11.08–11.93); ischemic stroke 2.06 (1.89–2.24); and myocardial infarction 3.41 (3.18–3.65).

Conclusions: In this large CKD population, the 1-yr window model appeared to capture a greater proportion of CVD outcomes versus other windows, indicating that progression of CKD may be better assessed using a 1 yr time window to estimate the impact of renal function in subjects with extensive follow-up time. One single slope or a 3 yr slope may only dilute the possible association between eGFR and CVD outcomes.

SOMAscan™–Based Discovery of More Precise Measures of Early Decline in GFR

Anders G. Christensson,[1] Steve Williams,[2] Laila Bruun,[1] Robert E. Mehler,[2] Britta Singer,[2] Barry H. Smith,[3] Daniel Levine,[3] Thomas Parker,[3] Robert Kirk Delisle.[2] *[1]Dept of Nephrology, Skåne Univ Hospital, Malmö, Sweden; [2]SomaLogic Inc, Boulder, CO; [3]The Rogosin Inst, New York, NY.*

Background: Glomerular filtration rate (GFR) is defined as the volume of fluid filtered by the kidney per unit time and, as an index of total functioning renal mass, is the best measure of renal function. Clearance by the kidney of certain exogenous substances from the blood allows measurement of GFR but is not suitable for routine clinical practice. Endogenous clearance markers creatinine and cystatin C are attractive because they offer simpler means of estimating GFR. However, these estimates are relatively imprecise, especially over the clinically relevant range of 60-100 ml/min/1.73m^2. Measuring both markers does not resolve this limitation. The result is that early significant loss of functioning renal mass may go unrecognized, and the opportunity for timely, focused intervention is lost.

Methods: Using SOMAscan™, a high-throughput, multiplexed proteomic assay that simultaneously measures >1100 proteins from small volumes of biological samples, we assayed 183plasma samples from male subjects with GFR > 60 ml/min/1.73m^2 as measured by iohexol clearance. The samples were collected at Skåne University Hospital, Malmö, Sweden. Models were developed to assess the ability of protein levels to predict GFR within the range of 60-120 ml/min/1.73m^2.

Results: The performance of these models were compared to those of creatinine, of cystatin C, and of both, and found to better predict measured GFR above 60 ml/min/1.73m^2 (predictive correlation of 0.70 compared to 0.55). In each model cystatin C was a strong contributor, but 7 other proteins in various combinations with cystatin C enhanced each model's performance. Four of those proteins were found to be increased as GFR went down, and 3 were decreased.

Conclusions: We conclude that it will be possible to develop a clinically useful blood test that measures GFR above 60 ml/min/1.73 m^2, thus enabling detection and intervention in cases of early, clinically relevant renal function loss.

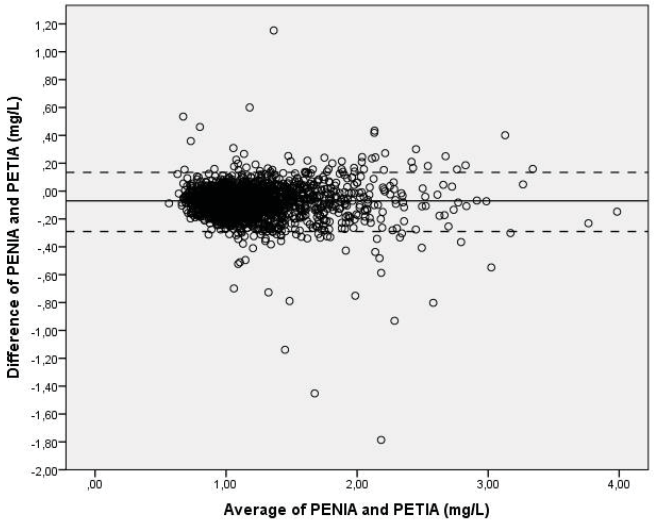
Systematic Analysis of Two Cystatin C Assays (PENIA and PETIA) Using Samples of 2057 Older Adults from the Berlin Initiative Study (BIS)

Natalie Ebert,[1] Pierre Delanaye,[2] Peter Martus,[3] Olga Jakob,[1] Jan Bartel,[4] Mirjam Schuchardt,[1] Etienne Cavalier,[2] Elke Schaeffner.[1] *[1]Charité, Berlin; [2]Univ, Liège; [3]Univ, Tübingen; [4]Limbach Lab, Heidelberg.*

Background: The role of cystatin C (cysC) as renal biomarker has gained importance. At present the two most commonly used methods to quantify cysC are nephelometry (PENIA) and turbidimetry (PETIA). If and how much cysC results may differ depending on the analytical method has been a longstanding debate.

Methods: We performed both, PENIA and PETIA cysC analyses in 2057 baseline serum samples from participants aged ≥70 of the Berlin Initiative Study. PENIA was performed using a BN™II System nephelometer and N Latex assay (Siemens Health Care Diagnostics). PETIA was performed with a Roche/Hitachi Cobas S system and Tina-quant assay. Modified Bland-Altman analysis (median, empirical 2.5% and 97.5% percentiles) was used for method comparison and Deming regression in order to account for random measurement errors.

Results: Modified Bland Altman analysis of both cysC assays in 2057 samples revealed a median difference between PENIA and PETIA of -0.0740 mg/L (95% CI: -0.079 to -0.070) and a standard deviation of 0,1269 mg/L. Non parametric limits of agreement were: -0.2890 to 0.1370mg/L (fig.1).



21 extreme outliers were excluded and Deming regression with inclusion of coefficient of variation (PENIA: 4.6%, PETIA: 5.57%) was performed revealing the following regression equation: PETIA = 0.0925 + 0.9879* PENIA. Details of the regression equation can be found in Table 1:

Parameter	Coefficient	Std. Error	95% Conf. Interval
Intercept	0.09246	0.009017	0.07478 to 0.1101
Slope	0.9879	0.008389	0.9714 to 1.0043

Conclusions: We demonstrated a good agreement between PENIA (Siemens) and PETIA (Roche) cysC assays in a cohort of elderly individuals. However a systematic difference of -0.0740 mg/L between both assays was observed.

SA-PO782

Impact of Two Cystatin C Assays (PENIA and PETIA) on Estimating GFR in a Population-Based Cohort of Older Adults, the Berlin Initiative Study (BIS)

Natalie Ebert,[1] Peter Martus,[2] Olga Jakob,[1] Jan Bartel,[3] Mirjam Schuchardt,[1] Elke Schaeffner.[1] *[1]Charité, Berlin; [2]Univ, Tübingen; [3]Limbach Lab, Heidelberg.*

Background: Cystatin C (cysC) as a renal biomarker is gaining importance and a variety of cysC-based GFR estimating equations have been developed recently. However, differences in cysC assays may have a strong impact on accuracy and precision of cysC-based GFR estimates.

Methods: We performed nephelometric (PENIA) and turbidimetric (PETIA) cysC analysis in 2057 baseline serum samples from participants aged ≥70 of the Berlin Initiative Study (BIS). PENIA was performed with the Siemens BN™ II System and PETIA with the Roche/Hitachi Cobas S System. CysC-GFR was estimated with BIS3 and CKD-EPIcys equations. Linear regression with PENIA as goldstandard was performed to correct PETIA values (PETIA corrected).

Results: Mean GFR values for BIS3 with PENIA were significantly higher ($p<0.001$, t-test) than with PETIA (60 versus 56 ml/min/1.73m^2), the same held true for CKD-EPI (64 for PENIA versus 59 ml/min/1.73m^2 for PETIA, respectively). Linear regression with PENIA values as goldstandard revealed the regression equation: PENIA=0.002+0.933 x PETIA. This regression equation was obtained by ordinary least squares and is different to the one with Deming regression for analysis of agreement. Median bias, Interquartile range (IQR), P_{30} and P_{15} values for BIS3 and CKD-EPIcys equations with PETIA as well as the corrected PETIA values and PENIA as goldstandard are shown in Table 1:

Name of Equation	Median Bias	IQR	P_{30} (%)	P_{15} (%)
BIS3 (PETIA)	-3.57	6.28	98.6	86.7
BIS3 (PETIA corrected)	-0.12	5.88	98.6	93.4
CKD-Epi CysC (PETIA)	-4.93	8.90	97.6	73.4
CKD-Epi CysC (PETIA corrected)	-0.15	8.26	97.8	83.6

Conclusions: GFR estimates with BIS3 and CKD-EPIcys equations vary significantly depending on the cysC assay (PENIA or PETIA). This difference of up to 4 ml/min/1.73m^2 may have a limited clinical relevance only. By correcting PETIA values for systematic assay bias, the precision and accuracy of GFR estimates of both equations with PENIA as goldstandard improved considerably. In conclusion the present study shows that both cysC assays can be used in BIS and CKD-EPI equations almost interchangeably.

Determination of Fluid Status in the General Population Using Bioimpedance Techniques Fansan Zhu, Samer R. Abbas, Peter Kotanko, Nathan W. Levin. *Renal Research Inst.*

Background: Normal fluid status (NFS) can be estimated by bioimpedance hydration markers (HM) in the general population. A population average HM could be used but it is likely that the HM measure is influenced by age and comorbidities. This study evaluates the effect of age and systolic blood pressure (SBP) on HM.

Methods: A general population (n=213, males 106) was studied. Whole body and calf bioimpedance spectroscopy measurements were made with subjects in the supine position (Hydra 4200 device). Body weight, height and SBP were measured as well as calf normalized resistivity (CNR), extracellular (ECV) and intracellular (ICV) volumes. ECV/total body water (TBW) were calculated. Subjects were stratified by age; G1: 18 to 35; G2: 36 to 60, G3: 61 to 80 years. One-way ANOVA was used for group comparisons.

Results: Body mass index (BMI), CNR, ICV and ECV/TBW differed significantly between age groups and genders (Table 1). Decrease in CNR (Fig.1a) and increased SBP (Fig.1b) were associated with older age. CNR and SBP were negatively correlated with all subjects (R^2=0.12, p<0.0001; Fig.1 c). CNR in G1 was at the same levels as in 36% of subjects in G2 and 12.5% of subjects in G3, respectively. Of note, in those G2 and G3 subjects with CNR comparable to G1 subjects, SBP was lower than in the remainders of the respective age groups.

Conclusions: Our study in subjects from the general population shows that CNR declines and ECV/TBW increases with age. Although CNR in about one third of the subjects older than 35 years was in same level as in G1, CNR in most subjects (>35 years) was lower which was associated with higher SBP because of fluid overload, indicating that CNR reflects the relationship between volume expansion and blood pressure regardless of age. Identifying hypertensive patients with volume expansion may inform decision making with respect to drug therapy, such as the preferential use of diuretics.

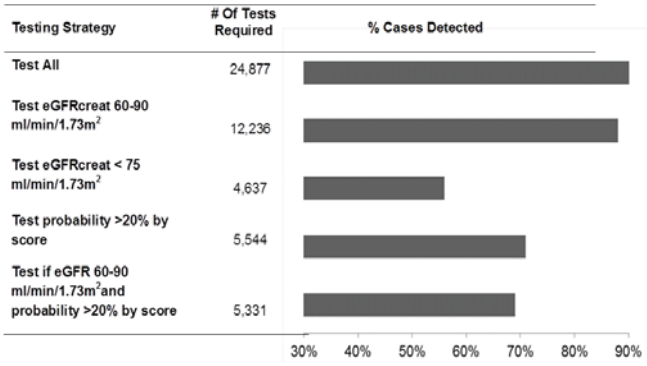
A Risk Score to Guide Cystatin C Testing to Detect Occult Chronic Kidney Disease Carmen A. Peralta,[1] Paul Muntner,[2] Rebecca Scherzer,[1] Suzanne E. Judd,[2] Michael Shlipak.[1] *[1]School of Medicine, Univ of California San Francisco, San Francisco, CA; [2]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Persons with occult chronic kidney disease (CKD), defined as eGFR< 60 ml/min/1.73m^2 by serum cystatin C but not creatinine, are at high risk for complications. Tools are needed to guide cystatin C testing among persons without CKD by creatinine.

Methods: We developed and validated a risk score to estimate an individual's probability of having occult CKD among 24,877 Black and White adults with eGFRcreat >60 ml/min/1.73m^2 in the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study. Occult CKD was defined as eGFRcys < 60 ml/min/1.73m^2 by the 2012 CKD-Epi equation. We used multivariable logistic regression to model the probability of occult CKD, including variables readily available to clinicians. Performance characteristics were assessed using calibration and discrimination measures. The score was externally validated in the Third National Health and Nutrition Examination Survey III (NHANES).

Results: Mean age was 64 years, 41% were Black, and 13.5% had occult CKD by cystatin C. The final risk function included age, eGFRcreat, race, diabetes, hypertension, cardiovascular disease, smoking, and BMI. The risk function had excellent calibration and discrimination (c-statistic 0.87 in REGARDS, and 0.84 in NHANES). Using the risk score, 71% of occult CKD cases could be detected by measuring cystatin C in 22% of participants. For comparison, using eGFRcreat cutpoints alone, 49% of participants would need to be tested to detect a similar proportion of cases.

Figure 1. Yield of Testing Strategies for Occult CKD based on eGFRcreat or risk score



Conclusions: A risk score using characteristics readily accessible in clinical practice can identify the majority of persons with occult CKD. The cost-effectiveness of this approach to guide cystatin C testing requires further research.

Liver Stiffness Is Independently Associated with Estimating GFR Using Serum Cystatin C in Chronic Kidney Disease Patients with Chronic Liver Disease Hoon Young Choi, Tae Hoon Kim, Ah Ran Choi, Miok Cho, Sung Chang Bae, Sung-Kyu Ha, Hyeong Cheon Park. *Dept of Internal Medicine, Gangnam Severance Hospital, Yonsei Univ School of Medicine, Seoul, Korea.*

Background: Liver disease, especially nonalcoholic fatty liver has been reported to associate with an increased chronic kidney disease (CKD) risk. The prognosis and management of chronic liver disease (CLD) depends strongly on the degree of liver fibrosis. Recently, FibroScan (Echosens, Paris, France) has been accepted as a highly reproducible technique that measures liver stiffness in CLD. We carried out a retrospective study to investigate the association between liver stiffness and kidney function represented asestimating GFR using serum cystatin C (cystatin C-eGFR) in CKD with CLD patients.

Methods: Estimated glomerular filtration rate was calculated using cystatin C level (Cystatin C-GFR) [77.239 X (1.0675 X cystatin C - 0.1)$^{-1.2623}$]. Liver stiffness measurement (LSM) using FibroScan® was performed by a well-trained physician.

Results: A total of 512 CKD with CLD patients were enrolled. Average level of LSM and cystatin C-eGFR were 13.1 ± 14.8 kPa and 96.8 ± 47.1 ml/min. Age adjusted partial correlation analysis showed that LSM (r=-0.294, p=0.000), uric acid level (r=-0.216 p=0.001), alkaline phosphatase level (r=-0.229, p=0.000), and CRP level (r=-0.282, p=0.012) significantly correlated with cystatin C-eGFR negatively. WBC count (r=0.394, p=0.000) and hemoglobin level (r=0.375, p=0.000) showed the significant positive correlation. Serum albumin, AST and ALT level, Hepatitis B or C positive status did not show the significant correlation with cystatin C-eGFR. On multiple regression analysis, LSM was only the independent risk factor affecting cystatin C-eGFR.

Conclusions: Our results suggest that the increase LSM is the potential risk factor for kidney dysfunction in CKD with CLD patients.

SA-PO786

Impact of Cystatin c on Metformin Use among Adult Veterans with Diabetes Delphine S. Tuot, Rebecca Scherzer, Luciana Mendiola, Michael Shlipak. *Univ of California, San Francisco.*

Background: Current recommendations for metformin use are dependent on eGFR category: eGFR >45 ml/min/1.73m^2 – "first-line agent"; eGFR 30-44 – "use with caution"; eGFR<30 – "do not use". Nationally, metformin is underused among persons with eGFR 30-60. Misclassification of metformin eligibility by creatinine-based MDRD GFR estimates (eGFRcr) may contribute to underuse. We investigated the impact of cystatin c estimates of GFR (eGFRcys) on metformin eligibility.

Methods: Metformin use was assessed in a randomly selected cohort of 550 adult Veterans with diabetes in San Francisco. eGFR categories were defined as <30, 30-44, 45-60, and >60. We defined discrepancy between eGFRcys and eGFRcr as cases where the eGFRcys category was more severe than the eGFRcr category with an absolute difference >5 ml/min/1.73m^2. Multivariable relative risk regression was used to model predictors of metformin use and of discrepancy between eGFRcys and eGFRcr.

Results: Cohort subjects were 95% male, diverse (45% White, 22% Black, 11% Asian, 22% unknown) and had a median age of 68 years. Metformin use differed by eGFR: 8% in eGFRcr <45, 45% in eGFRcr 45-60, and 63% in eGFRcr >60. Compared to eGFRcr >60, likelihood of metformin use was much lower for persons with eGFRcr 45-59 (aRR=0.77, 0.59-0.99) and eGFRcr 30-44 (aRR=0.18, 0.08-0.41). eGFRcys reclassified 36% of persons, including 20% for whom metformin eligibility changed.

eGFRcys	eGFRcr <30 "do not use" (n=31)	eGFRcr 30-45 "caution" (n=58)	eGFRcr 45-60 "first line" (n=93)	eGFRcr >60 "first line" (n=368)
<30 "do not use"	**27 (90%)**	23 (40%)	8 (9%)	1 (1%)
30-45 "caution"	3 (10%)	**31 (53%)**	38 (41%)	32 (9%)
45-60 "first line"	0	4 (7%)	**35 (38%)**	76 (21%)
>60 "first line"	0	0	12 (13%)	**259 (70%)**

Factors associated with eGFRcys reclassification to a worse eGFR category were older age (aRR=1.38 per decade, 1.44-1.82) and albuminuria > 30mg/g (aRR=1.40, 1.10-1.77).

Conclusions: Metformin use is low among Veterans with CKD. eGFRcys may serve as a confirmatory estimate of kidney function to allow safe use of metformin among patients with CKD, particularly among older individuals and those with albuminuria.

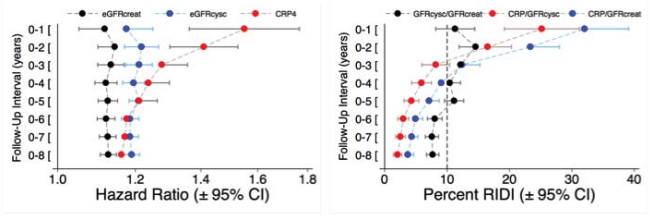
Adding C-Reactive Protein Improves the Risk Prediction for All-Cause Mortality with Estimating Equations for Glomerular Filtration Rate

David G. Warnock,[1] Nancy Jenny,[2] William M. McClellan,[3] Richard J. Glassock.[4]
[1]UAB, Birmingham, AL; [2]Univ of Vermont, Burlington, VT; [3]Emory Univ, Atlanta, CA; [4]UCLA, Los Angeles, CA.

Background: Cystatin-C based estimated GFR (eGFR) outperform creatinine-based eGFR for assessing all-cause mortality (Shlipak et al 2013), but not complication of chronic kidney disease ((Rule et al 2013). C-reactive protein (CRP) is associated with early deaths (Jenny et al 2007). We assessed the the mortality risk among participants in the REGARDS (Reason for Geographic and Racial Differences in Stroke) study when CRP quartiles were added to multivariable regression models based on eGFRcysc or eGFRcreat.

Methods: Regression models with 25,734 REGARDS participants; there were 3,020 deaths over 8 years. The performance of CRP quartiles (CRP4) was assessed with relative integrated discrimination improvement (rIDI; Pencina et al 2011). Covariates included demographics, cardiovascular risk factors and urine albumin to creatinine ratio (ACR).

Results: Average age was 65 (SD 9.4) years; 46% males, 40% Black; 22% had previous cardiovascular events; 21% type 2 diabetes; 14% current smokers; average systolic blood pressure was 127 (SD 17); total cholesterol, 192 (SD 40); body mass index, 29.3 (SD 6.1); and eGFRcreat, 85 ml/min/1.73 m^2 (SD 20). CKD with eGFRcreat less than 60 was present in 10.7%, and 14.6% had ACR ≥30 mg/g.



Hazard ratios (HR) for eGFRcreat and eGFRcysd were constant over 8 years follow up; while HR for CRP4 showed marked attenuation after 3 years. Addition of CRP4 improved performance for eGFRcysc and eGFRcreat models (RIDI significantly ≥10%) and was significantly better than the performance of the eGFRcysc model compared to the eGFRcreat model for the first 2 years of follow up.

Conclusions: Adding CRP quartiles significantly improves risk prediction for all-cause mortality when added to regression models based on eGFRcreat or eGFRcysc.

Correlation between Renal Apparent Diffusion Coefficients and Glomerular Filtration Rate in Chronic Kidney Disease

Geng-Xi Sun,[1] Hui-Qun Li,[2] Yan-Ru Chen,[2] Tan-Qi Lou.[2] *[1]Affiliated Hexian Memorial Hospital, Southern Medical Univ, Guangzhou, Guangdong; [2]The Third Affiliated Hospital of Sun Yat-sen Univ.*

Background: Studies have shown diffusion weighted imaging (DWI) can sensitively detect the diffuse movement of the water molecules, and we can learn the internal structure and composition of the diseased tissue by measuring the apparent diffusion coefficient (ADC) values. The objectives of the present study were to explore the correlation between renal apparent diffusion coefficient (ADC) values and glomerular filtration rates (GFR) in patients with chronic kidney disease (CKD).

Methods: 64 CKD patients (128 kidneys) were included as CKD group in our study, and 18 healthy adults (36 kidneys) were enrolled as the control group. The cortical and medullary ADC values were tested by diffusion weighted imaging (DWI). According to the single kidney glomerular filtration rate (SKGFR) calculated with 99Tcm-DTPA scintigraphy. The 128 kidneys of CKD group were divided into 2 groups: normal renal function (48 kidneys) and renal impairment (80 kidneys). The correlation of the cortical and medullary ADC values and SKGFR were analyzed.

Results: The cortical ADC values were significantly higher than the medullary ADC values in the control group and the CKD group (P<0.05). The cortical and medullary ADC values of normal renal group and renal impairment group were all significantly lower than the control group (P<0.05), ADC values of the renal impairment group were lower than those of normal renal function group (P<0.05). Pearson correlation analysis showed that the cortical and medullary ADC values were positively correlated with SKGFR (r=0.716(cortical), P<0.01, r=0.813(medullar), P<0.01).

Conclusions: DWI is a new noninvasive technique. Our study shows ADC values tested by DWI can reflect GFR, and it can be used as a marker for early detection of renal disfunction in CKD patients.

New Index Adjusted U-Pro$_{1.0}$ Is Useful to Estimate Urinary Protein by Eliminating the Effect of Protein Intake

Yushi Nakayama,[1] Yuichiro Izumi,[1] Hideki Inoue,[1] Tomoaki Onoue,[1] Hiroshi Nonoguchi,[2] Masashi Mukoyama.[1]
[1]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Dept of Internal Medicine, Kitasato Univ Medical Center, Kitamoto, Saitama, Japan.

Background: Urinary protein excretion (U-Pro) is a major target for the treatment of Chronic Kidney Disease (CKD). However, U-Pro is remarkably affected by the daily changes of protein intake (PI). Estimation of U-Pro with elimination of the effect of PI would be useful to evaluate the renoprotective effect of medication such as RAS blockers. For this purpose, we propose the new index, adjusted proteinuria$_{1.0}$ (adjusted U-Pro$_{1.0}$), which estimates urinary protein excretion in an assumption with protein intake of 1.0g/kg BW/day.

Methods: We collected the chemistry data of blood and 24hr urine sample from 151 patients with CKD (total points = 3882). Daily PI was calculated by the Maroni, Steinman, and Mitch method as follows. PI (g/day) = [Urine volume (UV;ml) x Urinary urea nitrogen (UUN;mg/dl)÷10^5 + Body Weight (BW;kg) x 0.031] x 6.25. Urinary urea nitrogen (mg/dl) adjusted by a protein intake of 1.0g/kg BW/day (UUN$_{1.0}$), was calculated by substitution of PI to BW in this formula (since PI=BW at protein intake of 1.0g/kg BW/day) and adjusted U-Pro$_{1.0}$ was estimated.

Results: The relation between UUN and UUN$_{1.0}$ is shown in Figure1. The adjusted U-Pro$_{1.0}$ was defined by following formula. Adjusted U-Pro$_{1.0}$ (g/gCr) = measured U-Pro (g/gCr) x UUN$_{1.0}$ / measured UUN. U-Pro$_{1.0}$ was larger than measured U-Pro (Figure2), which indicate that patients with CKD were under proper restriction of protein intake (average: 0.883±0.004 g/kg BW).

Conclusions: U-Pro is useful to examine the effects of low protein diet while adjusted U-Pro$_{1.0}$ is useful to examine the effect of RAS blockers on urinary protein excretion.

Evolution of Renal Function in Anorexia Nervosa

Jonathan Rouche.
Nephrology, CHU Le Bocage, Dijon, Burgondy, France.

Background: Anorexia nervosa (AN) is a frequent eating disorder that may be associated with chronic kidney disease (CKD) as described by the term "hypokalemic nephropathy", an ill-defined entity. The aim of this study was to clarify the evolution of glomerular filtration rate (GFR) in these patients and its determinants.

Methods: In a retrospective study, we analyzed the electrolyte disturbances and the evolution of GFR assessed on 104 patients in hospital who have AN by using the Cockcroft-Gault formula (CG). The CKD was defined as two GFR < 60ml/min for at least 3 months without subsequent return to normal value. We used the Chi2, Fisher, Student, Welch-Satterthwaite and Pearson tests.

Results: The cohort included 98 women and 6 men with a mean age 27 ± 11 years, and a BMI of 14.6 ± 3.04 kg/m2. Initial data were obtained from patient serums: K = 3.84 ± 0.72 mmol / L, Cl = 99.96 ± 8.16 mmol / L, HCO3 = 28.4 ± 6.07 mmol / L and creatinine = 73.22 ± 33 83 µmol / L. For 55 patients, we had a follow-up of serum creatinine over a period of 20.28 ± 10.2 months. 18/55 patients (32.7%) were diagnosed in CKD. They did not differ from other patients for the K + (3.75 ± 1.27 versus 3.94 ± 0.49 mmol / L; p = 0.73) and HCO3 - (32 ± 11.3 versus 28 ± 3.2 mmol / L; p = 0.15) initials. However, the initials serum chloride and BMI were significantly lower, respectively 93 ± 13.6 versus 101 ± 5.6 mmol / L (p = 0.007) and 12.69 ± 2.36 versus 15.36 ± 3.16 kg/m2 (p = 0.01).

Conclusions: The assessment of renal function in these patients with reduced muscle mass is difficult, but Delanaye et al [1] showed that the CG overestimates measured GFR but is the most reliable, compared with the others equations based on creatinine or cystatin C. Approximately one third of patients were diagnosed in CKD, and those are the ones in which AN was the most severe. The hypochloremia probably reflects the complexes electrolyte

disturbances of these patients. Our results strongly suggest that a regular follow-up of renal function should be recommended in AN. [1] Delanaye P et al, Clin Nephrol, 2009.

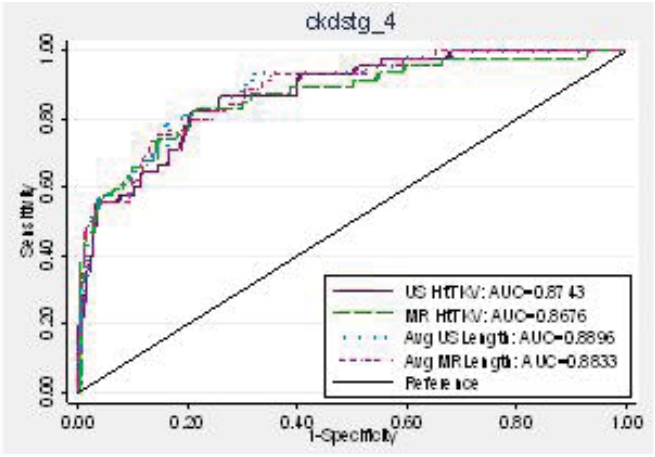
Ultrasound (US) and Magnetic Resonance (MR) Renal Imaging Predict Future Chronic Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Arlene B. Chapman,[1] Harpreet Singh Bhutani,[1] Frederic F. Rahbari-Oskoui,[1] Vicente E. Torres,[2] Alan S.L. Yu,[3] Kyongtae Ty Bae,[4] Peter C. Harris,[2] Michael F. Flessner,[5] William M. Bennett,[6] Jared J. Grantham,[3] Patrice Gibbs,[4] Doug Landsittel.[4] *[1]Emory; [2]Mayo; [3]KUMC; [4]UPitt; [5]NIDDK; [6]Legacy.*

Background: ADPKD is characterized by increasing cyst burden and height corrected total kidney volume (htTKV) decades prior to loss of kidney function. We determined if kidney length (KL) by US or MR could predict future CKD stages 3,4 and 5 as well as htTKV.

Methods: The Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease is a prospective, observational, longitudinal, multicenter study of 241 ADPKD adults with preserved kidney function. Demographic, physical, lab and imaging data were collected at baseline and follow up visits. CKD stage was determined using iothalamate clearance. Subjects were followed for up to 12 years. ROC curves were developed for each CKD Stage for baseline htTKV and KL from US and MR. A logistic regression model was used adjusting for age and serum creatinine. Optimal correct classification and the cut point associated with these were determined.

Results: As of June 2014, 31, 47, 70 and 99 participants reached CKD Stage 5,4, 3b and a respectively. ROC analyses for each CKD stage demonstrated similar AUC. As a single example, Figure 1 demonstrates ROCAUC for CKD stage 4. Table 1 shows the cut points associated with optimal combined sensitivity and specificity for each imaging method for CKD Stage 4.



Modality MR or US	Sensitivity (%)	Specificity (%)	Correct classification (%)	Cut point ml/m or cm
MR htTKV (ml/m)	73	73	73	650
US htTKV (ml/m)	75	74	74	750
MR Kidney Length (cm)	73	75	74	17
US Kidney Length (cm)	76	78	78	18

Conclusions: Both KL and htTKV strongly predict future CKD stages 3,4 and 5 in ADPKD, over a decade prior to their occurrence. US and MR performed equally well in predicting all CKD stages.

Urinary mRNA for Vimentin Could Serve as a Potential Novel Biomarker of Renal Fibrosis Yuhan Cao, Linli Lv, Lihong Ding, Bi-Cheng Liu. *Inst of Nephrology, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Renal fibrosis is a common histologic outcome of primary glomerular diseases (PGD) progression. However, it is still a challenging issue to find a sensible parameter which could predict or reflect the development of renal fibrosis. Here, we demonstrated that detection of urinary mRNA for vimentin (a major cytoskeletal component of mesenchymal cells which play a critical role in fibrosis generation) might serve as a novel biomarker for evaluation of renal fibrosis in PGD.

Methods: In screening set, we collected urine samplesfrom 26biopsy-proven PGD patients and 8 healthy controls. Urinary mRNA array of 86 genes were quantified and analyzed the correlation with clinical parameters and fibrosis grades. The potential biomarkers were confirmed in validation set with 32 glomerular disease patients and 8 controls.

Results: In screening study, urinary mRNA profiles showed a total of 12 mRNAs were differentially expressed between PGD patients and controls(P<0.05), among which vimentin mRNA was significantly increased by 6.63 fold in patients group. Spearman's rank correlation showed that mRNA levels of vimentin associated with serum creatinine and eGFR (r_s=0.623, P<0.001; r_s=-0.618, P<0.001, respectively). Additionally, vimentin mRNA correlated with glomerulosclerosis (r_s=0.418, P=0.033), severity of tubulointerstitial fibrosis (TIF) (r_s=0.533, P=0.006) and could discriminate PGN from controls with AUC of 0.938 (P<0.001). Moreover, vimentin could distinguish moderate–severe fibrosis from none–mild with AUC of 0.830 (P=0.006). Higher expression of vimentin in fibrotic kidney disease was confirmed by immunohistochemical test. In validation phase, urinary vimentin mRNA also performed well in discriminating PGD from controls(AUC=0.953, P<0.001) and could predict degree of TIF with AUC of 0.864(P=0.001)which confirmed the dignostic potential of vimentin mRNA inscreening study.

Conclusions: In both screening and validation study, urinary vimentin mRNA showed great potential as biomarker of PGD for monitoring both renal function and fibrosis.

Trends in the Prevalence of Decreased GFR in an Adult Korean Population: Comparison of the CKD Epidemiology Collaboration (CKD-EPI) and Modification of Diet in Renal Disease (MDRD) Study Equations Jung-Woo Noh, Ajin Cho, Youngki Lee, Ja-Ryong Koo, Eun Jung Kim, Jang Won Seo. *Internal Medicine, Hallym Kidney Research Inst, Hallym Univ College of Medicine, Seoul.*

Background: The estimated glomerular filtration rate (eGFR) calculated using the Modification of Diet in Renal Disease (MDRD) study equation is a representative index for the prediction of the glomerular filtration rate (GFR). Recently, the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation was developed, and the $eGFR_{CKD-EPI}$ was more accurately accurate and predictive, particularly for individuals with normal or mildly impaired kidney function. In this study, we evaluated the difference in the prevalence of decreased GFR determined using the two equations in the Korean general population.

Methods: Data from the Korea National Health and Nutrition Examination Survey (KNHANES) I (1998), II (2001), III (2005), IV (2007-09) and V (2010-12) were analyzed. A total of 55066 participants aged 20 or older with serum creatinine data were included. Decreased GFR was defined as estimated GFR < 60 mL/min/1.73m^2.

Results: The mean age in KNHANES I-V was 45±16, 45±15, 42±19, 49±16 and 51±16 years, respectively. The mean estimated GFR in KNHANES I-V was 87±15, 79±13, 81±19, 90±19 and 93±18 ml/min/m^2 using MDRD study equation and 91±16, 83±16, 85±19, 91±18 and 94±17 ml/min/m^2 using CKD-EPI equation, respectively. The prevalence of reduced GFR in KNHANES I-V was 2.2%, 7%, 6.8%, 3.8% and 2.8% using MDRD study equation and 2.5%, 6.8%, 6.8%, 4.3%, 3.3% using CKD-EPI equation, respectively. After adjusted by age, sex, BMI, diabetes and hypertension, prevalence ratio of reduced GFR in the later survey versus earliest survey (KNHANES I) were 4.0 (95% CI, 3.3-4.9), 4.0 (95% CI, 3.3-4.8), 1.1 (95% CI, 0.9-1.3) and 0.7 (95% CI, 0.6-0.9) using MDRD study equation and 3.5 (95% CI, 2.9-4.2), 3.7 (95% CI, 3.0-4.4). 1.0 (95% CI, 0.8-1.2), 0.7 (95% CI, 0.6-0.8) using CKD-EPI equation, respectively.

Conclusions: The mean $eGFR_{CKD-EPI}$ was higher than the mean $eGFR_{MDRD}$ in KNHANES I-V. The prevalence of reduced $eGFR_{CKD-EPI}$ in an adult Korean population has decreased since 2001 confirming the decrease observed in the prevalence of reduced $eGFR_{MDRD}$.

The Applicability of Different Equations for Estimating Glomerular Filter Rate (eGFR) in Chinese Elderly Patients Wei Liu, Wenke Hao, Wenna He, Feng Yu, Wenxue Hu, Yanhua Wu, Yuanjuan Qian, Xiaowu Fang, Wei Shi. *Div of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: The objective of this study was to evaluate the applicability of different equations compare with standard GFR (sGFR) measured by ^{99m}Tc-DTPA clearance using a dual plasma sampling method in elderly Chinese patients.

Methods: A total of 297 patients (205 men and 92 women) were enrolled, which aged 75.1±6.7 (range, 65-91) years. GFR estimated using the Cockcroft-Gault (formula 1), MDRD (formula 2) and CKD-EPI equations based on SCr (formula 3), Cys C (formula 4) and combining SCr with Cys (formula5). Bias was assessed as the median of the differences between sGFR and eGFR, and precision was assessed as the interquartile range (IQR) for the differences. Accuracy was assessed as the percentage of estimates within 30% of sGFR (P30). The consistency was tested by correlation analysis and Bland-Altman analysis.

Results: The averages of sGFR and eGFRs were 32.57±19.82, 32.36±22.63(formula 1), 36.89±28.01(formula 2), 36.59±27.36(formula 3), 31.76±23.06(formula 4) and 33.27±24.60(formula 5)ml/min/1.73m^2, respectively(P=0.904, 0.031, 0.041, 0.646 and 0.705 versus sGFR). The median differences were successively 0.31(formula 3), -0.84(formula 5), 0.95(formula 2), -1.54(formula 4) and -1.69(formula 1) ml/min/1.73m^2. The IQRs were 11.76(formula 5), 11.85(formula 4), 11.96(formula 1), 17.55(formula 3) and 18.42(formula 2)ml/min/1.73m^2, respectively. P30 for all equations were 60.9%(formula 1), 59.6%(formula 4), 57.6%(formula 5), 49.2%(formula 2) and 47.5%(formula 3), respectively. Significant correlation was found between sGFR and eGFRs calculated from formula 5(r=0.860), formula 2 (r=0.860), formula 3 (r=0.856), formula 1 (r=0.837) and formula 4 (r=0.806) (all P=0.000). Bland-Altman analysis also showed the mean differences of different equations were -0.21(formula 1), 0.7(formula 5), -0.8(formula 4), 4.0(formula 3) and 4.3(formula 2) ml/min/1.73m^2, respectively.

Conclusions: The CKD-EPIequation based on SCr and Cys had less bias, higher accuracy and precision in Chinese elderly patients. It could be preferentially applied to assess GFR in Chinese elderly patients.

System Dynamic Modeling for ESRD Fiscal-Impact and Outcomes Projections

Katharine L. Cheung,[1] Luca Paolo Fernandez,[2] Christopher Jones,[3] Richard J. Solomon.[1] *[1]Nephrology, Univ of Vermont College of Medicine, Burlington, VT; [2]Community Development and Applied Economics, Univ of Vermont, Burlington, VT; [3]Clinical and Translational Science- Global Health Unit, Univ of Vermont College of Medicine, Burlington, VT.*

Background: Current end-stage renal disease (ESRD) projections utilize Markov models but do not readily allow for simulating scenarios of policy change. System dynamic modeling (SDM) can quickly simulate such scenarios and are well suited for complex systems but have not yet been applied to ESRD.

Methods: We developed a causal diagram from critical care pathways in the ESRD continuum, including dialysis treated ESRD, transplantation and conservative care. We employed SDM using AnyLogic software (Version 7.0.3) and data from USRDS, specifically the prevalence rates from 2010 and averaged incidence, mortality and other flow rates from 2007-2011. We used age and primary diagnosis specific mortality rates to create 35 specific cohorts. We tested the ESRD SDM by running historical scenarios using data from 2000-2010 and 2005-2010 for 2010 projections. To forward simulate likely resource utilization, outcomes and cost, the ESRD SDM was calibrated against the output of the USRDS prediction for year 2020.

Results: To test the robustness of the model we ran three extreme scenarios: 200% increase in transplant rate, 30% increase in conservative care for patients 75 and older, and a 6-fold increase in peritoneal dialysis use (30% of dialysis patients). Projected results for 2020 from SDM and USRDS (2009 ADR) were similar: incidence rate was 136,623 versus 142,858; prevalence rate 838,906 versus 774,386; mortality rate 108,906 versus 118,617. Each of the scenarios ran successfully in the model and yielded expected results, e.g. a doubling of the transplant rate appropriately increased prevalence of ESRD and lowered the annual mortality rate to 92,965.

Conclusions: ESRD SDM is a viable approach to predicting and illustrating growth of the ESRD population in real time. ESRD SDM may be useful for modeling the impact of fiscal and policy changes to identify areas, ex ante, that could be made more efficient over a specified time horizon.

Risk Factors of Renal Functional Decline in Patients Receiving Antiviral Agents for Chronic Hepatitis B

Jung-Ho Shin, Kyungho Lee, Hee Jin Kwon, Do Hee Kim, Seung Yeon Son, Hye Ryoun Jang, Jung Eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh. *Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.*

Background: Renal functional decline frequently seen in patients receiving antiviral agents for chronic hepatitis B may limit aggressive treatment using antiviral agents and exert adverse effects on overall prognosis. In this study, we analyzed the risk factors of renal functional decline in chronic hepatitis B patients receiving antiviral agents.

Methods: Between January 1, 2008 and December 31, 2013, medical records of chronic hepatitis B patients treated with oral antiviral agents in Samsung Medical Center were retrospectively analyzed. End points were end-stage renal disease requiring renal replacement therapy, liver transplantation, death, and switching of antiviral agents.

Results: A total of 4178 patients (M:F=2892:1286) were recruited and the mean duration of follow-up period was 26.9 months. Antiviral agents included lamivudine (17.0%), entecavir (70.4%), tenofovir (4.0%), clevudine (4.3%), telbivudine (0.6%), or adefovir (3.7%). Estimated glomerular filtration rate (eGFR) of 706 (16.9%) patients decreased by more than 25% from baseline eGFR during total follow-up period. Age, hypertension, diabetes, history of liver or kidney transplantation, and concomitant treatment of diuretics showed increased hazard ratio (HR). Both entecavir and clevudine groups compared to the lamivudine group showed decreased HR. A total of 341 (17.4%) patients among 1959 patients, whose kidney function were measured at 1 year after starting antiviral agents, showed decreased eGFR by more than 5mL/min/1.73m^2 and was defined as rapid decline group. Baseline serum levels of albumin, uric acid, and cholesterol were lower in the rapid decline group. Age, diabetes, liver or kidney transplantation, and underlying chronic kidney disease (CKD) were identified as risk factors for rapid decline group.

Conclusions: Age, hypertension, diabetes, liver or kidney transplantation, concomitant treatment of diuretics, and underlying CKD were identified as risk factors for renal functional decline in chronic hepatitis B patients receiving antiviral agents.

SA-PO797

Progression of Diabetic Nephropathy and Tubulointerstitial Nephritis: Role of Asymmetric Dimethylarginine and Oxidative Stress

Jaromir Eiselt,[1] Daniel Rajdl,[2] Lukas Kielberger,[1] Jaroslav Racek.[2] *[1]Internal Dept 1, Univ Hospital, Plzen, Czech Republic; [2]Dept of Biochemistry, Univ Hospital, Plzen, Czech Republic.*

Background: Etiology of chronic kidney disease (CKD) is an important factor of progression. Asymmetric dimethylarginine (ADMA) and oxidative stress are also connected with progression of CKD. The aim of our study was to compare changes of ADMA and oxidative stress in patients with diabetic nephropathy (DN) and tubulointerstitial nephritis (TIN).

Methods: In a one-year follow-up (examinations at baseline, month 6 and 12), we measured plasma ADMA, advanced oxidation protein products (AOPP) and advanced glycation end-products (AGE) in 72 patients with CKD stages 3-5 (30 pts with DN, 42 pts with TIN). Glomerular filtration rate (eGFR) was estimated using CKD-EPI 2012 cystatin C formula.

Results: We observed a more rapid decrease of eGFR in DN than in TIN. Levels of AGE rose significantly in both groups, while AOPP rose in DN only. We did not find differences in ADMA values between the groups. Results are summarized in the table.

	baseline	month 6	month 12	*P* (DN *vs.* TIN)
eGFR DN (mL/min)	19 (16-28)	18 (14-25)	15 (12-24)	0.0004
eGFR TIN (mL/min)	22 (18-33)	24 (17-33)	21 (16-23)	
ADMA DN (μmol/L)	0.90 (0.85-0.99)	0.84 (0.73-0.93)[a]	0.87 (0.70-1.05)	0.9
ADMA TIN (μmol/L)	0.89 (0.81-0.98)	0.82 (0.74-0.91)[a]	0.96 (0.850-1.06)[b]	
AGE DN (FU/g of protein)	1.7 (1.3-1.8)	1.9(1.5-2.3)[a]	1.9 (1.6-2.3)[c]	0.7
AGE TIN (FU/g of protein)	1.6 (1.4-2.0)	1.8 (1.6-2.1)[a]	1.8 (1.6-2.1)[c]	
AOPP DN (μmol/L)	147 (136-172)	137 (130-155)	161 (142-190)[b,c]	0.01
AOPP TIN (μmol/L)	143 (126-177)	137 (117-155)	130 (116-174)	

Data are presented as median (interquartile range); Mann-Whitney and Friedman tests; significance ($p<0.05$): [a]=month 6 versus baseline, [b]=month 12 versus 6, [c]=month 12 versus baseline.

Conclusions: Diabetic nephropathy was associated with more rapid decline of eGFR and higher levels of AOPP than TIN. Differences in the rate of progression of CKD between DN and TIN are not caused by ADMA. Increase of AGE in both groups and AOPP in DN group only can be interpreted as general presence of oxidative stress in CKD that is more pronounced in DN patients and can contribute to more rapid eGFR decline.

SA-PO798

CKD Prevalence and Use of Formulas in Oldest Old Individuals

Antonello Pani,[1] Doloretta Piras,[1] Marco Masala,[4] Alice Atzeni,[1] Silvana Urru,[4] Alessandro Delitala,[2] David Schlessinger,[3] Francesco Cucca.[2] *[1]Ospedale Brotzu, Cagliari, Italy; [2]CNR, Cagliari, Italy; [3]NIA- NIH, Baltimore; [4]CRS4, Pula, Italy.*

Background: Equations to estimate GFR have not been well validated in the elderly, and may lead to misclassification of subjects with chronic kidney disease (CKD). We examined the prevalence of CKD and the degree of agreement between different eGFR equations in a cohort of nonagenarians.

Methods: All of 250 individuals living in 13 villages in the central Sardinia and aged ≥ 90 years were invited to participate in this study. About 89% accepted to join; serum creatinine (sCr) and cystatin C (Cys) were measured in 185 volunteers, and Pr/Cr ratio in 151. eGFR was estimated by CKD-EPI sCr, CKD-EPI Cys, CKD-EPI sCrCys, Berlin Initiative Study Equation (BIS) 1 (sCr based), and BIS2 (sCr and Cys based). CKD prevalence was assessed according to the KDIGO classification. Agreement of the estimating equations in identifying people with different eGFR categories (> 90; 60-90; 45-60; 30-45; 15-30; < 15 ml/min) was evaluated using the k statistic. CKD-EPI sCrCys was used as reference equation.

Results: Median age was 91.9 (interquartile range: 90.7- 94.1 ys). CKD prevalence was similar when evaluated by the different CKD-EPI formulas, but higher if calculated by the BIS equations. However, when GFR was estimated on single individuals, the eGFR category varied depending on the equation used: the agreement of CKD-EPI sCrCys was fair with BIS1 (K 0.37, 95% CI 0.28-0.46; total eGFR categories matches 53.6%); moderate with CKD-EPI Cr (K 0.54, 95% CI 0.45-0.64; total matches 68.9%) and with BIS2 (K 0.60, 95% CI 0.51-0.69; total matches 70.8%); and more substantial with CKD-EPI cys (k 0.67, 95% CI 0.58-0.76; total matches 76.2%).

Conclusions: CKD prevalence according to KDIGO classification was very high in individuals aged ≥ 90 years, as generally expected from the physiologic decline of renal function. It suggests care in identifying very old people as having CKD, especially because the equations used for estimating GFR have a significant impact on CKD classification in the elderly. Further studies using a gold standard GFR measurement are required to establish which equation fits the oldest old best.

SA-PO799

Public Health Impact of Chronic Kidney Disease Risk Stratification Estimates Annette Von Thun,[1] Maura A. Watson.[2] *[1]Navy Medical Personnel Development Command, United States Navy, Bethesda, MD; [2]Nephrology Service, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Chronic kidney disease (CKD) patients have increased mortality, morbidity, and healthcare utilization. Kidney Disease: Improving Global Outcomes (KDIGO) guidelines advocate a 2-dimensional matrix and the CKD Epidemiology Collaboration (CKD-EPI) equation versus Modification of Diet in Renal Disease (MDRD) for risk stratifiaction.

Methods: Community based, cross-sectional survey (National Health and Nutrition Examination Survey (NHANES), 2001-2010) of CKD prevalence, population differences and healthcare utilization using the KDIGO matrix, CKD-EPI and MDRD equations. Subjects: non-pregnant adults >20 years, not on dialysis and completed NHANES. Glomerular filtration rate and albuminuria estimated from blood and urine samples. Demographics, vitals, and comorbidities obtained by standardized survey. CKD stage and projected care utilization were calculated per KDIGO guidelines. Prevalence estimates were extrapolated to the 2000 U.S. census population to evaluate overall disease burden and U.S healthcare system impact.

Results: CKD prevalence was 12.5% (CKD-EPI) versus 15.5% (MDRD). Of those diagnosed with CKD by both equations, 12% had a more severe CKD stage by MDRD. MDRD equation use with the KDIGO matrix led to 5.6 million over-diagnoses, 730,000 excess referrals, and 8 million excess healthcare visits annually, extrapolated to the U.S. population. This cohort was more likely to be female, older, obese, and have CKD risk factors. By multivariate analysis, the over-diagnosed group was more likely to have hypercholesterolemia (15%), hypertension (20%) and cardiovascular disease (38%) after adjusting for age, sex and albuminuria.

Conclusions: Estimation of CKD by CKD-EPI identified 37% fewer subjects at risk versus MDRD. Appropriate diagnosis of CKD can impact healthcare availability and utilization. Subjects identified with CKD by the MDRD equation were associated with residual cardiovascular risk, warranting further investigation. The views expressed do not reflect the official policy of the Department of Defense or U.S. Government.

SA-PO800

Prevalence of Chronic Kidney Disease in the Primary Care Hypertensive Patients in Minhang District, Shanghai Yong Gu,[1,3] Xianwu Ye,[1] Yanping Zhao,[2] Jianying Niu.[1] *[1]Div of Nephrology, The Fifth People's Hospital of Shanghai, Shanghai, China; [2]Minhang Center for Disease Control and Prevention, Shanghai, China; [3]Div of Nephrology, Huashan Hospital, Shanghai, China.*

Background: Chronic kidney disease (CKD) is associated with adverse renal and cardiovascular outcomes. Its early identification greatly depends on the awareness of general practitioners (GPs). So far, no study has evaluated CKD prevalence among hypertensive patients in primary care in China.

Methods: Based on the electronic health record system in Minhang District of Shanghai (total population 2.5million), 111,067 hypertensive patients (47,090 men; age 22-103 years) with essential medical information including demographic data, BP values, serum creatinine, dipstick urinalysis/albumin-creatinine ratio (ACR) and the use of antihypertensive medications between 1 Oct.2012 and 31 Sep. 2013 were included in our study. eGFR was calculated by using the simplified MDRD formula, and CKD was defined as either an eGFR<60 mL/min/ 1.73 m^2 or proteinuria, which was defined as either ACR≥30 mg/g or dipstick urinalysis quantified urine protein≥1+.

Results: The prevalence of CKD was 32.43%, but the proportion of patients with a kidney disease diagnosed by GPs was only 1.5%. 87.65% of the CKD patients achieved BP<140/90 mmHg, while those who achieved BP<130/80 mmHg were only 21.47%. Multivariate logistic regression analysis showed the risk factors associated with CKD were diabetes mellitus (OR 1.90, 95%CI:1.85-1.95), female (OR 1.62, 95%CI:1.57-1.67), hypercholesterolemia (OR 1.62, 95%CI:1.57-1.67), hypertriglyceridemia (OR 1.21,95%CI:1.18-1.24), cardiovascular disease(1.14, 95%CI:1.10-1.89), obesity (OR 1.15, 95%CI: 1.10-1.20), smoking (OR 1.11, 95% CI:1.17-1.16) and older age (OR 1.04, 95% CI:1.03-1.04 per year), while BP<130/80 mmHg (OR 0.95, 95%CI:0.92-0.98) was a protective factor for CKD.

Conclusions: Our results suggest that hypertensive patients are frequently affected by CKD, and most of them failed to achieve strict BP control goal. However, GPs' awareness of CKD is still too low. It should be a high priority to prevent and control hypertension in reducing the burden of CKD in China.

SA-PO801

Incidence of Chronic Kidney Disease in the Irish Health System and Population: Findings from a National Surveillance Programme Austin G. Stack,[1,2] Hoang Thanh Nguyen,[2] Liam F. Casserly,[1,2] Cornelius John Cronin,[1,2] Howard Johnson,[3] Ailish Hannigan,[2] Rajiv Saran,[4] Gemma M. Browne,[5] John P. Ferguson.[2] *[1]Nephrology, Univ Hospital Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland; [3]Health Intelligence, Health Services Executive, Ireland; [4]Kidney Epidemiology and Cost Centre, Univ of Michigan; [5]Dept of Epidemiology, Univ College Cork, Ireland.*

Background: Improved detection and surveillance of chronic kidney disease (CKD) in the population may lead to improved disease management programmes and better clinical outcomes. We determined the incidence of new CKD and period trends in the Irish population.

Methods: We analysed data from a provincial health system between 2005 and 2011 (n=174,786). Estimated glomerular filtration rates (eGFR) were determined from the CKD-EPI equation from standardised serum creatinine values, excluding episodes of acute kidney injury (KDIGO definition). Incident CKD (ml/min/1.73m^2) was defined as new CKD cases per 100 persons at risk with median eGFR < 60 in the current year and > 60 or missing in previous year. Population at risk was defined from national census data. Incident CKD in the health system was defined as the number of adult patients with eGFR < 60 in current year and eGFR > 60 in previous year, per 100 patients at risk. Poisson regression modelled population incidence while logistic regression modelled hospital incidence.

Results: Incidence rates per 100 persons-at-risk ranged from 0.03 for subjects aged 18-40 years to 29.3 for subjects > 80 years in the population. Rates were significantly higher in women (1.78, 95% CI 1.70-1.90) than men (1.35, 95% CI1.30-1.40), varied by county and were relatively constant over time. In the health system, incidence rates per 100 patients-at-risk were 4.5 (95% CI 4.3-4.7) and multivariate analysis identified increasing age, county of residence, women, and acute kidney injury (Odds Ratio=2.70, 95% CI 2.47-2.95) as significant determinants.

Conclusions: Passive surveillance systems are effective in measuring the growth and trajectories of CKD in the Irish health system. These data are essential in planning preventive strategies and in determining future resource allocation.

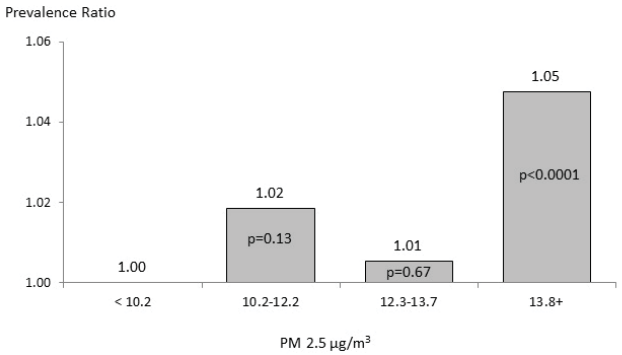
SA-PO802

County-Level Air Quality and the Prevalence of Diagnosed Chronic Kidney Disease in the U.S. Medicare Population Jennifer L. Bragg-Gresham,[1] Hal Morgenstern,[1] William M. McClellan,[2] Sharon Saydah,[3] Desmond Williams,[3] Neil R. Powe,[4] Delphine S. Tuot,[4] Yi Li,[1] Rajiv Saran.[1] *[1]Univ of Michigan, Ann Arbor; [2]Emory, Atlanta; [3]Centers for Disease Control, Atlanta; [4]Univ of California, San Francisco.*

Background: Considerable geographic variation exists in the prevalence of CKD across the U.S. Although part of this variation is explained by differences in individual-level risk factors, additional variability may be explained by environmental factors such as air quality.

Methods: Using data on 1.1 million persons from the 2010 5% Medicare sample and EPA air-quality data, we examined the association between a county-level measure of air pollution, particulate matter ≤2.5 μm (PM2.5) and the prevalence of diagnosed CKD, excluding individuals with ESRD, based on claims, for all U.S. counties. Modified Poisson regression was used to estimate associations (prevalence ratios [PR]) between county PM2.5 and individual CKD prevalence, adjusting for potential individual-level confounders: age, sex, race, hypertension, and diabetes.

Results: The estimated prevalence of diagnosed CKD ranged from 0% to 60% among counties (median = 16%). Treating PM2.5 level a continuous variable, the adjusted PR for an increase of 4 μg/m^3 was 1.03 (95% CI = 1.02, 1.05; p < 0.001). The results when categorizing PM2.5 by quartiles suggest a possible detrimental threshold effect at air quality index levels well below those typically considered unhealthy for sensitive groups, eg. the elderly (~40 μg/m^3).



Conclusions: We found that poorer air quality was associated with higher prevalence of CKD. However, the cross-sectional design and lack of individual exposure data precludes causal inference. Future investigations should include lab-based diagnosis of CKD, longitudinal observation, measures of multiple air pollutants and individual exposure, as well as more extensive control of confounding.

SA-PO803

Association of Body Composition and Estimated GFR in Elderly Males and Females Hrefna Gudmundsdottir,[1,2,3] Olafur S. Indridason,[1] Margret B. Andresdottir,[1] Runolfur Palsson,[1,3] Tamara Harris,[4] Vilmundur Gudnason,[3,5] Andrew S. Levey,[6] Thor Aspelund.[3,5] *[1]Landspitali - The National Univ Hospital of Iceland; [2]Icelandic Medicines Agency; [3]Univ of Iceland; [4]National Inst on Ageing; [5]Icelandic Heart Association; [6]Tufts Medical Center.*

Background: Changes in body composition (BC) and kidney function are commonly seen with aging, but limited data is published on their association in the elderly. The goal was to determine if there was an association between BC, strength and estimated GFR (eGFR) in elderly males (M) and females (F).

Methods: The data were obtained from the population-based AGES I - Reykjavik Study. A total of 940 (421 M, 519 F) of the 5764 participants had complete data for eGFR using the creatinine - cystatin C-based CKD-EPI equation. Creatinine and cystatin C assays were traceable to standardized reference materials. Body mass index (BMI) and abdominal circumference (AC) were measured using standardized protocols, fat% by bio-electrical impedance and leg muscle strength (LMS) by using a dynamometer chair. Descriptive statistics and linear regression adjusted for age, hypertension (HTN), diabetes (DM) and smoking were performed.

Results: All participants were white and 55% were F. The mean (SD) age was 76 (4) years, eGFR 74 (17) ml/min/1.73 m^2, 81% had HTN, 10% DM and 13% smoked. Mean LMS and BC measures and their change associated with 10 ml/min/1.73m^2 lower eGFR for M and F are shown in table. A significant interaction with sex was found for the association of eGFR with BMI, fat% and AC.

	n	Mean (SD)	M	F	Beta M *vs.* F
			Beta ± SE	Beta ± SE	
LMS (Newton)	889	327 (112)	-3.85 ± 2.98	-3.86 ± 2.08	
BMI (kg/m^2)	939	27 (4)	-0.16 ± 0.11	0.51 ± 0.12◊	◊◊
Fat (%)	587	29 (8)	-0.60 ± 0.21**	0.58 ± 0.15◊	◊◊
AC (cm)	939	100 (11)	-0.13 ± 0.29	1.41 ± 0.33*	◊

*p<0.01, **p<0.005, ◊p<0.0005, ◊◊p<0.0001

Conclusions: Measures of BC are associated with eGFR in older adults but the direction of this relationship may be different for men and women. These findings may reflect confounding by non-GFR determinants of serum creatinine and cystatin C and need to be confirmed using measured GFR.

Association of HCV with CKD: A Retrospective Study Ajay Singh Rathore,[1] Linda D. Green,[1] Xiaoxiao Lu.[2] *[1]Internal Medicine, Prince George's Hospital Center, Cheverly, MD; [2]MPH, Univ of Maryland, Greenbelt, MD.*

Background: Hepatitis C (HCV) is being identified in more patients and its impact on kidney function is being clarified. Previous studies have reached different conclusions about the risk of CKD in the presence of HCV. We sought to determine whether HCV was an independent risk factor for CKD in a largely African American(AA) population with other traditional risk factors.

Methods: A retrospective chart review study using EMR (Athena) in the Glenridge Cliinic reviewed records from Jan 2004 till Jan 2014. Patients with HIV were excluded. 106 HCV positive patients and 131 HCV negative patients were identified. CKD stage 3-5 was defined by the MDRD calculation or National Kidney foundation's KDOQI defination. Demographics included age, gender and race. Clinical factors included diabetes mellitus, hypertension, hyperlipidemia, anemia, smoking, alcohol use, cardiac diseases and illicit drug use.

Results: Mean age of study group was 57.4 ± 6.5 years. 78.1% were AA. Prevalence of CKD stage 3-5 in HCV infected and HCV negative patients was 17 (16.0%) and 8 (6.3%) respectively with p< 0.0158. Diabetes and smoking were less prevalent in HCV-infected cases compared with controls, 39 (29.8%) versus 35 (33.0%) and 37 (34.9%) versus 64 (48.9%) respectively. This reinforces the importance of HCV or other unknown factors on CKD. Univariate analysis showed that HCV infection had an OR, 2.87: 95% CI, 1.18-6.94. Multivariate logistic regression analysis showed that HCV had an OR, 5.04; 95% CI (1.46-17.44) and supports our hypothesis that HCV is an independent risk factor for CKD stage 3-5. Limitations include small sample size and predominantly AA population.

Conclusions: Our study results provide evidence that HCV infection is correlated with increased CKD prevalence and also potentially with the severity of CKD stage 3-5, beyond the well-known independent CKD risk factors. These findings strengthen the need for the prevention and treatment of HCV infection in patients with or without CKD.

SA-PO805

Prevalence and Complications of Chronic Kidney Disease in a Representative Elderly Population in Iceland Aghogho A. Okparavero,[1] Meredith C. Foster,[1] Hocine Tighiouart,[1] Vilmundur Gudnason,[2,3] Olafur S. Indridason,[4] Hrefna Gudmundsdottir,[3,4] Gudny Eiriksdottir,[2] Lesley Inker,[1] Andrew S. Levey.[1] *[1]Tufts Medical Center; [2]Icelandic Heart Association; [3]Univ of Iceland; [4]Landspitali Univ Hospital.*

Background: CKD is common in the elderly, but data are limited on the distribution of GFR and albuminuria and the prevalence of related complications.

Methods: We performed a cross-sectional study in 3173 adults (42% male, mean age 80 years) from the Age, Gene/Environment Susceptibility Reykjavik study. We evaluated the distribution of eGFR (CKD-EPI 2012 creatinine-cystatin C equation) and albumin-creatinine ratio (ACR from a spot urine sample), prevalence of CKD (eGFR<60mL/min/1.73m^2 or ACR>30 mg/g) and complications [anemia (hemoglobin g/dl<12 in women, <13.5 in men) and hypoalbuminemia (<3.5g/dL) in the overall cohort, and acidosis (bicarbonate<21mmol/L), increased anion gap (≥12mmol/L), hyperphosphatemia (≥4.5mmol/L), and hyperparathyroidism (intact PTH>70pg/mL) in a subcohort (n=773)] by CKD status.

Results: eGFR and ACR varied widely (**Table**), mean (SD) eGFR was 64 (18) mL/min/1.73m^2 and median (IQR) ACR was 8 (5-17) mg/g. The prevalence [95%CI] of eGFR<60, ACR>30 and CKD was 40% [38-41], 14% [12-15], and 45% [43-47], respectively.The prevalence of complications was higher among those with versus without CKD: anemia (26 versus 14%), hypoalbuminemia (19 versus 13%), acidosis (5 versus 1%), increased anion gap (36 versus 24%), hyperparathyroidism (38 versus 15%) (p≤0.001 for all), except hyperphosphatemia (1 versus 1%).

Table: Prevalence N (%) of eGFR and Albuminuria Categories. Shaded boxes represent CKD.

eGFR Categories (mL/min/1.73m^2)	Albuminuria Categories (mg/g)			Total
	< 10	10 - 30	> 30	
≥ 90	118 (3.7)	59 (1.9)	14 (0.4)	191 (6.0)
75 - 89	461 (14.5)	181 (5.7)	48 (1.5)	690 (21.7)
60 - 74	649 (20.5)	271 (8.5)	115 (3.6)	1035 (32.6)
45 - 59	456 (14.4)	218 (6.9)	117 (3.7)	791 (24.9)
30 - 44	161 (5.1)	98 (3.1)	86 (2.7)	345 (10.9)
< 30	38 (1.2)	32 (1.0)	51 (1.6)	121 (3.8)
Total	1883 (59.3)	859 (27.1)	431 (13.6)	3173 (100)

Conclusions: There is a high burden of CKD among community dwelling elderly Icelandic adults. The wide range of eGFR and ACR suggests heterogeneity in processes leading to CKD.

Optimal Screening Interval of Renal Function for CKD in Healthy People Keita Hirano,[1,2,3] Goki Eriguchi,[3] Osamu Takahashi,[2] Yasuhiro Komatsu,[3] Motoko Yanagita.[1] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine; [2]Center for Clinical Epidemiology, St.Luke's Life Science Inst; [3]Dept of Nephrology, St. Luke's International Hospital.*

Background: It is recommended to calculate eGFR from sCr once or twice a year in healthy people by KDIGO guideline 2012. However, there is little evidence to show the optimal intervals for the analysis of sCr as an indicator of the function of kidney for people with normal renal function. we aim to evaluate optimal screening interval of renal function for adequately early detection of CKD.

Methods: We planned a retrospective cohort study involving patients with normal renal function (eGFR≥60ml/min/1.73m^2) who had a health check up at the first time at St Luke's International Hospital from 2005 to 2007 and followed up to 9 years. In this study, we classified them into three groups by renal function; high risk (60≤eGFR<75), intermediate risk (75≤eGFR<90), and low risk (90≤eGFR). As univariate analysis, we analyzed the relationship of developing CKD to age, gender, proteinuria, and medical history such as diabetes and proteinuria. Optimal screening interval of renal function is defined as the estimated time until developing CKD for 5% of the patients. Applying accelerated failure time model, we analyzed the transitions to CKD and estimated the optimal intervals in each renal function group.

Results: 44,911 patients were involved and 53% of them were male. The mean age was 45.6 ± 11.8, serum Cr 0.72 ± 0.15 mg/dl, and eGFR 84.1 ± 14.4 ml/min/1.73m^2. The patients with urine protein-positive and diabetes were 323(0.7%) and 1,149(2.6%), respectively. The estimated optimal screening intervals of the renal functions for high, intermediate, and low risk groups were 0.6, 4.0, and 18.4 years, respectively. In addition, the estimated intervals were 0.4, 2.6, and 12.1 years for the patients with proteinuria and 0.4, 2.4, and 11.0 years for the patients with diabetes.

Conclusions: This study shows that approximately 18 years follow up time was needed in low risk group of renal function. People with diabetes or proteinuria need shorter intervals than that without these diseases. In the future, Cost-effectiveness analysis remains to be studied.

SA-PO807

Associated of Traditional Cardiovascular Disease Risk Factors with Kidney Damage Indicators in 33308 Adults Receiving Physical Examination Hao Zhang, Wei Li, Guo Xu, Jing Huang, Juan Mao, Ke Zhang. *Dept of Nephrology, The Third Xiangya Hospital of Central South Univ, Changsha, Hunan, China.*

Background: The traditional cardiovascular disease(CVD) risk factors (age, BMI, smoking, hypertension, diabetes, hyperlipidemia)was closely connected to the kidney damage indicators (proteinuria, albuminuria and eGFR), However, no survery has been done incorporating both kidney damage indicators and traditional cardiovascular disease risk factors among the healthy physical examination population in China.

Methods: We did a cross-sectional survey of 33308 Chinese adults who received healthy physical examination in the health management center of central south university third xiangya hospital from June 2013 to February 2014. Exclude hospitalized people within one year. Factors associated with the indicators of kidney damage analysed by multiple stepwise regression analysis.

Results: 33308 people were invited to participate, male-female ratio is almost 1.5:1, the average age was 44.7±14.5 years, about 89.8% for college grads, the prevalence of smoking was 30.1%, the detection of obesity,hypertension,diabetes mellitus,hyperlipidemia and hyperuricemia were 11.0%, 19.9%, 6.2%, 25.7% and 10.7%, respectively. Specific demographic characteristics had been found in the healthy physical examination population compared to the survery wich was published in the Lancet in 2012.The detection of proteinuria, albuminuria,eGFR less than 60 mL/min per 1·73 m², hematuria and abnormal renal ultrasound were 2.5%, 18.5%, 1.1%, 3.7% and 0.8%, respectively. Multiple factors Logstic stepwise regression analysis showed that: Diabetes, male, hypertension, smoking, hyperuricemia, high TG, age, BMI were independent risk factors for the proteinuria; Diabetes, hypertension, male, BMI, high TG, smoking are independent risk factors for the development of microalbuminuria; Hyperuricemia, age, low HDL - C, high LDL - C, hypertension, diabetes were independent risk factor for decline in eGFR.

Conclusions: Specific demographic characteristics had been found in the healthy physical examination population. Attention should be paid to people with traditional cardiovascular disease(CVD) risk factors in healthy physical examination.

SA-PO808

Renal Function in the Cardio Renal Syndrome: Dramatically Overestimated Sandrine Lemoine,[1,2,3] Florence Sens,[1] Fitsum Guebre-Egziabher,[1,2] Laurence Dubourg,[3] Aoumeur Hadj-Aissa,[3] Laurent Juillard.[1,2] *[1]Nephrology Dept, Edouard Herriot Hospital, Hospices Civils de Lyon, Lyon, France; [2]INSERM Carmen 1060, Univ Lyon 1, Univ de Lyon, France; [3]Renal Function Dept, Edouard Herriot Hospital, Hospices Civils de Lyon, Lyon, France.*

Background: Most of patients with a cardio-renal syndrome 2 (CRS2) eligible for ultrafiltration present with a chronic kidney disease (CKD) not requiring dialysis initially. The muscle mass loss could alter the estimation of renal function thus delaying the ignition of dialysis. The aim of this study is to test if MDRD, CKDEPI and Donatio formulas may estimate correctly renal function in CRS2 patients compared to a reference method.

Methods: Renal function was measured prospectively by inulin clearance (mGFR) during one year in 31 patients with CRS2. We measured the mean bias (eGFR-mGFR) and the accuracy 30%. The lean body mass was estimated simultaneously by impedancemetry. We tested a new formula developed by Donatio : dGFR = [lean mass (kg) x 2.554/Pcr (mg/dL) – 0.776] x 1.73/body surface area in women; [Lean mass(kg) x 2.700/Pcr (mg/dL) – 2.920] x 1.73/body surface area in men.

Results: mGFR was 23 ± 14 mL/min/1.73 m² eGFR was à 39 ± 17 mL/min/1.73 m² with MDRD and 39 ± 18 with CKD-EPI. The biases were 15 ± 16 and 15 ± 17 mL/min/1.73 m² for MDRD and CKD-EPI, respectively. Accuracy 30 was low, 33 and 40 % respectively. The lean body mass was low, estimated at 19 kg (27% of total body weight). The Donadio formula estimated the renal function more accurately: dGFR 27 ± 7 mL/min/1.73 m², with a bias of -3.9 mL/min/1.73 m².

Conclusions: Patients with CRS2 have a worse renal function than predicted by the MDRD and CKD-EPI formulas. This overestimation is explained probably by the diminished lean body mass due to the cardiac failure. If a reference method is not accessible, the Donatio formula should be used preferentially in patients with CRS2 for an optimal orientation towards ultrafiltration, dialysis or heart-kidney transplantation.

SA-PO809

Cystatin C Based GFR Equation Does Not Outperform Creatinine Base Formulas in Obese CKD Patients Sandrine Lemoine,[1,2] Marine Panaye,[1] Caroline Pelletier,[1] Laurent Juillard,[1] Laurence Dubourg,[2] Aoumeur Hadj-Aissa,[2] Fitsum Guebre-Egziabher.[1] *[1]Nephrology Dept, Edouard Herriot Hospital, Hospices Civils de Lyon, Lyon, France; [2]Renal Function Study Dept, Edouard Herriot Hospital, Hospices Civils de Lyon, Lyon, France.*

Background: Recent findings suggest that cystatin C is independently associated with obesity, body mass index and waist circumference. Hence, cystatin C based equation could overestimate the chronic kidney disease (CKD) prevalence for overweight and obese patients. The objective of this study was to assess the relation of cystatin C and body composition and evaluate the accuracy of cystatin C based equation for glomerular filtration rate (GFR) estimation.

Methods: This prospective study included 140 patients with BMI > 25 kg/m² in Lyon for measurement of gold standard clearance by inulin or iohexol (mGFR). Patients were separated in two groups, a group with a GFR < 60 mL/min/1.73m² and a group with GFR ≥ 60 mL/min/1.73m². All patients underwent bioelectrical impedancemetry for body composition analysis and cystatin C measurement. GFR was also estimated by equations derived from creatinine ($eGFR_{CKD-EPI}$), cystatin ($eGFR_{cyst}$) or both ($eGFR_{cyst-creat}$). Mean Bias (mGFR – eGFR) and accuracy 30% were calculated for the three equations.

Results: The mean age was 57 ± 15, mean BMI was 32 ± 4 (65% of BMI > 30) and mGFR was 62±2 mL/min. Cystatin c was positively correlated with fat mass (r=0.35, p=0.04) in the GFR ≥ 60 mL/min/1.73m² group, while no relation was found in the group with GFR < 60 mL/min/1.73m². In the group with GFR < 60 mL/min/1.73m², mGFR was 40.6 ± 1.5, $eGFR_{CKD-EPI}$ 44.8 ± 1.9, $eGFR_{cyst}$ 43.7 ± 2.6 and $eGFR_{cyst-creat}$ 43.7 ± 2.1 mL/min/1.73m². We found no difference between biaises of $eGFR_{CKD-EPI,}$ $eGFR_{cyst}$ and $eGFR_{cyst-creat}$ (-2.1. ± 4 versus -6 ±1, p=0.05 and -2.5 ± 0.7 mL/min/1.73m², p=0.1 respectively); The accuracy 30% was 87% versus 75% and 90 % for $eGFR_{CKDEPI}$, $eGFR_{cyst}$ and $eGFR_{cyst-creat}$ respectively.

Conclusions: Body fat is only a determinant of cystatin C in obese and overweight CKD patients with a GFR > 60 mL/min/1.73m², but not in patient with GFR < 60 mL/min/1.73m². $eGFR_{cyst}$ and $eGFR_{cyst-creat}$ could be used as an accurate estimation of GFR, but do not outperformed $eGFR_{CKDEPI}$.

SA-PO810

Prediction of GFR Trajectories in Autosomal Dominant Polycystic Kidney Disease Patients with Normal Renal Function Michal Mrug,[1] Sylvie Mrug,[1] Doug Landsittel,[2] Vicente E. Torres,[3] Kyongtae Ty Bae,[2] Peter C. Harris,[3] Lisa M. Guay-Woodford,[4] Michael F. Flessner,[5] William M. Bennett,[6] Alan S.L. Yu,[7] Jared J. Grantham,[7] Arlene B. Chapman.[8] *[1]U AL Birmingham; [2]U Pittsburgh; [3]Mayo Clinic; [4]Children's Nat Med Ctr; [5]NIH; [6]Legacy Good Samaritan Med Ctr; [7]U Kansas; [8]Emory U.*

Background: There is limited information on predictors of distinct renal function trajectories in patients with ADPKD.

Methods: We developed group-based models of renal function trajectories using data collected by the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP), a prospective, observational, longitudinal, multicenter study of 241 ADPKD adults with preserved renal function.

Results: The best fitting iothalamate clearance (GFR) trajectory model included five trajectory groups (1 quadratic, 3 linear and 1 intercept only). Three of these groups involved different levels of initial GFR (70, 85 and 106 mL/min/1.73m²) followed by gradual GFR decline (by 53, 36 and 6 mL/min/1.73m²). One group had high initial GFR (131) and no GFR loss over the next decade. Another group with comparably high initial GFR (122) had highest GFR decline (by 78 mL/min/1.73m²) over the next decade (Figure 1, bold line). Logistic regression analyses compared the rapidly declining group with the top two groups that had similar initial GFR but preserved GFR over time. Five baseline variables were identified as predictors of membership in the rapidly declining GFR group (age, gender, cyst number, height adjusted total kidney volume and systolic blood pressure). ROC analyses demonstrated an area under the curve (AUC) of 0.81 for a multivariable model with these predictors.

Conclusions: Group modeling of GFR trajectories has identified a subset of CRISP participants with rapidly declining GFR and led to development of predictive models to identify the high-risk ADPKD patients.

SA-PO811

Prevalence and Baseline Characteristics of Pulmonary Hypertension in Different CKD Stages Zhilian Li, Xinling Liang, Yuanhan Chen, Shuangxin Liu, Zhiming Ye, Ruizhao Li, Lixia Xu, Wenjian Wang, Wei Shi. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Pulmonary hypertension (PH) was recently recognized as a common complication of end-stage renal disease (ESRD) that causes an increased risk of mortality. Epidemiological data for this disorder in earlier stages of chronic kidney disease (CKD) and its association with cardiovascular (CV) morbidity are scarce.

Methods: We retrospectively analyzed 2,351 Chinese CKD patients with complete clinical records and echocardiography data between Jan 2008 and May 2012. The patients were divided into the following 6 groups: CKD Stages 1-4; Stage 5 for those not on or initiated on hemodialysis for <3 months; and Stage 5D for the patients undergoing hemodialysis for ≥3 months. The prevalence of PH and CV morbidity was investigated, and their association was evaluated with a logistic regression model.

Results: PH was detected in 426 patients (18.1%). Mild, moderate and severe PH was diagnosed in 12.1%, 4.9% and 1.1% of the patients, respectively. Severe PH was detected in CKD Stages 5 and 5D. CV morbidity was found in 645 patients (27.4%). Compared with the non-PH group, the PH group had a higher risk for cardiac disease but not for cerebrovascular disease risk. PH severity was associated with cardiac morbidity risk [odds ratio (95% CI) for mild PH: 1.79 (1.30-2.47); moderate PH: 2.75 (1.73-4.37); severe PH: 3.90 (1.46-10.42)].

Conclusions: Our study showed the epidemiology profile of PH across the spectrum of CKD. Mild-to-moderate PH occurs with more frequency in advanced CKD, and severe PH is scarce in non-ESRD CKD. PH might be a risk factor for cardiac disease but not for cerebrovascular disease in CKD patients. PH severity affects cardiac outcomes. Evidence from prospective studies addressing PH in this population is needed to predict cardiac events.

Risk Factors for Postoperative Renal Impairment after Adrenalectomy in Patients with Primary Aldosteronism

Do Hee Kim,[1] Hee Jin Kwon,[1] Kyungho Lee,[1] Hye Ryoun Jang,[2] Jung Eun Lee,[2] Wooseong Huh,[2] Yoon-Goo Kim,[2] Dae Joong Kim,[2] Ha Young Oh.[2] *[1]Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea; [2]Dept of Medicine, Div of Nephrology, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

Background: Primary aldosteronism (PA) may induce significant renal structural damage. However, renal functional impairment can be masked in patients with PA before surgical treatment because of glomerular hyperfiltration and aldosterone escape. In this study, renal functional changes after unilateral adrenalectomy in patients with PA and the risk factors of postoperative renal impairment were analyzed.

Methods: A total of 558 patients who received unilateral adrenalectomy between January 2002 and June 2013 were included: 422 patients with pheochromocytoma, Cushing's disease, or adrenal cysts (control group) and 136 patients with PA (PA group). Baseline characteristics and postoperative changes in estimated glomerular filtration rate (eGFR) were analyzed.

Results: There was no difference in preoperative eGFR between groups, but patients with PA were more likely to have hypertension and hypokalemia. Patients in the PA group showed a significant decrease in eGFR at 3 days, 2 weeks and 6 months after surgery compared to the control group. In the PA group, 60 patients (44.1%) showed postoperative eGFR decline by more than 25% of baseline. Multivariate regression analysis identified longstanding hypertension [$p<0.001$, $\beta=0.037$], lower BMI [$p=0.011$, $\beta=-0.036$] and higher levels of uric acid [$p=0.046$, $\beta=0.054$] as risk factors for significant renal functional impairment. Among the 89 patients with preoperative eGFR > 60mL/min/1.73m^2, 22 patients (24.7%) developed chronic kidney disease (eGFR < 60mL/min/1.73m^2) postoperatively. Lower preoperative eGFR [$p<0.001$, $\beta=-0.110$], longstanding hypertension [$p=0.034$, $\beta=0.182$], and higher levels of cholesterol [$p=0.036$, $\beta=0.019$] were associated with the development of chronic kidney disease.

Conclusions: Our study suggests that primary aldosteronism patients with risk factors are at increased risk of renal functional impairment after surgical treatment.

SA-PO813

Geographic Difference in the Prevalence of Proteinuria and Albuminuria in Japan: Okinawa versus Ibaraki

Kei Nagai,[1] Kunihiro Yamagata,[1] Chie Saito,[1] Kunitoshi Iseki,[2] Koichi Asahi,[2] Kenjiro Kimura,[2] Toshiki Moriyama,[2] Ichiei Narita,[2] Shouichi Fujimoto,[2] Kazuhiko Tsuruya,[2] Tsuneo Konta,[2] Masahide Kondo,[2] Tsuyoshi Watanabe.[2] *[1]Nephrology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Steering Committee for "Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkups".*

Background: The prevalence of chronic kidney diseases (CKD) which is defined by reduced estimated glomerular filtration rate in Okinawa prefecture (South in Japan) is significantly different from that in Ibaraki prefecture (East in Japan). However, Reasons for the difference in CKD prevalence in Japan remain speculative and regional differences in prevalence of proteinuria and albuminuria, that are risk of progressive CKD, is poorly evaluated.

Methods: We examined the prevalence of proteinuria and albuminuria among community-based screened populations from 40 to 80 years old in Okinawa (n=11,882) and in Ibaraki (n=2,596). Prevalence of proteinuria or microalbuminuria was defined as (+) or more, or more than 30 mg/g cre, respectively. The statistical analyses were performed by categorization with age by 10 years old.

Results: The participants in Okinawa exhibited higher body mass index, higher serum creatinine value than those in Ibaraki. Prevalence of proteinuria in subjects with 40-49 years old is significantly higher in Okinawa (2.43%) than in Ibaraki (0.49%). Interestingly, higher prevalence of that with 70-80 years old in Ibaraki (5.26%) was observed than in Okinawa (2.27%). Otherwise, prevalence of albuminuria in Okinawa (3.55% in age of 40-49 and 8.75% in age of 70-80) is lower than Ibaraki (8.96% in age of 40-49 and 30.86% in age of 70-80), regardless of their age.

Prevalence (%)	Proteinuria		Albuminuria	
Age category	Okinawa	Ibaraki	Okinawa	Ibaraki
40-49	2.43	0.49	3.55	8.96
50-59	2.49	2.26	5.12	16.52
60-69	2.81	3.68	6.62	22.99
70-80	2.27	5.26	8.75	30.86

Conclusions: The regional difference in prevalence of proteinuria and albuminuria may underlie the variation in CKD prevalence observed in Japan.

SA-PO814

Urinary Uromodulin as a Marker of Renal Mass and Function: Data From a Swiss Population-Based Study

Menno Pruijm,[1] Belen Ponte,[2] Daniel Ackermann,[3] Michel Burnier,[1] Pierre-Yves F. Martin,[2] Olivier Devuyst.[5] *[1]Nephrology, Univ Hospital Lausanne (CHUV), Lausanne, Switzerland; [2]Nephrology, Univ Hospital Geneva, Geneva, Switzerland; [3]Nephrology and Hypertension, Univ Hospital Bern (Inselspital), Bern, Switzerland; [4]Inst of Social and Preventive Medicine (IUMSP), Univ Hospital Lausanne, Lausanne, Switzerland; [5]Physiology, Univ of Zurich, Zurich, Switzerland.*

Background: Uromodulin (Tamm-Horsfall protein) is a protein exclusively produced by tubular cells lining the thick ascending limb of the loop of Henle, suggesting that it could be a marker of renal mass and function. We therefore analyzed the association of renal function markers, renal length and volume with urinary uromodulin.

Methods: In a multicentre Swiss population-based cohort including randomly selected adults (SKIPOGH), urinary uromodulin excretion rate (UER) was measured in a 24h urinary collection and renal ultrasound performed. Uromodulin was measured using a validated ELISA assay. Glomerular filtration rate was estimated with the CKD-EPI formula (eGFR) and with urinary 24h creatinine clearance (uGFR).Subjects with renal cysts were excluded from the analysis.

Results: We included 817 participants from SKIPOGH (53% women), with a mean age (±SD) of 45±7y, eGFR 98±17 ml/min/1.73m^2, renal length 11.0±0.8 cm, volume 137±34ml and UER of 43.9±22 mg/24h. The linear regression analysis adjusted for centre, age, gender, height and body weight, showed positive associations between square-root transformed UER and the dependent variables kidney length, kidney volume, eGFR, uGFR and urinary osmolality (all: $p<0.01$).

Conclusions: The positive associations between urinary uromodulin excretion, eGFR, uGFR, urinary osmolality, and ultrasound-assessed renal length and renal volume all suggest that urinary uromodulin excretion can be considered as a marker of renal function and tubular mass.

Chronic Kidney Disease with Chronic Obstructive Pulmonary Disease: Does Decline in Forced Expiratory Volume Correlate with Loss of Glomerular Filtration Rate?

Dearbhla Kelly,[1] Sarah Margaret Moran,[1] Desmond M. Murphy,[2] William D. Plant.[1] *[1]Dept of Renal Medicine, Cork Univ Hospital, Ireland; [2]Dept of Respiratory Medicine, Cork Univ Hospital, Ireland.*

Background: Chronic obstructive pulmonary disease (COPD) is associated with increased risk of both acute and chronic renal failure. Renal-endocrine mechanisms, tissue hypoxia and vascular rigidity all have a role in the pathophysiology. Chronic kidney disease (CKD) is under-recognized in this population and microalbuminura is a risk factor for overall mortality. We aim to determine if there is a relationship between the severity of airflow obstruction (forced expiratory volume - FEV1) and decline in glomerular filtration rate (GFR).

Methods: We conducted a retrospective review of oxygen-dependent COPD patients currently attending the respiratory service in a tertiary referral centre in southern Ireland. Patient records and clinical laboratory data were interrogated. For each oxygen-dependent COPD patient, we documented serum creatinine, estimated GFR (eGFR), spirometry, medications, Charlson comorbidity index, heart function and annual exacerbation frequency. eGFR was calculated using the Modification of Diet in Renal Disease (MDRD) formula.

Results: 38 patients in receipt of long-term oxygen therapy (LTOT) for a mean duration of 2.3 years (SD 1.9 years) were identified. The mean age of the group was 72.2 years (SD 7.5 years) and mean FEV1 was 49.7% predicted (SD 21.3%). 13.2% were diabetic and 21% had known ischaemic heart disease. 34.3% had frequent (3 or more) yearly exacerbations. The mean current eGFR was 80.1ml/min/1.73m2 (SD 26.3ml/min/1.73m2). 8 patients (21.1%) had stage 3 CKD (defined as eGFR<60ml/min/1.73m2) and no patient had stage 4 or 5 disease. There was a positive correlation between annual change in eGFR and FEV1 ($r = 0.384$, $r^2=0.148$, $n=28$, $p=0.043$).

Conclusions: Our study indicates that preserving lung function in COPD may benefit long-term renal survival. GFR has not previously been shown to correlate with the severity of airflow obstruction by spirometry. The relatively low level of advanced chronic kidney disease in this cohort may reflect the positive impact of LTOT on renovascular resistance and filtration fraction.

Medication Prescribing Patterns among Pre-Dialysis Malaysian Patients Muhammad Salman,[1,2] Amer Hayat Khan,[1,2] Syed Azhar Sulaieman,[2] Azreen Syazril Adnan,[1] Fauziah Jummaat,[3] Nurul Jannah Ambak,[1] Tauqeer Hussain Mallhi. *[1]Chronic Kidney Disease Resource Center, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia; [2]Dept of Clinical Pharmacy, Univ Sains Malaysia, Penang, Malaysia; [3]Dept of Obstetrics and Gynecology, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia.*

Background: Chronic kidney disease (CKD) is associated with numerous co-morbidities and complications which necessitate its management by complex therapeutic regimens. Therefore, it is imperative to evaluate medication prescribing patterns for effective treatment of CKD.

Methods: A retrospective, cross-sectional study was conducted on 612 pre-dialysis adult patients at Hospital Universiti Sains Malaysia from 2010-2013. Medical records were reviewed and data were extracted. Individual drugs were classified based on Anatomical Therapeutic Chemical (ATC) classification. Comparison was made between age groups (≤ 50 or > 50 years), gender, diabetic status (diabetes mellitus (DM) versus non-DM) and stages of CKD.

Results: There were 6960 prescriptions to 612 patients. Patients were 63.81 ± 12.04 years old, and prescribed 11.37 ± 4.39 (range 2-25) drugs. The top five prescribed medication groups were lipid modifying agents 78.6%, calcium channel blockers 63.9% and anti-thrombotic agents 62.7%, anti-diabetic drugs 56.7% and diuretics 54.9%. Underutilization of certain medications (erythropoietin, non-calcium/aluminum based phosphate binders, etc.) was apparent. Patient age and gender did not influence the number of medication used (p=0.523 and p=0.06, respectively). Diabetic patients were prescribed more drugs than non-diabetics (11.90 ± 4.36 versus 10.26 ± 4.26; p < 0.001). Furthermore, the number of prescribed drugs substantially increased with the declining GFR with the hierarchy (stage 2and 3a < stage 3b < stage 4 < stage 5).

Conclusions: Multiple medication use was observed in pre-dialysis patients. This audit also identified appropriate and questionable utilization of medication that indicated possible areas for improvement in prescription practices.

SA-PO817

Association of Dietary Sodium and Potassium Intake with Prevalence of Chronic Kidney Disease in Korea and U.S. NHANES Sang-Woong Han,[1] Jennifer L. Bragg-Gresham,[2] Hal Morgenstern,[2] Joo-Hark Yi,[1] Hyaejin Yun,[1] Meda E. Pavkov,[3] Desmond Williams,[3] Tanushree Banerjee,[4] Neil R. Powe,[4] Rajiv Saran.[2] *[1]Hanyang Univ, Seoul, Korea; [2]Univ of Michigan, Ann Arbor; [3]Centers for Disease Control, Atlanta; [4]Univ of California, San Francisco.*

Background: Evidence suggests that dietary intake of macrominerals is associated with CKD. We estimate and compare these associations in large representative population samples from the U.S. and Korea.

Methods: Study included 5,350 participants from U.S. (2009-2010) and 4,759 from Korea (2011), ≥20 years old. CKD was defined as: estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m²; elevated urinary albumin to creatinine ratio (ACR ≥30 mg/g); or either CKD indicator. Dietary intake was estimated by 24-hour dietary recall. Associations between Na and K and CKD were computed as prevalence ratios (PR) per 1000 mg/day intake, using modified Poisson regression models. Interaction terms between macromineral and country were included to test for country differences in these associations.

Results: CKD prevalence was higher in the U.S. than Korea (low eGFR: 5.4% versus 3.0%; high ACR: 7.9% versus 6.3%; combined indicators: 11.6% versus 8.5%). Na and K intake was higher in Korea versus U.S. (Na: 5,232 versus 3,605 mg/day; K: 3,144 versus 2,796 mg/day). In the U.S. only, low eGFR associated with high Na intake (PR=1.13) and low K intake (PR=0.81). High ACR and combined CKD indicators were inversely associated with K in both countries and unassociated with Na.

Outcome measure (per1,000 mg/day)	Korea		US		P for macro-mineral* country interaction
	PR	95% CI	PR	95% CI	
Low eGFR					
Na	0.96	0.91-1.02	1.13	1.04-1.22	0.001
K	1.01	0.90-1.13	0.81	0.72-0.92	0.006
High ACR					
Na	0.99	0.95-1.03	1.00	0.93-1.08	0.76
K	0.86	0.79-0.95	0.88	0.80-0.97	0.81
Combined					
Na	0.98	0.95-1.02	1.03	0.98-1.01	0.11
K	0.92	0.86-0.99	0.87	0.81-0.94	0.32

Adjusted for age, sex, race, BMI, DM, hypertension, total calorie intake.

Conclusions: In the U.S., low eGFR was associated with high Na and low K intake; in both countries, low K intake was associated with high ACR and with CKD defined by both ACR and eGFR. Further research may explain these associations in the context of dietary patterns in the two countries.

Febuxostat Reduce Renal Function Progression in Taiwanese Patients with Stage 3 to Stage 5 CKD Ming-Ju Wu, Kuo-Hsiung Shu. *Div of Nephrology, Dept of Medicine, Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Hyperuricemia is very common in advanced chronic kidney disease (CKD). However, the treatment of hyperuricemia is often inadequate because of frequent allopurinol related side effects. Febuxostat is a new, non-purine based-xanthine oxidase inhibitor with much less adverse reaction.

Methods: We conducted a 3 months open label prospective study to evaluate the efficacy of serum urate lowering and the impact of eGFR change with fixed dose 40mg/day febuxostat in patients with history of gout and stages 3 to 5 CKD.

Results: Totally, 461 patients complete the study. The distribution of the stage of CKD 3a, 3b, 4 and 5 were 16.6%, 21.1%, 31.6%, 30.8%, respectively. All patients aged 20 to 93 years old, with mean age of 63.6±13.3% and 50.8% aged over 65 years old. Seventy percent of patients were male. Before the use of febuxostat, 34.2% and 35.7% patients received treatment of allopurinol and benzbromazone. Three months febuxostat significantly decreased the serum uric acid from 9.3±2.3 mg/dL to 6.8±2.6 mg/dL, P < 0.0001. Febuxostat lead to serum uric acid less than 6.0 mg/dL in 44.4% patients. Besides, febuxostat improved the trend of eGFR decrease, in 3 months period before the treatment, from -2.4 to +0.8 ml/min/1.73m² (P=0.007).

Table 1. Febuxostat treatment improved the change of estimated GFR in patients with stage 3~5 chronic kidney disease

CKD Stage	Total	3A	3B	4	5
-3 Months	28.4±12.9	54.1±11.3	39.9±8.2	24.9±8.7	11.8±5.1
O Month	26.0±11.3	50.6±8.8	37.2±4.4	22.0±4.4	9.2±3.4
Change from -3 to 0 month	-2.4	-3.5	-2.7	-2.9	-2.7
+3 Months	26.8±10.9	52.4±9.1	39.0±7.0	22.1±6.5	9.4±3.8
Change from 0 to 3 month	+0.8	+1.8	+1.8	+0.1	+0.2
P value (+3~0 vs 0~+3)	0.007	0.026	0.002	0.005	<0.0001

(ml/min/1.73 m²)

Only 2.8% patients experienced recurrent episode of gout. The efficacy is more significantly in patients with stage 3 CKD. The most common side effects of febuxostat were elevated liver function and skin itching.

Conclusions: In summary, our results support aggressive treatment of hyperuricemia in patients with advanced CKD.

Funding: Private Foundation Support

SA-PO819

Incidence and Clinicopathological Characteristics of Nephrotic Syndrome following Allogeneic Hematopoietic Stem Cell Transplantation: 27-Year Experience in a Single Cancer Center Takeshi Tokoroyama,[1,2] Minoru Ando,[1,2] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Dept of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Dept of Hematology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan.*

Background: Nephrotic syndrome is a manifestation of graft-versus-host disease (GVHD) and is usually seen in the context of several organ manifestations of GVHD following hematopoietic stem cell transplantation (HCT). However, This type of renal involvement remains an ill-defined clinical entity.

Methods: Clinicopathological features of patients who manifested nephrotic syndrome after allogeneic HCT were retrospectively studied, using the data documented in electronic medical charts.

Results: The incidence of nephrotic syndrome was 0.068% (8 out of 1,175 allogeneic HCT) in the period of 27 years, from 1986 to 2013. Six patients were men, and mean age was 44.9 ± 15.1 years. Renal biopsy proved that 7 had membranous nephropathies (MNs) (87.5%) and 1 minimal change disease (12.5%). IgG_1 and IgG_4 were the predominant IgG subclasses in the glomerular deposits of MN. In addition, the glomerular deposition of C_3 was observed in 4 MN cases (50%), and that of both C_4 and C_{1q} only in 1 MN case. Seven (87.5%) were positive for anti-nuclear antibody in serum. Administration of prednisolone and/or cyclosporine reduced proteinuria and contributed to the complete or almost complete remission of the insult. No patients developed end-stage renal disease.The nephrotic syndrome occurred at the median time of 26 months [range, 14 to 40 months] following HCT and accompanied the mild relapse of chronic GVHD (cGVHD) including skin eruption, possibly due to the early cessation or decrease of immunosuppressant medications. This may indicate that the spectrum of immunological abnormalities that are associated with cGVHD is involved in the emergence of this renal disease.

Conclusions: Nephritic syndrome is a complication that rarely develops in the late phase following HCT, and the predominant histological change is MN. Nephrotic syndrome may represent a renal manifestation of cGVHD, according to the timing of the onset.

SA-PO820

Pregnancy Outcomes in Patients with IgA Nephropathy Xiaole Su, Jicheng Lv, Youxia Liu, Sufang Shi, Lijun Liu, Hong Zhang. *Renal Div, Peking Univ First Hospital, Beijing, China.*

Background: The outcomes of pregnancy in patients with IgA nephropathy(IgAN) remain much uncertain. Our prior study has suggest pregnancy in IgAN didn't increase the risk of kidney progression. In this extended study we aim pregnancy on the kidney function and also to identify risk factors for adverse pregnancy outcomes.

Methods: Female patients who had been with at least one pregnancy and with follow-up time more than 1-year from one large prospective IgAN database in North China were enrolled in this study. Pregnancies prior to the onset of kidney disease were excluded. We assessed the slope of estimated GFR decline, kidney diease progression and adverse pregnancy outcomes during the follow-up. Kidney disease progression was defined as eGFR halving or developing end-stage kidney disease. Adverse pregnancy outcomes include pre-eclampsia, intrauterine death, embryo damage, fetal malformation, voluntary or spontaneous abortions.

Results: From December 2003 to May 2014, 362 female patients entered the IgAN cohort and among them 79 women had 86 pregnancies. The pregnant patients had a median proteinuria at baseline of 1.04 (range 0.06 to 7.25) g/d and eGFR of 105.5 (range 40.0 to 136.2) ml/min/1.73m^2. During a mean follow-up of 52.2 months, 6/79(8%)patients in the pregnancy and 31/283(11%)in the non-pregnancy group had kidney disease progression events. After adjusted analysis including age, eGFR, MAP, proteinuria in the extended Cox proportion model, pregnancy was not associated with kidney disease progression events (HR=2.0; 95% CI 0.8 to 5.4; *P*=0.15). Similarly a linear regression analysis didn't show there was significant difference of the median rate of eGFR decline in two groups (-2.5 versus -2.9 ml/min/1.73 m^2 per year,95% CI -2.4 to 2.2; *P*=0.9). Adverse pregnancy outcomes were observed in 29patients. Proteinuria at the beginning of pregnancy (OR 2.9; 95% CI 1.3 to 6.6, *P*=0.007) was an independent risk factor of adverse pregnancy outcomes in the multivariate logistic regression model.

Conclusions: Pregnancy in IgAN with preserved or mild impaired kidney function does not seem to accelerate loss of renal function. Proteinuria at the beginning of pregnancy predict a higher rate of adverse pregnancy outcomes.

SA-PO821

The Relationship between Decoy Receptor 2 Expression and Stress Induced Tubular Senescence, Tubular Interstitial Lesion in IgA Nephropathy Bengang Huo, Huanzi Dai, Jurong Yang, Yani He. *Nephrology, Daping Hospital, ChongQing, China.*

Background: SIPS (stress induced premature senescence) plays a very important role in the development of chronic kidney disease. We found that SIPS participated in the progression of the IgA nephropathy. Recently, Decoy receptor 2 (DcR2) expression was found to be increased in senescence premalignant and fibroblast cells, suggesting that it can be involved in SIPS by resistence to apoptosis. This study aim to verify the relathionship between DcR2 expression and SIPS, tubular interstitial lesion in IgA nephropathy.

Methods: 116 primary IgA nephropathy patients aged 18-50 years without treatment and their relevant clinical data were enrolled. Oxford IgA nephropathy scoring system was used for the renal tissue lesion scoring. Renal tissue SA-β-gal expression detection, immunohistochemical detection and immunofluorescence detection were used for for p16 and DcR2.

Results: 1.Cell senescence markers were significant increased in IgA nephropathy patients: DcR2 was only expressed in renal tubular epithelial cells, SA-β-Gal positive cells were mainly tubular epithelial cells, and p16 was expressed in renal tubular epithelial cells, glomerular cells, renal interstitial cells, They all were low expression in normal kidney tissue, and increased with tubular atrophy/interstitial fibrosis score. 2. The correlation between SA-β-Gal,p16, DcR2 and clinical feature, kidney lesion score in IgA nepropathy: the percentage of p16, SA-β-Gal, DcR2 positive RTECs have a positive correlation with and blood pressure, urine NAG, uric acid, urea nitrogen, serum creatinine, urine protein to creatinine ratio, but a negative correlation with eGFR in IgA nephropathy patients. The percentage of p16, SA-β-Gal, DcR2 positive RTECs were positively correlated with segmental sclerosis/adhesion, interstitial fibrosis, arcuate arteriosclerosis/interlobular arteriosclerosis, arteriolar hyalinosis.

Conclusions: Our study confirms renal tubular epithelial cell senescence may lead the progression of IgA nephropathy. DcR2 as a marker of renal tubular epithelial cell senescence is initially proved, the expression levels of DcR2 is an important indicator for judging IgA nephropathy progression.

SA-PO822

Mitochondrial Nephropathy in Adults: Genetic, Clinical and Pathologic Features Zhihong Liu, Shuzhen Wen, Huimei Chen, Shutian Xu, Honglang Xie, Shaoshan Liang, Caihong Zeng. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing Univ School of Medicine, Nanjing, Jiangsu, China.*

Background: Mitochondrial nephropathy is a rare form of kidney diseases and caused by the defects in mitochondrial DNA (mtDNA). Currently its prevalence and genetic, clinical and pathologic features have not been well studied.

Methods: Mitochondrial nephropathy was diagnosed based on the presence of multisystemic involvements, ultrastructural renal lesions, and mtDNA defects. Its frequency and clinical and pathologic features were assessed. Literature review was performed for a comparison between adults and children.

Results: Review of 5,181 adults with biopsy-proven renal damage identified 21 (0.41%) patients as mitochondrial nephropathy candidates. Complete mtDNA sequence analysis identified 10 known pathogenic mtDNA mutations with 1/10 being a deletion and 3/10 3243 A>G mutation. Their heteroplasmy in kidney was over 50% and higher than that in blood. Eventually, mitochondrial nephropathy was diagnosed in 8 patients, resulting in an estimated frequency of 1.54 in 1,000 adult kidney disease patients, and prevalence of ~ 0.17 in 1,000 Chinese people. There were no sex and age preference in the distribution of the disease. The most common feature in these patients was glomerular proteinuria which correlated with renal dysfunction in half of the cases. Histological studies in kidney revealed focal segmental glomerulosclerosis (FSGS), abnormal mitochondrial morphology, and reduced activity of cytochrome c oxidase and succinate dehydrogenase in tubuli. The multisystemic involvements varied and lacked distinctive manifestations. Based on published studies, the percentage of patients with glomerular proteinuria, FSGS lesions or mtDNA mutations is higher in adult than children. Other clinical manifestations in adults included diabetes and ear/eye lesions, but were nonspecific.

Conclusions: mtDNA mutations often cause mitochondrial nephropathy in adults characterized with glomerular defects and mitochondrial abnormity. The genetic and clinical features of the disease are diverse, and the awareness and correct diagnosis of this disease entity are needed for effective treatment.

SA-PO823

Food Access and Kidney Disease in the U.S. Jonathan J. Suarez,[1] Tamara Isakova,[2] Cheryl A. Anderson,[4] L. Ebony Boulware,[3] Myles S. Wolf,[2] Julia J. Scialla.[1] *[1]Univ of Miami; [2]Northwestern Univ; [3]Duke Univ; [4]UC San Diego.*

Background: Diet is a risk factor for hypertension and CKD. CKD prevalence demonstrates geographic clustering and socioeconomic disparities. Geographic areas with limited access to grocery stores (i.e. food deserts) may promote unhealthy diets and contribute to CKD disparities.

Methods: We linked data from adults in the 2003–2010 National Health and Nutrition Examination Survey (n=21,281), a survey of the non-institutionalized U.S. population to food desert data (www.ers.usda.gov) by census tracts. Food deserts are defined by the USDA as low-income tracts in which ≥500 people or 33% of the population lives >1 mile (urban) or >10 miles (rural) from a supermarket or large grocery store. We summarized dietary intake (24h recall) and behaviors as weighted means and frequencies. We used weighted linear and logistic regression to assess the association of food desert residence and income (i.e. ratio of family income to the poverty line) with mean systolic blood pressure (SBP) and odds of CKD.

Results: Participants living in food deserts consumed less protein (79.4 versus 83.3 g; p=0.03) and potassium (2544 versus 2728 mg; p=0.002), with higher net endogenous acid production (60.7 versus 58.4 mEq; p=0.03), among other differences. Participants with lower income displayed similar intake patterns. Availability of fruit at home was lower in food deserts; availability of fruits and vegetables was lower with low income (each p<0.001 by χ^2). Living in a food desert was associated with higher SBP, whereas low income was associated with higher SBP and greater odds of CKD.

	Odds Ratio of CKD (95% CI)‡	Difference in SBP (95% CI)§
Residence* †

1–1.5	**1.75 (1.48, 2.07)**	**2.67 (1.84, 3.51)**
1.5–2	**1.49 (1.22, 1.81)**	**2.07 (1.06,3.09)**
2–3	**1.27 (1.11, 1.45)**	**1.00 (0.07, 1.94)**
>3	Ref	Ref

*Adjusted for age, sex, race/ethnicity
†Additionally adjusted for income
‡CKD defined as eGFR<60 mL/min/1.73m^2 or urine albumin to creatinine ratio >30 mg/g
§Difference in SBP represents the absolute difference in mean SBP in each category compared to the reference category.
Boldface indicates p<0.05

Conclusions: SBP is higher in food deserts independent of demographics and income, but poverty may be more strongly associated with higher SBP and prevalence of CKD. Food access and poverty may each represent targets for CKD prevention.

SA-PO824

Electronic Health Record Patient Portal Use: Correlates and Outcomes Manisha Jhamb,[1] Mark L. Unruh,[2] Khaled Abdel-Kader.[3] *[1]Renal Div, Univ of Pittsburgh; [2]Div of Nephrology, Univ of New Mexico; [3]Div of Nephrology, Vanderbilt Univ.*

Background: Electronic health record (EHR) portals allow patients to access health information and communicate with their care team. While portals support patients with chronic diseases, inequities in internet access (ie, a digital divide) may reinforce care disparities. We are not aware of publications on nephrology portal use.

Methods: In 2009, an outpatient nephrology clinic implemented an EHR portal allowing patients to perform 'active' (eg, communicate with providers) and 'passive' tasks

(eg, review labs). We describe portal use in non-dialysis outpatients seen >=2 times from 1/1/2010-12/31/2012. We also examine sociodemographic correlates of portal use and associated process of care outcomes using multivariable logistic regression.

Results: Of 2,640 patients, 1,020 (39%) used the portal and 316 (31% of users) communicated with the renal team. 'Active' users most commonly requested medical advice (70%) and medication refills (35%). Correlates of portal use are shown.

Variable	Adjusted OR (95% CI)
Age (per 10 years)	0.81 (0.75 - 0.86)
Race	
Black vs. white	0.42 (0.33 – 0.54)
Other vs. white	0.82 (0.46 – 1.45)
Sex (Female vs. Male)	1.16 (0.97 - 1.38)
Marital Status (Married vs other)	1.75 (1.46 – 2.11)
Insurance	
Medicaid vs. Private	0.58 (0.40 – 0.85)
Medicare vs. Private	0.73 (0.60 – 0.90)
Self-pay/uninsured	0.67 (0.47 – 0.97)
HTN	1.38 (1.02 – 1.87)
Hyperlipidemia	1.47 (1.21 – 1.79)
Kidney transplant	1.65 (1.29 – 2.11)
Tobacco (active vs. other)	0.60 (0.47 – 0.77)
eGFR (per 10ml/min/1.73m^2)	1.04 (1.01 – 1.08)
Baseline proteinuria (>1+ on dipstick)	0.71 (0.59 – 0.86)

Portal use was not associated with ACEi/ARB use in proteinuric patients or with optimal BP control in adjusted analyses.

Conclusions: Many (39%) nephrology outpatients used an EHR portal and 31% of users communicated with the renal care team. Portal use associated with younger age, white race, and private insurance, but not with processes of care. As health systems enhance online communication tools, they should devote attention to access for vulnerable populations and ensure that portals reduce care disparities.

Rates of Cardiovascular Events and Death in African-Americans with CKD: The Jackson Heart Study

Nisha Bansal, Ronit Katz, Bessie A. Young, Jonathan Himmelfarb, Bryan R. Kestenbaum, Ian H. de Boer. *UW.*

Background: Chronic kidney disease (CKD) and cardiovascular disease (CVD) are particularly common among African-Americans. The extent to which CKD contributes to specific CVD risk is not well defined in this population.

Methods: We studied 5,187 participants in the Jackson Heart Study, a community-based cohort of African-Americans. CKD was defined at baseline as eGFR <60 mL/min/1.73m2 (CKD-EPI equation). Subsequent stroke, coronary heart disease (CHD) and death were adjudicated. Poisson regression was used to calculate adjusted incidence rates (IR) and incidence rate ratios (IRR) of each outcome in participants with and without CKD.

Results: At baseline, the mean age was 55 (13) years, 37% of participants were men, 22% had diabetes, 61% had hypertension and mean eGFR was 95 (22) ml/min/1.73 m2. Participants with CKD (N=307) had a mean eGFR of 46 (12) ml/min/1.73 m2. With adjustment for age and gender, those with CKD had higher rates of death, incident CHD and stroke compared to those without CKD (Figure). Adjusting for age, gender, family history of CVD, prevalent CVD, hypertension, diabetes, BMI, tobacco use, plasma lipid concentrations, and pertinent medications, IRR comparing participants with CKD to those without CKD were 1.83(1.02, 3.27) for stroke, 1.45(0.84, 2.49) for CHD, 1.96 (1.30, 2.95) for non-CVD death, 1.76(1.15,2.68) for CVD death and 1.88(1.41, 2.51) for all-cause death.

Conclusions: Among a community-based cohort of African-Americans, rates of CVD events and death were significantly greater among participants who had CKD. Targeted CVD risk reduction may improve outcomes among African-Americans with CKD.

SA-PO826

Effects of Race and Sex on Measured GFR in the Elderly: Multi-Ethnic Study of Atherosclerosis

Lesley Inker, Tariq Shafi, Aghogho A. Okparavero, Hocine Tighiouart, John H. Eckfeldt, Ronit Katz, Craig Johnson, Zarqa Tariq, Imene Benayache, Ann Talbot Martz, Wendy S. Post, Josef Coresh, Andrew S. Levey, Michael Shlipak. *MESA-Kidney.*

Background: Blacks and men have higher incidence of end stage renal disease (ESRD). No prior studies have measured GFR in a community-based cohort of older adults with adequate representation of Blacks and Whites. We conducted MESA Kidney, an ancillary study within MESA, to compare measured GFR in a sample of older Black and White men and women from a representative cohort.

Methods: MESA Kidney participants were recruited from the Johns Hopkins University MESA site after the 5th examination cycle. 670 participants were invited, 294 completed the protocol and 292 have been analyzed to date. GFR was measured using plasma clearance of iohexol computed from 5-6 blood samples and a two compartment model. Using linear regression, we compared GFR, indexed to body surface area (BSA), in Blacks versus Whites and men versus women; models were unadjusted and adjusted for age, diabetes, hypertension and sex/race.

Results: Mean (SD) GFR was 73 (19) ml/min/1.73 m^2, age was 71 (9) years, 47% were Black, 47% were women, 25% were diabetic, and 64% were hypertensive. Mean GFR was slightly, but not significantly, higher in Blacks compared with Whites. Men had higher GFR than women, even after adjustment (Table). Differences were greater in magnitude when GFR was not indexed for BSA; after adjustment, Blacks had a 4.3 ml/min (-0.7, 9.4; p=0.09) and men a 23.2 ml/min (18.3, 28.1; p<0.001) higher GFR.

	Mean difference (95% CI) in mGFR (ml/min/1.73 m^2)	
	Blacks vs. White	Men vs. Women
Unadjusted	3.0 (-1.3, 7.3)	**9.2 (5.0, 13.4)**
Adjusted for age, sex or race	1.2 (-2.5, 4.9)	**10.4 (6.7, 14.1)**
Adjusted for age, sex or race, diabetes status and hypertension status	2.3 (-1.6, 6.2)	**11.0 (7.2, 14.8)**
Bold indicates p <0.05. P-values >0.4 for sex/race interactions.		

Conclusions: Mean GFR was similar in Blacks compared to Whites and higher in men compared to women in community-based older adults. Mean GFR was not lower in the demographic groups with the highest risk of ESRD. The higher incidence of ESRD in Blacks and men cannot be explained by levels of average GFR in the population.

SA-PO827

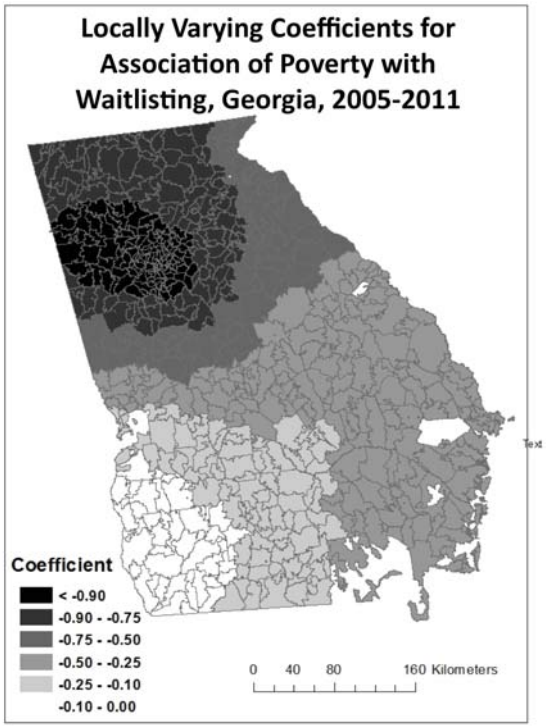
Area Poverty and Access to Kidney Transplantation in Georgia: Multilevel versus Spatial Approach

Laura Plantinga, Curtis Travers, Juan L. Rodriguez, Rachel E. Patzer. *Emory Univ, Atlanta, GA.*

Background: Georgia has the lowest kidney transplantation rates in the nation. While area poverty is a known barrier to transplant access in the Southeast, the contribution of spatial patterns of poverty to this association remains relatively unexplored.

Methods: Using linked United States Renal Data System (2005-2011) and American Community Survey (2007-2011) data, we examined the association of zip code tabulation area (ZCTA)-level poverty (% living below federal poverty threshold) with waitlisting (within 1 year of ESRD start), among U.S. incident black and white dialysis patients aged 18-69 (*n*=12,130) in multilevel mixed-effects models. Geographically weighted regression (GWR) of the association of poverty and waitlisting (both ZCTA-level) was then used to assess potential effect modification by spatial patterns of poverty.

Results: With adjustment and allowing for random effects, patients living in ZCTAs with greater poverty (mean, 20.2%) were ~30% less likely to be waitlisted for each increase in ZCTA poverty of 10% (OR=0.73, 95% CI, 0.67-0.79). Modest spatial autocorrelation of ZCTA poverty (Moran's I = -0.10, P<0.001) was eliminated with GWR using 30-km bandwidth kernel density estimation, and the median change in % ZCTA-level waitlisting per 1% increase in ZCTA-level poverty was -0.60 (IQR =-1.19,-0.22). Compared to ordinary least squares regression with no spatial component, no substantial improvement in model fit was seen with GWR.



Conclusions: In Georgia, greater area poverty is associated with significantly decreased likelihood of waitlisting. While coefficients indicated the greatest effect of poverty in northwest Georgia (including the Atlanta area) and least effect in rural southeast Georgia, accounting for spatial patterning did not contribute significantly to the association between area poverty and waitlisting in Georgia.

SA-PO828

CKD Risk Factor Control in the Urban Healthcare Safety Net

Yoshio N. Hall,[1] Marlena Maziarz,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb.[1]
[1]Medicine, Univ of Washington, Seattle, WA; [2]Medicine, Stanford Univ, Palo Alto, CA.

Background: Socially disadvantaged patients with CKD are often invisible to much of the U.S. healthcare system unless and until they reach ESRD. We sought to examine CKD risk factor management and determine the degree to which it influences disease progression and mortality in an urban safety net healthcare setting.

Methods: We conducted a cohort study of 12,123 patients with moderate-to-advanced CKD who received ambulatory care during 2000-2009 within a regional safety net health system and who were followed for death and ESRD through 2011. We examined the associations of CKD risk factor control and rates of death and progression to ESRD using proportional hazards regression.

Results: Overall, hypertension was the most common risk factor (47%) for CKD progression followed by diabetes (23%). Patients at highest risk (fifth quintile, n=2,425) for progressing to ESRD were significantly younger and had a higher prevalence of hypertension (70%), diabetes (41%), substance abuse (49%) and chronic viral disease (29%) than lower risk counterparts. Only 27% and 45% of high-risk patients achieved BP (<140/90 mmHg) and glycemic (A1c<8%) control, respectively, compared with 39% and 56% of the larger CKD cohort. Proportionately fewer high-risk patients received RAAS inhibitors and nearly half of high-risk patients were subsequently lost to follow-up. High-risk patients who did not achieve BP control and who were lost to follow-up experienced significantly higher rates of death and ESRD than counterparts who achieved BP control or remained in care.

Conclusions: In this public health setting, we observed missed opportunities to mitigate risks of death and progression of CKD. Intervention approaches aimed at identifying and retaining high-risk patients in care may facilitate care delivery and reduce CKD morbidity and mortality among vulnerable populations.

SA-PO829

KDIGO Screening and Treatment among CKD Stage G3A Patients with Uncontrolled Hypertension

Robert M. Perkins,[1] Alex R. Chang,[1] Josef Coresh,[2] M. Grams.[2] *[1]Center for Health Research/Nephrology, Geisinger; [2]Welch Center for Prevention, Epidemiology, and Clinical Research, Johns Hopkins Univ.*

Background: For patients with eGFR 45-59 ml/min/1.73 m^2 (CKD Stage G3a), KDIGO guidelines recommend yearly albuminuria screening, one-time dyslipidemia screening, statin treatment for patients ≥50 years, and cystatin C testing for patients with <30 mg albumin/g creatinine. Uptake of these guidelines is unknown. High-risk patients in particular may benefit from evidence-based screening and care.

Methods: We retrospectively analyzed adherence to KDIGO guidelines in the adult primary care population within the Geisinger Health System (a rural, integrated health care system in Central PA) for the period January 1, 2013 through December 31, 2013. We limited the analysis to "high-risk" patients, defined as those with CKD Stage G3a and an average outpatient systolic or diastolic blood pressure reading ≥150 or 85 mm Hg, respectively. We excluded patients with <2 blood pressure readings.

Geisinger high-risk cohort characteristics (N=341)	
Age (years), median (IQR)	69.6 (24.0, 72.0)
Male sex, %	40.8
Smoking status (current), %	15.2
Diabetes, %	17.3
History of congestive heart failure, %	7.0
History of myocardial infarction, %	4.4
History of stroke or TIA, %	10.9
Hospitalized between 1/1/13-12/31/13, %	32.3
PCP visits between 1/1/13-12/31/13, mean (SD)	2.5 (1.7)
Systolic blood pressure (mm Hg), mean (SD)	151 (21.9)
Diastolic blood pressure, mm Hg, mean (SD)	81 (12.8)
Last reported eGFR (ml/min/1.73m^2), mean (SD)	53.0 (3.9)
Last reported UACR, mg/g, mean (SD)	113 (56)
Last reported LDL (mg/dL), mean (SD)	107 (39)

Results: Of 70,847 active primary care patients, 341 patients met the definition of high risk. Albuminuria and dyslipidemia screening were performed in 25.2% and 48.7% in the prior 12 months, respectively. Among the 3 patients with < 30 mg albumin/g creatinine, none had cystatin C testing. Of the 309 patients over 50, 49.8% were treated with a statin.

Conclusions: KDIGO guideline-based screening and treatment of high risk stage G3a CKD patients is suboptimal in this integrated health care system. Novel strategies to improve guideline-based care are warranted.

SA-PO830

Added Value of Screening for Chronic Kidney Disease Among Elderly or Persons with Low Socioeconomic Status

Priya Vart,[1] Sijmen A. Reijneveld,[1] Ute Bültmann,[1] Ron T. Gansevoort.[2] *[1]Health Sciences; [2]Nephrology, UMC Groningen, Netherlands.*

Background: For chronic kidney disease (CKD) screening, it is not known whether adding elderly or persons with low socioeconomic status (SES) to the traditional high risk groups is effective. Therefore, we aimed to compare three screening approaches (i.e. Approach 1, traditional, screening only persons with known diabetes mellitus, hypertension or cardiovascular (CV) disease history; Approach 2, as approach 1 + elderly; and Approach 3, as approach 1 + persons with low SES) on their ability to detect CKD cases and, to identify those CKD cases that have a higher rate of incident CV events and renal function decline.

Methods: A sample of 3,421 participants representative for the general population in the Netherlands was examined. Persons with age >60 years were classified as elderly. SES was assessed from educational level and classified as low, medium and high. The presence of CKD was determined during examination at an outpatient clinic. Participants were followed for 9.4 ± 2.6 years during 5 screening rounds.

Results: At baseline, the percentage of the general population to be screened was 16%, 29% and 25% in Approaches 1, 2 and 3, respectively. From a total of 325 CKD cases at baseline, 38% were identified by the traditional screening approach. Adding elderly to the traditional CKD screening groups detected the largest number of CKD cases (65%),

whereas adding the low SES group detected more than half of the CKD cases (53%). Rate of incident CV events, when compared to participants without CKD, was significantly higher in detected and undetected CKD cases in Approach 2 while the rate was only significantly higher in detected CKD cases in Approach 3. Rate of renal function decline, when compared to participants without CKD, was significantly higher in detected and undetected CKD cases in Approach 2 and Approach 3, and was lower in undetected CKD cases in screening Approach 3 compared to undetected CKD cases in Approach 2.

Conclusions: Adding persons with low SES, rather than adding elderly, to the traditional high risk groups may be of help for detecting CKD cases that have a higher risk for future CV events and renal function decline.

SA-PO831

Socioeconomic Disparities in Chronic Kidney Disease: A Systematic Review and Meta-Analysis Priya Vart,[1] Ron T. Gansevoort,[2] Michel M. Joosten,[2] Ute Bültmann,[1] Sijmen A. Reijneveld.[1] *[1]Health Sciences; [2]Nephrology, UMC Groningen, Netherlands.*

Background: Evidence on the strength of the association between low socioeconomic status (SES) and chronic kidney disease (CKD) (defined as low eGFR, high albuminuria, low eGFR/high albuminuria or end-stage renal disease) is sparse and sometimes conflicting. Therefore, we aimed to summarize the strength of the associations between SES and CKD in a systematic review and meta-analysis, and to identify study level characteristics related to the strength of the SES-CKD association.

Methods: We conductedasystematic review and meta-analysis of observational studies published in Medline and EMBASE until January 2013. Association measures from individual studies were pooled using random-effects models. Meta-regression analysis was used to identify study level characteristics related to the strength of the association between SES and CKD, with SES defined using individual/household/family income, educational attainment, occupational class/status, composite or area based SES measures.

Results: Out of 2472 citations, 35 studies were found to be relevant (with 3,632,531 individuals including 832,948 CKD cases).Compared to high SES, low SES was associated with low eGFR (OR=1.27, 95% CI: 1.10 – 1.43), high albuminuria (OR=1.52, 1.22 – 1.82), low eGFR/high albuminuria (OR=1.38, 1.03 – 1.74) and renal failure (OR=1.55, 1.40 – 1.71). Different definitions of SES were not related to the strength of association between low SES and any of the CKD measures (for low GFR: p=0.63, high albuminuria: p=0.29, for low eGFR/high albuminuria: p=0.54 and renal failure: p=0.31). Regarding study level characteristics, variations in the strength of the association were only related to the level of covariate adjustment for low eGFR (p<0.001) and high albuminuria (p<0.001). Study design, geographic setting, baseline risk of study population and number of SES categories had no impact.

Conclusions: Socioeconomic disparities in CKD were fairly strong, irrespective of how SES was measured. Variations in the strength of the associations were only related to the level of covariate adjustment in case of low eGFR and high albuminuria.

SA-PO832

Mediators of the Association between Low Socioeconomic Status and Chronic Kidney Disease in the United States Priya Vart,[1] Ron T. Gansevoort,[2] Deidra C. Crews,[3] Sijmen A. Reijneveld,[1] Ute Bültmann.[1] *[1]Health Sciences; [2]Nephrology, UMC Groningen, Netherlands; [3]Johns Hopkins Univ School of Medicine.*

Background: The factors linking low socioeconomic status (SES) and Chronic Kidney Disease (CKD) are poorly understood. We, therefore, investigated potentially modifiable factors linking SES to CKD for their magnitude of mediation.

Methods: A samlple of 9,823 participants in the 2007-2008 and 2009-2010 National Health and Nutritional Examination Surveys (NHANES) was examined. SES was defined using tertiles of the poverty income ratio (PIR). High, middle and low PIR tertiles were denoted as high, middle and low SES, respectively. Main outcome was CKD, defined as eGFR <60 mL/min/1.73m2 (CKD-EPI) and/or urinary albumin-creatinine ratio (ACR) ≥30mg/g. Mediation analyses tested the health-related behaviors (smoking, alcohol intake, diet, physical activity and sedentary time), comorbid conditions (diabetes, hypertension, obesity, abdominal obesity and hypercholesterolemia) and factors related to health care access (health insurance and routine visits for health care)for their contribution to the SES-CKD association. Mediation analysis was performed using counterfactual approach.

Results: Compared to high SES, low SES was associated with an increased odds of CKD (OR=1.92, 95% CI: 1.64, 2.26). Except sedentary time and diet, all examined health-related behaviors, comorbid conditions and factors related to health care access mediated the SES-CKD association, and contributed 20%, 32% and 11%, respectively, to this association. In ethnicity specific analyses, the identified mediators tended to explain a greater proportion of the SES-CKD association in non-Hispanic blacks than in other ethnic groups.

Conclusions: Potentially modifiable factors like health-related behaviors, comorbid conditions and health care access contribute substantially to the association between low SES and CKD in the U.S., especially among non-Hispanic blacks.

SA-PO833

Prescribing Metformin According to eGFR Rather Than Serum Creatinine Can Enhance Its Use, Particularly among Younger Non-Hispanic Black Men Delphine S. Tuot,[1] Feng Lin,[1] Michael Shlipak,[1] Jerry Yee,[2] Rajiv Saran,[3] Sharon Saydah,[4] Desmond Williams,[4] Neil R. Powe.[1] *[1]Univ of California, San Francisco; [2]Henry Ford Hospital; [3]Univ of Michigan; [4]Centers for Disease Control and Prevention.*

Background: Recent guidelines recommend using eGFR rather than serum creatinine (sCr) to determine metformin eligibility among adults with diabetes mellitus (DM). Compared to sulfonylureas, metformin is associated with less cardiovascular risk, CKD progression and death. We examined the potential impact of these guidelines on metformin eligibility among U.S. adults.

Methods: Metformin eligibility was assessed among 3902 adults with DM who participated in the 1999-2010 National Health and Nutrition Examination Surveys and reported routine access to health care. We compared eligibility using conventional sCr cutoffs (eligible if < 1.4mg/dL for women; < 1.5mg/dL for men) and eGFR cutoffs (eligible if >45ml/min/1.73m^2; contraindicated if <30ml/min/1.7m^2), using different estimating equations: 4-variable MDRD, CKD-EPIcr, CKD-EPIcys and CKD-EPIcr-cys and Cockcroft-Gault to estimate creatinine clearance (CrCl). DM was defined by self-report or glycosylated hemoglobin ≥6.5%. We used logistic regression to estimate odds of newly eligible populations adjusted for age, race/ethnicity and sex. Results were weighted to the U.S. adult population.

Results: Among adults with sCr above conventional cutoffs, those newly eligible for metformin by MDRD eGFR were predominantly male (aOR=33.3, 95%CI 7.4-151.5), <60 years old (aOR=66.3, 1.26-31.7) and non-Hispanic black (aOR versus whites=14.8, 4.27-51.7). No individuals with sCr below prior cutoffs had an MDRD eGFR <30ml/min/1.73m^2. The population eligible for metformin expands when using any of the equations estimating GFR or CrCl: +86,883 (CKD-EPIcr); +104,248 (MDRD); +113,943 (CKD-EPIcys); +141,472 (CKD-EPIcr-cys); +834,740 (Cockcroft-Gault).

Conclusions: Using estimated GFR or CrCl to determine metformin eligibility rather than sCr expands the adult population with DM for whom metformin is considered safe to use, particularly among younger non-Hispanic black men. Enhancing metformin use in these populations may help mitigate disparities in diabetes and CKD outcomes.

SA-PO834

Directly Measured Kidney Function Is Linked to Frailty and Frailty Predicts Mortality Independent of GFR Cynthia Delgado,[1,2] Barbara A. Grimes,[4] David V. Glidden,[4] Michael Shlipak,[5] Mark J. Sarnak,[3] Kirsten L. Johansen.[1,2] *[1]Nephrology Section, San Francisco VA Medical Center, CA; [2]Div of Nephrology, Univ of California, San Francisco, CA; [3]Div of Nephrology, Tufts Medical Center, Boston, MA; [4]Dept of Epidemiology and Biostatistics, Univ of California, San Francisco, CA; [5]Medicine, Univ of California, San Francisco, CA.*

Background: Frailty is prevalent in patients with CKD, including non-elderly patients. Most studies of frailty and CKD have estimated GFR using creatinine in cohorts not enriched for CKD. We evaluated the association of measured GFR with frailty among patients with known CKD and determined whether frailty was associated with death after including mGFR.

Methods: We ascertained death in those enrolled in the randomized Modification of Diet in Renal Disease (MDRD) study (1989-1993) (baseline GFR 33 ±12 ml/min/1.73m2) through 2007 with NDI and USRDS linkage. GFR was measured using iothalamate (mGFR), and we estimated GFR using the CKD-EPI (eGFR) equation. We defined frailty using questionnaire data on exhaustion, physical function and activity, and weight loss. Frailty was defined by a score of ≥3 points. We used multivariable logistic regression models to evaluate the association of GFR with frailty and Cox models to assess the association of frailty with death after adjusting for mGFR or eGFR and other covariates.

Results: 812 MDRD participants (96%) had complete data on frailty and GFR. 16% were frail. Median follow-up time was 17 (IQR 11-18) years with 371 deaths. Higher mGFR was associated with lower odds of frailty (OR 0.76, 95% CI 0.64-0.90 per 10ml/min/1.73m2). Similarly, eGFR was inversely linked to frailty (OR 0.80, 95% CI 0.69-0.94 per 10ml/min/1.73m2). Frailty was associated with a higher risk of death (HR 1.67, 95% CI 1.24-2.20), which did not differ when mGFR (HR 1.46, 95% CI 1.10-1.97) or eGFR (HR 1.50, 95% CI 1.10-2.00) was included as an indicator of kidney function (covariate).

Conclusions: We found an inverse association between kidney function and frailty that was similar for mGFR and eGFR. Frailty was associated with higher risk of death after adjustment for multiple covariates including GFR.

SA-PO835

Lower Dialysis Facility Staff to Patient Ratio Associated with Kidney Transplant Referral in Georgia Rachel E. Patzer,[1,6] Laura Plantinga,[6] M. Ahinee Amamoo,[2] Eric M. Gibney,[4] Stephen O. Pastan.[5] *[1]Surgery, Div of Transplantation, Emory Univ School of Medicine, Atlanta, GA; [2]Southeastern Kidney Council of ESRD Network 6, Raleigh, NC; [3]Piedmont Hospital, Atlanta, GA; [4]Medicine, Renal Div, Emory Univ School of Medicine, Atlanta, GA; [5]Epidemiology, Emory Univ, Atlanta, GA.*

Background: Georgia (GA) has the lowest kidney transplant rates in the U.S. and worst racial disparities in these rates. Prior studies have shown that fewer dialysis facility staff may be associated with reduced transplant access. We examined whether facility patient-to-staff ratio was associated with kidney transplant referral among GA dialysis patients.

Methods: We collected patient-level transplant referral data on all kidney transplant referrals to each transplant center in GA from 2008 to 2011 as part of our RaDIANT (Reducing Disparities in Access to kidNey Transplantation) Community study. We linked these data to 2008-2011 Centers for Medicare and Medicaid Services (CMS) Dialysis Facility Report (DFR) data to determine number of staff and calculated 4-year annual kidney transplant referral (% of facility patients aged <70 referred in calendar year) for GA dialysis facilities (n=273). We examined whether the patient-to-staff ratio was associated with kidney transplant referral using linear regression models.

Results: A total of 273 dialysis facilities treating >12,000 patients, who were 56% African American and had a mean age of 60.6 years, were examined. The mean number of full-time staff was 11.5 (SD: 5.8; range: 0-43) and mean patient-to-facility staff ratio was 4.5 (SD: 1.5). Median 5-year kidney transplant referral was 14.8% (IQR: 9.2-21.3%). Each unit increase in patient-to-staff ratio was associated with ~1.5% lower kidney transplant referral within GA dialysis facilities (β = -0.01471, SE: 0.00372, p<0.0001).

Conclusions: Identifying characteristics of facilities associated with low transplant referral rates could help improve access to kidney transplantation. For example, targeting interventions among dialysis facilities with high patient-to-staff ratios could help improve referral for kidney transplantation.

Abstract Withdrawn

SA-PO837

Access to the Preemptive Registration on the Waiting List for Cadaveric Renal Transplantation: A Hierarchical Modeling Approach Natacha Riffaut,[1] Thierry Lobbedez,[1] Marc Hazzan,[2] Dominique Bertrand,[3] Gabriel Choukroun,[4] Bruno Hurault de Ligny.[1] *[1]CHU Clémenceau, Caen, France; [2]CHRU Lille, France; [3]CHU Bois Guillaume, Rouen, France; [4]CHU Amiens, Saloul, France.*

Background: It has been shown that preemptive kidney transplantation (KT) is associated with both higher patients and graft survival compared with transplantation performed after dialysis. Therefore, we believe, like others, that patients should be registered on the waiting list before dialysis onset when feasible. This study was carried out to estimate the association between the renal units and the preemptive registration on the waiting list for first cadaveric KT in a French network of care.

Methods: From 2008 to 2012, 1529 adult-patients followed in 48 centers of the French North-West network, and registered on the waiting list for a first cadaveric KT, were included. We used a mixed logistic regression with renal unit as random-effects term for statistical analysis.

Results: Of the 1529 patients included in the study, 407 were placed on the waiting list preemptively. The non-adjusted mixed model showed a significant variability across renal units (variance 0.452; SD 0.672). In multivariate analysis, factors independently associated with preemptive registration were cardiovascular disease (OR 0.47, 95% CI 0.41 to 0.78), social deprivation (OR 0.75, 95% CI 0.58 to 0.98), and characteristics of the units (Ownership of the facility: academic hospital, reference – community hospital, OR 0.43, 95% CI 0.22 to 0.80 – private hospital, OR 0.34, 95% IC 0.16 to 0.69; and Transplant center; p<0.05). Variability between renal units was reduced after taking into account for their characteristics (proportional change in variance, 45%) but was not influenced by patients characteristics.

Conclusions: Preemptive registration is associated with renal units, transplant centers, social deprivation, and can be partly explained by disparities in practices. In view of these findings, public health actions should be implemented to facilitate the preemptive access to the waiting list, especially among the most disadvantaged populations.

SA-PO838

Using Hypothetical Patient Scenarios to Assess Nephrologists' Perceptions Regarding Choice of Treatment for End Stage Renal Disease Ankita Tandon,[1] Ming Wang,[2] Kevin C. Roe,[1] Surju Patel,[1] Nasrollah Ghahramani.[1] *[1]Dept of Medicine, Penn State Milton S. Hershey Medical Center, Hershey, PA; [2]Dept of Public Health Sciences, Penn State College of Medicine, Hershey, PA.*

Background: Kidney transplantation (KT) is the most effective treatment for end stage renal disease (ESRD). Factors related to nephrologists and their perceptions of suitable patient characteristics are likely contributors to patients referred for KT.

Methods: Using an online survey, 250 nephrologists were asked whether they would recommend dialysis or kidney transplant (KT) for hypothetical patients with ESRD. The 4 scenarios varied in race, living situation (alone or with spouse), and rural location. 215 nephrologists provided complete responses.

Results: In multivariate analysis, rural patients (OR:0.71, p= 0.005) were less likely to be recommended for KT. Nephrologist factors associated with lower likelihood of recommending KT included lack of academic affiliation (p=0.01), and longer time since completing fellowship (p<0.01). Adjusted for rural location, attending 4 or more national nephrology meetings (p=0.01) and longer time practicing in the current location (p<0.01) were associated with significantly higher likelihood of recommending KT; practice as a non-transplant nephrologist (p<0.01) was associated with lower likelihood of recommending transplant (p<0.05).

Conclusions: Rural patients are less likely to be referred for KT. Lack of academic affiliation, length of time since fellowship, frequency of attendance to national meetings and whether the nephrologist is a transplant nephrologist significantly impacts the decision regarding KT referral.

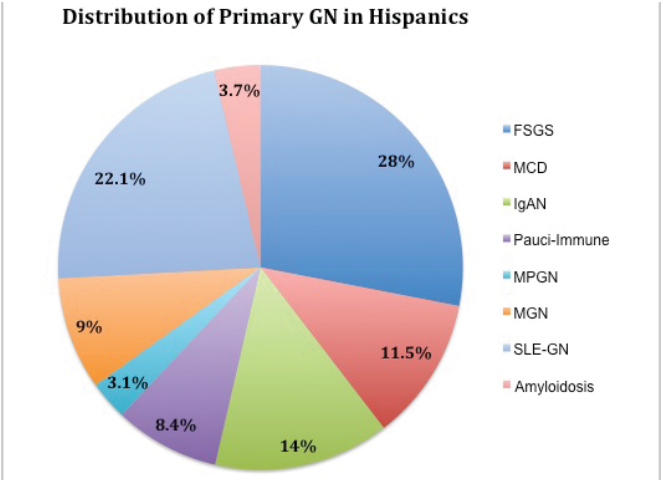
Distribution of Primary Glomerulonephropathies among Hispanics Taurino N. Avelar,[1] Aviv Hever,[1] Michael Batech,[1] Teresa N. Harrison,[1] Sejal Vora,[2] Leslie Vollenweider,[2] Anna Pavlova-Wolf,[2] John J. Sim.[1] *[1]Internal Medicine, KP LAMC, Los Angeles, CA; [2]Questcor Pharmaceuticals, Inc.*

Background: Few U.S.-based studies have described primary glomerular diseases in the Hispanic population. Small observations suggest Hispanics are more likely to be affected by focal segmental glomerulosclerosis (FSGS) and IgA nephropathy/ Henoch-Schönlein Purpura nephritis (IgAN). We sought to describe the distribution of primary glomerulonephropathies (GNs) amongst Hispanics in Southern California.

Methods: Retrospective chart review study of all renal biopsy reports within Kaiser Permanente Southern California from 1/1/2006 - 12/31/2009. Results for Hispanics were categorized based on the primary diagnoses. Primary GN's [FSGS, minimal change disease (MCD), IgAN, pauci-immune crescentic glomerulonephritis/vasculitis (pauci-immune), membranoproliferative glomerulonephritis (MPGN), membranous glomerulonephritis (MGN), lupus glomerulonephritis (SLE-GN), and amyloidosis] were identified and patients were characterized within those GN's.

Results: A total of 321 Hispanics had a primary GN diagnosis. The mean age was 38 years, 51.7% were female, and 49.2% had a median household income $50,000 - $99,999. The primary GN distribution was: FSGS n=90 (28%), SLE-GN 71 (22.1%), IgAN 45 (14%), MCD 37 (11.5%), MGN 29 (9%), pauci-immune 27 (8.4%), amyloidosis 12 (3.7%) and MPGN 10 (3.1%).



FSGS was most common among males and SLE-GN among females. Hypertension was most commonly associated with MPGN and least with IgAN. Diabetes was most commonly associated with pauci-immune and least with IgAN. Systemic lupus erythematous was also commonly associated with FSGS.

Conclusions: In a large Hispanic population in Southern California, FSGS, SLE-GN and IgAN were the most common GN's. This cohort may provide future insights on comparative outcomes in CKD and among different races/ethnicities.

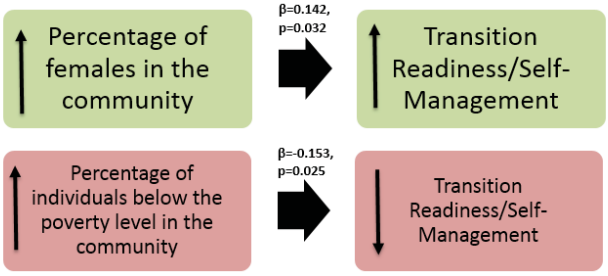
SA-PO840

Ecological Disparities as Predictors of Transition Readiness/ Self-Management Among Adolescents/Emerging Adults Seen in the Adult and Pediatric Nephrology Clinics at the UNC Kidney Center
Karina Javalkar, Meredith Johnson, A. V. Kshirsagar, Karin A. True, Randal K. Detwiler, Sofia Ocegueda, Maria E. Ferris. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

Background: The influence of ecological factors on the readiness to transition from pediatric to adult care and/or disease self-management skills among adolescents/emerging adults (youth) with chronic conditions is yet to be characterized.

Methods: IRB-approved consents/assents were signed by youth ages 12 to 29 in both the adult and pediatric nephrology clinics at the UNC Kidney Center. Transition readiness/self-management was measured by the UNC TRxANSITION™ scale, a provider-administered 33-item scale. Age, gender, race, and insurance type were used as control variables. Ecological factors (e.g. percent individuals below poverty level in the community, percent females in the community) were identified for each participant's zip code using the published U.S. Census data. We conducted linear regression analyses in SPSS.

Results: We enrolled 169 participants with the following characteristics:59% females; 37% White; 46% African American; 33% private insurance; 57% public insurance and 10% self-pay; mean age 21 years (±5). Their diagnoses included:CKD (39%), Transplant (28%), lupus nephritis (21%) and other diagnosis (12%). Participants whose communities had a greater proportion of females had greater transition readiness/self-management of their disease (β=0.142, p=0.032). However, in communities with a greater percentage of individuals below the poverty level, participants had lower transition readiness/self-management of their disease (β= -0.153, p=0.025).



Conclusions: Ecological factors and community characteristics appear to be important factors in the transition from pediatric to adult health care and/or in disease self-management. Our findings highlight disparities that need further exploration.

Apolipoprotein L1 (*APOL1*) Renal Risk Alleles and Glomerular Causes of Chronic Kidney Disease (CKD) in Children
Robert Woroniecki,[1] Derek Ng,[2,4] Sophie Limou,[3] Cheryl Ann Winkler,[3] Craig S. Wong,[4] Mark Mitsnefes,[4] Susan L. Furth,[4] Bradley A. Warady,[4] Jeffrey B. Kopp,[5] Frederick J. Kaskel.[4,6] *[1]SUNY at Stony Brook, NY; [2]Johns Hopkins Univ, Baltimore, MD; [3]NIH/NCI, Frederick, MD; [4]CKiD Study; [5]NIH/NIDDK, Bethesda, MD; [6]Children's Hospital at Montefiore, Bronx, NY.*

Background: While studies demonstrated strong recessive association of *APOL1* G1 and G2 genetic variants with glomerular and vascular disease progression in African-American (AA) adults, there is limited information on *APOL1* role in children with CKD.

Methods: We investigated children with CKD in the Chronic Kidney Disease in Children (CKiD) cohort. *APOL1* G1 (rs73885319, S342G) and G2 (rs71785313, NY388-389 deletion) renal risk variants were genotyped in AA patients. Linear mixed effects models with random intercepts and slopes were used to describe changes in renal function. The main effects of AA with low risk (LR) *APOL1* (0 or 1 risk allele, n=68) and AA high risk (HR) *APOL1* (2 risk alleles, n=21), and their interactions with time were included, with non-AA (no *APOL1* risk allele, n=675) as the reference group.

Results: Glomerular disease (GD) was a cause of CKD in 26% (175 out of 675) non-AA children, 19% (13 out of 68) LR, and 81% (17 out of 21) HR *APOL1* AA subjects (p<0.001). GD subjects data:

	non-AA (n=175)	LR (n=13)	HR (n=17)	P-value
Age at entry	14 [10,15]	13 [10, 15]	14 [13, 15]	0.33
Female	46% (81)	46% (6)	53% (9)	0.91
Abnormal birth history	23% (38)	40% (4)	41% (7)	0.14

HR were more likely to have a smaller proportion of life with CKD, despite being about the same age: 34% non-AA, 83% LR, 25% HR (p= 0.06). While not significant, HR tend to have a lower GFR at entry than LR and non-AA (54, versus 57.3, versus 61 ml/min/1.73m2, p= 0.33) and a faster GFR decline (-11%, versus 8%, versus -8.2%, p=0.50). All groups had similar level of proteinuria at baseline but it increased more in LR than in HR and non-AA (+44%, versus 11.4%, versus 5.5% per year respectively, p<0.001).

Conclusions: HR *APOL1* is strongly associated with an underlying glomerular cause of CKD in children. Further study of larger population of children is required to determine if an accelerated decline in GFR occurs in association with HR, as it does in adults.

Primary Care Providers Perceptions of Racial/Ethnic and Socioeconomic Disparities in Hypertension Control
Jessica B. Kendrick.[1,2] *[1]Div of Renal Diseases and Hypertension, Univ of Colorado School of Medicine, Aurora, CO; [2]Denver Health Medical Center, Denver, CO.*

Background: Primary care providers (PCP) play an important role in reducing racial/ethnic and socioeconomic disparities in hypertension control. The purpose of this study was to evaluate the attitudes and perceptions of PCPs regarding racial/ethnic and socioeconomic disparities in hypertension control.

Methods: We conducted an online survey of PCPs at the University of Colorado Hospital and Denver Health Hospital. We included physicians, nurse practitioners and physician assistants. The survey assessed provider recognition and perceived contributors of racial/ethnic and socioeconomic disparities in hypertension control.

Results: 115 providers completed the survey (response rate 64%). Respondents were primarily female (66%), non-Hispanic white (84%) and physicians (80%). Among respondents, 67% and 73% supported the collection of data on the patients' race/ethnicity and socioeconomic status, respectively. Eighty-six percent and 89% agreed that disparities in race/ethnicity and socioeconomic status existed in hypertension care within the U.S. health system. However, only 33% and 44% thought racial/ethnic and socioeconomic disparities existed in the care of their own patients. Providers were more likely to perceive patient factors rather than provider or health system factors as mediators of disparities. However, most supported interventions such as improving provider communication skills (87%) and cultural competency training (89%) to reduce disparities in hypertension control.

Conclusions: Most providers acknowledged that racial/ethnic and socioeconomic disparities in hypertension control exist in the U.S. health system, but only a minority reported disparities in care among patients they personally treat. Increased provider awareness about disparities, provider training and hypertension guidelines at the local level are needed to reduce disparities in hypertension control.

Late Referral, Physician Practice and Healthcare Seeking in Pre-Dialysis – A Population-Based Study
Ming-Yen Lin,[1,2] Charles tzu Chi Lee,[3] Shang-Jyh Hwang,[1,4] Yiwen Chiu.[1,4] *[1]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [2]Instrument Technology Research Center, National Applied Research Laboratories, Hsinchu, Taiwan; [3]Faculty of Public Health, College of Heath Science, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [4]Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: Late referral is common in CKD care with poor prognosis and unclear mechanism. We conducted this national survey to clarify the association between late referral with physicians' practice and patients' healthcare seeking.

Methods: All incident log-term dialysis population from 2002 through 2007 at Taiwan is included. The timing, frequency and specialty of medical visits and laboratory tests were evaluated retrospectively every 3 months before dialysis. Missing was defined as no any medical visit (or test) in a 3-month interval. No more than one missing every year and having the rest all done at the same hospital/clinic was defined as regular follow-up. Risk factors were identified for both irregular follow-up of eGFR and medical visit before dialysis.

Results: Total 46,626 patients were included. Near one fourth of the incident patients never had their eGFRs tested until one year before dialysis. In the observation periods of one, two and three years before dialysis, 87, 66, and 50% of patients had regular medical visit, but only 44, 21, and 12% had the regular visit at nephrology. In addition, only 49, 23, and 12% of incident patients had regular eGFR test in the above observation periods. Finally, risk factors of irregular eGFR follow-up included age(95%CI:1.03-1.07), cardiac disorder(1.03-1.24), stroke(1.17-1.44), regular surgery visit(1.07-1.41), orthopedics visit(1.18-1.65), other specialty visit (1.01-1.25) and primary clinic visit(1.22-1.41); while risk factors of irregular follow-up at nephrology were diabetes(1.95-2.20), cardiac disorder(1.47-1.74), stroke(1.70-2.06) and any specialty regular visit(OR range:1.32 to 5.58).

Conclusions: Regular medical visit was common in late CKD patient, but late referral and much less frequent did they receive regular eGFR measurement.

SA-PO844

Risk Factors for Rapid Renal Function Decline and Incident Chronic Kidney Disease (CKD) among African Americans: The Jackson Heart Study (JHS)
Bessie A. Young,[1] Ronit Katz,[1] Bryan R. Kestenbaum,[1] Ian H. de Boer,[1] Wei Wang,[2] Nisha Bansal,[1] Cassianne Robinson-Cohen,[1] Michael Griswold,[2] L. Ebony Boulware,[3] Adolfo Correa.[2] *[1]KRI, UW, Seattle, WA; [2]JHS CC, Univ of Mississippi, Jackson, MI; [3]Medicine, Duke, Durham, NC.*

Background: African Americans (AA) with known CKD are at greater risk for endstage renal disease compared to whites; however, less is known regarding risk factors for rapid renal function (RRF) decline and incident CKD amongst a population-based cohort of AA with preserved kidney function.

Methods: We evaluated RRF decline and incident CKD among a cohort of 2382 AA JHS participants with renal function data from three examinations (2000-2004, 2005-2008, and 2009-2013). Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI equation. RRF decline was defined as an absolute decline of >3ml/min/1.73 m^2

annually. Incident CKD was defined as eGFR decline to <60ml/min/1.73 m^2 and an annual decrease of eGFR >1% over 10 yrs. We quantified the association of baseline risk factors with odds of RRF decline and incident CKD using logistic regression.

Results: At baseline, mean age was 54 (SD=12) years, 37% were male, average body mass index (BMI) was 31.8 (7.0), average systolic blood pressure (SBP) was 125 (17), 18% had diabetes, 59% had hypertension, mean eGFR was 97.0 (20) ml/min/1.73m2, and albumin to creatinine ratio (ACR) was >30mg/g in 10%. RRF decline was found for 350 (14.7%) participants. Factors associated with greater odds of RRF decline were: older age; SBP (OR=1.29, 95% CI 1.12-1.48, per SD); smoking (OR=1.64, 95% CI=1.04-2.59); and doubling of ACR (OR=1.40, 95% CI,=1.23, 1.38. Factors associated with incident CKD were: age (OR=1.86, 95% CI=1.48-2.34, per 10 years); SBP (OR=1.40, 95% CI=1.16-1.69, per SD); and doubling of ACR (1.30, 95% CI=1.17-1.45). BMI was not statistically associated with RRF in the multivariate models (OR=1.14, 95% CI=0.91-1.41) per 7 kg/m2).

Conclusions: Among AA in JHS, age, SBP, and ACR were associated with RRF decline and incident CKD, while the influence of BMI was less supported. Efforts to reduce the burden of traditional risk factors may decrease RRF and the prevalence of kidney disease in African Americans.

Characterizing Barriers to Health Care Among Chinese Immigrant Populations with the Kidney Disease Screening and Awareness Program (KDSAP)

Laura C. Polding,[1] Li-Li Hsiao.[2] *[1]Harvard College; [2]Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: Culture-specific social and ethnic factors influence access to health care, quality of physician-patient interactions and individual health outcomes among Asian immigrant populations in the U.S. To eliminate immigrant health care disparities, care providers must construct service models that facilitate the dissemination of culturally competent care. The free community health clinic offers a model for gathering demographic, social and health service information that will inform strategies for reducing cultural care barriers.

Methods: A bilingual questionnaire was administered to 82 participants at four KDSAP renal health screenings in Boston's Chinatown from 2011 to 2013. The following topics were addressed: language, education, general health, communication barriers, difficulty of receiving care, insurance, cost of medications, health information sources and usage of herbal/traditional medicines.

Results: Primary languages included Cantonese, Mandarin, Taishanese and Southern Min. 39% of participants attained an education level of grade school or less. 50% rated their health "Fair" or "Poor." One quarter reported experiencing language barriers when communicating with physicians, while 21% experienced "some" to "extreme" difficulty in obtaining care. Primary sources of health information included newspapers (62%), television (30%) and community centers (18%). 29% of participants reported taking herbal/traditional medicines, for which the chief information source was non-health-professional family or friends. 14% denied having insurance coverage while 22% lacked benefits to pay for medications.

Conclusions: Population-specific cultural assessment identified salient characteristics that may inform the design of care tailored to the Chinese immigrant population in Boston by addressing issues of accessibility, linguistic diversity, dissemination of health information and the physician-patient communication gap. Health clinics serving ethnic groups nationwide must prioritize the collection of relevant social and cultural information to enhance local health services design and effect policy changes toward eliminating disparities in immigrant health care.

SA-PO846

Socio-Economic Status Influences Survival in CKD

Beng Hock So,[1,3] Shona Methven,[4] Jamie P. Traynor,[2] Mario D. Hair,[1] Alan G. Jardine,[3] Mark Steven Macgregor.[1] *[1]Univ Hospital Crosshouse; [2]Monklands Hospital; [3]Inst of Cardiovascular Medicine and Sciences, Univ of Glasgow, United Kingdom; [4]Univ of Bristol.*

Background: Socio-economic status(SES) is associated with poor outcomes and has had limited attention in chronic kidney disease(CKD). We hypothesised that lower SES is associated with poorer outcomes (mortality, initiation of RRT).

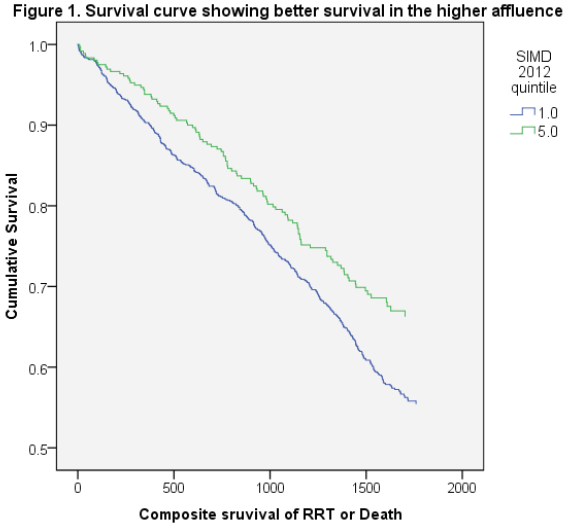
Methods: We identified all CKD patients from our centralised laboratory database between 2009-2012(n=21,035) with an algorithm to confirm chronicity. Data were linked to regional Scottish Index of Multiple Deprivation quintiles(SIMD: 1=most, 5=least deprived), hospitalisations, and date of death for the following 5 years; obtained from Information Services Division Scotland. To avoid lead-time bias, patients were 'enrolled' when eGFR fell to less than 45mL/min/1.73m^2(n=3,122). Multivariate Cox hazard models were generated.

Results: There were 1,238 deaths and 95 who started RRT. Demographics and comorbidity for SIMD quintile 1 and 5 are shown in table 1.

	SIMD 1	SIMD 5	p-value(t-test, X^2)	Exp(B)	95% CI
Age(mean±SD)	75±11	76±12	0.28	1.53	1.39, 1.69
eGFR(mean±SD)	34±9	33±9	0.15	0.96	0.95, 0.97
Female(%)	65	61	0.17	1.47	1.24, 1.75
Statin use(%)	52	41	<0.05	0.68	0.57, 0.82
HTN(%)	49	38	<0.05	0.97	0.81, 1.17
CHD(%)	30	22	<0.05	1.51	1.25, 1.83
DM(%)	22	15	<0.05	1.17	0.94, 1.45
CVA(%)	10	9	0.53	1.25	0.96, 1.63
PVD(%)	6	4	0.14	1.06	0.75, 1.52

Survival analysis was carried out after adjustment for the factors listed. SIMD 5 versus SIMD 1 was associated with a hazard ratio of 0.71 (95% CI 0.57,0.89).

Figure 1. Survival curve showing better survival in the higher affluence quintile



Conclusions: We demonstrated an association between SES and survival in a community-based prevalent cohort with CKD. These associations might be explained by prevalence of other comorbidities (eg smoking, alcohol), or other unknown effects of deprivation. Further work will be required to differentiate between these possibilities.

Transition Readiness Outcomes following Establishment of Formal Transition Nephrology Program

Hsiao Ling Lai,[1] Basema I. Dibas,[2] Guillermo Hidalgo.[2] *[1]Dept of Internal Medicine and Pediatrics, East Carolina Univ, Greenville, NC; [2]Dept of Pediatrics, East Carolina Univ, Greenville, NC.*

Background: Outcomes in adolescents and young adults (AYA) with chronic kidney disease (CKD) following transfer to adult practitioners remains poorly defined.

Methods: We evaluate the effect of a formal Nephrology Transition program on outcomes in AYA with pediatric-onset CKD. Patients between ages 12 and 22 years were identified and referred for enrollment into formal transition. STARx survey tools: Physician Survey, Transition Readiness Survey and Scoring, Realm Literacy tool, Parent survey of Transition Burden and Quality of Life (QOL) tools were used to evaluate patients during transition process.

Results: Forty-seven patients from a single academic pediatric nephrology practice were identified as eligible, and 22 (46.8%) were referred for Transition. Patients were average on average 18 ± 1.67 years old, 64 % female, 73% Black, 18% White, 9% Hispanic. Half of referred patients were evaluated in Nephrology Transition clinic between April 2013 and January of 2014. Four patients refused transition because of resistance to provider transfer and increased travel burden. The remaining 7 patients had not yet engaged in Transition. The average patient transition readiness score was 7.17 out of 10, with parent score of 8.66. Patients averaged 4-6th grade reading skills and parents averaged 7th-8th grade reading skills. Patient and parental QOL scores averaged 75, 71, 65, 29 and 87.9, 68.7, 65.3, 37.3 out of 100 for physical, emotional, social and school arenas. Use of assistive tools for medication management improved with ongoing transition.

Conclusions: Social factors including low literacy, travel constraints and resistance to leaving the pediatric setting remain major barriers to successful management and transition of AYA with CKD. CKD in AYA also significantly affects school performance. On-line self-assessment tools and patient portals can promote self-efficacy and facilitate distance transition in this age group. Improved engagement of pediatric and adult practitioners remains key to a successful transition program.

SA-PO848

Access to Pre-ESRD Nephrology Care in Rural Areas: A Nationwide Perspective Brendan P. Lovasik,[1] Hua Hao,[2] Stephen O. Pastan,[1] Howard Chang,[2] Rachel E. Patzer.[1,2] *[1]Emory Univ School of Medicine, Atlanta, GA; [2]Emory Univ Rollins School of Public Health, Atlanta, GA.*

Background: Rural areas are disproportionally affected by the nationwide physician shortage. ESRD patients residing in rural areas have geographic and economic barriers that limit access to specialized nephrology care; regional studies have shown lower rates of pre-ESRD nephrology care in rural areas.

Methods: 3,819 dialysis facilities across the U.S. were geocoded into rural and non-rural categories according to the U.S. Office of Management and Budget Metropolitan Statistical Area and National Center for Health Statistics. A marginal mixed generalized estimating equation model was used to estimate the association of facility-level characteristics and the proportion of patients within a facility who received pre-ESRD nephrology care.

Results: Rural dialysis facilities show a similar proportion of patients receiving any pre-ESRD nephrology care as non-rural facilities (70.11% versus 68.16%, OR=1.007, P=0.085); this was consistent for care greater than 6 months (46.26% versus 47.59%, OR=0.998, P=0.472) and care greater than 12 months (24.27% versus 22.33% OR=1.007, P=0.098). Rural facilities show higher rates of erythropoiesis-stimulating agent use (29.11% versus 22.39%, OR=1.017, P<0.001), but no difference in arteriovenous fistula use (P=0.442). There was no difference in rural versus non-rural dialysis facility Standardized Mortality Ratio (P=0.549). Medicare coverage was higher in rural facilities (21.54% versus 19.32%, OR=1.009, P=0.048), while Medicaid coverage (P=0.178) was similar between rural and non-rural facilities.

Conclusions: Dialysis facilities in rural areas show similar rates of pre-ESRD nephrology care as non-rural dialysis facilities on the national level. Rural facilities have high rates of outcome-improving measures, including erythropoiesis-stimulating agent and arteriovenous fistula use, that show strong primary medical management of ESRD. However, access to nephrology care in this patient population should be carefully monitored as the rural physician shortage intensifies.

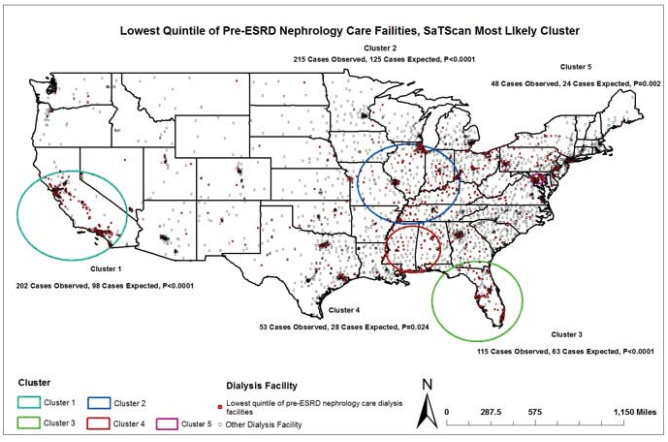
SA-PO849

Geographic Determinants of Low Pre-ESRD Nephrology Care in the United States Brendan P. Lovasik,[1] Hua Hao,[2] Stephen O. Pastan,[1] Howard Chang,[2] Rachel E. Patzer.[1,2] *[1]Emory Univ School of Medicine, Atlanta, GA; [2]Emory Univ Rollins School of Public Health, Atlanta, GA.*

Background: Pre-end stage renal disease (ESRD) nephrology care is crucial for optimizing clinical outcomes for patients with ESRD. Geographic variation of pre-ESRD nephrology care coverage has not been studied nationally.

Methods: A marginal mixed generalized estimating equation model was used to estimate the association of the proportion of patients within a facility who received pre-ESRD nephrology care and facility-level neighborhood characteristics among 5,387 dialysis facilities across the United States. SaTScan testing was utilized to detect geographic clusters of dialysis facilities with low pre-ESRD nephrology care coverage.

Results: Dialysis facilities in the lowest quintile of pre-ESRD nephrology care were geographically clustered in 5 distinct areas (P<0.05), including San Francisco, Los Angeles, Chicago, Miami, and Baltimore and along the corridors of Mississippi and Ohio River.



Facilities in the lowest quintile of pre-ESRD nephrology care were more likely to be located in inner cities compared to those in the highest quintile (45.8% versus 21.8%, OR=1.88, P=0.014). Lowest quintile facilities were significantly more likely to be in high-poverty neighborhoods (24.2% versus 16.6%, OR=1.96, P=0.030). The proportion of racial minorities within a neighborhood was not associated with pre-ESRD nephrology care rates (P=0.929).

Conclusions: The proportion of patients receiving access to pre-ESRD nephrology care within a facility varies by geographic region. Policy makers and ESRD Networks should target these low-pre-ESRD facilities and regions to improve access to nephrologist care with interventions and specific pilot programs aimed at improving patient outcomes. Further examination of what factors make geographic regions better or worse at providing pre-ESRD nephrology care is warranted.

Funding: Other NIH Support - National Institute on Minority Health and Health Disparities (R. Patzer)

SA-PO850

Incidence of Diabetes-Related End-Stage Renal Disease Declined but Racial/Ethnic Disparities Remained Nilka Rios Burrows, Israel Hora, Desmond Williams, Linda S. Geiss. *Div of Diabetes Translation, Centers for Disease Control and Prevention, Atlanta, GA.*

Background: In the United States, diabetes is the leading cause of end-stage renal disease (ESRD), a condition associated with premature death that disproportionately affects racial/ethnic minorities. To assess progress in closing the disparity gap, we examined racial/ethnic-specific trends in incidence of diabetes-related ESRD in the United States.

Methods: From the U.S. Renal Data System, we obtained the number of non-Hispanic white (White), non-Hispanic blacks (Black), and Hispanic adults aged ≥18 years who began therapy for ESRD with diabetes listed as primary cause (ESRD-DM) between 1997 and 2011. Incidence was calculated using racial/ethnic-specific estimates of the adult population with self-reported diabetes from the National Health Interview Survey, and age-adjusted to the 2000 U.S. standard population. Joinpoint regression was used to analyze trends.

Results: From 1997 to 2011, the total number of White, Black, and Hispanic adults who began ESRD-DM therapy increased from 33,286 to 46,090, but the overall age-adjusted ESRD-DM incidence rate decreased by -3.7% per year (276.2 to 197.7 per 100,000 diabetic population) (p<0.001). Throughout the period, age-adjusted rates declined by -4.2% per year among Whites (243.9 to 148.4 per 100,000 diabetic population), and by -2.3% per year among Blacks (449.1 to 352.8 per 100,000 diabetic population) (both p<0.001). Among Hispanics, after an initial period of no significant change, age-adjusted rates declined by -3.9% per year from 2000 to 2011 (385.4 to 247.2 per 100,000 diabetic population) (p<0.001). In 2011, compared with Whites, the age-adjusted ESRD-DM incidence rate was 2.4 times higher among Blacks and 1.7 times higher among Hispanics.

Conclusions: The declining ESRD-DM incidence in the population with diabetes is likely due in part to a reduction in prevalence of ESRD risk factors, improved treatment and care, and other factors. However, compared with Whites, ESRD-DM continues to disproportionately affect Blacks and Hispanics with diabetes. Continued efforts might be considered to sustain and improve these encouraging trends, particularly among U.S. minority populations.

SA-PO851

The Differential Effect of Socio-Economic Status on Body Mass Index among Aboriginal Children and Adolescents Siah Kim,[1,2] Petra Macaskill,[2] Louise Alison Baur,[2,3] Elisabeth M. Hodson,[1,2] Jennifer Daylight,[1] Rita Angeline Williams,[1] Rachael Kearns,[1] Nicola Vukasin,[1] David M. Lyle,[4] Jonathan C. Craig.[1,2] *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [2]School of Public Health, Univ of Sydney, Camperdown, NSW, Australia; [3]Discipline of Paediatrics and Child Health, Univ of Sydney, Camperdown, NSW, Australia; [4]Dept of Rural Health, Univ of Sydney, Camperdown, NSW, Australia.*

Background: Obesity is a known risk factor for chronic kidney disease (CKD), and earlier onset of obesity associated with increased risk of CKD in adult life. Aboriginal children have a higher prevalence of overweight and obesity with the contribution of socioeconomic status (SES) unclear. We aimed to determine changes in BMI between Aboriginal and non-Aboriginal children as they move through adolescence into young adulthood.

Methods: A prospective cohort study of Aboriginal and non-Aboriginal school children commenced in 2002 across 15 different screening centers involving 213 high schools across urban, regional and remote NSW. SES was recorded at study enrollment and participants BMI were measured every 2 years. We fitted a series of mixed linear regression models adjusting for age, sex, Aboriginality and socioeconomic status.

Results: 3418 (1949 Aboriginal) participants were screened over a total of 11, 387 participant years follow up. The prevalence of obesity was 14.2% (mean age 11 years) at baseline, and increased to 17.2% at eight years follow up (mean age 16 years). The mean BMI SDS increased with age and we found that SES had a differential effect on mean BMI for Aboriginal children compared to non-Aboriginal children (P for interaction = 0.01). Aboriginal children of highest SES status had a BMI SDS 0.16 higher than non-Aboriginal children, whilst Aboriginal children of lowest SES had mean BMI SDS 0.17 lower than non-Aboriginal children.

Conclusions: Socio-economic status has a differential effect on adiposity for Aboriginal children, similar to that seen in low middle income countries. Interventions to reduce the prevalence of obesity are needed, and within the Australian Aboriginal community they need to also focus on those who are of socioeconomic advantage to maximise their impact.

Prevalence of Chronic Kidney Disease in a Brazilian Former Slave Population: Preliminary Findings from the Prevrenal Study

Joao Victor Salgado,[1] Joyce S. Lages,[1] Giselle Andrade dos Santos Silva,[1] Dyego Jose de Araujo Brito,[1] Elisangela Milhomem Santos,[1] Vinicius Giuliano G. Mendes,[1] Francisco Chagas Monteiro Jr,[2] Ricardo Sesso,[3] Natalino Salgado Filho.[1] *[1]Nephrology, Univ Hospital of Federal Univ of Maranhão, São Luís, Maranhao, Brazil; [2]Cardiology, Univ Hospital of Federal Univ of Maranhao, São Luís, Maranhao, Brazil; [3]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: In Brazil, ethnic minority populations, such as indigenous and former slave communities, still live in isolated regions, which results in lack of awareness of chronic kidney disease in these groups. The PREVRENAL study was established to investigate the prevalence of CKD in a Brazilian former slave population.

Methods: The PREVRENAL was designed as a cohort study and has been conducted by a multidisciplinary staff from the Federal University of Maranhão and in technical cooperation with the Federal University of São Paulo Brazil. PREVRENAL studied afro-descendant patients with restricted access to public health system. This population was recruited from 32 remaining quilombos communities of the municipality of Alcântara, state of Maranhão, northeast Brazil. Firstly, all patients underwent extensive clinical and laboratory evaluation, including GFR estimation using the CKD-EPI formula. The diagnosis of systemic hypertension (SH) was based on arterial blood pressure ≥ 140/90 mmHg or documented antihypertensive drug therapy. We considered as reduced the eGFR lower than 60ml/min/1,73m² and as albuminuria the spot urine creatinine/albumin ratio >30 mg/g.

Results: A total of 1.539 participants were enrolled with mean age ± SD of 44.3 ±17.6 yr; 51.4% were women, and 21.3% had an age ≥ 60 yr. Approximately 30% of the patients were identified as hypertensive and 4.5% had diabetes. Reduced eGFR and albuminuria were found in 6.4% and 7.3% of the patients, respectively.

Conclusions: Although, roughly one-third of the participants are hypertensive, the prevalence of CKD was lower than those described in other population studies. Particularities related to the lifestyle of the current population may explain this finding.

Funding: Government Support - Non-U.S.

SA-PO853

Prevalence of Chronic Kidney Disease among Persons with Serious Mental Illness

Donald G.O. Mitema,[1] Airong Yu,[2] Deidra C. Crews,[1] Edgar R. Miller,[2] Lawrence J. Appel,[2] Gail Daumit.[2] *[1]Dept of Medicine/Nephrology, Johns Hopkins Univ School of Medicine, Baltimore, MD; [2]Div of General Internal Medicine, Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Background: The prevalence of CKD in persons with serious mental illness (SMI) is uncertain, but likely under-recognized in spite of their increased risk of cardiovascular disease, use of nephrotoxic medications (e.g., lithium), and premature mortality.

Methods: The baseline prevalence of CKD among 288 overweight/obese adult ambulatory participants with SMI in a multi-center behavioral weight loss intervention study was compared with age, sex, race and overweight/obesity matched participants of the 2009-2010 National Health and Nutrition Examination Survey. CKD was defined as eGFR of 15-59 mL/min/1.73 m². SMI was defined by a diagnosable (DSM III-R) mental, behavioral, or emotional disorder that resulted in functional impairment or limited major life activities.

Results: Persons with SMI had a mean age of 45 years. 50% were male and 38% were non-Hispanic black. 58% of the participants had schizophrenia or a schizoaffective disorder, 22% had bipolar disorder, and 12% had major depression. The prevalence of CKD among persons with SMI was 9.5% (95% CI 3.7-10.5) compared with 3.2% (CI 2.2-4.3) in NHANES. Participant characteristics by CKD status in the SMI cohort and NHANES indicate that CKD in SMI occurred at earlier age and in persons without diabetes (see Table).

Participant Characteristics by CKD Status						
	SMI Cohort			NHANES 2009-2010		
	Non-CKD *n=259*	CKD *n=29*	p value	Non-CKD *n=3516*	CKD *n=236*	p value
Mean age (years)	44.5	53.5	<0.0001	45.2	63.1	<0.001
Male (%)	50	55	0.58	51	41	0.197
Non-Hispanic Black (%)	39	28	0.245	37	47	0.003
Mean BMI (kg/m²)	36	36	0.85	32	35	0.18
Diabetes (%)	29	21	0.35	12	43	0.042
HTN (%)	57	79	0.02	41	83	<0.001
HIV (%)	0	4	0.002	0.5	9	0.35
Hepatitis B or C (%)	5	10	0.21	3	5	0.72
Lithium (%)	12	10	0.96			

Conclusions: The prevalence of CKD among persons with serious mental illness may be more than 3 times that of the general population, and is present at a younger age. Studies examining causal/temporal relationships between SMI and CKD are warranted to guide risk modification in this high risk population.

SA-PO854

Racial Variation in Renal Conditions after Living Kidney Donation

Krista L. Lentine,[1] Janet E. Tuttle-Newhall,[1] Amit X. Garg,[2] Daniel C. Brennan,[3] Dorry L. Segev.[4] *[1]Saint Louis Univ; [2]Univ W Ontario; [3]Washington Univ; [4]Johns Hopkins.*

Background: Recent studies have raised concerns for increased risks of renal failure among African American (AA) and biologically related living kidney donors (LKD).

Methods: We examined a novel database that links national U.S. transplant identifiers for LKD (1987-2007) to billing claims from a private health insurer (2000-2007 claims) to identify post-donation categories of non-infectious renal diagnoses as reported by ICD-9 coding. Cox regression with left and right-censoring was used to estimate the cumulative incidence of diagnoses over time after donation, and associations (adjusted hazards ratios, aHR) of donor traits with study outcomes.

Results: Among 4650 sampled LKD, 13.1% were AA and 76.3% were white race; 81% were biologically related to their recipient (including 88% of AA, and 79% of white LKD). Median time from donation to end of insurance data was 7.7 yrs. Diagnosis of any renal condition was reported in 14.9% of AA versus 9% of white LKD by 7 yrs post-donation. Compared with white LKD, AA LKD experienced trends towards increased likelihoods of all the renal diagnoses after donation; statistical significance (P<0.05) was reached for nephrotic syndrome (aHR 15.7), chronic kidney disease (aHR 2.32), proteinuria (aHR 2.27) and the composite of any renal diagnosis (aHR 1.71) (**Table**). Associations persisted, and also included coded renal failure (aHR 2.28), after adjustment for biological relationship to recipient. AA race was also associated with increased renal risk among samples limited to related LKD.

RACIAL VARIATION IN RENAL CONDITION DIAGNOSES AFTER LIVING KIDNEY DONATION

	Age & Sex-Adjusted 7 yr Incidence		Adjusted Impact of AA vs White Race
	White	African American	
	(%)	(%)	aHR (95% CI)
Nephrotic syndrome	0.1	1.3	15.7 (2.97-83.0)†
Nephritis & nephropathy	0.9	1.7	1.99 (0.73-5.44)
Acute kidney failure	1.0	1.7	1.69 (0.57-5.66)
Chronic kidney disease	5.6	12.6	2.32 (1.48-3.62)†
Renal failure, unspecified	1.6	2.6	2.23 (1.00-4.98)*
Disorders from impaired renal function	0.9	1.8	2.14 (0.77-5.94)
Proteinuria	3.6	5.7	2.27 (1.32-3.89)†
Any renal diagnosis	9.0	14.9	1.72 (1.23-2.41)†

Incidence adjusted to average sample age & sex distribution at donation
aHR, adjusted hazards ratio; * P=0.05; † P <0.05

Conclusions: AA race is associated with increased likelihood of renal diagnoses after living kidney donation, independent of biological relationship to the recipient. Future research to identify prognostic markers for renal outcomes among higher risk LKD is warranted.

SA-PO855

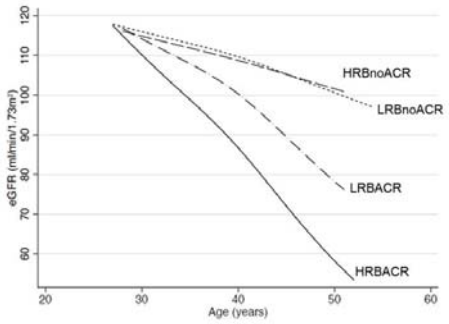
Onset of *APOL1* Kidney Disease Manifests as Incident Albuminuria and Declining Glomerular Filtration Rate but Does Not Fully Explain Race Differences

Carmen A. Peralta,[1] Kirsten Bibbins-Domingo,[1] Jeffrey B. Kopp,[2] Cheryl Ann Winkler.[2] *[1]Medicine, Univ of California San Francisco, San Francisco, CA; [2]Kidney Diseases Branch, National Inst Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: The role of *APOL1*, socioeconomic position (SEP) and traditional risk factors in explaining race differences in albuminuria and kidney function decline in a community-based sample of young healthy adults is unknown.

Methods: We included 3,031 Blacks and Whites with repeated measures of cystatinC (eGFRcys) and ACR in CARDIA (Years 10, 15, 20). We categorized blacks as high risk (HRB) if they had 2 *APOL1* risk alleles and low risk (LRB) if 0/1 alleles. We examined differences in incident albuminuria (ACR ≥ 30 mg/g) and annualized rates of eGFRcys decline, by generalized models adjusting for age, gender, income, education, caretaker education, smoking, BMI, systolic blood pressure, and diabetes.

Results: At baseline, mean age was 35±3.6 and eGFRcys 111 ± 12 ml/min/1.73m². 13.2% of Blacks had high risk *APOL1*. Risk of incident albuminuria was increased in both HRB (HR4.83, 2.80-8.35) and LRB (HR2.06, 1.45-2.93), compared with whites (age and sex adjusted). Associations were moderately attenuated after full adjustment in HRB (HR3.60, 2.02-6.41), and lost significance in LRB (HR 1.41, 0.95 to 2.10). *APOL1* status was associated with eGFRcys decline only among blacks with albuminuria during follow up (p-interaction *APOL1**ACR 0.005).



Age	High risk with albuminuria vs. low risk no albuminuria	High risk no albuminuria vs. low risk no albuminuria	Low risk with albuminuria vs. low risk no albuminuria
30	0.001	0.96	0.02
35	0.04	0.98	0.01
40	<0.001	0.59	<0.001
45	0.02	0.54	<0.001
50	<0.001	0.55	<0.001

eGFRcys decline was fastest in HRB with albuminuria: (3.4% ml/min/1.73m^2 (2.9%-3.8%) per year), followed by LRB with albuminuria, 2.1% (1.9%-2.4%), compared with 0.8% (0.7-0.9%) in whites.

Conclusions: Onset and progression of *APOL1* kidney disease is characterized by albuminuria and reduced eGFR. However, reduction of race disparities in CKD requires strategies for detection and management among Blacks with and without *APOL1*.

SA-PO856

Association of Perceived Racial Discrimination and Kidney Function Decline among African Americans and Whites Angedith Poggi-Burke,[1] May A. Beydoun,[1] Alan B. Zonderman,[1] Michele Kim Evans,[1] Deidra C. Crews.[2] *[1]NIA, NIH; [2]Johns Hopkins U.*

Background: Psychosocial factors such as perceived racial discrimination (PRD) have been associated with chronic diseases including hypertension, however, little is known about the relationship of PRD with kidney function decline (KFD).

Methods: We examined whether PRD was associated with KFD over 5 years of follow-up in the Healthy Aging in Neighborhoods of Diversity across the Life Span study (Baltimore, MD). A total of 1,574 participants (whites=630; African Americans (AAs)=944) aged 30-64 years at baseline were included. PRD was defined using an adaptation of the Experience of Racial Discrimination questionnaire. Mixed-effects regression models with random intercepts and slopes were used to compare linear trends in mean estimated GFR (eGFR), with adjustment for age, sex, race, education, poverty status, tobacco use, body mass index, hypertension and diabetes status.

Results: A total of 319 (20%) participants reported 'a lot' of PRD, and these persons were more likely to be AA, male, more educated, but were less likely to have diabetes mellitus than those reporting none or 'some' PRD. Overall, PRD was significantly associated with KFD. Sex and race stratified models revealed PRD was associated with decline in eGFR only among AA women.

Change in eGFR over 5 Years of Follow-Up (95% Confidence Interval) by Baseline Perceived Racial Discrimination

RD	N	Overall (N=1574)	Whites (N=630)	AA (N=944)	AA Men (N=382)	AA Women (N=562)
Not at all	459	Ref	Ref	Ref	Ref	Ref
A little/ Some	796	-0.5 (-2.4, 1.5)	-0.1 (-2.3, 2.0)	-.7 (-3.8, 2.5)	0.6 (-5.3, 6.4)	-0.9 (-4.7, 2.9)
A lot	319	-2.5 (-5.0, -0.1)*	0.8 (-3.5, 5.1)	-3.0 (-6.5, 0.5)	0.1 (-6.0, 6.2)	-4.9 (-9.4, -0.5)*

* p-value < 0.05

Note: Sex stratified results provided only for AAs, as association NS among whites.
Models were adjusted by sociodemographic, lifestyle and health-related factors.
Baseline systolic blood pressure mediated 14.9% (95% CI 11.4, 19.4%) of this association.

Conclusions: Perceived racial discrimination, a psychosocial stressor, may impact risk of KFD, particularly among AA women. Stressors such as PRD, are worthy of further study regarding their potential contributions to disparities in kidney disease.

Funding: Other NIH Support - National Institute on Aging Intramural Research Program

Racial and Ethnic Differences in Pre-ESRD Care in U.S. Counties Guofen Yan,[1] Keith C. Norris,[2] Alfred K. Cheung,[3] Wei Yu,[1] Jennie Z. Ma,[1] Tom Greene.[3] *[1]Univ of Virginia; [2]UCLA; [3]Univ of Utah.*

Background: While prior studies document that racial and ethnic minorities are less likely to receive specialist care before ESRD, our understanding of the geographic contribution to this disparity is limited. We therefore examined whether this national difference exists within small geographic units, such as individual counties (i.e., county-level disparity).

Methods: We identified incident patients in the USRDS aged ≥18 years who initiated first dialysis between 2005 and 2010. The analysis for black-white comparison included 1270 counties that had ≥5 patients of each race, resulting in 346,368 patients (39.3% non-Hispanic blacks and 60.7% non-Hispanic whites). The Hispanic-white analysis included 613 counties with ≥5 patients of each race, resulting in 224,286 patients (25.7% Hispanics and 74.3% non-Hispanic whites). We examined two pre-ESRD care indicators (yes/no): nephrologist care at least 12 months before ESRD and arterio-venous fistula (AVF) at first outpatient dialysis. Using two-stage logistic regression, we obtained the disparity estimate for each county, expressed as county-specific odds ratio (CSOR) of black (or Hispanic) versus white in receiving such care.

Results: Overall, the percentage of patients who received pre-ESRD nephrologist care was lowest in Hispanics (20.0%), intermediate in blacks (23.8%), and highest in whites (30.0%). There was a similar disparity for AVF with 11.6%, 12.1%, and 14.7%, respectively. After covariate adjustment, the significant disparity for blacks versus whites in receiving nephrologist care was evident in 66.9% (849/1270) of counties (CSOR ranging from 0.46 to 0.9). The significant disparity for Hispanics versus whites in nephrologist care was evident in 96.7% (593/613) of counties (CSOR from 0.52 to 0.9). Counties with larger disparity level (CSOR<0.8) tended to be of lower socio-economic status and healthcare resources, and were more likely to be located in the South and large metropolitan areas.

Conclusions: Although disparities in pre-ESRD care were more likely in certain geographic areas, they existed in diverse locations and in most U.S. counties. Therefore, efforts to improve pre-ESRD care should be implemented nationally rather than regionally.

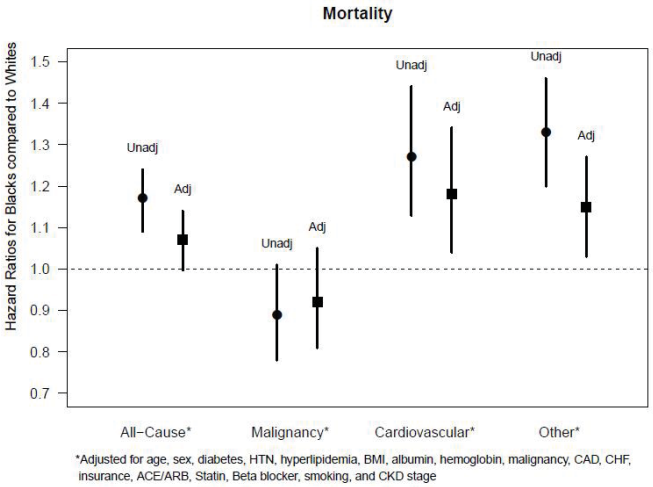
SA-PO858

Causes of Death Are Different between Whites and Blacks with Non-Dialysis Dependent Chronic Kidney Disease Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Susana Arrigain,[2] Victoria Konig,[2] Stacey Jolly,[3] Joseph V. Nally.[1] *[1]Nephrology, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]Medicine, Cleveland Clinic.*

Background: Chronic kidney disease (CKD) is associated with a higher risk of death overall, but cause specific death is less known. Using a large CKD registry and state death data, we examined the leading causes of death and assessed if racial differences existed among a non-dialysis CKD population.

Methods: We obtained death and cause-specific mortality details from the Ohio state death index for 46,785 white and black patients who had CKD (two estimated GFR <60 ml/min/1.73 m^2 90 days apart or had an ICD-9 code for various kidney disease) and resided in the state of Ohio between January 2005 and September 2009. We classified the causes of death as reported by the Center for Disease Control and racial differences were explored using Cox Proportional hazards model.

Results: During the study period, 7358/46,836 CKD patients died during a median follow up of 2.3 years. Overall, malignant neoplasms (31.9%) and heart disease (28.1%) were the leading causes of death. Among whites, malignant neoplasm (33.1%) is the leading cause of death while among blacks the leading cause of death is heart disease (30.3%). In the adjusted models, blacks had similar overall-mortality hazard ratios compared to Whites. However, blacks had higher hazard ratios for cardiovascular death and deaths due to other causes (non-cardiovascular and non-malignant) compared to whites in both unadjusted and adjusted models.



Conclusions: Malignancy and cardiovascular diseases were the leading causes of death among those with CKD. Blacks were more likely to die of cardiovascular disease and due to non-malignant, non-cardiovascular reasons compared to whites. Future studies are needed to understand the reasons for these differences so that interventions can be designed to improve outcomes.

SA-PO859

Assessment of Racial Disparity in Mortality Among Patients with End Stage Renal Disease due to Systemic Lupus Erythematosus
Jorge I. Martinez Osorio,[1] Christina M. Yuan,[1] Dustin J. Little,[1] Maura A. Watson,[1] Lawrence Agodoa,[2] Kevin C. Abbott,[1] Robert Nee.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Insts of Health, Bethesda, MD.*

Background: A recent study showed an increased risk for mortality in African American (AA) patients with end-stage renal disease (ESRD) secondary to lupus nephritis (LN). Our study aim is to assess the impact of socioeconomic factors and kidney transplantation on the racial disparity in survival of this patient population.

Methods: Using the United States Renal Data System database, we identified 12,350 patients with LN as the cause of ESRD in a retrospective cohort of 1,125,365 patients, initiated on chronic dialysis between January 1, 1995 to December 31, 2006, followed until December 31, 2010. We merged data on median household income from the United States Census based on the ZIP code.

Results: In multivariate Cox regression analyses, AA patients with LN (versus non-AA) had an increased risk of death (adjusted hazard ratio [AHR], 1.18; 95% confidence interval [CI], 1.11-1.25). Adjusting for income and insurance status, the AHR was 1.09 (95% CI 1.02-1.15). Further adjustment for kidney transplantation as a time-dependent covariate resulted in an AHR 0.99 (95% CI 0.93-1.05). AA patients were significantly less likely to receive a kidney transplant than non-AA with LN (29.5% versus 41.8%, p<0.001).

Conclusions: Contrary to the lower mortality rate among AA patients in the general ESRD population, AA with LN were at increased risk of death which was attenuated by income and kidney transplantation. The apparent higher risk of death among AA with ESRD due to LN appears mediated substantially by lower rates of kidney transplantation. *The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy of the Department of the Army, the Department of the Navy, the Department of Defense, or the U.S. government.*

SA-PO860

Profound Impact of Community Risk Factors on Time to Death and Dialysis Initiation among Patients with Chronic Kidney Disease
Jesse D. Schold, Sankar D. Navaneethan, Stacey Jolly, Susana Arrigain, Victoria Konig, Joseph V. Nally. *Cleveland Clinic, Cleveland, OH.*

Background: Numerous factors explain outcomes in the general population beyond individual demographic characteristics and clinical diagnoses. We hypothesized that community risk factors were independently associated with outcomes of Chronic Kidney Disease(CKD) patients.

Methods: The study population derived from a single center registry of CKD patients within our state identified by laboratory measurements and diagnosis between 2005-09(n=46,735), follow up to 2011. We merged data with a national registry(CountyHealthRankings) which compiles risks for >25 medical and social characteristics for each U.S. county derived from the CDC, U.S. Census, Dartmouth Health Atlas(among others) based on patients' primary zip code. We generated a community risk score and evaluated the independent association with time to death and dialysis(validated by USRDS) using multivariable Cox models.

Results: Patients' community risk score ranged from 5(0=lowest risk) to 40(highest risk); mean=25,std=6. Patients in high risk communities(>=30) were more likely young, African American, male, lower eGFR at CKD diagnosis and Medicaid primary insurance. Following adjustment for baseline eGFR, numerous comorbid conditions, demographics and insurance status, patients from highest risk communities had independent significant risks for death(Adjusted Hazard Ratio[AHR]=1.26,95% C.I. 1.15-1.37), dialysis initiation(AHR=1.71,95% C.I. 1.32-2.21) and composite endpoint of death or dialysis(AHR=1.34,95% C.I. 1.21-1.48). Risks were slightly attenuated but remained highly significant with adjustment for zipcode level household income.

Conclusions: CKD patients from high risk communities have significantly higher rates of death and dialysis initiation. Risk factors in patients communities are likely a proxy for multiple factors including underlying comorbid conditions, socioeconomic status, access to and quality of healthcare and environmental and behavioral risks. Tailored treatment for CKD patients from high risk communities is an important aspect of patient-centric care and further understanding of mechanisms for these associations are needed to identify effective interventions.

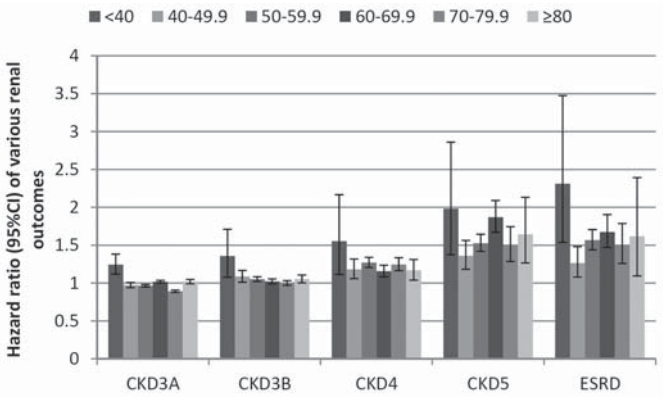
SA-PO861

Association of Age and African American Race with Incidence of CKD
Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[2] Robert L. Davis,[2] Jun Ling Lu,[2] Jennie Z. Ma,[3] L. Ebony Boulware,[4] Keith C. Norris,[5] Kamyar Kalantar-Zadeh.[6] *[1]Memphis VAMC; [2]Univ of Tennessee; [3]Univ of Virginia; [4]Duke Univ; [5]UCLA; [6]Univ of California Irvine.*

Background: African Americans (AA) are disproportionately affected by CKD. It is unclear if the risk of CKD associated with AA race is different in younger versus older individuals.

Methods: We examined the incidence of CKD stages 3a, 3b, 4, 5 and ESRD in a nationally representative cohort of over 2.8 million U.S. veterans (n=517,980 AA and n=2,355,829 white) with baseline eGFR >=60 ml/min/1.73m^2. Associations were examined in Cox models, adjusted for age, gender, baseline eGFR, comorbidities, BP, BMI, markers of socioeconomic status, adherence with medical interventions, and medication use. The effect of age on the association of AA race with CKD incidence was examined by categorizing patients into 6 age groups (<40 (N=226,522); 40-49.9 (N=369,269); 50-59.9 (N=900,811); 60-69.9 (N=651,711); 70-79.9 (N=521,530) and >=80 years (N=202,083)).

Results: Patients' mean (SD) age was 60.0 (13.6) years, 94% were male, and the mean (SD) baseline eGFR was 84 (16) ml/min/1.73m^2. Events occurred in 586,611 (CKD3a); 136,210 (CKD3b); 27,560 (CKD4); 8,705 (CKD5), and 6,756 (ESRD) patients. AA race was associated with overall adjusted HRs (95%CI) of 0.96 (0.95-0.97), 1.04 (1.02-1.06), 1.25 (1.21-1.29), 1.61 (1.54-1.70) and 1.58 (1.49-1.68) for CKD stages 3a through ESRD, respectively. The HR (95%CI) of various CKD stages associated with AA race in the different age categories was highest in patients <40 years old and tapered with advancing age (Figure).



Conclusions: AA race is associated with increasing risk for more advanced stages of CKD. At all stages (3a-ESRD) the risk of CKD associated with AA race is highest in younger individuals. Screening and preventive efforts aimed at lowering CKD incidence in AA individuals should focus on the youngest age groups.

Non-Pharmacological Interventions for Improving Sleep Quality in CKD Patients: Systematic Review and Meta-Analysis
Bo Yang, Zhiguo Mao. *Dept of Nephrology, Changzheng Hospital, Second Military Medical Univ, Shanghai, China.*

Background: Growing evidence indicates favourable effects and less adverse events of non-pharmacological interventions (NPIs) on primary sleep disorders. But the results of clinical research in CKD population were conflicting. We conducted the meta-analysis to quantify the effects of NPIs for improving sleep quality in CKD patients.

Methods: We searched PubMed, EMBASE, WOS, Cochrane Library and clinicaltrials.gov (up to Dec. 2013) for RCTs and prospective cohort studies comparing effects and safety of NPIs versus standard control in CKD patients. Meta-analyses were used to compute changes in mean values for PSQI score (including its constituent) and relative risks for binary outcomes.

Results: We identified 12 RCTs including 709 patients and one prospective cohort study involving 14 patients. There was a significant global PSQI score reduction in the NPI groups over the control (SMD 1.50, 95% CI 0.91 to 2.09). All three types of NPIs could result in a greater PSQI score reduction: 1) cognitive-behavioural therapy (CBT) (SMD 0.85, 95% CI 0.37, 1.34); 2) physical training (PE) (SMD 3.36, 95% CI 2.16, 4.57) and 3) acupuncture and its variants (ACU) (SMD 1.77, 95% CI 0.80, 2.73). CBT may shorten sleep latency, alleviate sleep disturbance and reduce the use of sleep medications. ACU may ameliorate subjective sleep quality, shorten sleep latency, elongate sleep duration, increase habitual sleep efficiency and improve daytime function of patients. Intervention of CBT and ACU can significantly alleviate fatigue, but PE could not alleviate subjective feeling of fatigue. The finding of the cohort study suggested sleep quality improvement for intradialytic aerobic exercise training on HD patients with restless leg syndrome.

Conclusions: NPIs can improve the general sleep quality in CKD patients. However, the evidence is confined to the ESRD patients on dialysis. CBT, furthermore, could shorten sleep latency, alleviate sleep disturbance and reduce the use of sleep medications. ACU and PE are promising interventions but the results in these subgroups are needed to be interpreted cautiously due to the concern of methodological quality and potential confounding factors.

The Impact of Socioeconomic Status as an Unmeasured Confounder for Claims Based, Comparative Analysis of Dialysis Provider Type and Its Effect on Dialysis Unit Economics
Fadi Almachraki,[1] Michael Tuffli,[1] Paul Lee,[1] Mark Desmarais,[2] Huai-Che Shih,[2] Allen R. Nissenson,[1] Mahesh Krishnan.[1] *[1]DaVita HealthCare Partners, Denver, CO; [2]The Moran Company, Arlington, VA.*

Background: Socioeconomic (SES) factors demonstrably affect health care outcomes (worse outcomes are associated with poverty and rural/urban areas). For dialysis patients, outcomes have been shown to vary by SES. Yet, previous research comparing provider types does not adjust for potential SES confounding. We used geomapping to demonstrate the distribution of SES factors by dialysis provider types.

Methods: Using the Dialysis Facility Compare files (Centers for Medicare and Medicaid Services) and business rules from the Dialysis Outcomes and Practice Patterns Study, dialysis providers were categorized as large (LDO), medium (MDO), small (SDO), hospital/university/government (HUG), for-profit (FP), and non-profit (NP). Poverty by zip code was obtained from 2012 census data. Geography definitions were obtained from the Office of Management and Budget. The Local Indicator of Spatial Association was calculated for poverty in each county. By county, the index of spatial autocorrelation was calculated based on bordering counties.

Results: Variability existed between dialysis provider types and SES factors. A majority of clinics were owned by LDOs (69%; MDO 12%; SDO 10%, HUG 10%) and FP providers (82%; NP 15%; unknown 3%). While providers were concentrated in urban areas, LDOs disproportionately (65%) served rural areas as did FP providers (78%). In high poverty areas, LDOs owned a majority of clinics (metropolitan, 69%; micropolitan, 75%; rural, 75%) and 66% of clinics in extremely poor areas. Similarly, FP providers owned a majority of clinics in poor areas (metropolitan 84%; micropolitan 85%; rural 90%) and 87% of clinics in extremely poor areas.

Conclusions: Due to negative impact of low SES on dialysis-related outcomes plus the over representation of FP LDOs in areas of low SES, the issue of unmeasured confounding emerges. Results suggest that dialysis provider types should be compared using adjustments for SES confounders. Furthermore, in urban, rural, and poverty areas, FP LDOs operate a disproportionate number of clinics.

Associations of Obstructive Sleep Apnea and Cardiovascular Outcomes in Patients with End Stage Renal Disease: A Systematic Review and Meta-Analysis Manoj Das, Shashikumar Yellappa, Qasim Malik, Michael Saleeb, Louis Romel Crevecoeur, Anita A. Kumar, Ghanshyam Palamaner Subash Shantha. *Internal Medicine, The Wright Center For Graduate Medical Education, Scranton, PA.*

Background: Obstructive sleep apnea (OSA) increases risk for cardiovascular outcomes in the general population. Small observational studies that assessed these associations in patients with end stage renal disease (ESRD) lacked precision. Hence, this systematic review and meta-analysis is an effort to pool all available evidence to identify the associations of OSA and cardiovascular outcomes in patients with ESRD.

Methods: Medline, Embase, Cochrane central library, and electronic databases were searched for relevant studies in all languages and without time restriction. Studies were included if: 1) they studied patients with OSA and ESRD, and 2) reported cardiovascular outcomes; stroke, coronary artery disease (CAD) and cardiovascular mortality. Two investigators independently reviewed retrieved citations and assessed eligibility. Discrepancies were resolved by consensus. Data were pooled using a random-effects model.

Results: From a total of 3977 retrieved citations, 5 observational studies were included, representing 1850 patients with ESRD (37% with OSA and 67% without OSA). All 5 were sleep clinic based studies, 4 used apnea-hypopnea index (AHI) > 5 events/hour to define OSA, while 1 defined OSA if AHI was > 15 events/hour. In the pooled analysis, ESRD patients with OSA were at a higher odds for stroke (OR: 1.97, 95% CI: 1.58 – 2.85, P = 0.03, I^2: 48%, 5 included studies), but not CAD (OR: 0.91, 95% CI: 0.57 – 1.51, P = 0.56, I^2: 74%, 4 included studies) or cardiovascular mortality (OR: 1.11, 95% CI: 0.71 – 1.48, P = 0.31, I^2: 63%, 4 included studies) when compared to ESRD patients without OSA. Factors responsible for high heterogeneity between studies could not be assessed due to lack of relevant data.

Conclusions: ESRD patients with OSA are at higher odds for developing stroke. Possible determinants in this association; atrial fibrillation and obesity, need assessment in future studies. Since, all were sleep clinic based studies, population based studies are needed to eliminate selection bias in this association.

SA-PO865

The SNORE Study: Baseline Data from a Longitudinal Study of Sleep Apnea and CKD Progression Nicole Kay,[1] Areef Ishani,[2] I. David Weiner,[1,3,4] Richard Berry,[1,4] Rebecca Beyth,[1,4] Muna T. Canales.[1,3,4] *[1]Malcolm-Randall VAMC; [2]VAMC, Minneapolis, MN; [3]Div of Nephrology; [4]Dept of Medicine, Gainesville, FL.*

Background: Identification of new modifiable risk factors to slow progression of CKD could substantially improve clinic outcomes. We hypothesize that sleep apnea(SA), through recurrent episodes of hypoxia, hypercapnia and arousal during sleep, may be a novel risk factor for CKD progression and poor quality of life(QOL).

Methods: The SNORE Study is an ongoing prospective study of 250 veterans with eGFR of 15-44 ml/min/1.73m^2. At baseline, veterans undergo sleep study, renal function measures, KDQOL-SF and Epworth Sleepiness Scale (ESS). Renal function and QOL are re-assessed annually. SA was defined by the apnea-hypopnea index (AHI, at cut-points of 5, 15, 30 events/h for mild, moderate, severe). Outcomes of the study are time to doubling of SCr or ESRD, and change in KDQOL-SF scores. Enrollment will occur over 2y with 3y follow-up for each veteran.

Results: Enrollment began 3/18/14; as of 5/1/14, 134 subjects have been enrolled. Mean age was 75±9y; 98% were male; 82% were Caucasian; Mean BMI was 30±5 kg/m^2. 95% had HTN, 46% had DM; mean eGFR was 34±9 ml/min/1.73m^2, median [IQR] ACR, 43[12-210]. By KDQOL-SF, 25% reported excellent or very good health. Physical and Mental Health Component Summary Scores were 38.9±10 and 51.3±10, respectively. Burden of kidney disease and sleep (pre-specified domains) were 81±22 and 62±19, respectively. 44% had excessive daytime sleepiness(ESS>10). From the 73 scored studies to date, median[IQR] AHI was 11[4-22]; with no, mild, moderate, severe SA in 30%, 29%, 25%, 16%, respectively. Baseline eGFR did not correlate with severity of SA(p trend 0.67). An ACR≥30 was present in 41% without SA versus 65% with any SA(p=0.06).

Conclusions: The SNORE Study is on track to complete enrollment as planned. The prevalence of SA and daytime sleepiness is high among veterans with CKD. Veterans with SA are more likely to have albuminuria than those without SA. QOL is comparable to other studies of non-veteran populations with CKD. Once complete, the SNORE Study will provide much needed longitudinal data regarding the impact of SA on CKD progression and QOL in veterans with CKD.

The Factors Associated with Arrhythmia During Dialysis Course in Maintained Hemodialysis Patients Lixia Xu, Liyi Mo, Lu Cai, Wei Dong, Yiming Tao, Ruizhao Li, Jianxun Wu, Chenggen Xiao, Xinling Liang, Wei Shi. *Hemodialysis Center, Guangdong General Hospital, Guangdong Academy of Medical Science, Guangzhou, Guangdong, China.*

Background: Cardiovascular mortality and morbidity are high in maintained hemodialysis patients. Arrhythmia is known to predispose to sudden cardiac death. This study was conducted to assess the occurrence of arrhythmia during dialysis course and analyze the factors of arrhythmia in these patients.

Methods: Two hundred and forty-eight maintained hemodialysis patients were assessed by standard examination including heart rate, 15-lead electrocardiography and laboratory tests like electrolytes (Na (+), K (+), Ca (++), Mg(++) phosphate), urea, and creatinine, uric acid, blood glucose at beginning, 2h, ending of HD. The PR intervals, QRS duration and QT intervals for each lead were measured manually by one observer using calipers. Patients with arrhythmia at beginning of dialysis were excluded.

Results: Arrhythmia is found in 128 patients during dialysis course. The age, baseline heart rate and heart rate variability during dialysis course were comparable between the two groups. The mean PR intervals, QRS duration of pre, 2h and post dialysis increased significantly in arrhythmia group (pre 178.35±37.71ms versus 169.95±30.35ms and 103.01±61.88ms versus 87.68±9.45ms, 2h 171.79±31.20ms versus 164.31±22.39ms and 98.52±19.08ms versus 88.98±9.62ms, post 174.64±36.84ms versus 162.91±24.27ms and 102.42±34.44ms versus 90.33±9.31ms respectively $p<0.05$). The mean of QT dispersions and the corrected QT interval dispersions changed were similar in two groups. The baseline urea, electrolytes, uric acid were comparable between two groups, only the creatinine level of arrhythmia group was lower than the other one (956.06±287.31mmol/L versus 1033.01±317.91mmol/L $p<0.05$). The rate of serum phosphate descent at 2h of dialysis course was lower in arrhythmia group (45.29±11.88% versus 48.85±8.50%).

Conclusions: PR interval and QRS duration prolongation were correlated with attack of arrhythmia in maintained hemodialysis patients. Serum phosphate clearance increase maybe depresses the arrhythmia.

SA-PO867

Impact of Ventricular Arrhythmia in Chronic Kidney Disease Patients after 24 Months of Follow-Up Fabiana Oliveira Bastos Bonato,[1] Marcelo Lemos,[1] Jose Luiz Cassiolato,[2] Renato Watanabe,[1] Maria Eugenia F. Canziani.[1] *[1]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Cardiology, Cardios, Sao Paulo, SP, Brazil.*

Background: In general population, ventricular extrasystoles are associated with increase in the risk of death. Although arrhythmia is a common finding in chronic kidney disease (CKD) patients, the role of ventricular extrasystoles in this population remains unknown. In this study, we aimed at evaluating the impact of ventricular arrhythmias (VA) on cardiovascular events, hospitalization and mortality in a nondialyzed CKD population followed for 24 months.

Methods: This prospective study evaluated 109 CKD patients (eGFR 34.8±16.1 mL/min/1.73m², 57±11.4 years, 61% male, 24% diabetics). VA was assessed by 24-hr electrocardiogram. Echocardiogram, multi-slice computed tomography, 24-hr ambulatory blood pressure monitoring and laboratory parameters were performed. The occurrence of cardiovascular events, hospitalization, and death was recorded over 24 months.

Results: At baseline, VA was found in 34% and complex VA in 14% of the patients. During the follow-up, the occurrence of 15 cardiovascular events, 15 hospitalizations, and 4 deaths was registered. The presence of VA was associated with a greater number of deaths ($p = 0.012$) and these patients tended to have more cardiovascular events ($p = 0.088$). The group with complex VA had a superior mortality rate ($p = 0.008$) and a higher frequency of cardiovascular events ($p = 0.006$) and hospitalization ($p = 0.033$). During the 2-yr follow-up, a lower survival was observed in patients with VA ($p = 0.005$) and complex VA ($p < 0.001$). Patients with complex VA had also a shorter cardiovascular ($p = 0.001$) and hospitalization ($p = 0.018$) event-free times. Adjusting for several confounders, complex VA remained as an independent risk factor for cardiovascular events (HR = 16.66, 95%CI = 3.16 - 87.93, $p = 0.001$) and hospitalization (HR = 5.44, 95%CI = 1.26 - 23.52, $p = 0.023$).

Conclusions: The presence of VA in nondialyzed CKD patients should be considered as an adjuvant factor to the risk stratification in this population.

SA-PO868

Comparative Effectiveness of Coronary Revascularization Procedures for Multivessel Coronary Artery Disease in Patients with Chronic Kidney Disease John K. Roberts,[1] Sunil V. Rao,[1] Linda K. Shaw,[1] Dianne Gallup,[1] Oscar C. Marroquin,[2] Uptal D. Patel.[1] *[1]Duke Clinical Research Inst, Duke Univ Medical Center, Durham, NC; [2]Dept of Medicine, Univ of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Patients with CKD are at increased risk for cardiovascular disease and death. Although some studies have compared revascularization strategies in patients with CKD, few account for anatomic differences. We sought to evaluate whether reductions in mortality differed by coronary revascularization strategies across patients with different severity of CKD and multivessel coronary artery disease.

Methods: We created a cohort of 4,687 adults who underwent cardiac catheterization and were found to have multivessel coronary artery disease (CAD; ≥50% stenosis). We used Cox-proportional hazard regression weighted by the inverse probability of treatment to examine the association between four revascularization strategies (medical management, PCI-BMS, PCI-DES, and CABG) and mortality across all strata of eGFR (CKD-EPI) at a median follow up of 5.1 years.

Results: CABG was associated with a reduced risk of death compared with medical management for patients across all levels of eGFR except those on dialysis. Although trends were similar, there were no significant differences in mortality between PCI and CABG except for a decreased risk of death in patients with severe CKD who received CABG relative to bare metal stents. (see table 1)

eGFR (N)	CABG vs Med	CABG vs BMS	CABG vs DES
≥ 60 (3,144)	**0.47 (0.37, 0.6)**	0.78 (0.59, 1.04)	0.99 (0.77, 1.26)
45-59 (760)	**0.59 (0.40, 0.86)**	0.67 (0.43, 1.02)	0.79 (0.54, 1.14)
30-44 (408)	**0.43 (0.29, 0.63)**	0.67 (0.42, 1.06)	0.65 (0.42, 1.0)
< 30 (240)	**0.44 (0.28, 0.68)**	**0.42 (0.24, 0.75)**	0.65 (0.41, 1.02)
Dialysis (135)	0.81 (0.43, 1.53)	0.94 (0.37, 2.38)	0.85 (0.45, 1.64

Conclusions: Compared with medical management, surgical revascularization for multivessel CAD was associated with reduced mortality in patients with CKD who were not on dialysis. Similar, but non-significant trends toward lower mortality were also observed with CABG when compared with PCI. A prospective, randomized trial in patients with CKD is warranted to confirm these findings.

Funding: NIDDK Support

SA-PO869

Geriatric Nutritional Risk Index Predicts Cardiovascular Events in Patients with Pre-Dialysis Chronic Kidney Disease Midori Hasegawa, Hiroshi Takahashi, Kazuo Takahashi, Hiroki Hayashi, Shigehisa Koide, Yukio Yuzawa. *Nephrology, Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan.*

Background: We investigated whether geriatric nutritional risk index (GNRI), developing as a simplified marker of the protein-energy wasting (PEW), predicts adverse cardiovascular disease (CVD) events in pre-dialysis chronic kidney disease (CKD) patients.

Methods: A total of 406 patients with CKD (stage 3; 141, stage 4; 159 and stage 5; 106) were enrolled. The GNRI was calculated using formula as follows; GNRI = (14.89 × serum albumin) + [41.7 × (body weight / body weight at BMI of 22)]. The patients were divided into tertiles according to GNRI levels; tertile 1 (T1): < 95.5, T2: 95.5 – 99.8 and T3: > 99.8, and were followed up for 4 years. CVD events were defined as hospitalization or death due to acute coronary syndrome, worsen heart failure or stroke. To assess additive incremental value of GNRI into an established risk model for predicting of CVD events, C-index, net reclassification improvement (NRI) and integrated discrimination improvement (IDI) were also evaluated.

Results: During follow-up period (median: 31months), 79 CVD events occurred and 32 patients died. Four-year event-free survival rates were 56.9%, 65.0% and 87.9% for CVD events (p<0.0001), and were 79.7%, 90.9% and 95.1% for mortality (p=0.0006) in T1, T2 and T3, respectively. After adjustment for significant risk factors such as age, diabetes, history of CVD, cystatin C, UACR, hemoglobin and hs-CRP on univariate analysis, the GNRI [hazard ratio (HR) 2.84, 95% confidence interval (CI) 1.31-6.13, p=0.0079 for T1 versus T3], history of CVD (HR 3.42, 95%CI 2.09-5.61, p<0.0001) and cystatin C (HR 1.34, 95%CI 1.01-1.78, p=0.042) were identified as independent predictors for CVD events. The addition of the GNRI to a prediction model based on significant risk factors for CVD events had effect on model discrimination as measured by the C-index (0.728 to 0.779, p=0.045) and improved the NRI (0.619, p<0.0001) and the IDI (0.074, p<0.0001). Similar results were also obtained for all-cause mortality.

Conclusions: Declined GNRI levels could strongly predict CVD events and mortality in pre-dialysis CKD patients.

SA-PO870

Annual Decline in Estimated Glomerular Filtration Rate Is a Risk of Cardiovascular Events Independent of Proteinuria Kei Nagai,[1] Kunihiro Yamagata,[1] Chie Saito,[1] Koichi Asahi,[2] Kunitoshi Iseki,[2] Kenjiro Kimura,[2] Toshiki Moriyama,[2] Ichiei Narita,[2] Shouichi Fujimoto,[2] Kazuhiko Tsuruya,[2] Tsuneo Konta,[2] Masahide Kondo,[2] Tsuyoshi Watanabe.[2] *[1]Nephrology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Steering Committee for "Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkups", Japan.*

Background: Chronic kidney disease is a risk factor of the development of cardiovascular disease (CVD). However, it is not clear whether decline of glomerular filtration rate (GFR), not reduced GFR, is a risk factor for the occurrence of CVD independent of proteinuria.

Methods: By using a population-based 521,123 person-years longitudinal cohort receiving the Japanese national health program from 2008 to 2011, we examined whether the annual decline of estimated GFR is a risk factor for CVD development independent of proteinuria by Cox-hazard model.

Results: During the follow-up period, there were 4,426 stroke events and/or 8,298 cardiac events. The median annual changes in eGFR from eGFR at the baseline year were -0.45 (10, 25, 75, or 90 percentile; +8.65, +1.34, -5.33, or -12.43, respectively) % per year among males and -0.44 (10, 25, 75, or 90 percentile; +10.34, +0.21, -4.60, or -13.85, respectively) % per year among females. Rapidly decreasing over 10% per year in estimated GFR was a significant and independent risk factor for the incidence of stroke and cardiac events with covariant adjustment for proteinuria and reduced estimated GFR.

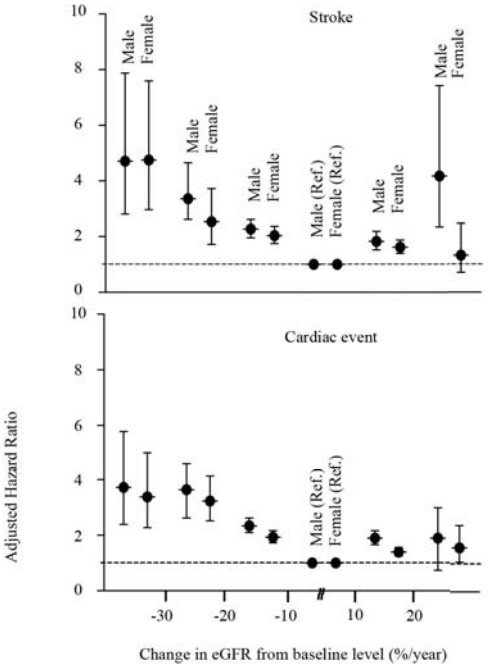

Figure. Multivariable adjusted hazard ratio for the incidence of CVD in subpopulation based on annual change of eGFR.

Adjusted for age, BMI, hypertension category, dyslipidemia, taking anti-dyslipidemia drugs, hyperglycemia, taking hypoglycemic drugs, body mass index, reduced eGFR at baseline, proteinuria and smoking. Bars indicates 95% C.I.

Conclusions: Annual decline of GFR is an independent risk factor for CVD.

SA-PO871

CKD Measures and Future Risk of Peripheral Artery Disease Hospitalizations: The Atherosclerosis Risk in Communities (ARIC) Study Kunihiro Matsushita, Yingying Sang, Shoshana Ballew, M. Grams, Elizabeth Selvin, Bernard G. Jaar, Josef Coresh. *Johns Hopkins Univ, Baltimore, MD.*

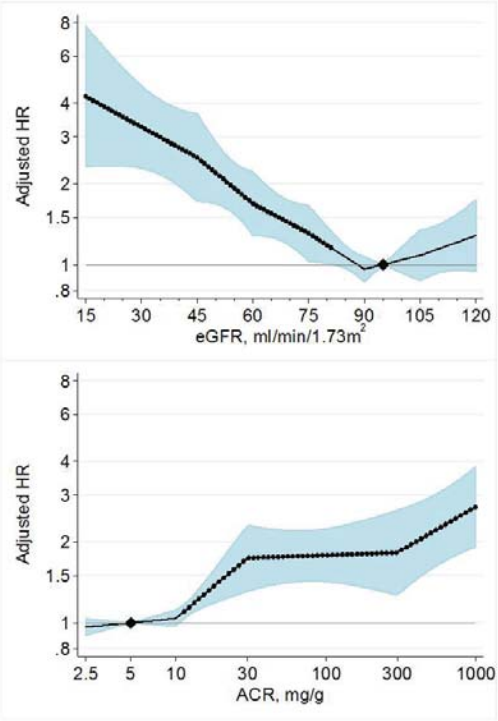
Background: Several studies have reported an association of CKD with peripheral artery disease (PAD). However, most of them were cross-sectional and/or investigated either eGFR or albuminuria, but not both, leaving uncertainty in their respective prospective contributions to PAD risk.

Methods: We studied 9,936 ARIC participants without a history of PAD at baseline (1996-98). Cox models were used to quantify the associations of creatinine-based eGFR and urine albumin-to-creatinine ratio (ACR) with clinically significant PAD-related hospitalizations with adjustment for each other and traditional risk factors.

Hospitalizations were considered "PAD-related" when there was a discharge diagnosis of leg revascularization procedure, ischemic ulcer, gangrene, or amputation. We also evaluated whether eGFR and/or ACR improved PAD risk prediction.

Results: There were 728 PAD hospitalizations during a median follow-up of 14 years (5.8 per 1,000 person-years). Both low eGFR and high ACR were significantly associated with PAD hospitalization risk (Figure). Of note, both eGFR and ACR significantly improved PAD risk discrimination beyond the model with traditional risk factors alone (c-statistic difference: 0.011 (95% CI: 0.004-0.018) with the addition of eGFR; 0.009 (0.001-0.016) with ACR; and 0.016 [0.007-0.025] with both). Results were largely consistent when restricted to the most severe PAD outcomes (ischemic ulcer, gangrene, or amputation).

Conclusions: Both low eGFR and high ACR were independently associated with future PAD hospitalization risk and significantly improved its prediction, suggesting the usefulness of CKD measures to identify high risk patients who may benefit from more intensive PAD risk reduction interventions.



Adjusted for age, sex, race, smoking, diabetes, systolic blood pressure, antihypertensive drugs, total and high-density lipoprotein cholesterols, history of coronary disease, stroke, and heart failure, and each CKD measure.

Funding: Other NIH Support - The Atherosclerosis Risk in Communities Study is carried out as a collaborative study supported by National Heart, Lung, and Blood Institute contracts (HHSN268201100005C, HHSN268201100006C, HHSN268201100007C, HHSN268201100008C, HHSN268201100009C, HHSN268201100010C, HHSN268201100011C, and HHSN268201100012C), Private Foundation Support

SA-PO872

eGFR, Dipstick Proteinuria, and Cause-Specific Mortality in a Large Population-Based Cohort from Korea Yejin Mok,[1,2] Kunihiro Matsushita,[1] Yingying Sang,[1] Shoshana Ballew,[1] M. Grams,[1] Josef Coresh,[1] Sun Ha Jee.[2] *[1]Johns Hopkins Univ, Baltimore, MD; [2]Yonsei Univ, Seoul, Korea.*

Background: The link of chronic kidney disease (CKD) to cardiovascular disease (CVD) mortality is well known. However, its link to mortality due to other causes like cancer is less clear.

Methods: We studied 367,932 adults (20-93 years) in the Korean Heart Study (health check-up database from 14 centers in Korea with baseline between 1994-2004 and follow-up until 2011) and assessed the associations of creatinine-based eGFR and dipstick proteinuria with mortality due to CVD (1,315 cases), cancer (4,035 cases), and other causes (3,445 cases) after adjusting for potential confounders (demographic, lifestyle, and clinical risk factors including history of cancer and CVD).

Results: Low eGFR was significantly associated with CVD, other-cause, and all-cause mortality (Table). Cancer mortality risk demonstrated a J-shaped association with the lowest risk at GFR 45-59 and higher risk at eGFR <45 (reached significance with eGFR 45-59 as a reference [HR 1.64, 95% CI 1.12-2.42]). High proteinuria was consistently associated with mortality due to CVD, cancer and other causes. Examining finer causes of death, low eGFR (<60 versus ≥60) was significantly associated with deaths due to coronary heart disease, oropharyngeal cancer, and diabetes, whereas proteinuria (≥trace versus negative) was related to mortality from coronary disease, stroke, stomach cancer, liver cancer, lung cancer, diabetes, infectious disease, liver disease and chronic obstructive pulmonary disease.

CVD	Reference	1.42 (1.13-1.77)	1.58 (1.35-1.85)	2.37 (1.87-3.01)
Cancer	Reference	1.21 (1.05-1.38)	1.20 (1.09-1.32)	1.54 (1.29-1.84)
Other causes	Reference	1.46 (1.27-1.68)	1.32 (1.19-1.46)	2.61 (2.26-3.01)
All-cause	Reference	1.33 (1.22-1.46)	1.29 (1.21-1.37)	2.10 (1.90-2.32)

Conclusions: Both low eGFR and high proteinuria were independently associated with mortality due to CVD, cancer, and other causes. These findings suggest the need for multidisciplinary prevention and management strategiesin individuals with CKD.

SA-PO873

A Low Baseline Glomerular Filtration Rate Predicts Poor Clinical Outcome 3 Months After Acute Ischemic Stroke Jwa-Kyung Kim,[1] Myung Jin Choi,[2] Jung-Woo Noh,[3] Jiwon Ryu,[2] Ji Suk Han.[1] *[1]Internal Medicine, Hallym Univ Sacred Heart Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Hallym Univ Chuncheon Sacred Heart Hospital, Seoul, Republic of Korea; [3]Internal Medicine, Hallym Univ Gangnam Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: Chronic kidney disease (CKD) is an established risk factor for cardiovascular disease including stroke. However, the effect of decreased estimated glomerular filtration rate (eGFR) on stroke outcome remains controversial. In this study, we evaluated the association between eGFR and 3-month stroke outcomes and assessed whether CKD and its severity could affect clinical outcomes or not.

Methods: In this prospective cohort study with a hospital-based stroke registry, 1,373 patients with acute ischemic stroke were enrolled. Patients were divided into 4 groups (eGFR ≥60, 45–59, 30–44, and <30 mL/min/1.73m^2) according to the CKD Epidemiology Collaboration equations. Primary endpoint was 3-month death or dependency as poor functional outcome [mRS (modified Rankin Scale) score ≥3], and secondary endpoints were neurological deterioration (increased NIHSS ≥4 at discharge compared to baseline NIHSS) or mortality during hospitalization.

Results: Mean eGFR was 84.5 ± 20.8 mL/min/1.73m^2. The distribution of baseline renal impairment was as follows: 1,218 patients with eGFR ≥60 mL/min/1.73m^2, 82 with eGFR 45 - 59 mL/min/1.73m^2, 40 with eGFR 30 - 44 mL/min/1.73m^2 and 33 with eGFR <30 mL/min/1.73m^2. At 3 month after the stroke, 476 (34.7%) patients showed poor functional outcome, and that was more frequently occurred at more advanced stages of CKD (31.9%, 53.7%, 55.0% and 63.6% in CKD stage 1-2, 3a, 3b and 4-5, respectively, $p < 0.001$). Multivariate analysis showed that a baseline eGFR <30 mL/min/1.73m^2 increased the risk of poor functional outcome by 2.37-fold ($p = 0.047$). In addition, baseline renal dysfunction was also closely associated with neurological deterioration during hospitalization and in-hospital mortality, too.

Conclusions: A low baseline eGFR was highly predictive of both poor functional outcome 3 months after ischemic stroke and neurological deterioration/mortality during hospitalization.

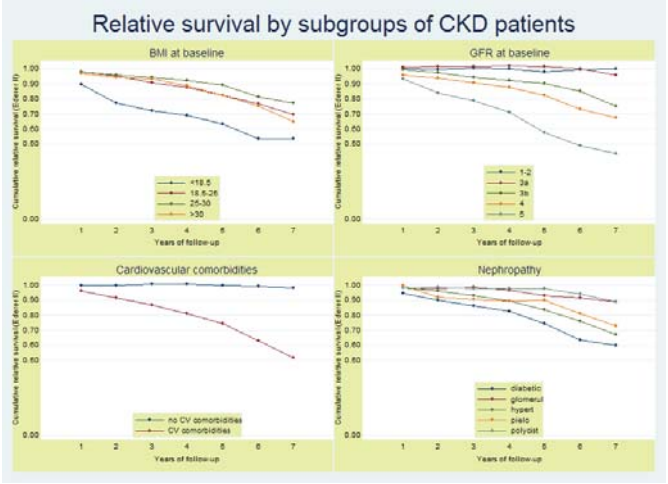
SA-PO874

An Estimation of CKD Cause-Specific Mortality Using Relative Survival Dino Gibertoni,[1] Stefano Torroni,[1] Marcora Mandreoli,[2] Antonio Santoro.[3] *[1]Dept of Biomedical and Neuromotor Sciences, Alma Mater Studiorum - Univ of Bologna, Bologna, Italy; [2]Nephrology and Dialysis Unit, Ospedale S.Maria della Scaletta, Imola, Italy; [3]Nephrology, Dialysis and Hypertension Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy.*

Background: The estimation of cause-specific mortality is usually based on cause of death recordings, that may be incomplete or inaccurate. Relative survival (RS) estimates the attributable mortality as a ratio between the observed survival and the expected survival in the general population obtained by matching mortality tables.

Methods: We applied RS to a cohort of 2179 patients who entered the PIRP registry between 2006 and 2011 in Emilia-Romagna, a North-Eastern Italian region. The PIRP registry collects clinical data on CKD patients who receive pharmacological and dietary treatment aimed to reduce CKD progression. Matching with general population survival by calendar year, gender and age was made using regional ISTAT mortality tables. Patients were followed up for at least one year until 2012 or death. Excess mortality rate ratios (EMRR) among risk groups were found using a multiple flexible parametric survival analysis.

Results: Overall 7-years RS estimate was 0.712. In the multivariate analysis, factors significantly associated with excess mortality attributable to CKD were: previous CV events (EMRR=4.3), CKD stage (EMRR=2.1 for stage 5 versus stage 3b), underweight (EMRR=3.5 versus normal BMI), proteinuria (EMRR=2.3), diabetes (EMRR=1.74), higher phosphate (EMRR=1.46).



Conclusions: Our findings further underline that CKD patients are a particularly frail population with a 28.8% excess mortality over the general population. Because the majority of patients are in CKD stages 3 and 4, our results provide additional useful information for primary care physicians and nephrologists about factors to be monitored to decrease the risk of death from the onset of the disease onwards.

SA-PO875

Interactions of Frailty and CKD with Mortality Xiaorui Chen,[2] G. Wei,[2] E. Constantz,[2] R. Boucher,[2] Tom Greene,[2] Srini Beddhu.[1,2] *[1]VAMC SLC; [2]Univ of Utah.*

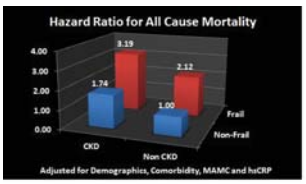
Background: Frailty is common in CKD population. It is unclear whether 1. the combination of frailty and CKD is additive or multiplicative for mortality risk and 2. the associations of frailty with mortality are accounted for by muscle mass and inflammation.

Methods: 2136 participants in the 1999-2002 National Health And Nutrition Examination Survey aged 50 yrs or older were included. 5 frailty criteria were: Unintentional weight loss (>5 lbs) in the past year, exhaustion (difficulty walking from one room to another room in the same level), physical activity (↓ compared to last yr), slowness (time to complete 20 ft walk), and ↓ muscle strength (assessed by dynamometer). Mortality data was through 12/31/2006. As even the presence of 1 or more conditions was associated with mortality (table), non-frail was defined as the presence of 0 conditions. Mid-arm muscle circumference (MAMC) was used as an indicator of muscle mass. HsCRP was used as inflammatory marker. Cox regression models were used to relate CKD and frailty with all-cause mortality.

Results: Mean age was 67.9, 45.8% were male, 6.9% were black, 18.8% had CKD. Prevalence of the number of frailty conditions and the unadjusted mortality rate in non-CKD and CKD are summarized in the table.

# Frailty conditions	Prevalence (%)		Morality rate (deaths/ 100 pt years)	
	Non-CKD	CKD	Non-CKD	CKD
0	56.2	46.4	1.13	2.92
1	31.6	34.2	2.22	7.26
2	9.4	11.4	4.28	5.54
≥3	2.8	8.0	4.52	13.84

Adjusted for demographics and comorbid conditions, compared to non-frail, mortality risk for frail was higher in non-CKD and CKD which persisted after adjustment for MAMC and CRP (figure).



A multiplicative interaction term for CKD and frailty was non-significant (p=0.47).

Conclusions: Frailty and CKD are ~ additive but not synergistic mortality risk factors. These associations are independent of muscle mass and inflammation.

SA-PO876

Chronic Kidney Disease Outcomes in Patients Risk Stratified Using an End Stage Renal Disease Risk Calculator Candace D. Grant,[1] Shayan Shirazian,[1] Navdeep Tangri,[2] Joseph Mattana.[1] *[1]Medicine, Winthrop-Univ Hospital, Mineola, NY; [2]Medicine, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: Accurate determination of the risk of development of end stage renal disease (ESRD) can be helpful in preparing patients with chronic kidney disease (CKD) for renal replacement therapy (RRT) as well as avoiding such preparation in those at low risk for this event. ESRD risk calculators have been developed which provide risk estimations based on age and other variables but have not seen widespread application to date. In this study we risk stratified a cohort of patients with stage 4 CKD using a validated risk assessment tool and carried out an observational study to assess outcomes.

Methods: 189 patients with stage 4 CKD had their ESRD risk determined using the risk calculator developed by Tangri et al. (JAMA 2007;305:1553-9) which incorporates age, gender, eGFR, urine albumin to creatinine ratio, calcium, phosphorus, albumin, and bicarbonate. A 2-year risk of progression to ESRD of <10% was considered low risk (LR) and ≥ 10% was considered high risk (HR). Over the following year development of ESRD, access creation and death were recorded.

Results: The average age of the patients was 71 years, 50% were men, 78% were white, mean eGFR was 23 ml/min/1.73m^2 and 43% were determined to be LR. For the group as a whole, vascular access was placed in 13%, 12% reached ESRD, and 13% died during the one year time period. When the LR and HR groups were compared, we found that 1% of the LR group reached ESRD versus 21% of the HR group, vascular access was placed in 6% of the LR group versus 19% of the HR group and there was no difference in mortality rate (13% each).

Conclusions: These preliminary findings suggest that using this validated risk calculator to assign patients to LR and HR groups appears to help predict clinical outcomes, with a very low incidence of ESRD in LR patients despite being stage 4 CKD. The use of ESRD risk calculation might be a useful tool in individualizing risk of ESRD and helping guide proper selection of patients for preparation for RRT.

SA-PO877

Abrupt Decline in eGFR prior to Initiating Hemodialysis (HD) Predicts Mortality after ESRD: Results from the CRIC Study Raymond K. Hsu,[1] Jason Roy,[2] Boyang Chai,[2] Amanda Hyre Anderson,[2] Nisha Bansal,[3] Harold I. Feldman,[2] Alan S. Go,[4] Jiang He,[5] Edward J. Horwitz,[6] John W. Kusek,[7] James P. Lash,[8] Akinlolu O. Ojo,[9] James H. Sondheimer,[10] Raymond R. Townsend,[2] Min Zhan,[11] Chi-Yuan Hsu.[1] *[1]UCSF; [2]UPenn; [3]UWash; [4]KPNC; [5]Tulane; [6]Case Western Reserve; [7]NIH; [8]UIC; [9]UMich; [10]Wayne State; [11]UMaryland.*

Background: Sudden transition to ESRD may partly explain why some patients initiate HD with catheters, receive little or no nephrology care prior to ESRD, or experience adverse outcomes. Thus the rate of loss of kidney function during the transition from CKD to ESRD may be an important risk factor for outcomes after HD initiation.

Methods: Among the 3939 participants in the Chronic Renal Insufficiency Cohort (CRIC) Study, we studied 740 who initiated maintenance HD during follow-up. We incorporated annual eGFR's into mixed effect models to estimate patient-specific GFR's at 3 months prior to start of HD. Abrupt decline was defined as having an extrapolated GFR of >30 ml/min/1.73m^2 at that time point. Proportional hazards models were used to assess the association between abrupt decline and all-cause mortality after HD initiation.

Results: Among the 740 incident cases of HD, 72 (9.8%) experienced abrupt decline in eGFR, and 192 died after initiating HD. Abrupt decline in eGFR was associated with a higher rate of all-cause mortality (unadjusted hazard ratio [HR] 1.85, 95% CI 1.25-2.75, p<0.05). After adjustment for age at ESRD, sex, race-ethnicity, diabetes and cardiovascular disease, abrupt decline remained independently associated with death (HR 1.87, 95% CI 1.25-2.80, p<0.05). 75 (39%) of 192 deaths occurred within one year of HD start. There was an even stronger association between abrupt decline in eGFR and one-year mortality: unadjusted HR 3.34 (95% CI 1.99-5.91, p<0.001) and adjusted HR 3.62 (95% CI 2.09-6.29, p<0.001).

Conclusions: Abrupt decline in eGFR prior to ESRD occurs in a significant minority of patients and is an independent risk factor for death—especially early death—after onset of ESRD. Factors responsible for this rapid decline need to be identified.

SA-PO878

Comorbidity and Survival in CKD Stage 3 Simon D.S. Fraser,[1] Natasha J. Mcintyre,[2] Richard J. Fluck,[2] Chris W. McIntyre,[3] Paul J. Roderick,[1] Maarten W. Taal.[3] *[1]Academic Unit of Primary Care and Population Science, Southampton Univ, Southampton, Hampshire, United Kingdom; [2]Dept of Renal Medicine, Derby Hospital, Derby, Derbyshire, United Kingdom; [3]Div of Medical Sciences and Graduate-Entry Medicine, Nottingham Univ, Derby, Derbyshire, United Kingdom.*

Background: In ageing populations, increasing multimorbidity prevalence has implications for patients, clinicians and policy makers. CKD is often considered in isolation but commonly occurs with other chronic conditions. Little information exists on the prevalence and prognostic implication of comorbidity combinations in moderate CKD. Aim: to investigate comorbidity prevalence and survival in a cohort of people with CKD stage 3.

Methods: People with eGFR 59-30ml/min/1.73m^2 on 2 occasions prior to inclusion were recruited from Primary Care. Medical history was obtained and participants underwent clinical assessment, urine and serum biochemistry tests. Comorbidities included

hypertension (HT), diabetes, ischaemic heart disease, heart failure, peripheral vascular disease, and cerebrovascular disease. Cox proportional hazards models were used to compare survival in those with CKD+/-1 comorbid condition with those with CKD+2 or more conditions (CKD+2).

Results: 1741 people with CKD were recruited.Mean age was 73±9 years and baseline eGFR 52±10ml/min/1.73m^2. Prevalence of isolated CKD, CKD+1 and CKD+2 were 9%, 50% and 41% respectively. The comorbid condition was HT in 95% of those with CKD+1. After a median 3.6 years 63 (6%) of those with CKD+/-1 had died compared to 112 (16%) of those with CKD+2 (p<0.001).Cox regression identified CKD+2 or more comorbidities as an independent predictor of all-cause mortality

	HR (95% CI)	p
CKD+2 (vs CKD+/-1)	1.84 (1.34-2.51)	<0.001
Age (years)	1.06 (1.04-1.09)	<0.001
Sex (M vs. F)	1.36 (1.00-1.84)	0.05
eGFR (ml/min/1.73m^2)	0.97 (0.95-0.98)	<0.001
Log urine ACR (mg/mmol)	1.16 (1.04-1.30)	0.01

Conclusions: Isolated CKD was rare even in this cohort recruited from primary care. Having more comorbidities was independently associated with mortality. CKD should therefore not be managed in isolation. Further research should focus on methods to reduce risk across multiple comorbidities in people with CKD while considering treatment burden.

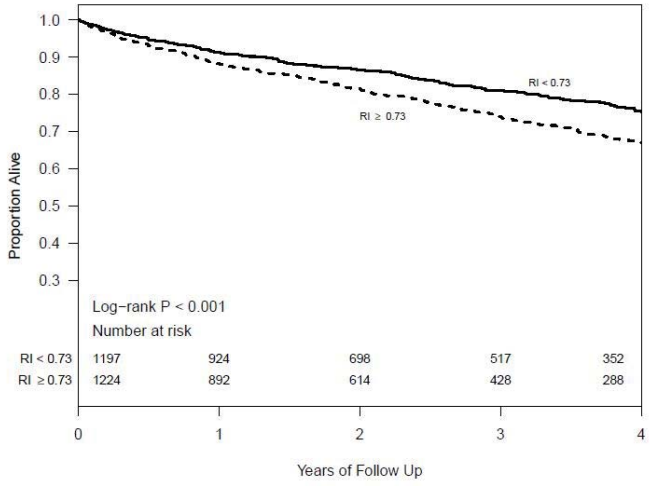
SA-PO879

Renal Resistive Index Is Associated with Increased Mortality in Chronic Kidney Disease Ma Clarisse M. Toledo, George Thomas, Jesse D. Schold, Susana Arrigain, James F. Simon, Joseph V. Nally, Sankar D. Navaneethan. *Cleveland Clinic Foundation, OH.*

Background: Renal resistive index (RRI) measured by Doppler ultrasonography associates with worse outcomes in hypertensive, diabetic and elderly patients. However, its role in predicting mortality in CKD is unknown. We studied the factors associated with high RRI and whether high RRI is associated with increased mortality in CKD patients without renal artery stenosis.

Methods: We included 2,421 patients with eGFR 15-59.9 ml/min/1.73 m^2 and RRI measured using renal Doppler ultrasonography (performed in the same department/ institution) between January 2005 to October 2011 from an existing CKD registry. Participants with renal artery stenosis >60% were excluded. High RRI was defined as RRI >0.73 (median value of the study population). Multivariable logistic regression model was used to study factors associated with high RRI and its associations with mortality was studied using Kaplan-Meier plots and Cox Proportional Hazards model.

Results: Patients with and without higher RRI differed on various factors. In the multivariable logistic regression, older age, female gender, diabetes mellitus, and use of ACEI/ARB (p<0.05) were associated with higher odds of having a high RRI. During a median follow-up of 2.3 years, 570 patients died. After adjusting for age, gender, race, hypertension, diabetes, smoking, BMI, use of ACEI/ARB and statins, RRI >0.73 was associated with increased mortality (adjusted HR 1.30, 95% CI, 1.09-1.54). Results were similar when we compared RRI >0.70 to those with RRI <0.70.



Conclusions: Higher RRI is associated with increased mortality in CKD patients without renal artery stenosis after accounting for other significant risk factors. Its evaluation may allow early identification of those who are at risk thereby potentially preventing or delaying adverse outcomes.

SA-PO880

Kidney Function and Mortality Risk in Community Dwelling Individuals: Hierarchical Importance of Threshold Values Donal J. Sexton, Scott Reule, Robert N. Foley. *Div of Renal Diseases and Hypertension, Dept of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: We attempted to identify threshold values of measures of kidney function and other classic risk factors to maximally discriminate all-cause mortality in community dwelling individuals.

Methods: We retrospectively identified eGFR (CKD-EPI equation), and urinary albumin-creatinine ratio (ACR) thresholds to maximize sensitivity and specificity (Max Sn/Sp) for death in NHANES III participants from 1988 to 1994 with mortality follow up through 2006. Classification tree methodology was used to rank eGFR and ACR thresholds in addition to; age, sex, race, smoking status, blood pressure (BP), serum LDL and HDL cholesterol, body mass index, waist-hip ratio (WHR), high sensitivity C-reactive protein, hypertension, diabetes, and cardiovascular disease.

Results: N = 6285 subjects were identified for inclusion, with mean (SD) age 47.4 (19) yrs., eGFR 99.9 (24) ml/min/1.73m^2 and median (25-75th centile) ACR 6.1 (3.6-11.9) mg/g. 10.5% were African American, 4% were Hispanic, and 53.1% were female. Mean follow up was 13.4 years. The Max Sn/Sp of eGFR (0.71/0.70 for 93 ml/min/1.73m^2) and ACR (0.62/0.65 for 7 mg/L) thresholds exceeded those of many classic factors. Sn/Sp were (0.01/0.99) for eGFR ≤ 30, (0.2/0.99) for ≤ 60 ml/min/1.73m^2 and (0.2/0.95) for ACR ≥ 30 mg/g. In a classification tree with exclusion of variables used at parent nodes in subsequent nodes; age 54 yrs. was initially selected, WHR and systolic BP appeared in the second round and systolic BP and ACR in the third.

Conclusions: Urinary ACR and eGFR may be at least as useful for mortality risk triage as most other classic risk factors in community dwelling adults.

SA-PO881

The Crude Annual Mortality Rate of Patients with End Stage Renal Disease Slightly Decreased and the Crude Incidence Rate of End Stage Renal Disease Continued to Increase in the Disaster Area in the following Year of the Great East Japan Earthquake 2011 Masaki Ohsawa. *Hygiene and Preventive Medicine, Iwate Medical Univ, Iwate Prefecture, Japan.*

Background: The Great East Japan Earthquake and Tsunami (March 11th 2011) caused significant damage to people in Iwate Prefecture (North-east area in Japan). Patients with end-stage renal disease (ESRD) are thought to be vulnerable for disasters and prolonged sedentary lifestyle during evacuation may contribute to worsening diabetic and hypertensive status of the refugees. We reported a preliminary study using dataset of 2010 and 2011 from people living in northern part of Iwate Prefecture last year. This year we will report results using data from all people in Iwate Prefecture from 2010 to 2012.

Methods: The Iwate ESRD registry program based on inventory survey was initiated in 2010 and this program has been continued to the present. We obtained data from the database of Iwate ESRD registry program from Iwate Medical Association. We counted total annual number of deaths in ESRD patients and total annual number of incident ESRD in Iwate Prefecture in 2010, 2011 (disaster year) and 2012.

Results: The results are shown in the table.

Date	2009/12/31	2010/1/1 ~2010/12/31	2010/12/31	2011/1/1 ~2011/12/31	2011/12/31	2012/1/1 ~/12/31	2012/12/31
total population of adults	1,094,712		1,091,233		1,077,559		1,077,437
No. of ESRD	2,399		2,645		2,852		3,010
point prevalence of ESRD (/million)	2,191		2,424		2,647		2,794
total number of deaths		316		444		411	
annual crude mortality rate (/1000 patient-years)		131.7		167.9		155.3	
total number of incident ESRD		337		386		418	
annual incidence rate of ESRD(/1000 person-years)		0.308		0.354		0.388	

Conclusions: The crude annual mortality rates in patients with ESRD increased in 2011 (disaster year) and somewhat decreased in 2012. The crude annual incidence rate of ESRD continued to increase in the following year of the disaster.

SA-PO882

Middle-Aged Patients with Pediatric End-Stage Renal Disease Are Extremely at Risk for Squamous Cell Carcinoma

Sophie Ploos van Amstel,[1] Judith Leonoor Vogelzang,[1] Markus Starink,[3] Kitty J. Jager,[2] Jaap Willem Groothoff.[1] *[1]Pediatric Nephrology, Academic Medical Center, Amsterdam, Netherlands; [2]Dept of Medical informatics, Academic Medical Center, Amsterdam, Netherlands; [3]Dept of Dermatology, Academic Medical Center, Amsterdam, Netherlands.*

Background: End-stage renal disease (ESRD) is associated with an increased risk for malignancies, but little is known if this effect is enhanced if ESRD exists since childhood. We analysed the prevalence of cancer in patients with paediatric onset of ESRD after median 25 years of follow-up.

Methods: All Dutch patients, born <1979 who started Renal Replacement Therapy in 1972-1992 were followed up until 2010. Data on occurrence of malignancies were retrieved form 37 hospitals in 2000 and 2010 and compared with the national registry for malignancies. Incidence rate and incidence rate ratios were calculated.

Results: A total of 5709 patient years were recorded. No patient was los to follow up until 2000; thereafter 2 patients migrated. The median follow-up was 25.33 years per patient. For 72 patients (29%) follow up was more than 30 years. Median age at transplantation was 12.67 years. Time on transplant was more than three times as long as time on dialysis with a maximum of 39.30 years. Of all patients, 95 died at median age of 22.8 years of whom 20.5% from malignancies. We found 105 primary malignancies in 54 out of all 249 patients after a mean RRT time of 22.9 years (0.25 – 39.90). Patients with cancer developed on average 2.7 tumours, leading to a total of 300, including metastases. The cumulative incidence of having cancer in patients alive after 30 years was 42%. Squamous Cell carcinoma was by far most prevalent. PTLD was the second most common malignancy. The mean age of developing a malignancy was 36.89 (range 11.06 – 50.38, median 37.63) years. For all tumours, non-melanoma skin cancer (NMSC) and non cutaneous malignancies, IRRs were 16.5, 437.6 and 9.8, respectively, for patients aged 25-30 years, and, respectively 81.5, 2610 and 4.1 for patients aged 45-50 years.

Conclusions: Squamous cell carcinoma is extremely prevalent among patients with pediatric ESRD after 23 years of follow-up with a high rate of recurrence.

SA-PO883

Aortic Stiffness and Kidney Disease in an Elderly Population

Katherine H. Michener,[1] Gary F. Mitchell,[2] Farzad Noubary,[1] Margret B. Andresdottir,[3] Runolfur Palsson,[3,4] Vilmundur Gudnason,[4,5] Andrew S. Levey.[1] *[1]Tufts Medical Center, Boston, MA; [2]Cardiovascular Engineering Inc., Norwood, MA; [3]Landspitali- The National Univ Hospital of Iceland, Reykjavik; [4]Univ of Iceland, Reykjavik; [5]Icelandic Heart Association, Kopavogur.*

Background: The causes of chronic kidney disease in older people are not well understood. Aortic stiffness increases with age and results in transmission of increased pulsatility into the kidney microvasculature, potentially causing damage and contributing to the pathophysiology of kidney disease in older populations.

Methods: We utilized data from the Age, Gene/Environment, Susceptibility-Reykjavik Study, a community-based prospective cohort study of cardiovascular disease (CVD) in Iceland. Associations of carotid pulse pressure (CPP) and carotid femoral pulse wave velocity (CFPWV) with estimated glomerular filtration rate based on creatinine and cystatin C (eGFR) and urine albumin-creatinine ratio (ACR) were assessed using linear regression, adjusting for demographics and CVD risk factors.

Results: We studied 940 participants (mean age 76 years, mean eGFR 68 ml/min/1.73m^2, median ACR 3 mg/g). In participants with CPP greater than 85 mmHg (N=197), higher CPP was associated with lower eGFR in unadjusted analyses but not after adjustment. CPP was significantly associated with higher ACR in fully adjusted models. Higher CFPWV was associated with lower eGFR and higher ACR in unadjusted analyses but not after adjustment.

Relationship of aortic stiffness and kidney disease measures

	CPP (SD)		CFPWV* (SD)	
	eGFR (ml/min/1.73 m^2)	ACR* (mg/g)	eGFR (ml/min/1.73 m^2)	ACR* (mg/g)
Unadjusted	**-4.54 (-8.30, -0.78)**	**0.16 (0.08, 0.25)**	**-1.87 (-2.89, -0.85)**	**0.21 (0.12, 0.29)**
Adjusted	-2.72 (-6.23, 0.79)	**0.14 (0.03, 0.24)**	-0.29 (-1.46, 0.87)	0.01 (-0.09, 0.11)

Results are β (95% CI).
CPP and eGFR used a 2-slope model due to nonlinearity. Results shown for CPP > 85 mm Hg.
Adjusted models include sex, age, MAP, HDL, HbA1c, CRP, height and heart rate.
*CFPWV modeled as the negative inverse, ACR modeled as the natural log.
Bold results are statistically significant.

Conclusions: Greater aortic stiffness may be associated with higher levels of albuminuria in the elderly. The association with lower eGFR may be confounded by age and CVD risk factors.

SA-PO884

No Association between Central Parameters of Arterial Stiffness and Early Chronic Kidney Disease in the CARTaGENE Cohort

Dominique Dupuis,[1] Mohsen Agharazii,[2] Philip Awadalla,[3] Stephan Troyanov,[1] Francois Madore.[1] *[1]Nephrology, Hôpital du Sacré-Coeur de Montréal, Montreal, Canada; [2]Nephrology, CHUQ L'Hôtel-Dieu de Québec, Quebec, Canada; [3]Medical and Population Genomics Laboratory, Univ de Montréal, Montreal, Canada.*

Background: Advanced CKD, through various potential mechanisms, has been linked to vascular stiffness. However, recent findings in patients with early CKD have cast doubt over the association between CKD and vascular stiffness. We examined the association between parameters of vascular stiffness and early CKD.

Methods: We used data from the CARTaGENE survey, a randomly selected cohort from the general population, aged 40 to 69 years. Pulse wave analysis was performed by tonometry on radial artery and central pulse wave profile was obtained by generalized transfer function(Sphymocor SCOR-Px) on 17 464 subjects. Central pulse pressure (cPP), PP amplification (PPamp), augmentation index (Aix), augmented pressure (AP), timing of reflected wave (Tr) and forward pressure (Pf) were assessed. CKD was defined by an eGFR <60ml/min/1.73m^2(CKD-EPI equation).

Results: After application of stringent criteria to insure the validity of measurements, 6741 subjects were included for analysis. Mean age was 55±8 years, 44% of participants were women, 14% active smokers, 24% were treated for hypertension, 10% had diabetes, and 6% had known cardiovascular disease. CKD stage 3 to 5 was present in 275 patients(4%). **Table 1** shows the association between parameters of arterial stiffness and CKD.

	Univariable		Multivariable*	
Parameter	*ß coefficients*	*P*	*ß coefficients*	*P*
cPP(mmHg)	0.060	<0.001	0.004	0.646
PPamp	-0.017	0.154	0.006	0.434
Aix(%)	0.018	0.130	-0.004	0.665
AP(mmHg)	0.034	0.006	-0.008	0.332
Pf(mmHg)	0.067	<0.001	0.014	0.171
Tr(ms)	-0.048	<0.001	-0.014	0.185

*variables included: age, gender, BMI, smoking status, diabetes, total cholesterol, statin treatment, anti-hypertensive medication, cardiovascular disease, heart rate, and central mean pressure.

Conclusions: In this large cohort from the general population, prevalent early CKD was not independently associated with arterial stiffness. The impact of kidney function on arterial stiffness may only be manifest at advanced stages of kidney disease.

Compliance Index, a Marker of Peripheral Arterial Stiffness, Predicts Decline in Renal Function in Patients with Chronic Kidney Disease

Ming-Cheng Wang,[1] Te-Hui Kuo,[1] Wei-Hung Lin.[2,3] *[1]Div of Nephrology, Dept of Internal Medicine, National Cheng Kung Univ Hospital, Tainan, Taiwan; [2]Dept of Internal Medicine, National Cheng Kung Univ Hospital, Tainan, Taiwan; [3]Inst of Clinical Medicine, College of Medicine, National Cheng Kung Univ, Tainan, Taiwan.*

Background: Compliance index derived from digital volume pulse (CI-DVP), measuring the relationship between volume and pressure changes in fingertip, is a surrogate marker of peripheral arterial stiffness. The aim of this study was to investigate if CI-DVP can predict the risk of renal function progression, cardiovascular events and mortality in patients with chronic kidney disease (CKD).

Methods: In this prospective observational study, 149 CKD patients were included for final analysis. CI-DVP and brachial-ankle pulse wave velocity (baPWV) were measured using photoplethysmography and ankle brachial index-form device, respectively. The eGFR was determined according to the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations. Decline in renal function was assessed by the estimated glomerular filtration rate (eGFR) slope.

Results: The baseline serum creatinine and eGFR were 1.5 ± 1.1 mg/dL and 60 ± 28 mL/min/1.73m^2, respectively. The mean decline rate of eGFR and duration of follow up were 2.63 ± 2.50 mL/min/1.73m^2/year and 51 ± 12 months, respectively. Patients in CKD stage 3b to 5 had a higher baPWV and a lower CI-DVP value than those in patients with CKD stage 1 to 3a. The decline rate of eGFR was higher in the advanced CKD group than that in the early CKD group (3.24 ± 2.16 versus 2.28 ± 2.64 mL/min/1.73m^2/year, P =0.0275). Multivariate linear regression analysis showed that lower CI-DVP (P =0.0033) and greater proteinuria (P =0.0006) were independent determinants of higher eGFR decline rate. If CI-DVP was replaced by baPWV in multivariate regression analysis, higher baPWV was also a significantly independent determinant of higher eGFR decline rate (P =0.0112).

Conclusions: The present study demonstrated that compliance index (CI-DVP), a marker of peripheral arterial stiffness, is significantly associated with renal function decline in patients with CKD. A higher CI-DVP predicts a slower eGFR decline.

SA-PO886

Apparent Treatment-Resistant Hypertension Related to Chronic Kidney Disease in the Elderly Jean Kabore,[1,2] Marie Metzger,[1,2] Catherine Helmer,[3] Ziad Massy,[4,5] Benedicte Stengel.[1,2] *[1]Inserm U1018, CESP, Villejuif, France; [2]Univ Paris Sud 11, Paris, France; [3]Inserm U897, ISPED, Bordeaux, France; [4]Ambroise Paré Univ Hospital, Boulogne-Billancourt, France; [5]Paris-Ouest Univ-UVSQ, Paris, France.*

Background: The impact of chronic kidney disease in the occurence of resistant hypertension in the ederly has been poorly investigated. We assessed the prevalence of apparent treatment-resistant hypertension (aTRH) defined as BP ≥ 140/90 mmHg despite use of 3 or more antihypertensive drug classes or use of 4 or more regardless of BP level, and its relation with kidney function level, kidney function decline over time, and albuminuria.

Methods: This study includes 4265 participants over 65 years treated for hypertension (HT) from a population-based cohort. At baseline, adjusted odds ratios (OR) for aTRH and for uncontrolled non-TRH (ucnTRH) associated with estimated glomerular filtration rate (eGFR) level were estimated by multinomial logistic regression using controlled HT (cHT) as reference. ORs associated with eGFR decline and albuminuria (ACR ≥3 mg/mmol or PCR ≥30 mg/mmol) were studied in a subsample with 4-year follow-up.

Results: Baseline mean age was 74 ± 5 years, 40% of the participants were men, 10% had diabetes, and 13% were obese. Mean eGFR was 76 ± 16 ml/min/1.73m². Prevalences of aTRH, ucnrHT and cHT were 6.4%, 62.3 % and 31.2 %, respectively. Each 5 mL/min/1.73 m² decrease in baseline eGFR was associated with a significant increase in the OR of aTRH: 2.04 [1.51 to 2.75] independent of age, gender, obesity and diabetes, but not for ucnTRH. The mean decline in eGFR was -1.5 ± 2.9 ml/min/1.73m²/year. In the subsample, each 2 ml/min/1.73m² per year decrease in eGFR was associated with a significant increase in the adjusted OR for aTRH (1.23[1.08 to 1.41]), but not for ucnTRH. In addition, aTRH was associated with albuminuria (2.58[1.23 to 5.38]) independent of eGFR decline, diabetes, age, gender, mean eGFR and BMI.

Conclusions: This study shows that aTRH affects one elderly out of 15 treated for hypertension. Low eGFR level, rapid eGFR decline and albuminuria are strongly related to aTRH in this population, regardless of other known risk factors for resistant HT.

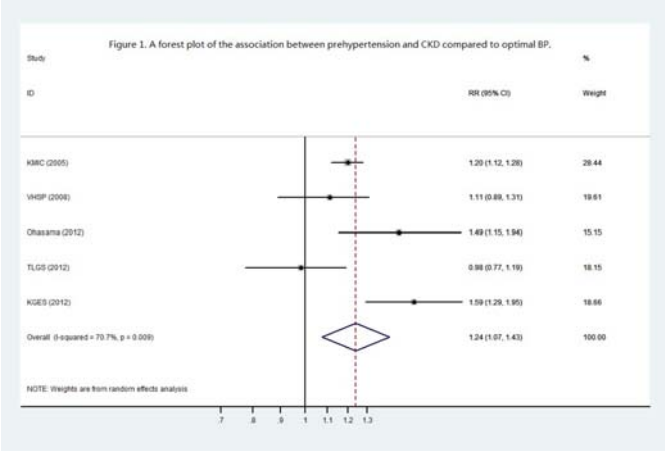
SA-PO887

Prehypertension Predicts Chronic Kidney Disease: A Meta-Analysis Yang Li, Jing Wang, Limeng Chen. *Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Recent studies have shown the association of prehypertension with increased risk of end stage renal disease, however there are conflicting evidences of the relationship between prehypertension and chronic kidney disease(CKD). This meta-analysis aims to find the association between prehypertension and the incidence of CKD, and whether gender or ethnical differences impact the connection.

Methods: MEDLINE, EMBASE, Cochrane Library (through May 2014) and article reference lists were searched for relevant studies about blood pressure and CKD. Prehypertension was defined with BPs ranging from 120-139/80-89mmHg. CKD was defined by eGFR of lower than 60 ml/min/1.73m² or proteinuria. Two reviewers extracted the data independently, and assessed the quality of studies included in meta-analysis using the Newcastle-Ottawa Scale (NOS). We performed the meta-analysis using Stata/SE 12.0(StataCorp LP). Random-effect models were chosen for heterogeneous analyses.

Results: Retrieving from 3,216 potentially relevant articles, we identified 5 cohort studies for 189,724 subjects by predefined selection criteria. Three were from Asia, and the other two were from Europe and Iranian, with the average age from 42.2 to 52.1 years, and the proportion of female from 46.4% to 52.0%. The median follow-up period was 2 to 10 years. Compared to optimal BP, prehypertension showed an increasing risk of CKD (pooled RR 1.24, 95% CI 1.07,1.43; P=0.003; I^2=70.7%). In subgroup analysis, we found the same trend only in men (pooled RR 1.17, 95% CI 1.08,1.28; P<0.01; I^2=0.0%), but not in women. And the effect was only seen in Asia (pooled RR 1.39, 95% CI 1.13,1.70; P=0.002; I^2=76.3%) rather than non-Asia people.



Conclusions: Prehypertension can be considered as one of the potential causes of CKD. There are gender and ethnical differences in this association.

SA-PO888

Elevated Systolic Blood Pressure Is Associated with Increased Incidence of Chronic Kidney Disease but Not Mortality James W. Lohr,[1,2] Mojgan Golzy,[3] Randy L. Carter,[3] Pradeep Arora.[1,2] *[1]Nephrology, Buffalo VA, Buffalo, NY; [2]Medicine, SUNY at Buffalo, Buffalo, NY; [3]Biostatistics, SUNY at Buffalo, Buffalo, NY.*

Background: The optimal blood pressure to prevent development of chronic kidney disease (CKD)and mortality in the elderly is unclear. the objective of this study was to determine the effect of differing levels of blood pressure on incidence of CKD and mortality in elderly veterans.

Methods: This is a retrospective cohort study of 16,221 individuals > 70 years of age without CKD (eGFR> 60 ml/min) seen in primary care clinic in VISN 2 between 2001 and 2008. Cox proportional hazard model with time dependent covariates was used to examine the association of explanatory variables on hazard ratios for each outcome of interest: incident CKD and death. Time independent variables included observations of sex, race, age, BMI, and occurrence of COPD, cancer, diabetes, and vascular disease. Time dependent covariates included HDL, LDL, TRIG, HGB, SBP,and DBP. The PHREG procedure in SAS with counting process style of input, was used for the analysis of each model.

Results: Overall, 16.0% of individuals with baseline eGFR > 60 ml/min/1.73m2 developed CKD during follow-up. Compared to reference of systolic BP of 130-140 systolic, there was an increased hazard of development of CKD with systolic blood pressure of 140-150 or higher. The following factors were associated with an increased hazard of developing CKD: higher serum triglycerides, age, female gender, use of antihypertensive medications, cancer, COPD, vascular disease, and presence of diabetes. Higher Hb was associated with a decreased hazard of incident CKD. Overall, a total of 1133 (7%) patients died during the mean follow up time of 1185 days This produced a mortality rate of 57 per 1000 patients per year. As compared to a reference range of 130-140 mmHg systolic blood pressure, the relative risk of mortality was higher in the range of 120-130 mmHg systolic BP or less.

Conclusions: The optimal systolic blood pressure in elderly patients to prevent the development of CKD is < 140 mmHg. However, lowering the systolic blood pressure below 130 mmHg is associated with increased mortality.

SA-PO889

Stature Is Related to Renal Impairment and Higher Pulse Pressure Only in Women Ivana Vukovic-Lela,[1] Vanja Ivkovic,[1] Zivka Dika,[1] Sandra Karanovic,[1] Joelle L. Nortier,[2] Jelena Kos,[1] Mario Laganovic,[1] Tomislav Teskera,[3] Ana Vrdoljak,[1] Bojan Jelakovic.[1] *[1]Dept of Nephrology, Hypertension, Dialysis and Transplantation, UHC Zagreb, Croatia; [2]Dept of Nephrology, Erasme Hospital, Belgium; [3]Dept of Nephrology, General Hospital Slavonski Brod, Croatia.*

Background: It was reported that short adult stature might be a risk factor for premature cardiovascular diseses.However,data on association of height and kidney function are sparse. Our aim was to analyze this association in general population with normal kidney function.

Methods: In this cross-sectional survey conducted in general population from continental area out of original cohort of 2412 subjects, 644 subjects (324 W;320 M) (age 40, 35-43) with eGFR MDRD>60ml/min/1.73m2 and ACR<30mg/g were enrolled.Blood pressure (BP) was measured according to the ESH/ESC guidelines.Men and women were separately divided into height quartiles (Q1 the lowest and Q4 the highest height).

Results: There were no differences in age and BMI between height Qs in both gender. Women in the tallest height Qs were more obese (p<0.001),had lower eGFR(79±10 versus 85±12, p=0.005) and lower pulse pressure (PP) (42±12 versus 48±13,p=0.032) compared to those in shortest height Q.There were no differences in BP,ACR and alpha1CR between height Qs.On univariate regression height was associated with eGFR (B=-0.34, SE=0.10;p=0.001) and ACR (B=0.13,SE=0.05;p=0.008).The association remained significant after adjustment for age,PP,BMI, ACR and alpha1CR for eGFR (B=-0.61,SE=0.13;p<0.001) and ACR (B=0.17,SE=0.06;p=0.008).There were no differences in eGFR,ACR and BP values between height Qs in men.On univariate regression we failed to find association of height with eGFR and ACR in men.

Conclusions: In the group of subjects without CKD,short stature is related to lower eGFR,higher ACR and higher pulse pressure only in women.Additionally,PP adjusted adult stature was related to renal impairment only in women.Further investigations are needed to confirm our findings and analyze whether higher PP could be related to the early renal impairment in subjects with taller stature.

SA-PO890

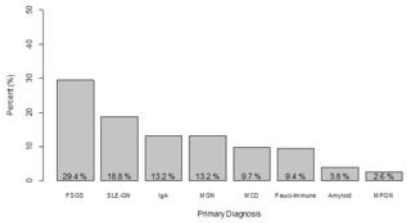
Distribution of Glomerulonephritis among an Ethnically Diverse United States Population John J. Sim,[1] Michael Batech,[1] Aviv Hever,[1] Teresa N. Harrison,[1] Sejal Vora,[2] Leslie Vollenweider,[2] Anna Pavlova-Wolf,[2] Kamyar Kalantar-Zadeh.[3] *[1]Nephrology and HTN, Kaiser Permanente LAMC, Los Angeles, CA; [2]Questcor Pharm; [3]UCI Med Ctr.*

Background: The incidence and prevalence of glomerulonephritis (GN) has varied across race/ethnicities and countries worldwide. This underscores the role of both innate biology and environment to occurrences of GN and its different types. We sought to describe the distribution of the most common non-diabetic GN's identified from a large ethnically diverse contemporary population.

Methods: This was a cross-sectional study conducted within Kaiser Permanente Southern California, an integrated health delivery system with 3.7 million members across 14 medical centers, in the period 1/1/2006-12/31/2009 using native renal biopsies results. Chart reviews of renal biopsy pathology reports were performed and the GNs were categorized based on the primary diagnosis on the renal pathology report. Data on age, sex, race/ethnicity, socioeconomics, comorbidities, and laboratories were extracted from administrative databases.

Results: In total, 879 cases of the most common GN's were identified. The mean age was 46 years and nearly half (47%) were females. The most common GNs were FSGS (29.4%), SLE (18.8%), IgAN (13.2%), membranous (13.2%) minimal change disease (9.7%), pauci-immune (9.4%), amyloid (3.8%), and membranoproliferative (2.6%). Among primary etiologies, IgAN was the second most common primary GN in Hispanics and Asians, while membranous GN was the second most common primary GN in whites and blacks.

	White	Black	Hispanic	Asian	Missing/unknown	Total
FSGS	58	70	90	37	31	258
SLE	25	40	71	25	34	165
IgAN	30	0	45	35	20	116
Membranous	41	30	29	13	10	116
Minimal Change	28	14	37	4	6	85
Pauci-immune	34	16	27	5	6	83
Amyloidosis	14	2	12	4	1	33
Membranoproliferative	9	3	10	0	5	23
Total	239	175	321	123	113	879



Conclusions: Among a diverse population, we observed FSGS as the most common primary GN across all races/ethnicities and ages. The distribution of GNs demonstrated that Hispanics and Asians had similar patterns of GN while whites and blacks were similar. Our findings suggest that GN's may occur differently within U.S. race groups compared to similar races in other countries.

SA-PO891

Effect of Statins on Survival in Patients with Vascular Access for End Stage Renal Disease Paola De Rango, Basso Parente, Beatrice Fiorucci, Luca Farchioni, Enrico Cieri. *Vascular and Endovascular Surgery Unit, Hospital S.M. Misericordia; Univ of Perugia, Perugia, Italy.*

Background: The benefit of statins therapy in patients with advanced chronic kidney disease remains unsettled. Many patients with end stage renal disease (ESRD) are not under statins. This study aimed to investigate the impact of statins use on survival of patients with vascular access performed at a single vascular surgery center.

Methods: Data from consecutive patients with ESRD admitted for vascular access surgery from 2006 to 2013 were reviewed. Data were collected prospectively. Information on therapy was retrieved and patients under statins therapy were compared to those without. Primary end-point was 5-year survival. Cox regression analysis with backward stepwise selection of covariates (age, gender, hypertension, cardiac disease, chronic obstructive pulmonary disease, obesity, diabetes,statins) was used to analyze independent predictors of mortality.

Results: Three hundred fifty-nine patients (230 males;mean age 69.2y) receiving 565 vascular accesses during the study period with available information on statins use were analyzed. One hundred twenty seven patients (35.4%) were on statins. Use of statins was more frequent in patients with hypertension (P=.034), hyperlipidemia (P<.0001), coronary disease (P=.43) diabetes (P=.001) and obesity (P<.001). Kaplan Meier survival rates at 3 and 5 years were 77.0% and 65.1% for patients without statins, and 84.4% and 75.9% for those under statins (P=.17). Cox regression analysis selected age as independent positive predictor (Odds Ratio,OR,1.04;95% Confidence Interval, CI, 1.02-1.05;P<.0001) and statins therapy as independent negative predictor (OR 0.57; 95%CI 0.33-0.98;P=.043) of mortality. There was a trend for higher primary patency rate at 3 years of the vascular access procedures performed in patients under statins but without statistical relevance (patency: 36% in patients without statins and 50% for those under statins:P=.45).

Conclusions: Statins therapy may reduce the risk of mortality in patients with ESRD including those receiving dialysis. Use of statins may be implemented in patients with vascular access.

SA-PO892

BK Virus as a Significant Predictor of Chronic Kidney Disease and Overall Survival in Hematopoietic Stem Cell Recipients Ala Abudayyeh,[1] Amir Hamdi,[1] Maen Abdelrahim,[1] Aimaz Afrough,[2] Yan Heather Lin,[1] Jeffrey J. Tarrand,[2] Elizabeth J. Shpall,[2] Katy Rezvani.[2] *[1]Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston; [2]Stem cell Transplantion, The Univ of Texas MD Anderson Cancer Center.*

Background: BK virus nephropathy is an evolving challenge in hematopoietic stem cell transplantation (HSCT) recipients. In contrast to kidney transplantation, where there are screening protocols for early detection and prevention of BK virus, there is no such guideline in HSCT. The aim of this study was to evaluate the role of BKV in renal function and survival of HSCT survivor population.

Methods: We analyzed all patients undergoing first allogeneic HSCT at MD Anderson Cancer Center between January 2004 and December 2012. We evaluated the renal outcome and survival of these patients as well as factors that contribute to them. BKV positivity was defined as BKV detection in urine by PCR testing. CKD was defined by constant decrease of 25% or more in GFR compared to the baseline at the time of transplant.

Results: We identified a total of 2477 patients with BK viruria in 25% (n=629). The median time from transplantation to BK viruria development was 42 days. Conditioning regimen consisted of a myeloablative regimen 19%,reduce intensity regimen 67%, and non-myeloablative regimen 14%. The median follow-up time for CKD was 690 days after transplant. A total of 1086 patients developed CKD (43.8%). In multivariate analysis, with the adjustment of age, gender, acute GVHD, chronic GVHD, preparative conditioning regimen, graft source, tacrolimus serum level, BKV showed significant association with CKD (HR)= 1.599 (1.386, 1.845), *P*-Value <0 .0001, and a significant association with overall survival (HR= 1.293 (1.134, 1.475), *P*-Value <0 .0001.

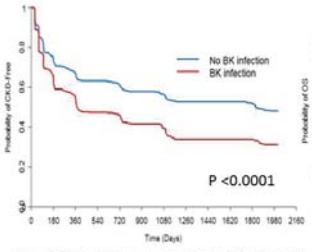

Figure 1a: Kaplan-Meier curve progression to CKD related to BK infection

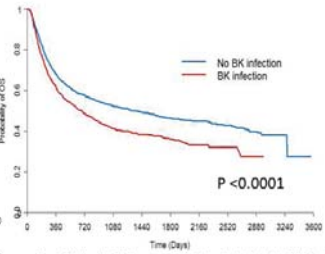

Figure1b: Kaplan-Meier curve overall survival related to BK infection

Conclusions: To our best of knowledge, this is the first study to identify BKV as a strong independent predictor of CKD and survival after HSCT.

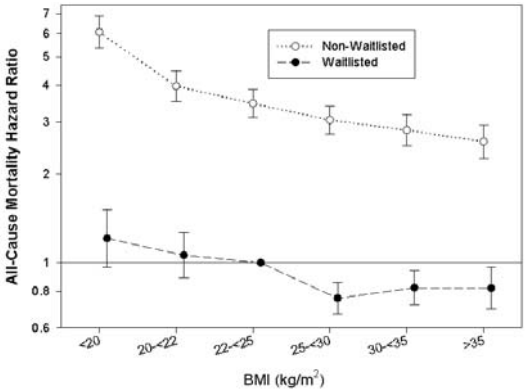
SA-PO893

Comparing the Associations of Body Mass Index with Survival in Kidney Transplant Waitlisted and Non-Waitlisted Hemodialysis Patients Rochelle Rogers,[1] Elani Streja,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Memphis VA MC, Memphis, TN.*

Background: Maintenance hemodialysis (MHD) patients who are waitlisted for kidney transplantation are often asked to lose weight if their body mass index (BMI) is in the obesity range despite the well-known obesity paradox in these patients. Few studies have compared the BMI-death association in non-waitlisted versus waitlisted MHD patients.

Methods: Using a large national dialysis database, we created a 1:2 propensity-matched cohort of 8,474 waitlisted and 11,989 non-waitlisted MHD patients who underwent treatment from 2001-2009. Associations between all-cause mortality and 6 groups of BMI were analyzed using Cox models in the total cohort and separately in non-waitlisted and waitlisted patients.

Results: Patients were 54±15 yrs old, 39% female, 53% diabetic, and 29% African American. In case-mix adjusted models, compared to the reference group (BMI of 22-25kg/m^2 waitlisted patients), both waitlisted and non-waitlisted patients showed improved survival with BMI>25kg/m^2. In each BMI increment, waitlisted patients had 4-6 times lower risk of death than non-waitlisted matched counterparts.



Conclusions: Both waitlisted and non-waitlisted HD patients exhibit evidence of an obesity paradox. Non-waitlisted patients showed an incrementally lower death risk with higher BMI, but had a 4 to 6 times higher death risk compared to waitlisted matched patients in the same BMI category. Studies are warranted to examine the need to change the current BMI recommendations for waitlisted patients.

Outcomes of Prepared versus Non-Prepared of Dialysis in Chronic Kidney Disease Patients Yi-Chih Lin, Wen-Chih Chiang, Chih-Kang Chiang. *Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: The creation of fistulas or grafts before starting dialysis is recommended, but whether it reduces survival and clinical outcomes still unknown. In clinical practice, there are may variations to decide when to start dialysis in stage 5 chronic kidney disease. Early preparation and then early dialysis were favored in the world without definite evidence, especially in Asia. In this study, we observed whether prepared dialysis has better survival rate and clinical outcoms among 440 patients with advanced chronic kidney disease in one medical centers in Taiwan.

Methods: We observed retrospectively 440 patients 18 years of age or order with advanced chronic kidney disease and divided these patients in two groups, prepared dialysis access and non-prepared before chronic dialysis starts.

A non-prepared patient occurred if the patient had at least one outpatient consultation with nephrology prior to dialysis start, and if the patient initiated dialysis using a double lumen catheter. The primary outcome was all cause mortality.

Results: We observed retrospectively a total of 440 adults and excluded 60 patients due to unknown preparation of dialyis and loss follow up(mean age 60.6 years old, 209 men and 172 women, 164 diabetes) between April 2007 and March 2011 via electronic medical records in National Taiwan University Hospital (NTUH). Almost randomized characteristics in these two group except eGFR while dialysis, DM patient number, HbA1c and LDL levels. Up to Dec 2013, 33 of 202 patients in prepared group and 24 of 178 patients in non-prepared group died. There was no significant difference between the groups in survival rate.

Conclusions: In this study, patients in advanced CKD stage with prepared dialysis access were not associated better survival or clinical outcomes.

Funding: Other NIH Support - National Taiwan University hospital

SA-PO895

Effects of Educational Intervention on Renal Outcome of Early- to Moderate-Stage Chronic Kidney Disease: A Cluster-Randomized Trial Kunihiro Yamagata,[1,2] Hirofumi Makino,[2] Kunitoshi Iseki,[2] Sadayoshi Ito,[2] Kenjiro Kimura,[2] Eiji Kusano,[2] Kimio Tomita,[2] Ichiei Narita,[2] Tomoya Nishino,[2] Yoshihide Fujigaki,[2] Tsuyoshi Watanabe,[2] Takashi Wada,[2] Seiichi Matsuo.[2] *[1]Dept of Nephrology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [2]On Behalf of Study Group for Frontier of Renal Outcome Modifications in Japan, FROM-J, Japan.*

Background: This study was designed to prove the effect of multidisciplinary treatment on the outcome of early- to moderate-stage CKD.

Methods: In this stratified open cluster-randomized study, we recruited 49 local medical associations (clusters); 26 clusters were randomly assigned to intervention group A (standard intervention) and 23 clusters were assigned to intervention group B (advanced intervention). The patients in groups A and B consisted of 1195 and 1184 patients. All patients were managed in accordance with the current CKD guidelines; in addition, group B patients received educational intervention every 3 months. The primary outcome measures were 1) the rate of continued consultation, 2) the collaboration rate between general practitioners and nephrologists, and 3) the progression of CKD.

Results: The rate of continued consultation was significantly higher in group B (16.2% of group A and 11.5% of group B ceased regular visits for 6 months, p=0.0121). Significantly higher referral and co-treatment rates were observed in group B (p<0.0001). Average speed of eGFR deterioration tended to be lower in group B (group A: 2.6+5.8 ml/min/1.73 m^2, group B: 2.4+5.1 ml/min/1.73 m^2, p=0.068). A significant difference in eGFR deterioration speed was observed in subjects with CKD stage 3 (group A: 2.4+5.9 ml/min/1.73 m^2, group B: 1.9+4.4 ml/min/1.73 m^2, p=0.028), while eGFR deterioration speeds were identical in other CKD stage subjects.

Conclusions: The educational intervention could achieve significantly higher rates of continued consultation referral and co-treatment. The progression of CKD stages was retarded by this multidisciplinary treatment in CKD stage 3 patients.

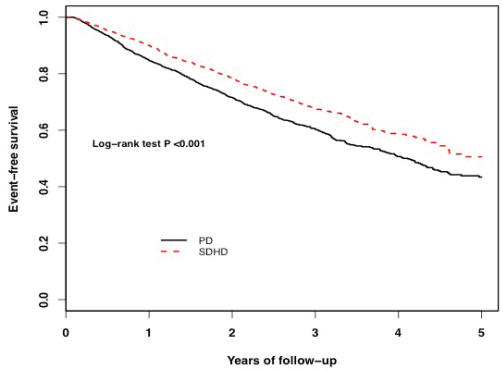
Comparative Effectiveness of Home Dialysis Therapies Gihad E. Nesrallah,[1,2] Lihua Li,[2] Rita Suri.[2,3] *[1]Nephrology Program, Humber River Hospital, Toronto, ON, Canada; [2]Dept of Medicine, Western Univ, London, ON, Canada; [3]Dept of Nephrology, Centre de Recherche, Centre Hospitalier de l'Univ de Montréal, Montreal, QC, Canada.*

Background: Increasingly, patients must choose between daily home hemodialysis (DHD) and peritoneal dialysis (PD), yet the comparative effectiveness of these therapies is unknown.

Methods: We linked a large U.S. dialysis organization (LDO) database to the USRDS for the years 2004 through 2011. We identified 3359 consecutive adult patients initiating DHD (≥5 days/week for ≥3 hours/day) through the LDO's home dialysis programs and matched them by propensity score to contemporaneous USRDS patients receiving home PD, yielding 2668 matched pairs. Comorbidities, demographics, and outcomes for both exposure groups were ascertained in the USRDS. We used Cox regression including the robust covariance estimator to compare all-cause mortality between groups. All patients were followed to October 31, 2012 or death; transplants were censored.

Results: After matching, between-group standardized differences for all baseline variables were <10%. Mean age was 51 years, 66% were male, 72% were white, and 29% had diabetes. During 10221 patient-years, 1493/5336 patients died. Compared to PD, DHD was associated with a significantly lower risk of death (PD versus DHD: 16.7 versus 12.7 deaths per 100 patient-years; HR 0.75 (95% CI 0.68– 0.82); p<0.001). During follow-up, 20% of DHD and 59% of PD patients switched to another therapy. Censoring modality switches at 90 days yielded HR 0.83 (95% CI 0.74–0.95; p=0.005) favoring DHD. Similar results were noted in multiple subgroups and with the use of several different analytic methods.



Conclusions: In this observational study, we found that among adult patients with end-stage renal disease, there was a significant long-term survival advantage among patients who underwent DHD as compared with patients who received PD.

SA-PO897

Lower Risk of Hospitalization in Daily Home Hemodialysis versus Peritoneal Dialysis Patients Eric D. Weinhandl,[1] Kimberly M. Nieman,[1] Allan J. Collins.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]School of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Frequent hemodialysis and peritoneal dialysis (PD) each offer unique benefits and risks pertaining to cardiovascular morbidity and infection. We aimed to compare the risk of hospitalization in U.S. patients initiating daily home hemodialysis (DHHD) or PD.

Methods: We identified new DHHD patients, Jan 1, 2007-Jun 30, 2010, from a registry of NxStage System One users and linked them to United States Renal Data System (USRDS) records; we identified new PD patients from USRDS records. We retained the subset of these patients with Medicare coverage. For each DHHD patient, we selected 1 matched PD patient according to the date of home dialysis initiation and a 33-factor propensity score of DHHD initiation. We followed patients from home dialysis initiation to the earlier of death or Dec 31, 2010. Admissions were ascertained from Medicare claims and causes of admission from principal diagnoses.

Results: We identified 3560 DHHD and 3560 matched PD patients. All-cause hospitalization rates per patient-year for DHHD versus PD were 1.71 versus 1.96 admissions and 10.2 versus 12.2 days. From Prentice-Williams-Peterson regression, the all-cause admission hazard ratio (HR) for DHHD versus PD was 0.92 (95% CI, 0.89-095); the HR was 0.89 (0.85-0.94) for first admission and 0.93 (0.89-0.96) for all subsequent readmissions (after first discharge). For admissions related to cardiovascular disease and to infection, HRs were 0.84 (0.79-0.89) and 0.89 (0.85-0.94), respectively. For admissions due to heart failure and to hypertensive disease, HRs were 0.80 (0.71-0.91) and 0.77 (0.69-0.87),

respectively. For admissions due to sepsis and to access infection (i.e., vascular access infection or peritonitis), HRs were 1.25 (1.11-1.41) and 0.88 (0.79-0.98), respectively.

Conclusions: DHHD was associated with lower risk of hospitalization than PD in multiple dimensions, including first admission; subsequent readmissions; admissions due to cardiovascular disease, including heart failure; admissions due to infection, including access infection but excluding sepsis; and cumulative days.

SA-PO898

Differences in Medication Use among Daily Home Hemodialysis, Peritoneal Dialysis, and In-Center Hemodialysis Patients

Eric D. Weinhandl,[1] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]School of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Anemia, hyperphosphatemia, and hypertension are common complications of end-stage renal disease. We aimed to compare use of medications for these indications in U.S. patients undergoing daily home hemodialysis (DHHD), peritoneal dialysis (PD), or in-center hemodialysis (IHD).

Methods: We identified new DHHD patients, Jan 1, 2007-Jun 30, 2010, from a registry of NxStage System One users and linked them to United States Renal Data System (USRDS) records; we identified new PD and prevalent IHD patients from USRDS records. We retained the subset of these patients with Medicare coverage. For each DHHD patient, we selected 1 matched PD and 5 matched IHD patients according to propensity scores of DHHD initiation. We followed patients to the earliest of dialytic modality change, kidney transplant, death, or Dec 31, 2010, and ascertained medication use from Medicare claims.

Results: We identified 3560 DHHD, 3560 matched PD, and 17,800 matched IHD patients. In DHHD, mean ESA dose increased, the percentage of patients using phosphate binders was stable, and the percentage of patients using antihypertensive agents decreased. Compared with DHHD, mean ESA dose was significantly lower in PD and IHD by month 12 of follow-up, and the percentage of patients using antihypertensive agents was significantly higher by month 1.

	DHHD	PD	IHD
ESA dose (IU per month)			
Month 1	48,500	39,900*	61,800*
Month 6	57,900	35,600*	57,800
Month 12	61,700	34,700*	57,600*
Month 24	63,200	40,700*	57,600*
Phosphate binder use (%)			
Month 1	51.9	49.0	50.0
Month 6	48.3	46.4	50.7
Month 12	47.7	42.4*	51.1*
Month 24	47.7	49.9	50.3
Antihypertensive agent use (%)			
Month 1	62.1	68.6*	66.0*
Month 6	53.4	63.5*	65.6*
Month 12	49.1	61.8*	65.3*
Month 24	48.5	63.7*	63.9*
**P < 0.05, compared with DHHD*			

Conclusions: DHHD initiation was followed by changes in ESA dose and antihypertensive agent use, but no change in phosphate binder use. Reasons for increased ESA use in DHHD are unclear; this merits further study. Lower antihypertensive agent use in DHHD likely reflects improved fluid control.

SA-PO899

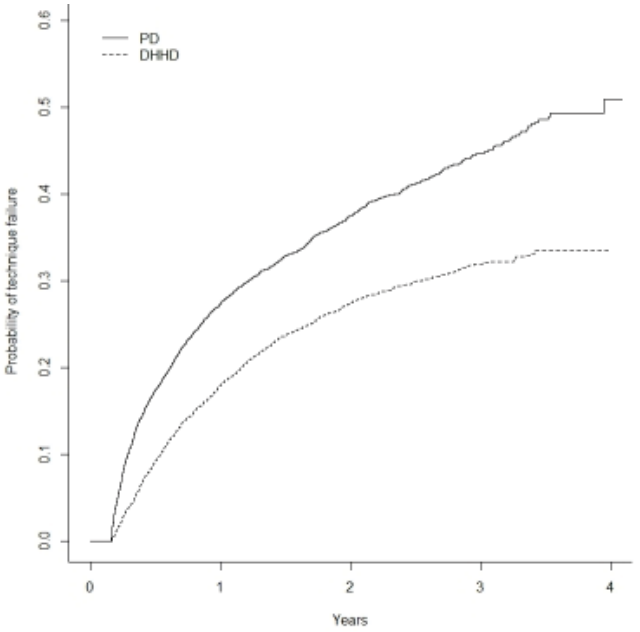
Lower Risk of Technique Failure in Daily Home Hemodialysis versus Peritoneal Dialysis Patients

Eric D. Weinhandl,[1] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]School of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Patient losses due to technique failure are an important impediment to the growth of home dialysis programs. We aimed to compare the risk of technique failure in U.S. patients initiating daily home hemodialysis (DHHD) or peritoneal dialysis (PD).

Methods: We identified new DHHD patients, Jan 1, 2007-Jun 30, 2010, from a registry of NxStage System One users and linked them to United States Renal Data System (USRDS) records. We identified new PD patients from USRDS records. For each DHHD patient, we selected 1 matched PD patient according to the date of home dialysis initiation and a 33-factor propensity score of DHHD initiation. We followed patients from home dialysis initiation to the earliest of technique failure, kidney transplant, death, or Dec 31, 2010; technique failure was declared at 2 months after the last home dialysis session.

Results: We identified 4460 DHHD and 4460 matched PD patients. Cumulative incidence of technique failure for DHHD versus PD was 9.1% versus 17.3% at 6 mo, 17.9% versus 27.3% at 1 yr, 27.3% versus 37.5% at 2 yr, and 31.9% versus 44.7% at 3 yr (figure). From Fine-Gray regression of cumulative incidence, the technique failure hazard ratio (HR) for DHHD versus PD was 0.62 (95% CI, 0.58-0.67). In patients (n = 1368 per group) initiating home dialysis within 6 mo following ESRD onset, the technique failure HR was 0.70 (0.60-0.82).



Conclusions: DHHD was associated with lower risk of technique failure than PD; this association was evident even in patients who initiated home dialysis within 6 mo following ESRD onset. Further study is needed to identify key differences in the distribution of causes of technique failure in DHHD and PD patients and whether relative hazards of technique failure vary by dialysis provider.

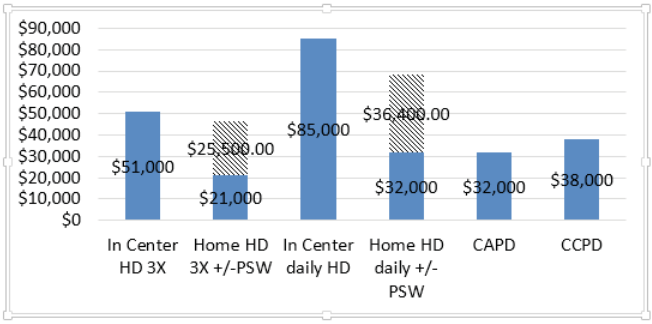
Use of Personal Support Workers for Home Hemodialysis – A Major Paradigm Shift

Andreas Pierratos,[1,2,3] Gokulan Kandasamy,[3] Graham Woodward.[3] *[1]Nephrology, Humber River Hospital, Toronto, ON, Canada; [2]Medicine, Univ of Toronto, Toronto, ON, Canada; [3]Ontario Renal Network, Toronto, ON, Canada.*

Background: Despite good clinical outcomes and low cost, home hemodialysis (HHD) is underutilized, mostly due to the lack of home patient support. Patient-based bundle funding in Ontario is provided by the Ontario Renal Network (ORN) supporting frequent dialysis both in-center and at home.

Methods: A pilot study examined the feasibility, cost and outcomes from the use of personal support workers (PSWs) to assist with HHD. Funding was secured initially by industry and then by the ORN. To allow future wider adoption and economies of scale, a non-hospital based industry partner assumed the human resource organizational role and risk. Three employed PSWs were trained by Humber River Hospital to support 3 patients. The project was approved by the hospital risk management and legal teams and insurance provider.

Results: Three patients have been dialyzed at home for 18 months by 3 PSWs. Three more patients received respite care when the PSWs were available. No clinical problems were encountered. There was a high level of satisfaction among patients and nurses. The hospital team provided back-up support as needed. The projected yearly cost, from payor perspective, assuming economies of scale of 30 patients is provided below (PSW cost in hatched columns).



Conclusions: Based on this pilot, use of PSWs to provide HHD is feasible, and based on ORN funding rates, is projected to be **less expensive than in-center HD for similar dialysis frequency**. This is being expanded to include enough patients to confirm the cost projections, when economies of scale are achieved and help understand patient eligibility and outcomes. It is predicted that significantly more patients can be dialyzed at home with the aid of PSWs, with significant implications in the provision of dialysis.

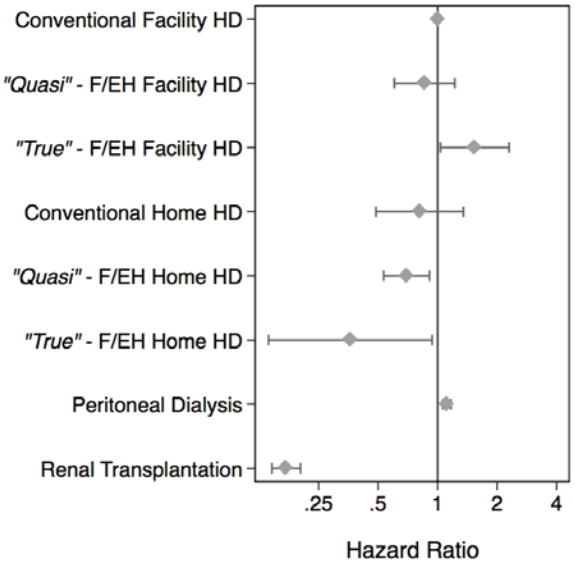
SA-PO901

Frequent/Extended Hour (F/EH) Hemodialysis (HD) and Mortality Risk in the Australia and New Zealand Dialysis and Transplant Registry (ANZDATA) Mark R. Marshall,[1] Carmel M. Hawley,[3] Peter G. Kerr,[4] Kevan Polkinghorne,[4] John W. MacD. Agar,[5] Stephen P. McDonald.[2] *[1]Faculty of Medicine and Health Sciences, Univ of Auckland, Auckland, AKL, New Zealand; [2]Australia and New Zealand Dialysis and Transplant Registry, The Royal Adelaide Hospital, Adelaide, SA, Australia; [3]Dept of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]Dept of Nephrology, Monash Medical Centre, Clayton, VIC, Australia; [5]Renal Unit, Geelong Hospital, Geelong, VIC, Australia.*

Background: A previous study using ANZDATA showed that Home HD was associated with lower mortality risk than Facility HD and PD, although F/EH regimens per se were not associated with change in mortality risk. That analysis was limited by the absence of time varying-co-morbidity for some patients (only available in ANZDATA from 31 Mar 2001), informative censoring for renal transplantation (RT), and categorization of alternate-day HD with more frequent HD.

Methods: We repeated analyses in an updated, larger inception cohort from 31 Mar 1996 to 31 Dec 2011 (n=38773, 2054990 pt-mths, 18130 deaths), with time-varying comorbidity available for the vast majority, modelling RT as a competing risk, and categorizing HD regimens as - Conventional (3/week, ≤6 hrs/Rx); "Quasi" F/EH (>conventional, but <"True"); and "True" F/EH (≥5 x a week, any hrs/Rx). Marginal structural modelling was implemented with time-varying modality and co-morbidity via multinomial logit, adjusting for age, gender, race, eGFR at dialysis inception, late referral, DM, primary renal dis, coronary artery dis, peripheral vascular dis, cerebrovascular dis, lung dis, smoking.

Results: Results are below



Conclusions: RT is associated with the lowest overall mortality risk, "True" and "Quasi" F/EH Home HD with the next lowest, and "True" F/EH Facility HD the highest (possibly due to residual selection bias). Conventional Home and Facility HD are associated with similar mortality risk.

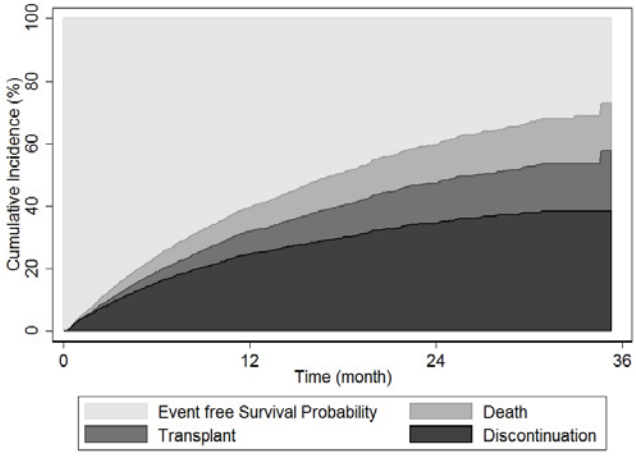
SA-PO902

Factors Associated with Discontinuation of Home Hemodialysis Rebecca Kurnik Seshasai, Michael Chaknos, Nandita Mitra, Jiaqi Li, Christopher Wirtalla, Dan Negoianu, Joel D. Glickman, Laura M. Dember. *Univ of Pennsylvania, Philadelphia, PA.*

Background: Home hemodialysis (HHD) is associated with improved clinical and quality of life outcomes compared with in-center hemodialysis but remains an underused modality in the U.S. Discontinuation from HHD is an important contributor to the low utilization of this modality. The rate, timing and contributing factors to HHD discontinuation are largely unknown.

Methods: Using DaVita clinical data, we identified a nationally representative cohort of patients who initiated HHD from 2007 - 2009 (n=2925). This cohort was linked with 1) USRDS data to obtain demographic and treatment history information, 2) 2000 U.S. Census data to estimate income, and 3) Rural Urban Commuting Area (RUCA) data to characterize the rural/urban nature of residence. Dialysis discontinuation was defined as ≥60 days with no HHD treatments; death and transplant were treated as competing risks. Competing risks regression was used to identify socio-demographic and clinical variables associated with HHD discontinuation.

Results: Mean age was 52.1±14.2 yr; 70.1% were white and 65.9% were male. Median duration of HHD was 253 days. 1-yr discontinuation and 1-yr mortality were 24.6% and 7.6%, respectively. Diabetes and smoking/alcohol/drug use were associated with increased risk of HHD discontinuation [HR (95% CI) 1.33 (1.07-1.66) and 1.4 (1.07-1.83), respectively]. Listing for kidney transplant and rural residence (RUCA ≥ 7) were associated with decreased risk of HHD discontinuation [HR (95% CI) 0.73 (0.61-0.87) and 0.76 (0.59-1.0), respectively].



Conclusions: Patients with diabetes, substance use, non-listing for transplant and urban residence are at greater risk for HHD discontinuation. Incorporating patient factors into HHD modality selection and targeting high-risk patients for increased support from clinical teams are potential strategies for reducing HHD discontinuation.

SA-PO903

Time to Recovery from Haemodialysis – Does Dialysis Location Matter? Anuradha Jayanti, The Basic-Hhd, Sandip Mitra. *Dept of Nephrology, Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: Patient recovery time from the effects of hemodialysis (HD) has been proposed as an indicator of the impact of HD on quality of life (QoL), in recent studies. Studies engaging HD patients, receiving institutional care and those self-caring, are limited by small patient numbers. We examined associations between patient-reported recovery time and patient characteristics in home and hospital HD patients.

Methods: In a cross-sectional study design, demographic and clinical data were obtained from a multicentre study in the UK (BASIC-HHD study). Hospital HD (N) = 213; Self-care facility-based patients (7)/Home HD (93) = 100. Patients responded to the question, 'Typically, how long does it take you to recover from a hemodialysis session'? Recovery time has been treated as a continuous variable in this analysis.

Results: Mean time to recovery from HD amongst hospital and home HD patients is significantly different ($p<0.01$). On controlling the cohort to which the patients belonged, in the univariate analysis, variables that were associated with lesser recovery time include male gender, no heart failure, higher albumin, higher systolic blood pressure and Beck depression score <15. Lower recovery time (RT) was associated with higher physical component score on SF-36, a quality-of-life questionnaire. Greater than 3 dialysis sessions/week, dialysis vintage, comorbidity index, diabetes, ethnicity and BMI were not found to be a significantly associated with a lower RT trend in this study. In the multivariate regression analysis, being a home haemodialysis recipient reduced the time to recovery by 103 minutes, having heart failure increases recovery time by 139 minutes, and each unit increase in systolic blood pressure (SBP) reduces recovery time by about 3 minutes-the range of SBP recorded (69 to 219mmHg).

Conclusions: Home as the destination for hemodialysis impacts RT positively. Self-care HD independent of dialysis prescription variables influences perceived quality of life.

SA-PO904

Evaluation of Non-Linear Heart Rate Variability (HRV) Parameters and Their Associations to Cardiac Function, Fluid Accumulation and Physical Performance in the Frequent Hemodialysis Network (FHN) Daily Trial Jochen G. Raimann,[1] Manuela Ferrario,[2] Brett Larive,[3] Andreas Pierratos,[4] Stephan Thijssen,[1] Sanjay Rajagopalan,[5] Tom Greene,[6] Gerald J. Beck,[3] Christopher T. Chan,[4] Peter Kotanko,[1] The FHN Trial Group.[7] *[1]Renal Research Inst; [2]Politecnico di Milano; [3]Cleveland Clinic; [4]Univ Health Network Toronto; [5]Univ of Maryland Medical Center; [6]Univ of Utah; [7]NIDDK, NIH.*

Background: An association between HRV and cardiovascular outcomes is known. More frequent hemodialysis (HD) decreases left ventricular (LV) mass, extracellular volume (ECV) and HRV, and also improves physical functioning and health (PF, PH; FHN Trial Group). We analyzed non-linear HRV indices and their correlates at baseline in the FHN Daily Trial.

Methods: Spectral Power Slope (SPS), Detrended Fluctuation Analysis (DFA), Multiscale Entropy Slope (MSE), Multiscale Sample Entropy (MSE SampEn), Multiscale Approximate Entropy (MSE ApEn), ApEn and SampEn were computed from 24-hours Holter recordings prior to randomization. Correlations between HRV parameters and left

ventricular ejection fraction (LVEF), left ventricular end-diastolic volume (LVEDV), ECV/total body water (TBW), PH and PF (both assessed with SF-36) were tested in diabetic and non-diabetic subjects (D, ND) using linear regression.

Results: We obtained the following measurements in 210 subjects [49.8±13.5 years, 62% males, 42% D, 56.7±11.2 % LVEF]: ECV/TBW 0.52±0.07, DFA 1.07±0.07, SPS 1.32±0.22, MSE SampEn 0.01±0.06, MSE ApEn 0.01±0.07, ApEn 0.91±0.37, and SampEn 0.64±0.34. In ND, MSE SampEn and MSE ApEn correlated positively with LVEF, PF and PH, and inversely with LVEDV and ECV/TBW (correlation coefficient r ranging from 0.20 to 0.32; P<0.05). SPS correlated positively with ECV/TBW (r=0.27). In ND subjects, irregularity measures (MSE ApEn, MSE SampEn) correlated positively with LVEDV (r=0.19 and 0.20). Ds showed an inverse correlation between MSE SampEn and ECV/TBW.

Conclusions: This to date largest assessment of nonlinear HRV parameters in HD patients indicated associations between cardiac function, fluid status, physical condition and HRV indices in HD patients. HRV in D was less affected by differences in clinical parameters.

Funding: NIDDK Support

SA-PO905

Efficacy and Safety of Tinzaparin Anticoagulation of the Extracorporeal Circuit with a Single Bolus Administration in Nocturnal Home Hemodialysis

Robert Zoël Bell, Vincent Pichette, Jean-Philippe Lafrance, Martine Leblanc, Georges Ouellet, Linda Nolin, Sarah Bezzaoucha, Annie-Claire Nadeau-Fredette, Joannie Lefebvre, Caroline Lamarche, Michel Vallee. *Nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: Tinzaparin (T) has shown practical benefits over unfractionated heparin for extracorporeal circuit anticoagulation during in-center hemodialysis treatments. However,efficacy and safety of anticoagulation with T has not been substantiated in patients with extended dialysis sessions, as in nocturnal home hemodialysis (NHD). The aim of the study was to evaluate the efficacy and safety of the use of T as a single bolus injection into the arterial line of the extracorporeal circuit of patients requiring 8 hours of anticoagulation in NHD.

Methods: 23 hemodialysis patients (NHD group) admitted to our NHD program between 2009 and 2014 had their first 8-hour in-center dialysis session receiving twice the T dose that gave adequate anticoagulation for their usual 4-hour dialysis treatment. Safety and dose/response were assessed by measuring anti-Xa levels at time 0 and at 15,30,60,120,240,360 and 480 minutes after administration of the T bolus. Anticoagulation efficacy was evaluated visually by assessing clot formation in both the dialyzer and the venous bubble trap through a simple scoring system. 7 chronic hemodialysis patients (HD group) paired for weight, age and sex receiving 4 hours of dialysis also had serial anti-Xa measurements at time 0 and at 15,30,60,120 and 240 minutes after administration of the T bolus.

Results: In terms of efficacy, the appearance of the dialyser and the bubble trap for the 8-hour dialysis sessions were similar to those of the 4-hour dialysis sessions. In terms of safety, there was no minor nor major bleeding events during the 8-hour dialysis sessions. The mean dose of T for 8 hours of hemodialysis was 111+/- 20 anti-Xa units/kg before and 113+/-15 anti-Xa units/kg after dose adjustments for patients with stage 3 coagulation.

Conclusions: Our study is the first to demonstrate that a single weight-based bolus injection of tinzaparin into the arterial line of the extracorporeal circuit in nocturnal home hemodialysis is effective and safe.

SA-PO906

Economic Evaluation of High Dose Hemodialysis versus Conventional in-Center Hemodialysis in the Netherlands

Raymund Zinck,[1] Frank Xiaoqing Liu,[2] Cees Adriaansen,[1] Anna Trisia Beby.[1] *[1]Baxter, Utrecht, Netherlands; [2]Baxter, Deerfield.*

Background: Evidence shows that clinical and humanistic outcomes of hemodialysis (HD) improve by increasing the dose from conventional in-center HD (three times a week). The best results are seen when there are no consecutive days without dialysis and the weekly Kt/V is at least 3.0 (high dose HD). This analysis explores the cost-effectiveness of high dose HD versus conventional in-center HD in the Netherlands.

Methods: A Markov model was developed from payer perspective to compare high dose HD performed in-center and at home over a 10-year period to conventional in-center HD. Inputs included: epidemiology (incidence, prevalence, transplant rates), costs (dialysis, complications, transport, monitoring, medications), complications (all-cause hospitalizations), utilities (EQ-5D) and survival. Data from Dutch registries (such as Renine) or the ERA-EDTA registry, official tariffs and medical literature were used to populate the model. One-way and probabilistic sensitivity analyses were performed to test the robustness of the conclusions.

Results: In the Netherlands, the willingness-to-pay lies between €20,000 and €80,000 per QALY depending on the underlying disease. Using the latest available tariffs, doing high dose in-center shows an incremental cost-effectiveness ratio (ICER) of €76,142 per QALY over 10 years. In contrast, high dose HD at home costs €42,930 less while producing 0.669 more QALYs than conventional in-center HD over 10 years.

Conclusions: This preliminary analysis shows that high dose HD when performed in-center is cost-effective in the Netherlands, almost reaching the limit of willingness-to-pay. However, when performed at home high dose HD provides better outcome with less costs. This indicates that there is room to increase the current weekly tariff for high dose HD at home in order to compensate for its additional production costs without compromising the cost-effectiveness of this regimen.

SA-PO907

Impediments to Adaptation of Home Hemodialysis (HHD)

Mary Gellens,[1] Catherine Firanek,[1] Lucy Barker Todd,[1] Ann Mancini,[1] Sara L. Garza,[2] Karen Lattrel,[3] Ann Robar,[4] James A. Sloand.[1] *[1]Baxter Healthcare Corporation, Deerfield, IL; [2]US Renal Care, Plano, TX; [3]Greenfield Health Systems, Detroit, MI; [4]Satellite Healthcare, San Jose, CA.*

Background: According to the United States Renal Data Systems (USRDS), as of 2011 92% of prevalent dialysis patients in the United States were on in-center hemodialysis (ICHD) while only 1.3% were on HHD. Many ICHD patients would benefit from HHD and Medicare "Conditions for Coverage" mandates that at least annually all patients be educated on the HHD option. Knowledge and perceptions of HHD by ICHD staff may impact patient use of HHD.

Methods: A validated, on line survey was developed to assess knowledge of evidence based clinical outcomes and perceptions about home dialysis. Nursing directors of 4 dialysis chains sent the survey to 580 dialysis health care professionals (DHCP). The survey took 10 minutes to complete and was conducted from 2/24/14 through 4/18/14.

Results: 274 individuals completed the survey (47% response rate). Thirty two percent of the respondents were ICHD nurses and technicians, 31% were peritoneal dialysis (PD) nurses, 24% were administrators/managers and 13% other dialysis staff. On average, respondents thought that 17% of US dialysis patients used HHD. When asked what dialysis modality they would choose for themselves, 56% chose PD and only 34% chose HHD. The majority of respondents felt that HHD was superior to ICHD in the following clinical categories: blood pressure control, survival, hospitalization rate, phosphate control, left ventricular mass, dialysis recovery time and cognitive function. They felt that the number one and two primary obstacles to patients starting HHD were fear of performing dialysis on their own and lack of patient education respectively. The majority felt that other obstacles to HHD included unwillingness to leave the ICHD space, lack of motivation and concern with the home set up.

Conclusions: ICHD staff has a good understanding and positive perception of HHD. They do not feel that clinical outcomes are an impediment to HHD but patient knowledge and patient perception of the therapy are. To increase use of HHD robust patient support programs and education are necessary.

SA-PO908

Self-Reported Experiences with Short Daily Hemodialysis: Interim Results from the FREEDOM Study

Fredric O. Finkelstein,[1] Hocine Tighiouart,[2] Diane Wuerth,[3] Susan Finkelstein,[1] Bertrand L. Jaber.[4] *[1]Yale Univ School of Medicine, New Haven, CT; [2]Inst of Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA; [3]Yale New Haven Hospital, New Haven, CT; [4]Tufts Univ School of Medicine, St. Elizabeth's Medical Center, Boston, MA.*

Background: Standardized surveys have been used extensively to examine the self-reported benefits of more frequent dialysis. However, the use of open-ended questions has received little attention. The FREEDOM study is a prospective cohort study investigating the clinical benefits of at-home short daily hemodialysis.

Methods: At month-4 (M4) and month-12 (M12), study participants were asked the following open-ended question: "What is the one thing that has changed the most for you since starting daily dialysis?" Two dialysis social workers classified the responses into 5 positive and 5 negative categories of self-reported experiences.

Results: Of the 499 enrolled patients, 289 completed the question at M4 and 199 at M12. At M4 and M12, 78% and 76% of responses reflected positive experiences with daily hemodialysis, respectively, and 22% and 24% of responses reflected negative experiences. The categories of positive and negative experiences are shown in the table:

	M4 (n=362)	M12 (n=235)
Positive		
1. Improved physical function	20%	19%
2. Feeling better	18%	17%
3. Flexibility of therapy	18%	19%
4. Improved overall quality of life	12%	17%
5. Physiological improvements	13%	13%
Negative		
1. Burden of treatment	4%	3%
2. Burden of treatment time	5%	6%
3. Disrupted daily routine	2%	1%
4. Decreased physical function	1%	2%
5. Physiological declines	0.3%	2%
Unclassifiable	4%	8%
No response	20%	15%

Results presented in rows are not mutually exclusive.

Conclusions: In summary, these data provide confirmation of the positive impact of at-home daily hemodialysis on quality of life, using individual patient responses as opposed to standardized questionnaires. Negative responses were cited by only 22 to 24% of patients, the most important involving burden of treatment and time. These findings should be incorporated into patient education programs, and clinicians should address the burden of therapy for patients receiving home dialysis.

Funding: Pharmaceutical Company Support - NxStage Medical, Inc.

SA-PO909

On-Site, Short Daily Hemodialysis Is an Effective Renal Replacement Therapy at Skilled Nursing Facilities Marvin V. Sinsakul. *Circle Medical Management, Chicago, IL.*

Background: As the number of patients with ESRD admitted to skilled nursing facilities (SNF) continues to grow, there remains a need to provide dialysis for patients while at these facilities. We present our early experience with using short daily hemodialysis prescribed 5 days weekly on-site at skilled nursing facilities using the NxStage System One Home HD device.

Methods: Data of monthly QAPI reports from six SNF with on-site, SDHD programs was aggregated and reviewed.

Results: From January 2014 through April 2014, 2187 treatments were provided for a total of 41 patients. The average number of patients per facility was 7 (range 3-11) with a mean of 53.08±3.73 treatments per patient. The average length of stay was 10.4 weeks. The percentage of patients completing the prescribed number treatments during the course of their stay was 97%, with a mean occurrence of 13.17 missed treatments and 1.83 shortened treatments per facility. Evaluation of clinical data revealed that 81% percent of patients achieved the targeted kt/V of 2.0, while only 2% of patients had a hemoglobin of <9.0gm/dl. Sixty-one percent of patients had TSATs between 20-40% and 47% of patients had a ferritin of >1000ng/mL. Regarding MBD parameters, 45% of patients had iPTH <300, 69% had a serum calcium between 8.4-10.9mg/dL and 70% had a serum phosphorus between 3-6mg/dL. Only 32% of patients in the program had a serum albumin of >3.5gm/dL. The average distribution of patients with AVF, AVG and catheters were 34%, 26% and 27%, respectively.

Conclusions: We conclude that providing short daily hemodialysis (5 days weekly) is an effective modality for ESRD patients admitted to SNFs. The use of a home HD device alleviated the need to install a water treatment system at these facilities. The patients ultimately completed a high percentage of prescribed treatments without the disruption leaving the facility for off-site dialysis. Based on the relatively low serum albumin and high ferritin of these patients, this sub-acute, post-hospitalization population remains more ill than the ambulatory, in-center HD population. The relatively short stay of these patients may make goals that require titration of the dialysis prescription or medication more difficult to achieve.

SA-PO910

No Improvement in Arterial Stiffness or Pro-Inflammatory Cytokines with Quotidian Haemodialysis in End-Stage Renal Disease Patients Kenneth Yong,[1,2] Gursharan K. Dogra,[1] Neil Boudville,[1,2] Wai Hon Lim.[1] *[1]Dept of Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; [2]School of Medicine and Pharmacology, Univ of Western Australia, Perth, Western Australia, Australia.*

Background: Pro-inflammatory cytokines such as interleukin(IL)-12 and IL-18 are implicated in the pathogenesis of cardiovascular disease (CVD) in end-stage renal disease (ESRD) patients. Increased serum IL-18 levels are independently associated with vascular stiffness and CVD mortality in ESRD patients. Quotidian HD improves parameters such as left ventricular hypertrophy, which may be related in part to enhanced clearance of pro-inflammatory mediators and improved arterial stiffness.

Methods: To assess the effects of quotidian haemodialysis (HD) upon clearance of pro-atherogenic cytokines and arterial stiffness. **Methods:** We conducted a longitudinal study of 14 stable conventional HD patients commencing quotidian home haemodialysis (HHD) between 2012 and 2013. We measured arterial stiffness [augmentation index (AIx), pulse wave velocity (PWV), pulse pressure (PP)] inflammatory markers (hs-CRP, IL-12, IL-18) and bioimpedance analysis (ECW:ICW ratio) prior to commencement of quotidian HD and between 3-6 months following commencement of quotidian HD.

Results: The mean±SD age was (51.9±9.2) years and 79% were males. The median (IQR) duration of conventional HD was 11(1.5-34.5) months. After commencement of HHD, the median hours of dialysis hours per week increased from 12.5(12-13) to 16(16-17). HHD did not significantly reduce inflammatory mediators such as hs-CRP (5.3±1.4 versus 41.±1.4g/L), IL-12 [240(181-349) versus 222(156-392)pg/mL], IL-18 [379(328-573) versus 336(306-435)pg/mL] or arterial stiffness such as PP (66±6.1 versus 61±5.4mmHg), PWV (7.6±1.1 versus 7.8±1.1m/s) and AIx (20±3.5 versus 18±4.2%) or ECW:ICW ratio (0.89±0.04 versus 0.80±0.08) (all p>0.05).

Conclusions: Changing to quotidian HD did not improve arterial stiffness or inflammatory markers in this small cohort of stable patients on conventional HD. Extension of this study to a larger cohort and longer follow-up period is warranted to determine if quotidian HD provides improved CVD outcomes.

SA-PO911

Is Progression of Arteriosclerosis in ESRD Patients Inhibited By Nocturnal Hemodialysis or Renal Transplantation? One Year Results From the NOCTX Study Franka E. Van Reekum,[1] Marianne C. Verhaar,[1] Petrus F. Vos,[2] Akin Ozyilmaz,[3] Brigit C. Van Jaarsveld.[4] *[1]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Dianet Dialysis Center, Utrecht, Netherlands; [3]Dialysis Center Groningen, Groningen, Netherlands; [4]VU Medical Center, Amsterdam, Netherlands.*

Background: Coronary artery calcification (CAC) is associated with increased cardiovascular events and mortality. The objective of this prospective cohort study is to determine the influence of dialysis modality and renal transplantation on CAC progression in ESRD patients.

Methods: The NOCTX study is scheduled to measure CAC scores (CACS), expressed as the standardized Agatston score, at baseline and after 1, 2, and 3 yr with multislice CT of the heart in 4 different groups: pts treated with conventional hemodialysis (HD 3-4x/week, 3-4 hr), peritoneal dialysis (PD), incident nocturnal HD (5-7x/week, 6-8 hr) and kidney transplant after dialysis. Inclusion aim will be a total of 160 pts. We analyzed available one-year results, to study CACS progression in the different patient groups.

Results: At present, 112 pts are included in the study by 7 centers. So far, 73 patients underwent multislice CT at baseline and after 1 yr of treatment. In these pts, overall mean (SD) and median CAC score increased from 649 (1397) and 86 (IQR 0-642) at baseline to 812 (2126) and 103 (IQR 1-830) at 1 yr. Of the 23 pts with no calcifications at baseline, 78% remained without calcification. Of the 49 pts with baseline CACS > 10, 35% had an increase in CACS of >15%: 50% in the HD group, 33% in the PD group, 27% in the nocturnal HD group and 29% in the transplant group (NS). We performed a transformation of the CACS to ln(CACS+1) to enable more detailed comparison between the groups. As expected, with the present number of pts no significant difference in progression of CACS between the 4 groups could be found.

Conclusions: In this preliminary analysis of NOCTX data, most pts with CACS=0 at baseline remained without calcification, and of pts with calcification 35% progressed >15% in CACS. With the present number of inclusions, no difference in progression of CACS could be observed between pts treated with HD, PD, nocturnal HD or transplantation after 1 yr of follow-up.

SA-PO912

Comparing Residual Kidney Function Pattern among Patients with Twice-Weekly, Thrice-Weekly, or More Frequent Hemodialysis Treatments Kamyar Kalantar-Zadeh,[1] Elani Streja,[1] Vanessa A. Ravel,[1] Connie Rhee,[1] Csaba P. Kovesdy,[4] Steven M. Brunelli,[3] Rajnish Mehrotra.[2] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Harborview MC, Univ of Washington, Seattle, WA; [3]DaVita Clinical Research, Minneapolis, MN; [4]Memphis VA MC, Memphis, TN.*

Background: ignificant differences in residual kidney function (RKF) may exist among different hemodialysis (HD) frequency regimens, but the RKF pattern across contemporary HD practices is less well-known. We hypothesized that RKF is higher in HD patients (pts) with less frequent HD.

Methods: Among all pts who started in-center HD during 2007-2011 and were treated for at least 60 days in a dialysis chain, each in-center HD pt was assigned one of 3 HD frequencies (2x/wk, 3x/wk, ≥4x/wk) for each 91-day (quarter) period from the date of first HD up to 3 yrs (12 quarters).

Results: We identified 1173 2x/wk, 125,751 3x/wk, and 126 ≥4x/wk HD pts who were 69.6±13.7, 62.1±15.2 and 55.0±18.5 yrs old and included 49%, 43% and 49% women, 13%, 31% and 21% Blacks, and 54%, 57% and 59% diabetic, respectively. In 673, 42,251, and 53 of these pts, respectively, the RKF was documented by Kru and was 6.0±3.7, 4.2±3.6 and 2.4±2.2 ml/min, respectively, in the first quarter. These differences in Kru maintained over a 12 qtr observation period, in that 2x/wk HD pts continued to exhibit significantly higher Kru than 3x/wk HD patient in each of the 12 qtrs, (p<0.001 for all differences in all qtrs) whereas ≥4x/wk HD pts had lower Kru than 3x/wk HD pts. Figure shows median trends:

	Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10	Q11	Q12
2x/wk	673	454	557	398	418	307	295	245	180	155	127	102
3x/wk	42251	17124	18898	12913	12099	9159	8284	6553	5618	4479	3605	2918
≥4x/wk	53	47	63	49	58	48	53	39	42	40	29	17

Conclusions: Selection of HD frequency for an in-center HD pt by nephrologists in the U.S.A. is associated with consistent differences in Kru, in that 2x/wk HD pts exhibit the highest Kru both at the start of HD and up to 3 yrs thereafter, while ≥4x/wk HD pts have consistently the lowest Kru. Whether HD frequency affects preservation or loss of RKF cannot be answered by observational studies and requires RCT.

SA-PO913

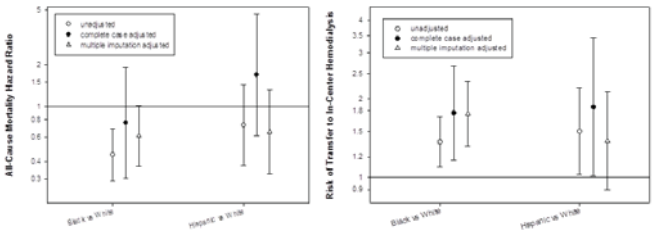
Association of Race with Risk of Mortality and Transfer to In-Center Hemodialysis in Home Hemodialysis Patients

Melissa Soohoo,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Sooraj Kuttykrishnan,[2] Miklos Zsolt Molnar,[1] Kamyar Kalantar-Zadeh,[1] Rajnish Mehrotra.[2] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Univ of Washington, Seattle, WA.*

Background: Previous studies have reported that Blacks and Hispanics undergoing hemodialysis (HD) have a lower risk for death than whites. Home hemodialysis (HHD) is a convenient treatment modality for chronic kidney disease and increasingly being used. However, there are no data on racial differences in survival and time on therapy for patients undergoing HHD.

Methods: We examined the probability of treatment with HHD among Blacks, Hispanics, and Whites from among 162,671 patients who received dialysis in a large dialysis organization in calendar years 2007 through 2011 and the risk for all-cause mortality and rate of transfer to in-center HD for a cohort of 2,523 HHD patients from a large dialysis organization (553 Blacks, 144 Hispanics, and 1,826 Whites).

Results: Blacks and Hispanics were less likely to use HHD (Blacks, OR: 0.50; Hispanics, OR: 0.27) in comparison to Whites. Among Blacks, Hispanics, and Whites treated with HHD, the mean+SD age was 47+13, 48+15, and 55+14 years and included 33%, 34% and 45% women; and 60%, 67% and 60% diabetics, respectively. Compared to Whites, there was no significant difference in risk for death for Blacks or Hispanics, even after adjusting for case mix and laboratory parameters. However, there was a significantly higher risk for Blacks treated with HHD to transfer to in-center hemodialysis (HR: 1.8, 95% CI: 1.31-2.34) compared to Whites; there was no significant difference in the risk for Hispanics.



Conclusions: Racial-ethnic minorities are less likely to use HHD for treatment. There are no racial differences in survival of patients treated with HHD. However, Blacks have a significantly higher risk for transfer to in-center hemodialysis. Additional studies are needed to examine these racial-ethnic differences.

SA-PO914

Technique Survival and Remoteness in Home Haemodialysis

Tracey Ying,[1] Blair S. Grace,[2] Stephen P. McDonald,[2,3] John W. MacD. Agar.[1] *[1]Dept of Renal Medicine, Geelong Hospital, Geelong, Victoria, Australia; [2]ANZDATA Registry, Adelaide, South Australia, Australia; [3]Discipline of Medicine, Univ of Adelaide, Adelaide, South Australia, Australia.*

Background: Home haemodialysis (HHD) is associated with significantly improved quality of life, survival and fewer hospitalisations compared with in-centre HD. However, little is known about how long patients remain on HHD, and whether this is associated with remoteness.

Methods: Patients who commenced chronic renal replacement therapy between 2000 – 2012 were classified by postcode as either major city or other, using the Australian Bureau of Statistics' Remoteness Area Classification. Uptake of HHD was analysed using Cox models, censored for death, transplantation or PD. Technique failure (TF, dialysis modality change lasting more than 30 days) similarly censored at death or transplantation. Results were presented both as univariate and after adjustment for age, race, gender, BMI and primary kidney disease.

Results: Uptake of HHD was not associated with remoteness in adjusted or unadjusted analyses (P≥0.6). Of 8064 non-indigenous patients who commenced HHD, 5481 (67.9%) lived in major cities. Patients outside major cities were generally older, had higher BMI and more comorbidities. Five years after commencing HHD, 28.2% of major city patients had TF compared with 32.5% of other patients. Associations between remoteness and TF varied with time on HHD. There was no difference in TF in unadjusted analyses within the first 3 years (hazard ratio [HR] versus major city 0.90, 95%CI 0.72-1.12, P=0.35), but patients outside major cities were more likely to suffer subsequent TF (HR 1.72 95%CI 1.16-2.54, P = 0.007). Adjustment made little difference (HR during first 3 years 0.82 95%CI 0.65-1.03 P = 0.095; HR after 3 years 1.69, 95%CI 1.11-2.55, P = 0.012).

Conclusions: Contrary to the belief that HHD is more prevalent in remote areas due to lesser availability of satellite HD advantage, our data suggests otherwise. Patients outside major cities were also more likely to cease HHD beyond 3 years. Understanding the reasons for this may facilitate strategies to improve technique survival in remote patients.

SA-PO915

Errors in Self Cannulation and Access Manipulation Identified by Vascular Access Audit Is Associated with Infections in Home Hemodialysis

Mathieu Rousseau-Gagnon, Karlien Francois, Christopher T. Chan. *Nephrology, Univ Health Network, Toronto, ON, Canada.*

Background: Vascular access-related infection is an important adverse event in home hemodialysis (HHD). We hypothesize that errors in self-cannulation or manipulation of dialysis access is associated with increased incidence of access-related infection.

Methods: We conducted a retrospective cohort study of all prevalent HHD patients at the University Health Network. All vascular access-related infections were recorded from 2006 to 2013.

Results: Selected patient characteristics are presented in Table. Median HHD vintage differed between patients with and without appropriate vascular access technique. The overall rate of infection between patients with and without appropriate vascular access technique was similar. Among patients who were identified with errors in dialysis access manipulation, patients with≥ 5 errors were associated with higher rate of access related infection (0.65 versus 0.24 infection/patient-year, p=0.017).

Variable	Error (n=49)	No error (n=43)	p value
Age at vascular access audit	46.4 ± 11.7	46.2 ± 12.8	0.938
Sex			0.486
Male	33 (67%)	25 (58%)	
Female	16 (33%)	18 (42%)	
Home Hemodialysis Vintage	5.8 (1.5-9.4)	2.3 (0.9-5.0)	0.005*
Dialysis session length	8 (7-8)	8 (7-8)	0.785
Weekly number of dialysis sessions	5 (4-5)	5(5-5)	0.479
Vascular access at vascular access audit			0.105
AV fistula using rope ladder cannulation	6 (12%)	11 (25%)	
AV fistula using buttonhole cannulation	25 (51%)	12 (28%)	
AV graft	3 (6%)	2 (5%)	
Tunneled catheter	15 (31%)	18 (42%)	
Charlson Comorbidity Index	3 (2-4)	3 (2-4)	0.828
Use of immunosuppressive drugs			0.374
Yes	14 (29%)	17 (40%)	
No	35 (71%)	26 (60%)	
Requirement of caregiver to dialyze			0.544
Yes	9 (18%)	5 (12%)	
No	40 (82%)	38 (88%)	

*: Statistically significant.

Conclusions: Patients with a longer median HHD vintage are at higher risk of inappropriate vascular access technique. Patients with multiple erroneous steps in vascular access technique are at high risk of dialysis access related-infection. Prospective evaluation of the impact of vascular access audit on recurrent infection is warranted.

SA-PO916

Protein-Bound Uremic Toxins, Carbonyl Stress, and Advanced Glycation End-Products in Conventional and Extended Hemodialysis and Hemodiafiltration

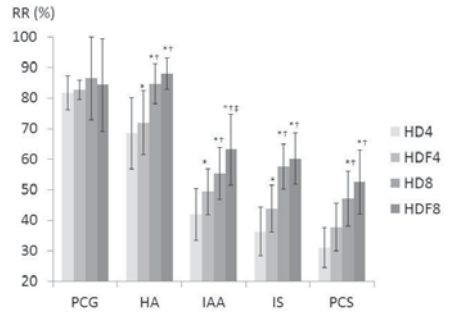
Tom Cornelis,[1] Sunny Eloot,[2] Griet Lrl Glorieux,[2] Karel M. Leunissen,[1] Raymond C. Vanholder,[2] Frank van der Sande,[1] Casper Schalkwijk,[1] Jeroen Kooman.[1] *[1]Nephrology, Maastricht Univ Medical Centre, Maastricht, Netherlands; [2]Nephrology, Ghent Univ Hospital, Ghent, Belgium.*

Background: Protein-bound uremic toxins (PBUT), carbonyl stress and advanced glycation end-products (AGEs) are associated with cardiovascular disease in dialysis. We aimed to study reduction ratio (RR) and total solute removal (TSR) of these toxins in extended hemodialysis (HD) and hemodiafiltration (HDF).

Methods: Thirteen conventional HD patients randomly completed 4h HD (HD4), 4h HDF (HDF4), 8h HD (HD8) and 8h HDF (HDF8). RR and TSR of PBUT [indoxyl sulphate (IS), p-cresylsulphate (PCS), p-cresylglucuronide (PCG), 3-carboxyl-4-methyl-5-propyl-2-furanpropionic acid (CMPF), indole-3-acetic acid (IAA), hippuric acid (HA)], AGEs [N^{ε}-(Carboxymethyl)lysine (CML), N^{ε}-(Carboxyethyl)lysine (CEL), N_{δ}-(5-hydro-5-methyl-4-imidazolon-2-yl)-ornithine (MG-H1), pentosidine], as well as dicarbonyl compounds [glyoxal (GO), methylglyoxal (MG), 3-deoxyglucosone (3-DG)] were measured.

Results: Extended HD and HDF increased TSR (mg) and RR of total (Figure 1) and/or free PBUT (except CMPF), as well as carbonyl stress and free AGEs.

	PCG	***HA***	***IAA***	***IS***
TSR_{HD4}	108.0±139.0	622.7±411.4	14.6±10.9	148.2±80.3
TSR_{HDF4}	133.5±183.5	657.7±450.3	16.5±10.0	176.5±91.2
TSR_{HD8}	169.0±182.5*	965.0±802.2*†	22.4±13.9*	239.5±128.4*
TSR_{HDF8}	180.7±235.1*	945.5±615.7*†	19.6±11.9*	249.1±130.0*
* P <0.05 versus HD4; † P <0.05 versus HDF4				



* P<0.05 versus HD4; † P<0.05 versus HDF4; ‡ P<0.05 versus HD8

Conclusions: Increased dialysis time had a major effect on RR and/or TSR of most PBUT, as well as on RR and TSR of carbonyl stress and free AGEs. Convection had an additive effect on the RR of selected PBUT, free CML and CEL, as well as on TSR of 3-DG (in HDF8).

SA-PO917

The Wnt Signaling Pathway Is Activated During Peritoneal Fibrosis

Peter Margetts,[1] Manreet K. Padwal,[1] Limin Liu,[1] Genyang Cheng.[2] *[1]Medicine, McMaster Univ, Hamilton, ON, Canada; [2]Nephrology, First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.*

Background: Peritoneal fibrosis is a complex process with multiple pathways involved. The wnt signaling pathway is involved in cellular transition and has been associated with fibrosis in other organ systems. We investigated the regulation of the wnt signaling pathway in an animal model of peritoneal fibrosis.

Methods: C57BL/6 mice were treated with an adenovirus expressing active transforming growth factor beta (AdTGFB) or control adenovirus (AdDL). We evaluated histology, downstream proteins of the wnt pathway by western blot, and gene expression by Nanostring 4 and 10 days after infection.

Results: There were no histologic changes to the peritoneal membrane after exposure to control adenovirus. After exposure to AdTGFB, we observed cellular proliferation, angiogenesis, submesothelial thickening and fibrosis. Gene expression of Wnts 2 and 4 were significantly upregulated by TGFB, as was the receptor FZD1 and the co-receptor ROR2. Other co-receptors LRP5 and 6 were unchanged by TGFB. Wnt 7b and 8a were both significantly downregulated in mice treated with AdTGFB. By western blot, we found that b-catenin was significantly upregulated and GSK3B phosphorylation was increased by TGFB. The common post-receptor signaling molecule DVL was also increased after exposure to AdTGFB.

Conclusions: There is evidence that wnt signaling pathway is active in the setting of experimental peritoneal fibrosis. Elements of both canonical and non-canonical wnt signaling appear to be upregulated by TGFB.

SA-PO918

Twist Accelerates Peritoneal Membrane Fibrosis by Regulating YB-1

Shiren Sun.[1] *[1]Dept of Nephrology, Xijing Hospital, the Fourth Military Medical Univ, Xi'an, Shaan xi, China; [2]Dept of Nephrology, Xijing Hospital, the Fourth Military Medical Univ, Xi'an, Shaan xi, China; [3]Dept of Nephrology, Xijing Hospital, the Fourth Military Medical Univ, Xi'an, Shaan xi, China.*

Background: Both E-box–binding transcription factor Twist and YB-1 controls gene expression through both transcriptional and translational mechanisms. We have previously shown that Twist is overexpressed in high glucose induced human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis. Structural analysis of the YB-1 promoter reveals that several E-boxes, as Twist may participate in the regulation of YB-1 expression.

Methods: To investigate Twist regulate YB-1 impacts on growth of HPMCs and EMT-derived fibrosis in PM, we isolated HPMCs from the effluents of patients with end-stage renal disease (ESRD) to observe the response of PM to Twist and YB-1.

Results: Here, our results demonstrated the overexpression and activation of Twist and YB-1 of HPMCs under extensive periods of PM fibrosis ex vivo. In immortal HPMCs and in HG-induced PD animal model, high glucose (HG, 60 mmol/L) also stimulated Twist and YB-1 overexpression and a transformed fibroblastic phenotype of HPMCs. Evidence from chromatin immunoprecipitation and reporter assays further supported that Twist transcriptionally regulated YB-1 by directly binding to its promoter. Collectively, these data suggest that YB-1 is a major downstream target of Twist. Re-expression of Twist led to decrease HPMCs growth, induced cell cycle arrest and increase PM fibrosis. Silencing of Twist could also down-regulate YB-1 expression, promote cell cycle progress of HG-induced HPMCs growth and also inhibited PM fibrosis.

Conclusions: Our data suggested that activation of Twist/YB-1 pathway might contribute to the growth retardation of HPMCs and the progressive PM fibrosis during PD.

SA-PO919

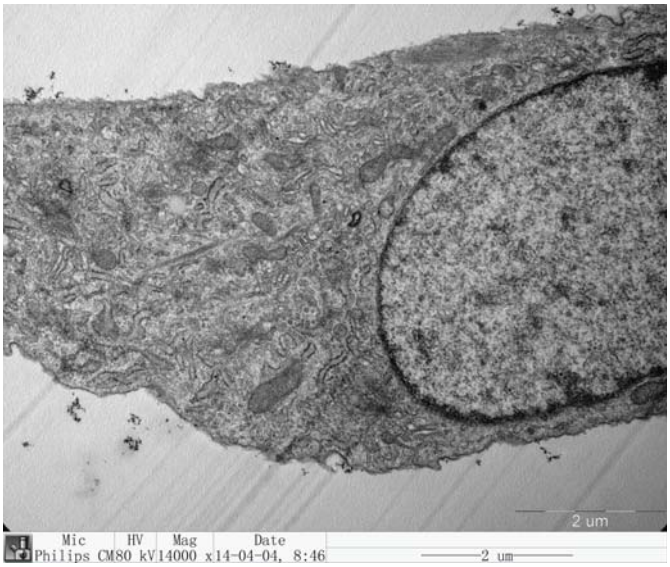
Primary Cultured Peritoneal Pericyteand Tests of Its Function

Nan Chen,[1] Hong Fu Yan,[2] Jingyuan Xie,[3] Hong Ren.[4] *[1]Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, Shanghai, China; [2]Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, Shanghai, China; [3]Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, Shanghai, China; [4]Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, School of Medicine, Shanghai, Shanghai, China.*

Background: This research is to establish a method of primary cultured peritoneal pericytes, providing a new strategy for the study of angiogenesis in UF.

Methods: Using the traditional enzymatic digestion, we successfully cultured and purified primary peritoneal pericytes from visceral peritoneum, and light microscopy, immunofluorescence, electron microscopy, flow cytometry, western blotting were used to identify and detect its function.

Results: Using electron microscopy, the primary cells presents pericyte's characteristics,while cell length reaches 50-70um, collagen does not exist between the cells.



Immunofluorescence was used to detect the surface biomarkers expression of primary cells repeatedly: pericyte in normal SD rats, surface biomarkers are PDGFR-ß (+), integrinα3 (+), α-SMA (+),CD248(+),Desmin(-/+),NG_2(+/-),while in uremic rats are PDGFR-ß(-/+), integrinα3(-/+),α-SMA(+),CD248(+), Desmin(+~++), NG2(+).The flow cytometry confirmed uremic state can affect the relationship between pericytes and basement/ endothelial, the presence of glucose enhanced this phenomenon, also confirmed by western blotting.

Conclusions: Using the traditional enzymatic digestion, we successfully cultured, purified primary peritoneal pericytes in visceral peritoneum. State of uremia can change the surface biomarkers of pericytes. Uremic state affect therelationship between pericytes and basement /endothelial cells, The existence of glucose enhanced this phenomenon.

SA-PO920

Histological Study and Analysis of Vascular Calcifications in Peritoneal Biopsies: Adipocytes as New Players in Encapsulating Peritoneal Sclerosis?

Joelle L. Nortier,[2] Tooulou Monika,[1] Pieter Demetter,[2] Anwar A. Hamade,[2] Agnieszka Anna Pozdzik.[1] *[1]Nephrology, Erasme Hospital, ULB, Brussels, Belgium; [2]Pathology, Erasme Hospital, ULB, Brussels, Belgium.*

Background: Histological study and analysis of vascular calcifications in peritoneal biopsies: Adipocytes as new players in encapsulating peritoneal sclerosis?

Methods: We approached both hypotheses by studying tissue expression of AE1/AE3 (mesothelial cells), calretinin (adipocyte marker), α-smooth muscle actin [α-SMA] (mesenchymal cells) in peritoneal tissue samples from 3 patients suffering from EPS. We also assessed interstitial inflammation and neoangiogenesis (CD3, CD4, CD8, CD20, CD68 and CD31 immunostainings, respectively) and analyzed the mineral composition of vascular calcifications (infrared microspectroscopy).

Results: Three patients (1M/2F; age 17, 64 and 39 years, respectively) developed EPS after 21, 90 and 164 months of PD therapy.Mesothelial cells expressed AE1/AE3 and calretinin in controls but this expression disappeared and there was no migration of mesothelial cell into the interstitium in all EPS patients. In comparison with normal tissue biopsy, the adipose tissue with calretinine+ adipocytes was replaced by severe sub-mesothelial fibrosis. In these areas, besides αSMA+ cells (as expected), we found a huge number of calretinin+ fusiform interstitial cells. We observed a neoangiogenesis in all EPS patients but vascular calcifications were detected in only 1 patient (8 PD-related bacterial peritonitis), which contained mainly carbapatite.

Conclusions: Despite the small number of this series, our results suggest that: (1) the involvement of MMT in peritoneal fibrosis remains unproven, (2) resident adipocytes

may represent underestimated sources of peritoneal fibroblasts and (3) the infrared microspectroscopy of tissue calcifications could be helpful in studying the link between peritoneal infections and vasculopathy in EPS.

SA-PO921

Contemporaneous Utilization of Biocompatible and Standard Peritoneal Dialysis Fluids Is Associated with a Similar Risk of Peritonitis M. Auxiliadora Bajo, David Menendez, Gloria Del Peso, Rafael Selgas. *Nephrology, Hospital U. La Paz. IdiPAZ. REDinREN.IRSIN, Madrid, Spain.*

Background: Peritoneal dialysis (PD)-related peritonitis is an important cause of morbidity, mortality and technique failure in PD patients. The risk of peritonitis depending on the peritoneal solution type is controversial, with data suggestive of a higher risk for those patients using more-biocompatible solutions. The peritoneal membrane protection associated with these solutions might be challenged. The aim of this study was to compare peritonitis risk in patients contemporaneously using more biocompatible (BC) solutions and standard solutions (SS) at one experienced PD center.

Methods: This retrospective cohort study included incident patients on PD at one center from January, 1999 to December, 2013. All patients used the same peritoneal dialysis solution during their whole follow-up. Multicompartimental solutions were defined as BC. 324 patients with a mean follow-up of 24.7±18 months were included. 151 patients (47%) used BC solutions and 173 patients (53%) SS. In the BC group, there was a higher prevalence of diabetes (26 versus 15%, p=0.015), but no differences in age, gender and time on PD were observed between groups.

Results: 131 patients had 229 peritonitis episodes. Patients with peritonitis were older and showed longer PD treatment, more comorbidity and were more frequently on CAPD. No difference in the incidence of peritonitis was observed with both fluids (44% in BC and 37% in SS, NS). A non-significant higher catheter loss was observed in the SS group (25% versus 12%, p=0.053), with no differences in hospitalization or peritonitis-associated death. The time to the first peritonitis was shorter in BC group, but with no statistical significance (HR 1.35 (95% CI 0.96-1.91), p=0.088). In multivariate analysis, only age, time on PD and CAPD use (versus APD) were independently associated with peritonitis, but not the type of solution used.

Conclusions: In this experience,the contemporaneous utilization of biocompatible and standard peritoneal dialysis fluids was associated with a similar risk of peritonitis. The use of biocompatible solutions cannot be questioned by this reason.

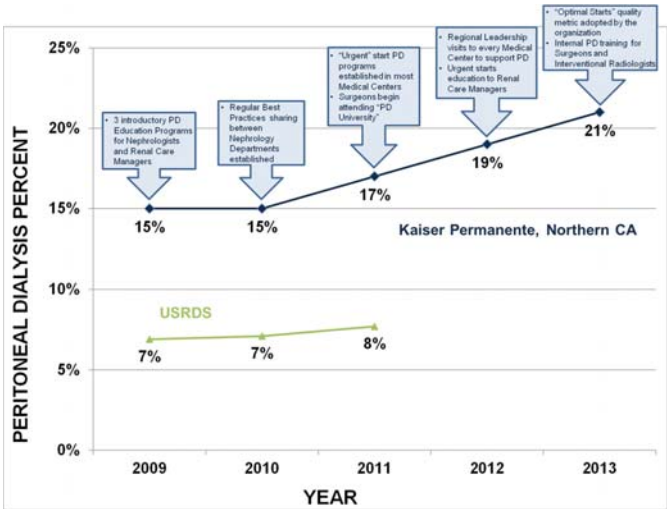
SA-PO922

Multidisciplinary Approach to Improve PD Prevalence in an Integrated Health Care Delivery System Leonid Pravoverov, Sijie Zheng. *Nephrology, The Permanente Medical Group, Oakland, CA.*

Background: The Permanente Medical Group (TPMG) recognized that Peritoneal Dialysis (PD) is an underutilized method of Renal Replacement Therapy (RRT). Through multiple organizational changes, TPMG has greatly increased PD prevalence and incidence.

Methods: Since 2009, the Kaiser Permanente Northern California (KPNC) region has developed a multidisciplinary approach to PD promotion in, including : **Patient / Family Education**. **Provider and Organizational Education**. **Operational Improvements Monitoring and continuous improvement**.

Results: Since 2009, KP Northern California saw a sustained growth in incident (31% of PD starts in 2013) and prevalent PD patients from 15% in 2009 to 22% by the end of 2013. This corresponds to growth from 630 to 975 prevalent PD patients in KP Northern California.



Conclusions: As an integrated health care system, Kaiser Permanent Northern California, has achieved higher prevalence and incidence of PD in our ESRD populations compare with the rest of the nation.

SA-PO923

Percutaneous Endoscopic Gastrostomy Feeding in Children on Peritoneal Dialysis: Experiences and Outcome Rainer Büscher, Anja K. Büscher, Julia Mohr, Peter F. Hoyer. *Pediatric Nephrology, Univ Children's Hospital, Essen, Germany.*

Background: Percutaneous endoscopic gastrostomy (PEG) feeding is common in children receiving chronic peritoneal dialysis (PD) but rarely used in adult PD patients. Only few studies on its effectiveness are available. The aim of our retrospective analysis was to obtain data on complications and outcome of PD children with PEG in a large pediatric dialysis center.

Methods: In this retrospective single center study we report our experience of PEG feeding in 24 children (14 males) on PD during an 8-year study period. All PEGs were placed under general anaesthesia and prophylactic antibiotics with or without antifungals were given at induction. Double-cuff straight Tenckhoff catheters were placed as a separate procedure and patients were on continuous cycling PD (n=11) or continuous ambulatory PD (n=13). Complications such as spontaneous peritonitis, number of Tenckhoff catheters or indications for change or removal of PEG/button gastrostomy were recorded.

Results: Eighteen out of twenty-four children, median age 2.5 (0.5–12.1) years had a PEG before starting PD and six children, age 0.6 (0.5–5.5) years, had a PEG after PD catheter insertion/start of PD. Most patients were malnourished, with standard deviation score (SDS) for body weight between –3.6 and –0.5 (median –2.4). In 18 patients (75%, 14 patients with PEG insertion before start of PD) no problems were encountered within the first year of observation. In the remaining 6 patients major complications were early bacterial peritonitis in 4 (17%) patients and 2 cessations of PD and temporary change to hemodialysis. Early peritonitis could effectively be treated with intraperitoneal antibiotics. In 6/24 patients, PD was successfully reinitiated shortly after PEG insertion.

Conclusions: Complication rates were lower in our patients than previously described. PEG insertion following PD initiation is possible but carries a risk for peritonitis and PD failure. Antibiotic and antifungal prophylaxis and a temporary stop of PD for 2 – 3 days are highly recommended. However, if possible, PEG insertion should be performed prior to the time of initiating PD.

SA-PO924

Below 0.8g/kg/Day of Protein Intake Restriction Succeeds Favorable Control of Serum Phosphate Levels without Induction of Malnutrition in Patients Treated with Peritoneal Dialysis Hironori Tayama, Tomoaki Miyazaki, Yoshikuni Nagayama, Eri Kawashima, Kiyoko Inui, Yoshihiko Inoue, Ashio Yoshimura. *Div of Nephrology, Dept of Medicine, Showa Univ Fujigaoka Hospital, Yokohama, Japan.*

Background: 0.9-1.2 g/kg/day of daily protein intake is recommenced to patients treated with peritoneal dialysis (PD) according to PD guidelines, because of the supplement for protein loss to PD water fluid. We studied the efficacy of further restriction of protein for clinical state of PD patients, because we have already reported that protein restriction in pre-dialysis has induced favorable peritoneal function at the start of PD treatment.

Methods: Two groups of PD patients, such as 0.9-1.2 g/kg/day of protein intake (HPD, n=12) and 0.5-0.8g/kg/day (LPD, n=14), were studied. All patients of LPD has been continuing protein intake restriction from several years before PD induction. Two groups were compared in residual renal function, urine volum, PD ultrafiltration, index for nutrition (total protein, albumin, Hb), serum phospahe, serum calcium, blood pressure, and amount of protein in PD water after treatment.

Results: Serum phosphate level was siginificantly low in LPD compared to HPD (4.8±1.0 mg/dl versus 5.8±0.9, p<0.03, mean±SD). LPD also induced lower Kt/V (1.52±0.24) than HPD (2.1±0.46, p<0.03). There was no significant difference in amount of protein in PD water after treatment between two groups. There was no siginificant difference in index for nutritional state and other indices studied between two groups.

Conclusions: Below 0.8g/kg/day of protein intake restriction succeeded in better control of serum phosphate levels without induction of malnutrition in patients treated with PD. There was no significant increase in protein loss to PD fluid. Control of serum phosphate levels is critically important for dialysis patients, therefore protein restriction (0.5-0.8g/kg/day) should be recommended to PD patients.

SA-PO925

A Retrospective Observational Study of Peritoneal Dialysis Associated Peritonitis and Encapsulating Peritoneal Sclerosis During Therapy with a Twin-Bag System and Biocompatible Peritoneal Dialysis Solutions Masatsugu Nakao, Izumi Yamamoto, Nanae Matsuo, Yukio Maruyama, Yudo Tanno, Ichiro Ohkido, Masato Ikeda, Keitaro Yokoyama, Takashi Yokoo. *Internal Medicine, The jikei Univ School of Medicine, Tokyo, Japan.*

Background: The clinical relevance of single-bag versus twin-bag systems and conventional versus biocompatible peritoneal dialysis (PD) solutions are unclear. This study investigated PD-associated peritonitis prevalence, its causative microorganisms and encapsulating peritoneal sclerosis (EPS).

Methods: The study included 527 patients who received PD between January 1980 and December 2012 at a single center.We divided patients undergoing PD into three groups according to the type of PD system used, namely single-bag and conventional PD solutions (n = 145), twin-bag and conventional PD solutions (n = 171) and twin-bag and

biocompatible PD solutions (n = 211), and analysed PD-associated peritonitis and EPS incidences. The independent risks of PD-associated peritonitis and EPS were determined by univariate and multivariate logistic models.

Results: PD-associated peritonitis and EPS incidences (times per patient-months) were 1/54.1, 1/102.2 and 1/106.8, respectively, and 13.1%, 12.3% and 0%, respectively. Only the twin-bag system and PD duration were associated with PD-associated peritonitis. Further, peritonitis episode numbers and PD durationas well as β2 microglobulin (β2MG) level and dialysate-to-plasma creatinine ratio were risk factors for EPS. The duration of peritonitis, rather than PD duration, was independently associated with EPS risk in patients with PD-associated peritonitis.

Conclusions: Use of the twin bag system and PD duration, rather than the use of biocompatible PD solutions, decreased PD-associated peritonitis risk. The duration of peritonitis was a risk factor for EPS in addition to β2MG level and D/P Cr.

SA-PO926

Serum Asymmetric-Dimethylarginine, Apelin and N-Terminal Prohormone of Brain Natriuretic Peptide Levels in Dialysis Patients Hulya Taskapan, Recep Bentli. *Nephrology, Inonu Univ, Malatya, Turkey.*

Background: Asymmetric-dimethylarginine (ADMA) is an L-arginine analogue that inhibits endothelial nitric oxide synthase. The physiological effects of apelin are opposite to the actions of angiotensin-II. It may prevent excessive fluid retention by its actions on central vasopressin release. The relationships among serum apelin, Asymmetric-dimethylarginine (ADMA), N-terminal probrain natriuretic peptide (NT-proBNP) levels, and blood pressures in dialysis patients are not well known.

Methods: In age and sex matched 30 hemodialysis (HD), 30 peritoneal dialysis (PD) patients and 20 healthy controls the relationships among serum apelin-36, ADMA, NT-proBNP levels, and blood pressures were evaluated.

Results: Serum ADMA levels in HD patients were significantly higher than in PD patients and controls (0.57±0.17, 0.38±0.067, 0.40±0.06 μmol/L respectively; p: 0.000), ADMA levels in PD patients was not different from in the controls. HD patients had significantly higher serum apelin levels than those of PD patients (0.48±0.53 versus 0.23±0.47pg/mL). There was no difference between controls (0.28±0.34 pg/mL) and PD patients according to serum apelin levels (p>0.05). NT-proBNP levels were higher in both HD and PD patients (5949.66±7617.72; 11357.46±12321.52 pg/mLrespectively) compared to in controls (45.39±43.48 pg/mL) (p:0.000). In multiple regression analyses the predictors of serum apelin levels were BMI (β:0.281,p:0.021), ADMA (β:0.253,p:0.038) and systolic blood pressure (β:-0.243,p:0.046). The predictors of serum ADMA levels were being on HD (β:-0.579,p:0.000). The predictors of serum NT-proBNP levels were serum albumin (β:-0.416,p:0.000)and higher systolic blood pressure (β:0.414,p:0.000).

Conclusions: Being on HD is predictor of high ADMA levels. It may possible that ADMA removal rate by HD is lower. It seems that there is a relationship between serum apelin levels and blood pressure in dialysis patients. Further studies with larger populations are needed in order to clarify the relationship of serum apelin and blood pressure in dialysis patients.

SA-PO927

No Increase in Small-Solute Transport in Peritoneal Dialysis Patients Treated without Hypertonic Glucose for Fifty-Four Months Dominique C. Pagniez,[1] Celia Lessore,[1] Jean-Baptiste Beuscart.[2] *[1]Nephrology, Centre Hospitalier Univ, Lille, France; [2]Geriatrics, Centre Hospitalier Univ, Lille, France.*

Background: Glucose is widely used as an osmotic agent in peritoneal dialysis (PD) patients, but exerts untoward effects on the peritoneum, starting with an increased small-solute transport. The potential protective effect of a reduced exposure to hypertonic (3.86%) glucose solutions has never been investigated.

Methods: The cohort of PD patients attending our center, which tackled the challenge of a restricted use of hypertonic glucose solutions, has been prospectively followed since 1992. Small-solute transport was assessed using an equivalent of the glucose peritoneal equilibration test after 6 months, and then every year. Study was stopped on July 1st, 2008, before the use of biocompatible solutions became common. A linear regression of the D4/D0 ratios with a variance analysis using a marginal mixed model was applied in patients treated with PD for 54 months.

Results: In the study period, 44 such patients were treated for a total of 2376 months, 2058 without hypertonic glucose. There was one episode of peritoneal infection every 18 patient-months. The mean of slopes of the regression lines for D4/D0 ratios was found to be significantly positive (Student's test, p<.001). This result reflected a significant decrease of small-solute transport.

Conclusions: In this large series of long-term PD patients, avoiding hypertonic glucose solutions was associated with an overall decrease of small-solute transport within 54 months, despite a high rate of peritoneal infections.

SA-PO928

The Role of Telephone Follow-Up in the Management of Anemia in Patients with Peritoneal Dialysis Yan-Ru Chen, Hui Peng, Xun Liu, Hui-Qun Li, Wenbo Zhao, Tan-Qi Lou. *Nephrology Div, Dept of Medicine, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Regularly checking hemoglobin of dialysis patients and adjusting EPO dose in time are very important to keep hemoglobin in the target range (110~120g/L). However, since peritoneal dialysis (PD) is mostly performed at home,it is difficult to monitor hemoglobin regularly and timely adjust the EPO dose. The aim of the study is to find whether telephone follow-up could improve the adherence of EPO administration and anemia in peritoneal dialysis (PD) patient.

Methods: based on the previous data of 95 PD patients in our center, we found that patients with longer follow-up interval had lower level of hemoglobin. In order to improve anemia in these patients, we developed telephone follow-up intervention project: telephone follow-up was arranged every month when hemoglobin≥ 110 g/L; in those patients who was the first time using EPO or need to adjust EPO dose, telephone follow-up was arranged at the first 2 weeks, and then every month. And the nurse would urge patients to check routine blood and adjust the dose of EPO according to the results.

Results: In the study there were 37 patients adhering to the PD on–site clinic monthly while 58 with follow-up interval of 2 ~ 6 months. The average hemoglobin is 105.87 ±16.84 g/L before the intervention with target rate at 39%. The dosage of EPO is 103.5 ±39.6 IU/Kg per week. After six months of telephone follow-up intervention, hemoglobin reached 108.78 ±14.01g/L with the target rate at 56%, and dose of EPO was 105.5 + 105.5 IU/Kg per week. There was no difference in the level of hemoglobin or dose of EPO between before and after intervention. However, the patients had a significantly increased target rate after intervention(P = 0.020).

Conclusions: patients on PD in urban of China are difficult to take regularly clinic on-site follow-up. Our results show telephone follow-up would help nurses and doctors in PD center monitor the hemoglobin situation of PD patients and timely adjust their dosage of EPO. It could help to improve anemia of PD patients in China.

SA-PO929

Temporal Changes in Depression and Quality of Life in Incident Peritoneal Dialysis Patients Hye Eun Yoon, Eun Nim Kim, Bum Soon Choi, Yong-Soo Kim. *Internal Medicine, The Catholic Univ of Korea, College of Medicine, Seoul, Republic of Korea.*

Background: Temporal changes in depression and health-related quality of life (HRQOL) over time are not well described in peritoneal dialysis (PD) patients.

Methods: A multicenter prospective observational study was conducted in 343 incident PD patients. Beck's Depression Inventory (BDI), medical outcomes study short form 36-item quality of life instrument, and kidney disease quality of life short form were used to evaluate depression and HRQOL, respectively, at baseline and after 12 months. Bioimpedance analysis was also performed.

Results: The BDI score significantly increased after 12 months (P = 0.039). Scores of physical role significantly increased, but scores of kidney disease-related symptom/problem list, sleep and social support significantly decreased after 12 months. Increase in serum albumin significantly predicted decrease in BDI score (β = -3.7, P = 0.011). Charlson comorbidity index (β = -3.51, P = 0.028) and increase in plasma hemoglobin (β = 5.01, P = 0.001) and serum albumin (β = 11.29, P = 0.048) were independently associated with increase in physical QOL scores. Decrease in adipose tissue index (β = -0.83, P = 0.006) and increase in serum albumin (β = 6.88, P = 0.001) significantly predicted increase in mental QOL scores. Charlson comorbidity index (β = -1.35, P = 0.035) and decrease in peritoneal KT/Vurea (β = -2.7, P = 0.007) significantly predicted increase in kidney-disease related QOL scores.

Conclusions: In conclusion, depressive symptom is aggravated and HRQOL is impaired during 12months in incident PD patients. Changes in nutrition, anemia, adipose tissue and dialysis adequacy are associated with changes in depressive symptoms and HRQOL.

SA-PO930

The Association of Overhydration Status with Depression and Health-Related Quality of Life in Peritoneal Dialysis Patients Hye Eun Yoon, Eun Nim Kim, Bum Soon Choi, Yong-Soo Kim. *Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: This study was to determine the association of overhydration (OH) status with depression and health-related quality of life (HRQOL) in peritoneal dialysis (PD) patients.

Methods: A multicenter study was conducted in 628 PD patients. Body composition monitor, Beck's Depression Inventory (BDI), medical outcomes study short form 36-item quality of life instrument, and kidney disease quality of life short form were used to evaluate OH status, depression and HRQOL, respectively. Patients were divided into two groups according to the OH status; -2L≤OH≤2L group and OH>2L group.

Results: The BDI score did not differ between the two groups. However, the OH>2L group showed significantly lower physical, mental, and kidney-disease related quality of life (QOL) scores compared with the -2L≤OH≤2L group. The OH>2L group showed significantly lower scores in all of the physical QOL subcategories (physical functioning, role-physical, bodily pain, and general health) than the -2L≤OH≤2L group. Among the mental QOL subcategory, scores of social function were significantly lower in the OH>2L group than the -2L≤OH≤2L group. Among the kidney disease-related QOL subcategory, scores of effect of kidney disease, burden of kidney disease, and cognitive function were

significantly lower in the OH>2L group than the -2L≤OH≤2L group. In a multivariate analysis, OH status was not an independent predictor for BDI score and physical and mental QOL scores. However, OH status independently predicted kidney disease-related QOL score (β = -2.354, *P* = 0.012).

Conclusions: In conclusion, OH negatively affects HRQOL in PD patients. Intensive efforts to control fluid overload may improve HRQOL of PD patients.

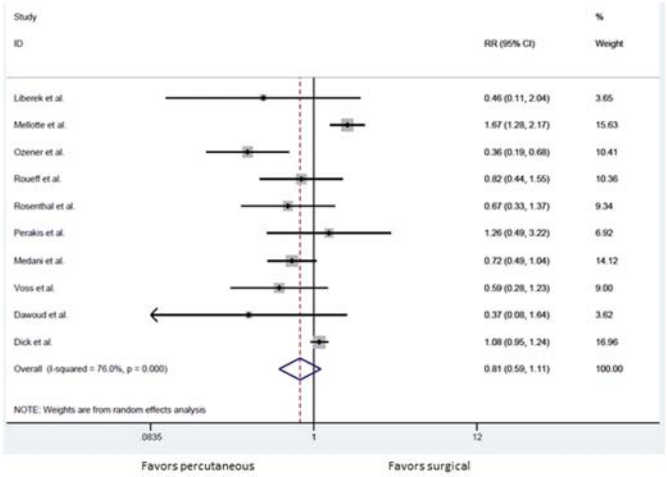
SA-PO931

Percutaneous versus Surgical Insertion of PD Catheters in Dialysis Patients: A Meta-Analysis Kevin Chapla,[1] Ning Fu,[1] Lamya Boujelbane,[1] Alexander S. Yevzlin,[1] Jung-Im Shin,[1,2] Brad C. Astor,[1,2] Micah R. Chan.[1] *[1]Nephrology, Univ of Wisconsin, Madison, WI; [2]Population Health Sciences, Univ of Wisconsin, Madison, WI.*

Background: Several small studies have suggested that the percutaneous method of PD catheter insertion is effective and has a lower complication rate than surgical techniques, though no randomized, controlled study has compared these methods. Our objective was to compare percutaneous PD catheter insertion versus surgical placement in terms of 1-year catheter survival, catheter dysfunction, fluid leak and incidence of peritonitis.

Methods: We searched Medline for English-language literature from 1966 through June 2014, along with national conference proceedings and reference lists of all included publications to identify relevant studies. Random effects models were used to derive the pooled risk ratios, differences in patency and their variations.

Results: Thirteen studies with a total of 2749 subjects met the inclusion criteria. There was no significant difference in 1-year catheter survival in percutaneous versus surgical PD catheter placement (relative risk [RR]=0.81; 95% confidence interval [CI]: 0.59-1.11, p=0.19). Catheter dysfunction also did not differ significantly between the groups (pooled odds ratio [OR]=0.86; 95% CI: 0.57-1.29, p=0.46) respectively. The prevalence of peritoneal fluid leak also was similar for percutaneous and surgical groups (OR=1.10; 95% CI: 0.58-2.09, p=0.77). However, there was a significant lower incidence of peritonitis among those with percutaneous placement (incidence rate ratio [IRR]=0.77; 95% CI: 0.62-0.96, p=0.02).



Conclusions: Our results suggest that there is no significant difference in catheter survival between percutaneous versus surgical placement of PD catheters. Whether there are significant benefits from percutaneous placement in terms of peritonitis rates requires further robust studies.

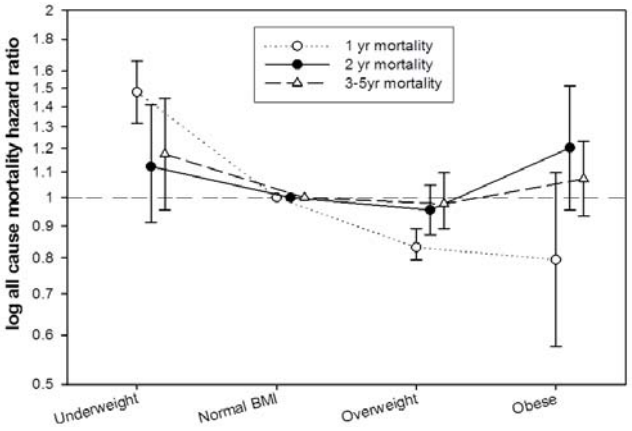
SA-PO932

Association of Body Mass Index with Mortality in Peritoneal Dialysis Patients: A Systematic Review and Meta-Analysis Seyed-Foad Ahmadi,[1] Golara Zahmatkesh,[1] Elani Streja,[1] Rajnish Mehrotra,[2] Connie Rhee,[1] Csaba P. Kovesdy,[3] Daniel L. Gillen,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons UC Irvine MC, Orange, CA; [2]Univ of Washington, Seattle, WA; [3]Memphis VA MC, Memphis, TN.*

Background: We aimed to synthesize the results from all large and robust studies that have evaluated the association of body mass index (BMI) with mortality in patients receiving peritoneal dialysis (PD).

Methods: We searched MEDLINE, EMBASE, Web of Science, CINAHL, and Cochrane CENTRAL, and screened 7,123 retrieved studies for inclusion. Two investigators independently selected the studies using predefined criteria and assessed each study's quality using the Newcastle-Ottawa Quality Assessment Scale. We meta-analyzed the results of the largest studies with no overlap in their data sources.

Results: We included eight studies (total "n": 90,181) in the systematic review and four studies in the meta-analyses. The largest included study revealed that BMI might be differentially associated with one-, two-, and three-year mortalities. Our similar meta-analyses showed that being underweight was associated with trends towards higher one-, two-, and three-to-five year mortalities, while obesity was associated with trends towards a lower one-year mortality and higher two- and three-to-five-year mortalities.



Conclusions: Lower BMIs are associated with higher mortality over both shorter and longer duration while higher BMIs are associated with a lower mortality over shorter duration but a higher mortality over longer duration in PD patients. A plausible mechanism is that obesity favorably impacts short-term outcomes by attenuating malnutrition, while adversely impacting long-term mortality via cardiovascular sequelae.

SA-PO933

Visit-to-Visit Variabilitiy of Systolic Blood Pressure and Outcomes of Peritoneal Dialysis Patients Hyung Ah Jo,[1] Jung Nam An,[1,2] Jung Pyo Lee,[1,2] Chun Soo Lim,[1,2] Kook-Hwan Oh,[1] Yun Kyu Oh.[1,2] *[1]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea.*

Background: Hypertension is common among patients with end stage renal disease and often remains poorly controlled in peritoneal dialysis (PD) patients. Many PD patients suffer of cardiovascular complications. Recent studies have suggested that a high visit-to-visit systolic blood pressure (SBP) variability is associated with an increase in subsequent cardiovascular events and complications. However, there are few studies about visit-to-visit SBP variability and outcomes in PD patients.

Methods: We reviewed 249 PD patients in Seoul National University Hospital from May 2005 to March 2011. Inclusion criteria were patients receiving PD at least 15 months. Subjects were followed up for an average of 42 months, during which time cardiovascular and mortality events were recorded. Among them, 39 patients were excluded due to short PD duration time and 2 patients had no SBP data. We retrospectively reviewed office SBP data up to two years later from PD start date. The subjects were grouped as quartile based on their office based SBP calculated using standard deviation. Primary outcomes were composite events of cardiovascular events and all cause mortality. Secondary outcome was residual renal function defined as anuria event.

Results: High SBP variability patients had significantly higher proportion of smoking history and C reactive protein and lower albumin and had more anti-hypertensive medications. During the follow-up, 15 patients had primary outcome. Although not significantly due to small event size, high visit-to-visit SBP variability patients had more cardiovascular events and all cause mortality. High SBP variability patients had significantly more experienced anuria events (Q1:5, Q2:8, Q3:13, Q4:17, p=0.010). Cox proportional hazard model revealed that fourth quartile of SBP variability patients had 5.223 hazard ratio than one quartile group.

Conclusions: Larger variability of visit to visit SBP in PD patients had more cardiovascular risk factors and correlated with renal function decline.

SA-PO934

Uric Acid and Mortality in Peritoneal Dialysis Patients Eunjin Bae, Hyunjeong Cho, Sunhwa Lee, Ji In Park, Nara Shin, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: Although hyperuricemia as well-known risk factor for hypertension, coronary heart disease and chronic kidney disease, however, a role of uric acid (UA) in chronic dialysis patients is still scarce. We explored the association between UA level and mortality according to dialysis mode.

Methods: Among 1,682 prevalent dialysis patient enrolled in Clinical Research Center for End Stage Renal Disease (CRC-ESRD) in Korea, we included patients with available UA level at the time of enrollment. UA levels were categorized as follows: <5.5, 5.5–6.4, 6.5–7.4, 7.5–8.4 (reference group), and ≥8.5 mg/dL. Cox regression analysis was used to calculate the hazard ratio (HR) of all-cause mortality according to UA group.

Results: A total of 908 hemodialysis (HD) and 637 peritoneal dialysis (PD) patients were included in final analysis. UA level was significantly higher in HD (median [IQR], 7.2 [6.1–8.3]) than in PD (6.7 [5.8–7.6]) patients (p<0.001). Interestingly, UA level showed different relation with mortality according to dialysis mode. In PD patients, UA was negatively associated with mortality rate (p<0.001), however, it could not showed significant association in HD patients (p=0.739). In the Kaplan-Meire curve, we proved the lowest UA group (UA< 5.5 mg/dL) showed highest mortality rate in PD patients during median 18.7

months of follow up (Log-rank P<0.001). Compared with UA 7.5–8.4 group, UA <5.5 mg/dL predicted all-cause mortality even after adjusted by age, sex, body mass index, dialysis vintage, systolic blood pressure, diabetes, hemoglobin, hs-CRP, albumin level (HR; 4.408, 95% confidence interval; 1.490–13.042, p=0.007) in PD patients.

Conclusions: In this study, we elucidated that UA level of chronic dialysis patients had a different influence on mortality according to dialysis mode. Interestingly, we found paradoxical associations between UA level and mortality in PD patients, not in HD patients. Further prospective studies are warranted to validate these findings.

SA-PO935

Diastolic Dysfunction Is Related to Thyroid Hormone in Incident Patients on Dialysis Marcela Avila,[1] Virginia Sanchez,[2] Oscar Orihuela,[3] Carmen María del Prado,[1] Francisco Martinez-Baca,[4] Carmen Josefina Mora,[1] Teresa Renata Romero,[1] Ramon Paniagua-Sierra.[1] *[1]Unidad de Investigacion Medica en Enfermedades Nefrologicas, Hospital de Especialidades, CMN S XXI IMSS, Mexico, D.F., Mexico; [2]Medicina Interna, Hospital General de Zona 1 Venados, IMSS, Mexico, D.F., Mexico; [3]Servicio de Cardiologia, Hospital de Especialidades, CMN SXXI IMSS, Mexico, D.F., Mexico; [4]Hospital de Cardiología, CMN SXXI IMSS, Mexico, D.F., Mexico.*

Background: Diastolic Dysfunction (DD) is a frequent findingin patients on dialysis. Thyroid hormones (TH) are related to anatomical cause of DD; however, information about the relationship with DDis scarce. Our aim was to know if this association holds true in incident patients on dialysis.

Methods: A cross-sectional study design with 197 incident patients on dialysis programs was performed. Clinical and demographic data were registered. Diastolic dysfunction was evaluated using early diastolic mitral and annulus inflow velocities (cm/s); e´, E/e´, E/A ratios, with pulsed-wave Doppler echocardiography.Plasma determination from TSH, total and free T3 (t/f), T4 (t/f) were measured by RIA Diagnostic Kits.

Results: Mean age was 47.1 years, 64% men, BMI 25.3 Kg/m^2, SBP and DBP; 135.2 and of 82.6 mm Hg respectively; 42% were diabetic (DM) and 58% were on CAPD. Plasma tT3 <0.6 ng/mL in 30.2% of dialysis patients,TSH ≥ 4.5 µIU/mL in 28.1%, TSH (4.5-10µIU/mL+ fT4 (7-18pg/mL) in 32%.DD was presented in 62%;grade I 18%; grade II 8% and grade III 36%. The patients with DD were older and more had DM (all p<0.001) than not. On multiple regression analysis, (t/f) T3was inversely associated with and E/é (r=-0.20, p<0.05 and r=-0.24 p<0.01). tT4 with E/é (r=-0.24, p<0.001) and with E/A (r=-0.22 p<0.01) fT4 with ejection fraction (EF), (r= -0.157, p<0.03). On multiple logistic regression analysis; OR (95%CI,); tT3; 8.72 (1.2-63,p<0.03) tT4; 0.96(0.94-0.98,p<0.002), tT4; 1.26 (1.06-1.49,p<0.007) and age; 0.89(0.85-0.93,p<0.001), were independently risk factor for DD, gender 0.57(0.22-1.41,p<0.22) and DM 0.66(0.29-1.48p<0.31) were not.

Conclusions: Our study showed high prevalence of diastolic dysfunction in incident patients on dialysis; the independent risk factors for DD were Total T3, Total and free T4, and age.

Stability of Intraperitoneal Antibiotics in Extraneal 7.5% Icodextrin Peritoneal Dialysis Bags Dwarakanathan Ranganathan,[1] Saiyuri Naicker,[2] Steven C. Wallis,[2] Jeffrey Lipman,[1,2] Sharad K. Ratanjee,[1] Jason A. Roberts.[1,2] *[1]Renal Medicine/Critical Care Medicine, Royal Brisbane and Women's Hospital, Herston, Brisbane, Queensland, Australia; [2]Burns, Trauma and Critical Care Reserch Unit, Univ of Queensland, Herston, Brisbane, Queensland, Australia.*

Background: The standard treatment of peritoneal dialysis (PD)-associated peritonitis is intraperitoneal administration of antibiotics into the PD solution. Effective empiric antibiotics include vancomycin (VCM) in combination with gentamicin (GTM). Patients with PD-associated peritonitis may be advised to store PD bags with pre-mixed antibiotics at home. The purpose of this study was to assess the stability of pre-mixed antibiotics in PD bags when stored at different temperatures over a 14 day period.

Methods: 27 Baxter 7.5% Icodextrin (Extraneal) PD bags were dosed with GTM alone (n=9), VCM alone (n=9) and GTM and VCM in combination (n=9). The concentration of GTM was intended to be 20 mg/L and VCM 1000 mg/L in all experiments. Bags were stored in triplicate at 37°C, room temperature (25°C) and refrigeration (4°C). Samples from the bags were taken at 0, 6, 24, 48, 96, 168 and 336 hours. Antibiotic concentrations were quantified using a validated chromatographic method for each antibiotic. The initial concentration of the 0 hour sample was considered as 100%. A storage interval was considered unstable if the concentration of the antibiotic dropped <90% of the initial value.

Results: GTM alone was found to be stable for 14 days at all temperatures. VCM alone was stable for 4 days at 37°C and for 14 days at both 25°C and 4°C. The combination of GTM and VCM was stable for 4 days at 37°C and for 14 days at 25°C and 4°C.

Conclusions: Icodextrin PD bags pre-mixed with GTM and VCM alone and in combination with each other can remain stable when stored at room temperature and refrigeration for up to 14 days. At an elevated temperature, 37°C, whilst GTM remained stable for 14 days, VCM was only stable for 4 days, as was the combination of the two. To our knowledge, the stability of VCM in combination with GTM in Icodextrin solution for 14 days has not been previously assessed.

Stability of Cephalosporin Antibiotics in Extraneal 7.5% Icodextrin Peritoneal Dialysis Bags Dwarakanathan Ranganathan,[1] Saiyuri Naicker,[2] Steven C. Wallis,[2] Jeffrey Lipman,[1,2] Sharad K. Ratanjee,[1] Jason A. Roberts.[1,2] *[1]Renal Medicine/Critical Care Medicine, Royal Brisbane Hospital, Brisbane, Queensland, Australia; [2]Burns ,Trauma and Critical Care Reserch Centre, Univ of Queensland, Brisbane, Queensland, Australia.*

Background: The standard treatment of peritoneal dialysis (PD)-associated peritonitis is intraperitoneal administration of antibiotics into the PD solution. Effective empiric antibiotics include cefazolin (CZL) in combination with gentamicin (GM) or ceftazidime (CTD). Patients with PD- associated peritonitis may be advised to store PD bags with pre-mixed antibiotics at home. The purpose of this study was to assess the stability of pre-mixed cephalosporin antibiotics in PD bags when stored at different temperatures over a 14 day period.

Methods: 36 Baxter 7.5% Icodextrin (Extraneal) PD bags were dosed with CZL alone (n=9), CTD alone (n=9), CZL and CTD (n=9), and CZL and GM in combination (n=9). The concentrations of CZN and CTD were intended to be 500mg/l and GM at 20mg/l. Bags were stored in triplicate at 37°C, room temperature (25°C) and refrigeration (4°C). Samples were taken at 0, 6, 24, 48, 96, 168 and 336 hours. Antibiotic concentrations were quantified using validated chromatographic method for each antibiotic. The initial concentration of the 0 hour sample was considered at 100%. A storage interval was considered unstable if the concentration of the antibiotic dropped ≤90% of the initial value.

Results: CZL alone was stable for 24 hours at 37°C, 7 days at 25°C and 14 days at 4°C. CTD alone was found to be stable for only 6 hours at 37°C, 2 days at 25°C and 14 days at 4°C. The combination of CZL and CTD was stable for 24 hours at 37°C, for 2 days at 25°C and for 14 days at 4°C. The combination of CZL and GM was stable for 1 day at 37°C, for 4 days at 25°C and for 14 days at 4°C.

Conclusions: Icodextrin PD bags pre-mixed with CZL alone, CTD alone, combination of CZL and CTD, and combination of CZL and GM can remain stable if refrigerated for up to 14 days. At room temperature, CZL stability approaches 7 days whilst CTD stability is only 2 days. To our knowledge, the stability of CZL in combination with CZL and GM in icodextrin solution for **14 days** has not been previously assessed.

SA-PO938

Inflammatory Biomarker Pairs as Outcome Measures in Peritoneal Dialysis Tiane Dai, Ying Wang, Sharon G. Adler. *Nephrology, Harbor-UCLA Medical Center, Torrance, CA.*

Background: We showed JAK/STAT pathway activation in the peritoneal membrane of rats receiving peritoneal dialysis (PD) with 4.25% Dianeal; concomitant PD with a JAK1/2 inhibitor attenuated inflammation, fibrosis, and hypervascularity. We also showed that Long-term (LT) PD patients had higher mean levels of the inflammatory and fibrotic STAT-regulated biomarkers MCP-1 and periostin than New PD patients (KI, in press). High MCP-1 and periostin levels in LT versus New patients were observed in a subset, but not all LT patients.

Methods: We measured inflammation/injury biomarkers in PD effluent and performed an analysis of pairs of baseline PD effluent inflammatory biomarkers in LT (n=8) and New (n=8) PD patients to identify pairs that separated LT patients with higher levels of inflammation/injury from New and LT patients with lower values. We then determined whether these pairs predicted a composite outcome of death and/or PD membrane failure (defined by the subsequent need for icodextrin or transfer to hemodialysis due to membrane failure) after a follow-up period of 29 +2months.

Results: Of 83 analytes tested, 28 could be reliably measured by electrochemiluminescence (Meso Scale Discovery, Rockville, MD). In this small sample, some analyte pairs separated LT from New PD patients. The best biomarker pairs included secreted protein acidic and rich in cysteine (SPARC, aka osteonectin) and were SPARC/Cadherin-3; SPARC/ICAM1; SPARC/TNFα; SPARC/CA125; and SPARC/MCP-1. Graphic representation of these relationships show a clustering of a subset of four LT patients whose PD effluent values distinguished them from other LT and New patients. These LT PD patients had a statistically significantly higher risk for the composite outcome than comparator patients (Chi square, p=0.02). The pairs associated with risk better than SPARC alone.

Conclusions: These data suggest that pairs of PD effluent inflammatory biomarkers may reflect evolving inflammation and fibrosis in PD patients. The concentration of SPARC in PD effluent, particularly in combination with MCP-1, may be useful in predicting membrane failure and/or death in LT PD patients.

SA-PO939

Rate of Decline of Residual Kidney Function before and after the Start of Peritoneal Dialysis Lian He,[1,2] Zita C. Abreu,[2] Tushar Malavade,[2] Charmaine E. Lok,[2] Joanne M. Bargman.[2] *[1]Peking Univ 3rd Hospital, Beijing, China; [2]Univ of Toronto, Toronto General Hospital, Toronto, ON, Canada.*

Background: There is a paucity of information on whether peritoneal dialysis (PD) slows the decline of residual kidney function (RKF)compared to the natural slope of RKF decline prior to dialysis start. Confounding factors may contribute to the change in RKF in patients who receive PD. Our aim was to analyze the course of RKF decline before and after initiating PD, and to determine the main factors affecting RKF decline during the PD period.

Methods: In this retrospective study, we determined individual glomerular filtration rates (GFR) (ml/min/ 1.73m^2 per month) for the 12 months before and 12 months after initiating PD in 77 new PD patients in a large academic medical center (2008-2012). The GFR was estimated by the MDRD equation in the predialysis period and by averaging 24-hour urine creatinine and urea clearances in the PD period. The rate of RKF decline was calculated using unadjusted linear regression analysis. Wilcoxon signed rank test was used to compare RKF decline before and after peritoneal dialysis initiation. Multivariate linear regression was used to identify independent risk factors for RKF decline.

Results: A slower mean rate of RKF decline was observed in the PD period compared with the predialysis period (–0.21±0.30 versus –0.59 ± 0.55 ml/min/1.73 m^2/month, P< 0.01). Higher baseline RKF, higher serum phosphate and older age were independently associated with faster decline of RKF (all P<0.01). There were no other clinical associations with the rate of RKF decline (e.g. gender, comorbidities, use of ACEI/ARB or use of diuretics during the 1styear of PD).

Conclusions: In patients with advanced chronic kidney disease, initiating PD was associated with a slower mean rate of RKF decline compared to the rate in the predialysis period. Higher RKF, higher serum phosphate and older age at PD initiation are independent factors for a faster decline of RKF in PD phase.

SA-PO940

Carotid Artery Changes in Uremic Patients Undergoing Peritoneal Dialysis Treatment Damir Rebic, Senija Rasic. *Clinic for Nephrology, University Clinical Center of Sarajevo, Sarajevo, Bosnia and Herzegowina.*

Background: We compared the structural and hemodynamic changes in the common carotid arteries (CCA) between end-stage renal disease (ESRD) patients before turning on the renal replacement therapy and after 18 months of peritoneal dialysis (PD) treatment with the objective to identify predicting risk factors for atherosclerosis and the impact of PD treatment on vascular remodeling.

Methods: This longitudinal study included 50 patients before start and 18 months after PD treatment. It was used B-mode ultrasonography to study changes CCA, were divided into groups of subjects according Mannheim consensus for carotid ultrasonography (groups AS0, AS1, AS2, AS3). A simplified peritoneal equilibration test was performed after 6 months of PD treatment, and at the end of the observation period. A multiple regression analysis was applied to examine the relationship between CCA ultrasound parameters (intima—media thickness (IMT), plaque score, CCA diameter, peak systolic velocity (PSV) and end-diastolic velocity (EDV)), parameters of PD and a set of clinical and laboratory parameters.

Results: After 18 months of PD treatment IMT, plaque score, PSV and EDV was significantly lower than patients in ESRD. The adequacy of dialysis, compared to other observed group was better in AS0 group of patients at the beginning, but at the end of the study. The value of endothelin-1 (ET-1) at baseline were higher in comparison with value after 18 months PD (6.32 versus 4.0 pg/mL), in contrast to nitric oxide (NO), which showed an inverse relationship (40.72 versus 48.0 µmol/L). At the beginning of the study 44% of patients had severe atherosclerosis (AS3) until after 18 months of PD treatment 26% of patients had AS3 (p <0.016).

Conclusions: Homocysteine, ET-1, low-density lipoprotein, high-density lipoprotein, lipoprotein(a), C-reactive protein and product CaxP are an independent risk factor for atherosclerosis and was significantly correlated with IMT CCA. The noninvasive carotid ultrasound can be used to monitor atherosclerosis in PD patients. The treatment with PD, with the regulation of these vasoactive molecules and other vascular risk factors, importantly impedes vascular remodeling.

SA-PO941

Prognostic Value of Predialysis Indices for Early Technique Failure in Peritoneal Dialysis Patients Masaru Matsui, Yasuhiro Akai, Katsuhiko Morimoto, Ken-Ichi Samejima, Yoshihiko Saito. *First Dept of Internal Medicine, Nara Medical Univ, Kashihara, Japan.*

Background: Peritoneal dialysis (PD) offers several advantages in preserving residual renal function and improving survival compared hemodialysis (HD). Early PD technique failure is defined as the switch from PD to HD in relatively early phase after instituting PD. This failure is often due to poor volume control and antibiotics resistant peritonitis. A number of predictors of early PD technique failure were reported but these factors were mostly obtained after starting PD, while predialysis predictors for early technique failure have remained unclear. We conducted this study to investigate the prognostic value of predialysis indices for early technique failure in PD patients.

Methods: We recruited consecutive 183 PD patients who were treated at Nara Medical University Hospital between April 1, 1997 and December 31, 2012. Forty-two patients were excluded because of transition from HD and withdrawal from PD within three months, leaving 141 patients for analysis. Clinical characteristics and laboratory data within three months BEFORE PD initiation were analyzed. The primary outcome was the composite of time to combined use of HD and transition to HD within two years after PD institution.

Results: Overall, mean age of the patients was 61±14 years and 89 patients (63%) were male. During study period, primary outcome was observed in 38 patients. Although diabetes, blood pressure and hemoglobin levels were similar between participants with and without outcome events, obesity and serum levels of albumin and corrected calcium were significantly different. Multivariate followed by univariate Cox proportional hazard regression analysis revealed that older age [hazard ratio (HR) 2.83(1.42-5.92)], obesity [HR 3.01(1.53-5.79)], low serum levels of albumin [HR 2.78 (1.40-5.55)] and corrected calcium [HR 2.78 (1.37-5.69)] were independent predictors of early PD technique failure.

Conclusions: Pre-dialysis older age, obesity and low serum albumin and calcium could be associated with early technique failure in PD patients.

SA-PO942

Cell-Free DNA: A New Method to Determine Acute Cell Damage in Peritoneal Membrane Grazia Maria Virzì, Sabrina Milan Manani, Alessandra Brocca, Massimo de Cal, Roberto Zambon, Chiara Pasqualin, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology-IRRIV, St. Bortolo Hosp.*

Background: Peritonitis remains a frequent complication of peritoneal dialysis (PD). Cell-free DNA (cfDNA) is a circulating extracellular DNA fragment and originates from necrotic and apoptotic cells. cfDNA is present in the peritoneal effluent of PD patietns (pts). The objective of this study was to compare cfDNA levels in the peritoneal effluent in PD pts with and without peritonitis.

Methods: We enrolled 53 PD pts: 30 pts without history of systemic inflammmation and peritonitis in the last 3 months (group A, 17 male, 66±14 years) and 23 pts with acute peritonitis (group B, 14 male, mean age 68 ±16 years). CfDNA was extracted from peritoneal effluent and was quantified by Real time PCR in Genome Equivalent (GE)/ml for β-globin gene.

Results: The median concentration of cfDNA in the peritoneal effluent in group A was 31 GE/ml (16-51), as previosly reported. The concentration in group B was 25523 GE/ml (IQR 18831-459541). Quantitative analysis of cfDNA showed significantly higher levels in pts with peritonitis compared with pts without (Figure 1) (p<.01), similarly as WBC increasing during acute peritonitis. A significant positive correlation was observed between cfDNA and WBC values (rho=.885, p<.01). In group B, there is no difference in cfDNA levels between Gram+/- peritonitis, pts with single episode and relapsing peritonitis, but there is a significantly difference in cfDNA concentration between PD pts with positive and negative outcomes (62137, IQR 12850-119541 versus 122793, IQR 20159-607353; p<.01).

Conclusions: Our data demonstrated that cfDNA is increased in peritoneal effluent of PD pts with acute peritonitis. We speculate that cfDNA quantification in peritoneal effluent could be an innovative method to determine acute cell damage *in vivo* origined by apoptosis and necrosis in peritoneal cells.

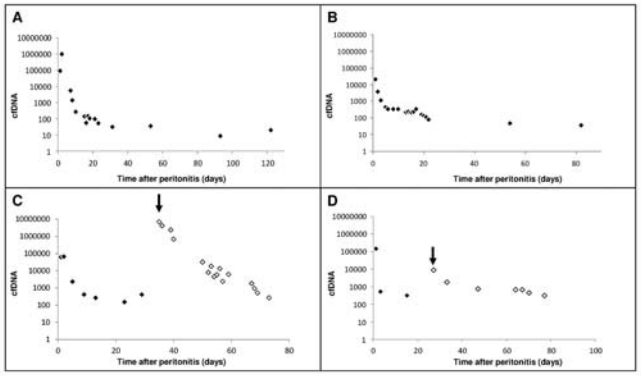
SA-PO943

Cell-free DNA Trend in 23 PD Patients with Peritonitis Sabrina Milan Manani, Grazia Maria Virzì, Alessandra Brocca, Silvia Pastori, Chiara Pasqualin, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology-IRRIV, St. Bortolo Hosp.*

Background: Peritonitis is still the major complication associated with peritoneal dialysis (PD). Perionitis treatment should aim for rapid resolution of inflammation. Cell free DNA (cfDNA) is present in the peritoneal effluent of PD patients (pts). There is no data on cfDNA in PD pts with peritonitis. We present a case series of 23 PD pts with peritonitis.

Methods: 23 PD pts (14 M; mean age 63.1±16.3) were enrolled. We collected peritoneal effluents from the first day of peritonitis until the 120th day. WBC counts were routinely measured. CfDNA was extracted from peritoneal effluents and quantified by Real time PCR for the β-globin gene (genome equivalents (GE)/ml).

Results: 17 pts were treated with CAPD and 6 with APD. The average length of PD treatment was 21 months (minimum: 3.6–maximum: 132.9). All pts were treated and clinically recovered from peritonitis after 13.5 days±5.4. 18 pts had a first episode of peritonitis and responded to first-line antibiotics. 5 had a relapsing episode of peritonitis; subsequently, responded to another course of intra-peritoneal antibiotics. We observed a similar cfDNA trend in all patients. The cfDNA concentration in the peritoneal effluent at the first day of peritonitis was very high, concordaly with WBC. Then, cfDNA level tended to progressively decrease during follow up for each patient. CfDNA level diminished slowerly than WBC count. In 5 relapsing peritonitis, at the first day, we observed a new rapid increased of cfDNA level (consistent with WBC). We reported 4 pts'trends.



Conclusions: We hypothesized that cfDNA in peritoneal effluent could be a specific indicator of peritonitis. However, the exact characteristics of cfDNA kinetics remained uncertain. Further studies are warranted to clarify the precise mechanism and clinical significance of elevated cfDNA in this population.

Peritoneal Dialysis Effluent and Serum Angiopoietin-Like Protein 2 Levels in Peritoneal Dialysis Patients Shinichi Abe,[1] Yoko Obata,[1] Tomoya Nishino,[1] Kumiko Muta,[1] Takehiko Koji,[2] Shigeru Kohno.[1] *[1]Second Dept of Internal Medicine, Nagasaki Univ School of Medicine, Nagasaki City, Japan; [2]Dept of Histology and Cell Biology, Nagasaki Univ Graduate School of Biomedical Science, Nagasaki City, Japan.*

Background: Angiopoietin-like protein 2 (Angptl2) is a protein which is structurally similar to angiopoietin, and is primarily secreted by adipose tissue. Recent reports suggest that Angptl2 induces chronic inflammation and angiogenesis via promoting the production of inflammatory cytokines such as IL-6. Meanwhile, chronic inflammation concerns the increase of peritoneal permeability in peritoneal dialysis (PD) patients, and there have been no studies which assess PD effluent or serum Angptl2 levels in PD patients. We measured Angptl2 levels in the PD effluent (P-Angptl2) and serum (S-Angptl2), and investigated the relationship between Angptl2 and peritoneal function.

Methods: Subjects were 33 PD patients in our hospital. PD effluent and serum samples of each patient were collected at the time of peritoneal equilibration test, which was performed at 12 and 24 months after the start of PD. Angptl2 and IL-6 levels were measured by ELISA, and retrospectively analyzed the relationship with D/P creatinine or other laboratory data.

Results: A positive correlation was observed between P-Angptl2 level and D/P creatinine, both at 12 and 24 months (12 months later: r=0.58, p=0.04, 24 months later: r=0.86, p<0.01). Meanwhile, S-Angptl2 level had no correlation with P-Angptl2 level or D/P creatinine. P-Angptl2 and PD effluent IL-6 levels showed positive correlation only at 24 months (12 months later: r=0.45, p=0.12, 24 months later: r=0.84, p=0.02). The comparison between P-Angptl2 and S-Angptl2 levels indicated that Angptl2 is locally secreted in peritoneal cavity.

Conclusions: Our results indicate that P-Angptl2 level may become an indicator of peritoneal function in PD patients. In addition, it is suggested that Angptl2 is locally secreted in peritoneal cavity and involved in the increased peritoneal permeability through IL-6 induction in PD patients.

SA-PO945

Incidence of Encapsulating Peritoneal Sclerosis: A Single-Center Experience with Long-Term Peritoneal Dialysis in Saudi Arabia Naveed Aslam, Seddeg Younis, Dildar Ahmed Laghari, Ebadur Rahman. *Nephrology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

Background: Encapsulating peritoneal sclerosis (EPS) is a serious complication of long-term peritoneal dialysis (PD). The reported incidence varies between 0.5% and 4.4% and increases with length of time on PD. According to our knowledge there is no data available on Epidemiology of EPS in Saudi Arabia. The aim of the present study was to assess the incidence of EPS and outcome in a tertiary care hospital in Riyadh.

Methods: In all the patients started on Peritoneal Dialysis from Jan 2000 to Dec 2013 in Prince Sultan Military Medical City and maintained on PD for 5 or more years, clinical symptoms were documented and abdominal computed tomography (CT) findings were reviewed. Patients were tracked whether they remained on PD, transferred to hemodialysis (HD), underwent transplantation or died.

Results: Among the total of 350 patients retrieved from data base, only 12 patients met the inclusion criteria (dialysis duration 5 or more years). 2 of them were transplanted, 2 were shifted on haemodialysis and 8 patients are still on PD.

Patient Age(Years)/Sex	Duration on PD (Years)	CT Score	Albumin (g/l) (38-51)	ESR (mm/hr) (nr 0-15)	CRP (mg/l) (nr 0-6)	CrCl	Kt/V
40/F	14	8	37	10	2	65	2.1
59/M	11	6	35	8	4	62	2.3
24/M	9	1	45	15	6	58	2.4
57/M	9	1	38	12	2	59	2.3
78/M	7	2	33	11	8	48	1.9
78/F	6	1	39	20	1	55	2.1
43/M	6	1	41	13	3	66	2.2
39/M	5	1	42	17	7	64	2.4

Abdominal CT imaging was done in all patients; only 2 patients had radiological features consistent with EPS, with a radiological score of 8 and 6; others had localized peritoneal calcification. None of the patients met the 2000 criteria of International Society of Peritoneal Dialysis for a diagnosis of EPS; all having good clearance and normal nutritional and inflammatory markers.

Conclusions: The present study suggests that, in patients maintained on PD for 5 or more years at our center, the incidence of EPS is nill. Localized Peritoneal calcification could be part of atherosclerotic changes. These findings need to be confirmed in other centers in Saudi Arabia.

SA-PO946

Clinical Characteristics and Outcome of Elderly Patients on Peritoneal Dialysis: A Retrospective Single Center Experience Naveed Aslam, Dildar Ahmed Laghari, Seddeg Younis, Ebadur Rahman. *Nephrology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

Background: The number of elderly ESRD patients is on rise in Saudi Arabia. A few studies specifically investigating elderly patients on PD (peritoneal dialysis) show great uncertainty on the factors involved in the vital prognosis; however, PD has recently become clinically acceptable as an appropriate therapy for these patients. The objective of this study is to describe outcome, in elderly patients (age > 65 years), in terms of technique and patient survival and possible correlation with peritoneal transport status (PTS), anthropometric data, biochemical data and dialysis adequacy (Kt/V).

Methods: In a retrospective, single-center study, we evaluated a total of 96 patients, aged 65 years and above, newly started on PD during January 2006 to December 2013. Serum albumin, hemoglobin, b2-microglobulin, CRP, triglyceride, creatinine, calcium, phosphate, PTH were assessed. Withdrawal from PD, peritonitis and death were recorded.

Results: The average age of patients starting PD was 78.3 ± 7.2 and the percentage of diabetes was 35%. The 2 and 5-year rates of patients survival were 86% and 63% respectively. Technique survival rates were 64% and 26% respectively. Only 10% of the patients could perform their PD therapy without the assistance of any family member or nurses. 78% of the patients showed high peritoneal transport property (High: 28%, High-Average: 50%, Low-Average: 20%, Low: 2%). Only 50% of the patients were on CAPD. Albumin level and CRP were negatively associated with patient survival.

Conclusions: Overall elderly patient survival was not different compared to younger patients. The high transport property is a contributory factor in low serum albumin levels. We consider that PD in elderly patients is safe with good efficacy and quality of life. There are no medical concerns to introducing PD therapy in elderly ESRD patients.

Funding: Government Support - Non-U.S.

SA-PO947

Hair Zinc Concentration Correlates with Cardiac Contractility in Peritoneal Dialysis Patients Hideki Yamahara,[1] Takanobu Imada,[1] Yoshiki Okuno,[1] Maiko Seo,[1] Tatsuyori Morita,[1] Keiko Kono,[1] Hiroya Masaki,[2] Mitsushige Nishikawa,[1] Ichiro Shiojima.[1] *[1]Dept of Medicine II, Kansai Medical Univ, Hirakata, Osaka, Japan; [2]Dept of Laboratory Medicine and Clinical Sciences, Kansai Medical Univ, Hirakata, Osaka, Japan.*

Background: Renal failure patients often have trace elements deficiency due to dietary restriction. Zinc is an essential micronutrient, and its deficiency is associated with many diseases including cardiovascular disease. Because serum zinc concentration shows a diurnal variation, we selected the zinc concentration in the hair as a long-term measure of body zinc content. Peritoneal dialysis (PD) is an important renal replacement therapy for end stage renal disease patients, since it improves their quality of life and reduces dietary restriction. Nevertheless, the association between various diseases and trace elements kinetics in PD patients are not well elucidated.

Methods: Hair zinc concentration (HZn) was measured in 16 PD patients using inductively coupled plasma mass spectorometry (La Belle Vie Inc. Japan). We also measured eGFR, serum zinc concentration (SZn), and body fluid volume markers (hANP, BNP, and NT-proBNP), and performed transthoracic echocardiography. Because fluctuation range is large in hair zinc concentration, common logarithm was used for statistical analysis.

Results: HZn in PD patients showed a distribution similar to normal control group (Average 165,948 ppb, -1SD 123,310ppb, +1SD 223,357ppb). There was no significant correlation between HZn and SZn (r=-0.149, p=0.589). HZn negatively correlated with NT-proBNP (r=-0.592, p=0.0183), but not with hANP or BNP. HZn positively correlated with ejection fraction (r=0.535, p=0.0385), and negatively correlated with left ventricular dimensions in end-diastole (r=-0.518, p=0.047) and end-systole (r=-0.552, p=0.0315). SZn did not correlate with any of these factors.

Conclusions: In PD patients, hair zinc concentration correlates with NT-proBNP and cardiac contractility. NT-proBNP was previously reported to be a predictor of cardiovascular

disease in renal failure patients. Whether body zinc content can be a predictor of cardiovascular disease in patients with end stage renal disease awaits further investigation.

SA-PO948

Epidemiological Characteristics and Modality Impact on Long-Term Survival in a Cohort of Elderly Incident PD Patients
Natalia Maria da Silva Fernandes,[1,2,3] Marcia R.G. Franco,[1,2,3] Abdul Rashid Tony Qureshi,[4,5] Jose C. Divino-Filho.[4] *[1]Dept of Internal Medicine, School of Medicine, Federal Univ of Juiz de Fora, Juiz de Fora, Brazil; [2]NIEPEN (Núcleo Interdisciplinar de Ensino e Pesquisa em Nefrologia), Federal Univ of Juiz de Fora, Juiz de Fora, Brazil; [3]IMEPEN Foundation, Juiz de Fora, Brazil; [4]Div of Renal Medicine, CLINTEC, Karolinska Instt, Stockholm, Sweden; [5]Baxter Novum Div of Renal Medicine, CLINTEC, Karolinska Instt, Stockholm, Sweden.*

Background: As the number of elderly patients starting renal replacement therapy (RRT) increases, it is important to understand their clinical characteristics as well as the most appropriate RRT for this group of patients**.** To describe a cohort of elderly incident PD patients and to evaluate the modality impact on the long-term survival.

Methods: Multicenter prospective cohort (Dez/2004-Oct/2007) with 2144 elegible patients; 762 ≥ 65 years old. Patients were followed up until transfer to HD, recovery of renal function, renal transplantation, death or loss to follow-up. Demographic and clinical data were evaluated at study enrollment and described as mean±SD, median or percentage. As RR is not proportional along the time, a time-dependent Cox analysis was performed, with PD modality (APD versus CAPD) as dependent variable.

Results: Mean age 74.6 ±6.7 yrs, 53% women, 69% Caucasians. Pre-dialysis nephrological care was given to 56% of the patients, 54 % received dialytic modalities information and only 23% chose PD as an option. In relation to family income, 31% earned up to 2 minimum wage per month, 58.1% had basic education and the most frequent co-morbidity were hypertension (78%) and diabetes (50%) with 47% presenting Davies score >=2. Death occured in 31% of the patients.

Follow-up time (Reference APD vs CAPD)	HR (CI)
<18months	1.11(0.45-1.46)
>18months	0.25(0.73-0.86)

Conclusions: Death risk changes along time in elderly incident PD patients, according to the modality. Up to 18 months there was no difference, but beyond this point in time APD is a protective factor.

SA-PO949

The Impact of Body Mass Index (BMI) and Longitudinal Body Weight (BW) Changes on Survival of Elderly Incident PD Patients: A Cohort Analysis
Natalia Maria da Silva Fernandes,[1,2] Marcia R.G. Franco,[1,2] Abdul Rashid Tony Qureshi,[3,4] Jose C. Divino-Filho.[3] *[1]Dept of Internal Medicine, School of Medicine, NIEPEN-Federal Univ, Juiz de Fora, Brazil; [2]Fundacao IMEPEN, Juiz de Fora, Brazil; [3]Dept Renal Medicine CLINTEC, Karolinska Instt, Sweden; [4]Baxter Novum, Karolinska Instt, Sweden.*

Background: The impact of BMI and BW changes on survival of elderly patients on PD is controversial. **GOAL**: To evaluate the impact of BMI and BW changes on survival of elderly patients on PD.

Methods: Multicenter prospective cohort (Dec/2004-Oct/2007) with 2144 elegible patients; 762 ≥ 65 years old and 733 with at least two BMI measurements. Patients were followed up until transfer to HD, recovery of renal function, renal transplantation, death or loss to follow-up. They were divided in two groups: PD as first therapy (PD-first: 333) and those transferred from HD (HD-first: 400). Comparison in between groups (PD and HD first) and, sociodemographic and clinical data compared among the patients classified according to BMI using ANOVA, Kruskal Wallis or Chi-square. Survival analysed with Kaplan Meier curve and Cox regression adjusted for confounding variables, besides longitudinal changes in BW during follow-up.

Results: Patients with higher BMI were older, had more comorbidities, higher levels of blood pressure and glycemia. Table 1- Analysis of the impact of BMI on survival (Cox regression adjusted and non-adjusted)

Non Adjusted	Malnourished	1.74(0.99-3.07)	1.88(1.00-3.55)
	Overweight	0.64(0.42-0.98)	0.89(0.55-1.43)
	Obese	0.67(0.37-1.19)	0.72(0.34-1.53)
Adjusted	Malnoursihed	1.24(0.66-2.33)	2.09(1.06-4.1)
	Overnight	0.70(0.45-1.10	1.02(0.60-1.72)
	Obese	0.61(0.33-1.14)	0.76(0.35-1.68)

Conclusions: Malnourished PD-first patients presented higher mortality. Those patients who gained BW during the first year in both groups had lower mortality.

SA-PO950

Serum Gamma-Glutamyltransferase Levels Predict Mortality in Peritoneal Dialysis Patients
Wooyeong Park,[1] Su Hyun Kim,[2] Euy Jin Choi,[1] Yon Su Kim,[3] Chul Woo Yang,[1] Yong Kyun Kim.[1] *[1]Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Dept of Internal Medicine, College of Medicine, Chung-Ang Univ, Seoul, Korea; [3]Dept of Internal Medicine, College of Medicine, Seoul National Univ, Seoul, Korea.*

Background: Increased gamma-glutamyltransferase (GGT) is associated with oxidative stress and all-cause mortality in the general population. However, its role in peritoneal dialysis (PD) patients is unclear. The aim of this study is to determine the association between serum GGT levels and mortality in PD patients.

Methods: PD patients were selected from Clinical Research Center registry for End Stage Renal Disease cohort in Korea. Patients were categorized into three groups by tertiles of serum GGT levels as follows: Tertile 1, GGT < 17 U/L ; Tertile 2, 17 ≤ GGT ≤ 27 U/L; Tertile 3, GGT > 27 U/L. Cox regression analysis was used to calculate the adjusted hazard ratio (HR) of mortality with a serum GGT levels of tertile 1 as the reference.

Results: A total of 757 PD patients were included. The median follow-up period was 28 months.The multivariate Cox proportional hazard model showed that the higher tertiles of serum GGT levels were associated with highermortality (Tertile 2: HR 2.10, 95% confidence interval (CI), 1.13-3.88, p=0.018, Tertile 3: HR 1.99, 95% CI, 1.10-3.61, p=0.023) after adjustment for clinical variables.

Conclusions: Our data showed that higher serum GGT levels were associated with increased mortality in PD patients. These findings suggest that serum GGT levels are useful predictor for mortality in PD patients.

SA-PO951

Peritoneal Dialysis in Patients with Refractory Congestive Heart Failure
Renhua Lu,[1,2] Leonardo Claudino Ribeiro,[2] Maria Jimena Mucino-Bermejo,[2] Enrico Tonini,[2] Sara Samoni,[2] Aashish Sharma,[2] Jose Jesus Zaragoza,[2] Carlo Crepaldi,[2] Alessandra Brendolan,[2] Ilaria Tantillo,[2] Claudio Ronco.[2] *[1]Dept of Nephrology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong Univ, Shanghai, China; [2]Nephrology, Dialysis and Transplantation of the San Bortolo Hospital, The International Renal Research Inst of Vicenza, Vicenza, Italy.*

Background: Refractory congestive heart failure (RCHF) is a major reason of mortality and morbidity. Leading cause of hospitalization even in patients receiving treatment. Diuretics as firstline therapy for RCHF are linked with worsening kidney function, and progression of heart failure. Peritoneal dialysis (PD) can be a good option. Our aim is to describe relative risk benefit ratio based on data reported for use of PD in RCHF.

Methods: Electronic database MEDLINE and relevant articles are included in the database from 1951 to February 2014 to identify studies on PD in the RCHF. References were screened for relevant articles. Eligibility criteria:(1)Prospective or retrospective(2) Age≥18years(3)RCHF(4)At least 10 PD treatments.

Results: Within 864 citations, 21 studies (n=673 patients) were identified including 14 prospective studies and 7 retrospective studies. The mean age is 66.9 years; the mean percentage of males is 71.5% (28.5% females). After PD, hospitalization days significantly declined (6.22 *versus* 1.19, p=0.0008), heart function improved significantly (LVEF:34.38 *versus* 39.07, p=0.0027; NYHA score: 3.55 *versus* 2.17, p=0.0000). No change in renal function at 1% significance level, but at 5% (p=0.0322). Body weight decreased (73.28 *versus* 69.54, p=0.0024) and diuretic use hold (229.20 *versus* 248.64p=0.7890). Yearly average peritonitis was13.9%, average mortality was 21.5%.

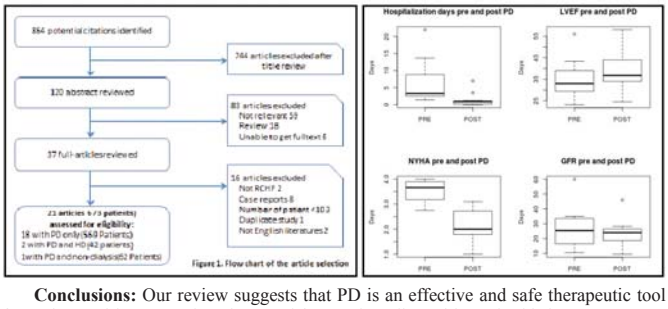

Figure 1. Flow chart of the article selection

Conclusions: Our review suggests that PD is an effective and safe therapeutic tool for patients with RCHF.There is a need for good-quality evidence in this important area.

SA-PO952

Report of Sudden Decrease in Rates of Culture Negative Peritonitis with Adoption of a New Policy: Single Center Experience in an Urban Inner City Peritoneal Dialysis Program
Suchita J. Mehta, Marcia Joseph, Adanim Luboa, Daniel Taiwo Adeneye, Clinton D. Brown, Barbara G. Delano, Subodh J. Saggi. *SUNY Downstate.*

Background: High rates of culture negative (CN) peritonitis are reflective of inadvertent administration of antibiotics and erroneous methods of collection of peritoneal fluid. Tracking of peritonitis rates with a focus on CN peritonitis rates was performed at our

center. Our focus was to curb the rising rates of CN peritonitis. Below we report the CN rates at our program and suggest a possible method to decrease these by strict adherence to a policy of collecting peritoneal fluid culture.

Methods: Comparison of peritonitis rates before and after the adoption of policy for collection of peritoneal fluid, mentioned below: 1) 50ml of effluent from an overnight dwell was placed in a sterile container, sent to the laboratory in 6 hours without refrigeration. 2) 5 to 10ml was also collected in anaerobic and aerobic blood culture bottles 3) For patients that were dry for the day, 1 liter of 1.5% dextrose was allowed to dwell for 2 hours before sample collection as described.

Results: 1) Peritonitis rates prior to the policy from January 2013 to August 2013: total peritonitis rates 8 episodes in 151 patient months 2) 62.% of them were culture positive, 37.5 culture negative 3) The most common organism was Enterococcus fecalis (60%) 3) Rates of culture negative peritonitis after instituting this policy in August 2013 until May 2014: 0 episodes.

Conclusions: Root-cause analysis for the explanations of our incidence of CN peritonitis was done. We noticed a dramatic decrease in the number of CN peritonitis once the home program adhered to the policy instituted. Since implementation we have had only two episodes of peritonitis both that were culture positive and no episodes of CN peritonitis thus far. In conclusion,the method of collection of peritoneal fluid appears crucial in reducing the rates of CN peritonitis and obtaining maximum yield of cultures from peritoneal fluid. Adoption of this policy with emphasis to its adherence resulted in a significant decrease in the episodes of CN peritonitis thus far at our urban inner city peritoneal dialysis center.

SA-PO953

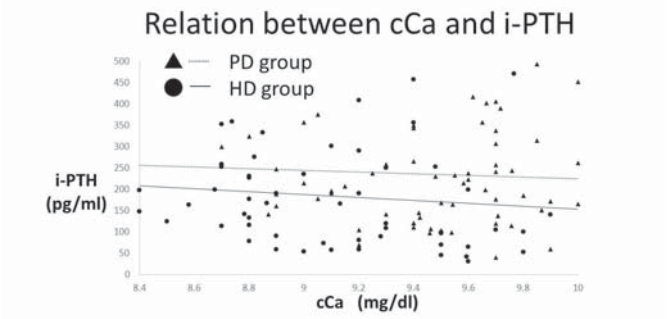
The Acid-Base Differences Affect the Calcium-PTH Axis of Dialysis Patients: Comparison Between Peritoneal Dialysis and Hemodialysis

Masamitsu Morishita, Masatsugu Nakao, Nanae Matsuo, Izumi Yamamoto, Yukio Maruyama, Yudo Tanno, Ichiro Ohkido, Masato Ikeda, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Serum ionized calcium (iCa) is the biologically active component of Ca. The ratio of serum iCa in corrected total Ca (cCa) has been already identified to be changed according to the serum acid-base status. Because peritoneal dialysis (PD) patients tend to be under metabolic alkalosis status due to the characteristics of PD dialysate, iCa levels of PD patients are expected to be lower than those of hemodialysis (HD) patients. We hypothesized that PD patients may present lower iCa levels than HD patients, and that lower iCa levels may affect their parathyloid hormone (PTH) levels.

Methods: We recruited 209 patients (101 on PD, 108 on HD) in multicenter. Their acid-base status, iCa, albumin, and intact-PTH (i-PTH) were measured, and cCa was calculated by Payne compensation formula recommended in Japanese guideline. The factors associated with Ca-PTH axis were assessed statistically.

Results: HCO_3 levels of PD group were significantly higher than those of HD group (26.8±2.4 versus 22.5±2.2mmHg), and HCO_3 levels and iCa/cCa ratio had inverse correration between them. The serum iCa levels and iCa/cCa ratio of the PD group were significantly lower than those of the HD group (iCa; 1.07±0.10 versus 1.12±0.09mmol/l, P<0.05: iCa/cCa; 44.6±3.1 versus 49.6±3.2%, P<0.05). After the adjustment of the dialysis vintage and the prescription of cinacalcet, i-PTH levels of the PD group were significantly higher than those of HD group (235±129 versus 184±129 pg/ml, P<0.05).



Conclusions: Because PD patients often present with metabolic alkalosis, they tend to have lower iCa levels, and in turn have higher i-PTH levels despite their cCa levels being within the recommended range.

SA-PO954

Retrospective Review on the Outcome of PD Associated Peritonitis Caused by Acinetobacter in a Single Center

Siu Kim Chan. *Medicine and Geriatrics, United Christian Hospital, Hong Kong.*

Background: PD associated peritonitis caused by Acinetobacter has low incidence rate of 2-5% but notorious in treatment difficulty, poor response and high morbidity. We perform this review to look into the magnitude of the problem and the predictors of poor outcome.

Methods: Single centre record from 1 Jan 2003 to 31 May 2014 were analyzed. Logistic regression of the predictors was performed for outcome prediction. Non-responders include relapse, failed treatment with PD catheter removal and death due to peritonitis.

Results: There are 55282.5 patient months during the review period, with 1207 episodes of peritonitis, rendering a rate of 1 in 45.8 months. Distribution of organisms were: 555(46%) gram positive organisms, 527(43.7%) gram negative organisms, 46 fungus, 27 episodes mycobacterium and 52 culture negative. 29 episodes were caused by Acinetobacter with 20 confirmed Acinetobacter baumanii and 9 episodes were due to Acinetobacter species but no multi-resistant strain was found. The characteristics of the patients were summarized in Table 1.

	Mean/Frequency (%), n = 29
Age	64.6
Male	17 (58.6%)
Presentation before 2008	22 (75.9%)
Polymicrobial peritonitis	10 (34.5%)
Antibiotics sensitivity, cefoperazon + sulbactam	29 (100%)
Sensitivity, ciprofloxacin	25 (86.2%)
Sensitivity, cotrimoxazole	26 (89.7%)
Sensitivity, gentamicin	26 (89.7%)
Initial antibiotics, cefazolin	24 (82.8%)
Initial antibiotics, gentamicin	24 (82.8%)
DM	16 (55.2%)
IHD	5 (17.2%)
Prior peritonitis within 30 days	9 (31%)
Day 1 WCC	1954/ml
Day 3 WCC	956/ml
Day 3 WCC after appropriate antibiotics	208/ml

Non-responders accounted for 34.5% of the episodes. Logistic regression found that older age, day 3 cell count after appropriate antibiotics (cut off 500) were independent predictors of treatment response (p-value=0.012 and 0.042 respectively).

Conclusions: Acinectobacter peritonitis has a very high rate of poor outcome while older age and day 3 cell count after appropriate antibiotics were independent predictors of poor outcome. Although the sample size of this study is small, the number of cases is actually among the largest from the case series reported so far. Prompt action to escalate treatment in high risk group could possibly improve outcome.

SA-PO955

A Comparison of Two Methods on Replacing Peritoneal Dialysis Transfer Set

Hui-Qun Li, Yan-Ru Chen, Hong-Li Shang, Hui Peng, Tan-Qi Lou. *Dept of Nephrology, The Third Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Peritoneal dialysis (PD) transfer set is one key part for the patients on peritoneal dialysis, and it should to be replaced at intervals not longer than 6 months or more frequently as specified by a physician. In China, however, there was no details about this operation in the Peritoneal Dialysis Standard Operating Procedure (SOP).The objective of this study was to evaluate the effect of two methods on replacingPD transfer set.

Methods: Two types of operation procedure on replace PD transfer set were showed and 80 patients (45 male, 35 female) were involved in this study. The mean age was 43 (from 18 to 75). All the patients were randomly divided into two groups. The traditional method was used in the control group (n=40) and the modified method was used in the observational group (n=40). The traditional method included the procedure of soaking the set twice in the iodine disinfectants, and the modified method included soaking only once.

Results: It took less operating time (p=0.005) in the observational group (24.8±1.6 minutes) to replace PD transfer set than in the control group (38.1±2.8 minutes). The cost of the materials in the observational group was obviously reduced (p=0.005).Results also showed that the shorter operation process made the patient more satisfied (p=0.001) and the occurrence of peritonitis in the two groups was 0.

Conclusions: This study shows that the modified method on replacing PD transfer set is more economical, more efficient, and the important thing is that it is safe for patients and easy to be accepted.

SA-PO956

Increased Aortic Stiffness Evaluated by MRI-Based Pulse Wave Velocity in Patients with Peritoneal Dialysis: A Cross-Sectional and Longitudinal Study

Kazuhiko Tsuruya,[1,2] Hisako Yoshida,[1] Takanari Kitazono.[2] *[1]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Medicine and Clinical Sciences, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Pulse wave velocity (PWV) is a biomarker directly related to arterial stiffness that has the potential to provide information on early atherosclerotic disease. MRI has shown good agreement with PWV determined with invasive intra-aortic pressure measurements (Grotenhuis et al. J Magn Reson Imaging, 2009). To date, very few studies have reported on MRI-based PWV in patients with chronic kidney disease (CKD), especially peritoneal dialysis (PD) patients. In the present study, we measured MRI-based PWV in patients with moderate to severe CKD including PD patients and examined what factors impact on higher PWV including PD versus non-dialysis dependent CKD (NDD-CKD) in those patients.

Methods: In a cross-sectional study, 181 CKD patients (NDD-CKD, n=106; PD, n=75) were recruited and underwent cardiovascular MRI. Among them, 107 patients (NDD-CKD, n=70; PD, n=37), who underwent a second cardiovascular MRI after 2 years, were recruited in a longitudinal study. Using cine and phase contrast sequences, the cross-sectional area for distensibility and average blood flow were measured between the ascending and the

proximal descending aorta and between the proximal descending aorta and the abdominal aorta just proximal to the iliac bifurcation. We constructedlinear mixed-effects models for the association of various independent factors with PWV.

Results: In the cross-sectional study, increasing age, male gender, diabetic, higher systolic blood pressure, higher logarithmic brain natriuretic peptide and PD patients were significantly associated with higher PWV. The association of increasing age, higher systolic blood pressure, and PD patients with higher PWV were also significant even after multivariable confounding factors. In the longitudinal study, these associations remained unchanged in the linear mixed-effects model.

Conclusions: Aortic stiffness is significantly increased in PD patients compared with NDD-CKD independent of age and blood pressure.

SA-PO957

Survival Differences Between Home Dialysis Therapies and In-Center Haemodialysis: A National Cohort Study Austin G. Stack,[1,2] Waleed Mohammed,[1,2] Mohamed Elsayed,[1,2] Cornelius John Cronin,[1,2] Liam F. Casserly,[1,2] John P. Ferguson.[2] *[1]Nephrology, Univ Hospital Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland.*

Background: Increasing use of home dialysis therapies may result in better survival for all patients who need dialysis treatment. It is unclear, however, whether home therapies offer superior survival to standard in-center haemodialysis for all new patients. We compared mortality between home therapies and in-center dialysis in a national cohort.

Methods: National data were available on 585, 911 patients from the U.S. Renal Data System recruited between 1/1/2005 to 31/12/2010 and followed until until death, transplantation, lost to follow-up, or 31/12/2010. Patients were classified as receiving continuous ambulatory peritoneal dialysis (CAPD) (n= 23, 166), continuous cycling peritoneal dialysis (CCPD) (n = 15,679), In-center HD (n = 543,851) or home HD (n = 3, 215). In-center HD was limited to 3 days per week, while Home HD was categorised as 3, 4, 5, or 6 times per week. Multivariable Cox regression evaluated the relative hazard of death (HR) by dialysis modality using intent to treat analysis adjusting for demographic characteristics, clinical conditions, lifestyle and functional factors, insurance status, erythropoietin use pre-dialysis, and laboratory factors (albumin, haemoglobin and eGFR at dialysis initiation using the CKD EPI equation).

Results: Compared to In-center HD, the adjusted HR over all years were significantly lower for patients treated with CCPD or CAPD and for patients treated with Home HD x 6 times per week

Dialysis Modality Type	Hazards Ratios and 95% confidence Intervals
In-center HD (referent)	1.00
CAPD	0.91 (0.88-0.93)
CCPD	0.88 (0.86-0.91)
Home HD (x3/week)	1.47 (1.40-1.55)
Home HD (x4/week)	1.37 (0.98-1.92)
Home HD (x5/week)	0.98 (0.72-1.34)
Home HD (x6/week)	0.74 (0.55-0.99)

Conclusions: Peritoneal dialysis and frequent Home HD (x 6 per week) conferred the greatest patient survival compared to In-center HD while Home HD (x 3 per week) conferred the poorest survival. Peritoneal dialysis and frequent Home HD should be considered as first-line dialysis therapies for all suitable dialysis patients who approach end stage kidney disease.

SA-PO958

Changes in pH during Hemodialysis Determine Indoxyl Sulfate Binding and Limit Its Removal Jonathan Chun, Sumit Kumar, Prabhjot Singh, Sachin Jhawar, Jerome Lowenstein. *Medicine, NYU Langone Medical Center, New York, NY.*

Background: There is increasing evidence that indoxyl sulfate(IS), as a uremic toxin, may be implicated in accelerated arteriosclerosis in ESRD. Protein binding limits the removal of IS by hemodialysis. In an earlier study (JASN 24:FRPO191) we observed that the protein-bound fraction of IS averaged 73% in pre-dialysis plasma and > 95% at termination. In this study we have examined the hypothesis that the pH increase during dialysis results in more avid binding of IS to protein (albumin) thereby further limiting the dialyzer's removal of IS.

Methods: Blood samples from the afferent dialysis line were drawn at the onset, midpoint, and end of a standard 3-3.5 hour hemodialysis session in 10 patients with stable chronic kidney disease. Blood pH was measured with a Siemens ABL90 blood gas analyzer. IS in plasma and ultrafiltrate (Amicon) was measured by HPLC.

Results: This study showed that pH increased from 7.39 to 7.52 in the first half of dialysis, then remained essentially unchanged for the remainder of dialysis. The IS binding increased from 80% to 94% by the midpoint and to 97% by the end of dialysis. Concomittantly, the amount of IS removed in the first half of dialysis as a fraction of all IS removed throughout dialysis was greater than in the second half ($p<0.025$).

	pH	HCO_3^- meq/l	IS_{total} µgm/ml	*$IS_{bound/total}$	Δ IS_{total} %
pre-dialysis	7.39	24.18	47.98	80.69	---
mid-point	7.52	31.06	37.42	93.94	62.63
post dialysis	7.55	33.00	29.86	97.14	37.36

*some values of free IS were below the limits for detection

Δ IS_{total} % represents the fraction of IS removed in the first half of dialysis vs the second half of dialysis

Conclusions: The data lead us to conclude that the dialyzer clearance of indoxyl sulfate, a major uremic solute, is limited by the pH increase during standard dialysis. The data suggest that the efficency of hemodialysis in removing indoxyl sulfate might be significantly enhanced by modifying the pattern of bicarbonate replacement during dialysis.

SA-PO959

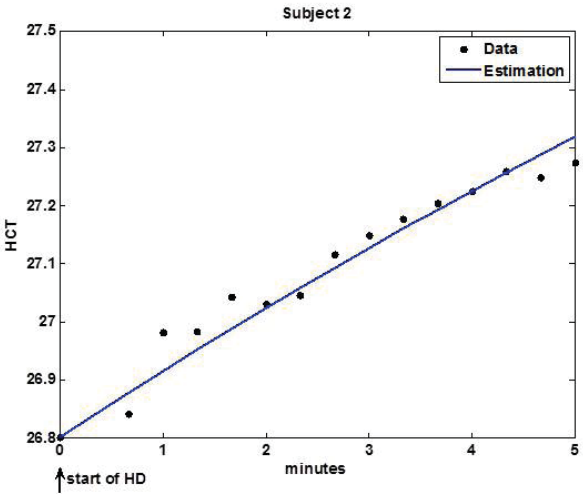
Estimating Intravascular and Interstitial Volume at the Start of Hemodialysis Session Cheng-Hung Chen,[1] Joseph Horowitz,[1] Christopher V. Hollot,[1] Rajiv P. Shrestha,[3] Michael J. Germain,[2] Yossi Chait.[1] *[1]Univ of Massachusetts; [2]Western New England Renal and Transplant Associates, PC; [3]Octet Research Inc.*

Background: Intradialytic hypotension is the most common hemodialysis (HD) complication and a significant cause of morbidity. Recent models of absolute blood volume in HD patients are based on bioimpedance, tracer dilution, relative blood volume measurements or combination thereof. The goal of this study was to investigate the feasibility of estimating pre-HD intravascular and interstitial volumes using Crit-Line data during routine HD conditions.

Methods: We describe fluid volume dynamics during HD using a two-compartment model comprising intravascular and interstitial volumes. We used retrospective hematocrit (HCT) data (Crit-Line) collected every 20 seconds from 24 HD patients. Nonlinear regression was used to estimate model parameters over the initial HD period.

Results: Pre-HD volumes were successfully estimated for all 24 data sets.

Pre-Hd	Mean	Median	SD	Min	Max
HCT (%)	28.71	28.57	2.88	22.60	33.77
Plasma (L)	4.03	4.05	0.39	3.02	4.64
Intravascular (L)	5.65	5.67	0.45	4.52	6.43
Red Blood Cells (L)	1.62	1.66	0.18	1.21	1.86
Interstitial (L)	11.92	10.99	2.22	10.00	16.13



The mean (SD) time period required for successful estimation was 6.3 (3.4) min. The mean (SD) root mean square estimation error of HCT was 0.13 (0.16).

Conclusions: Crit-Line HCT data can be used to estimate pre-HD intravascular and interstitial volumes in HD patients. The minimal length of data required for estimation depends on the initial refill profile driven by unknown osmotic and hydrostatic pressures. These results should be tested in a study with a larger number of patients, and validated against gold standards of absolute blood volume measurements. These results may be used to better estimate dry weight for dialysis dose prescription and red cell mass in anemia management.

Funding: NIDDK Support

SA-PO960

Dialysate Sodium: Do We Get What We Order? Sriram Narsipur,[1,4] L. A. Arbeit,[2,4] Philip Zager,[3,4] S. Paine.[4] *[1]SUNY, Syracuse, NY; [2]SUNY, Stony Brook, NY; [3]UNM, Albuquerque, NM; [4]DCI, Nashville, TN.*

Background: There is considerable controversy surrounding the optimal dialysate sodium (DNa) concentration. Recently, leaders of several dialysis providers have urged their medical directors to reduce DNa concentrations to the range of 134 to 138 mEq/L in an effort to reduce interdialytic weight gain (IDWG), blood pressure, hospitalization and mortality. However, in the effort to accomplish this, there has been little attention directed to comparing ordered versus measured DNa concentrations.

Methods: We compared ordered DNa to DNa concentration measured at the start of dialysis. The study was conducted in 340 patients across five facilities operated by Dialysis Clinic Inc., (DCI) and located in Albuquerque, Stony Brook and Syracuse, utilizing Fresenius, Cobe, and Gambro dialysate delivery machines respectively. The inline clearance feature was turned off during the study. All DNa values shown are expressed as mEq/L.

Results: The percentiles of ordered DNa, measured DNa and the absolute differences are shown in the table. The absolute difference was ≥ 4 and 6 in 25% and 10% of patients, respectively. Ordered DNa was ≤ 135 in 33.8%, 136 to 139 in 17.4% and ≥ 140 in 48.8% of patients. Among the 115 patients who had ordered DNa ≤ 135, 64 (55.7%) had a measured DNa ≥ 136. Among the 59 patients who had ordered DNa 136-139, 40 (67.8%) had a measured DNa ≥ 140. Overall among the 174 patients with an ordered DNa < 140, 46 (26.4%) had measured DNa levels ≥ 140. It was only among the patients with an ordered DNa ≥ 140 that the majority (95.2%) fell within the prescribed range. Results were similar across clinics.

Distribution of Dialysate Sodium: Ordered, Measured and Difference (mEq/L)			
DNa (percentile)	**Ordered**	**Measured**	**Difference**
1st	130	132	0
5th	134	134	0
10th	134	134	0
25th	134	137	1
50th	138	141	2
75th	140	143	4
90th	140	145	6
95th	140	146	7
99th	140	151	11

Conclusions: The majority of patients who had dialysis prescriptions for a DNa <140 appear to have been dialyzed with a higher DNa concentration. The effort to reduce DNa should include measurement of DNa and additional attention to preparing dialysate and machine calibration.

SA-PO961

Barriers to Dietary Sodium Restriction among Patients on Hemodialysis

Linton Cuff,[1] Robin L. Padilla,[1] Tanu P. Verma,[1] Brenda W. Gillespie,[1] Debra Peterman,[1] Michael Heung,[1] Scott L. Hummel,[1] Peter Kotanko,[2] Panduranga S. Rao,[1] Rajiv Saran.[1] *[1]Univ of MI, Ann Arbor, MI; [2]Renal Research Inst, NY, NY.*

Background: The low sodium (LS) diet is a key intervention for blood pressure (BP) and volume management in hemodialysis (HD). However, adherence to LS diet is difficult. We sought to assess potential barriers to following LS diet in HD.

Methods: As part of an ongoing randomized clinical trial of LS diet in HD, stable adults receiving outpatient HD treatment, were assessed for salt taste recognition using taste strips impregnated with 0-1.6% sodium chloride; mean sodium (Na) intake was estimated from 3-day food diary. A dietary sodium survey (DSS) was administered to assess Perceived Behavior Control (PBC) measured on a scale 0-(Not a barrier) to 4-(Extreme barrier), and Perceived Dietary Impact (PDI) on a scale 1-(Definitely True) to 5-(Definitely False). Depression symptom (DS) score was measured on a scale 0-(Not at all) to 3-(Nearly every day).

Results: 19 patients (11 male, 9 black, 7 white, mean age 57 ±14) are currently enrolled. Mean monthly pre-HD systolic BP was 151 ± 15 mmHg. Mean Na intake was 2.5 g/day (range: 1.3-5.2). A higher salt taste recognition threshold was associated with higher Na intake (r=0.37, p=0.14), particularly in patients who did not recognize salt taste at 1.6% compared to those who recognized salt taste (3.2 versus 2.2g/day; p=0.07). Of the 15 patients who completed the DSS, 13 reported following LS diet for a mean of 6.6yrs without much difficulty. Over half (8) reported ≥5 PBC barriers and 6 reported ≥6; the majority (9) expressed lack of knowledge. A higher DS score was significantly associated with a higher PDI score (i.e., less knowledge).

Conclusions: PDI, PBC, taste impairment and mood serve as potential barriers to following a LS diet. While all patients indicated the importance of following a LS diet, many were not aware of its relation to fluid overload and cardiovascular problems. Lack of availability of LS foods, food preference, taste and resolve were among the top barriers. The inability to recognize the taste of salt and DS also factor into patient ability to adhere to LS diet. Further study of these factors is warranted.

SA-PO962

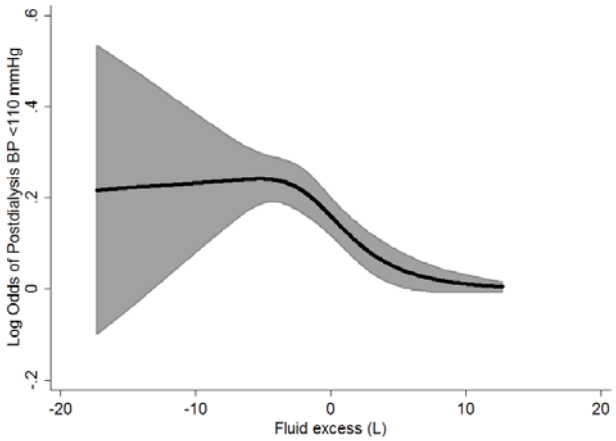
Association of Bioimpedance Spectroscopy-Based Volume Estimation with Postdialysis Hypotension in Hemodialysis Patients

Adrian P. Abreo,[1] Glenn M. Chertow,[2] Lorien S. Dalrymple,[3] George A. Kaysen,[3] Kirsten L. Johansen.[1] *[1]UCSF; [2]Stanford SOM; [3]UC Davis SOM.*

Background: Clinical examination to determine the dry weight of patients on dialysis has been problematic, with studies showing discordance between physician assessment and objective measures of volume status.

Methods: We studied the association between predialysis bioimpedance spectroscopy (BIS)-based estimates of fluid excess and postdialysis hypotension in 635 patients in the USRDS ACTIVE/ADIPOSE study receiving hemodialysis in the San Francisco and Atlanta areas recruited from July 2009 to August 2011. We recorded pre- and postdialysis weight and blood pressures over three consecutive dialysis sessions, and performed BIS before a single session. Using a previously reported method of estimating dry weight in hemodialysis patients from BIS data, we estimated fluid excess in liters in our population. We used multivariable logistic regression with extracellular water/total body water (ECW/TBW) or BIS-based fluid excess as the primary predictor and one or more postdialysis systolic blood pressures less than 110 mmHg as the primary outcome. Multivariable models were adjusted for ultrafiltration rate, body weight, congestive heart failure, sex, ESRD vintage, diabetes, age, African-American race, and albumin.

Results: Higher ECW/TBW was associated with significantly lower odds of postdialysis hypotension (OR 0.34, 95% CI 0.14-0.85 per 0.1 higher, p=0.02). Every liter of BIS-based fluid excess was associated with a lower adjusted odds of postdialysis hypotension (OR 0.88, 95% CI 0.82-0.95, p=0.001).



Conclusions: Prospective studies are needed to determine whether this application of BIS could improve current clinical efforts to minimize episodes of postdialysis hypotension without leading to volume overload.

SA-PO963

Reducing the Sodium Concentration in Dialysate Has a Favourable Effect on Interdialytic Weight Gain without Major Adverse Events

Monalisa Joseph,[1] Farhan Zahid,[2] Sandeep Aggarwal,[1] Ellie Kelepouris.[1] *[1]Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA; [2]Internal Medicine, Drexel Univ College of Medicine, Philadelphia, PA.*

Background: In chronic hemodialysis patients, high interdialytic weight gain and uncontrolled hypertension are still a management conundrum. Low dialysate sodium baths have been associated with hypotension and hyponatremia. We report the efficacy and safety results of reducing the dialysate sodium concentration in 24 patients at a dialysis clinic.

Methods: This was a quality improvement project in a single dialysis facility with 24 patients undergoing thrice-weekly conventional hemodialysis. Data was collected pre and post-intervention. The intervention was reduction in the sodium bath to 138, 136 or 134 meq/l from the standard of 140meq/l. The lower sodium bath of 134 or 136meq/l was chosen for patients with IDWG% of more than 3%. The measured primary outcomes were IDWG, IDWG % (indexed to dry weight), pre-dialysis and post-dialysis SBP, DBP and MAP; and lowest intradialytic SBP, DBP and MAP. The secondary outcomes were serum sodium concentration and the number of antihypertensive medications. These measurements were taken as averages in 6 dialysis treatments preceding the intervention and 6 dialysis treatments after 12 weeks of the intervention. Paired t-tests were used in IBM SPSS software.

Results: A statistically significant reduction in the post-intervention IDWG%, in comparison to the pre-intervention IDWG% was found with a P value of 0.033 and standard deviation of 1.21. The reduction in IDWG also reached near significance (P 0.063, SD 0.8049). We found no statistically significant differences between the pre and post-intervention blood pressures, measured as pre and post dialysis and lowest intradialytic SBP, DBP and MAP respectively. However, there was a significant reduction in the number of antihypertensive medications post intervention (P 0.001, SD 0.6). No significant hyponatremia occurred post- intervention.

Conclusions: Modest lowering of the dialysate sodium bath is a safe and effective tool in the management of high interdialytic weight gain.

SA-PO964

Comparison of the Impact of High-Flux Dialysis on Mortality in Hemodialysis Patients with and without Residual Renal Function

Yong Kyun Kim, Ho Cheol Song, Chul Woo Yang, Euy Jin Choi. *Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: The effect of flux membranes on mortality in hemodialysis (HD) patients is controversial. Residual renal function (RRF) has shown to not only be as a predictor of mortality but also a contributor to β2-microglobulin clearancein HD patients. Our study aimed to determine the interaction of residual renal function with dialyzer membrane flux on mortality in HD patients.

Methods: HD Patients were included from the Clinical Research Center registry for End Stage Renal Disease, a prospective observational cohort study in Korea. Cox proportional hazards regression models were used to study the association between use of high-flux dialysis membranes and all-cause mortality with RRF and without RRF. The primary outcome was all-cause mortality.

Results: This study included 893 patients with 24h-residual urine volume ≥ 100 ml (569 and 324 dialyzed using low-flux and high-flux dialysis membranes, respectively) and 913 patients with 24h-residual urine volume < 100 ml (570 and 343 dialyzed using low-

flux and high-flux dialysis membranes, respectively). After a median follow-up period of 31 months, mortality was not significantly different between the high and low-flux groups in patients with 24h-residual urine volume ≥ 100 ml (HR 0.86, 95% CI, 0.38-1.95, P = 0.723). In patients with 24h-residual urine volume < 100 ml, HD using high-flux dialysis membrane was associated with decreased mortality compared to HD using low-flux dialysis membrane in multivariate analysis (HR 0.40, 95% CI, 0.21-0.78, P = 0.007).

Conclusions: Our data showed that HD using high-flux dialysis membranes had a survival benefit in patients with 24h-residual urine volume < 100 ml, but not in patients with 24h-residual urine volume ≥ 100 ml. These findings suggest that high-flux dialysis rather than low-flux dialysis might be considered in HD patients without RRF.

SA-PO965

Relationship between Subjective and Objective Cognition Deficits in Patients Receiving Haemodialysis Anuradha Jayanti,[1] Alison J. Wearden,[2] The Basic-Hhd,[1] Sandip Mitra.[1] *[1]Dept of Nephrology, Manchester Royal Infirmary, Manchester, United Kingdom; [2]Dept of Psychology, Univ of Manchester, Manchester, United Kingdom.*

Background: Cognitive impairment is common in haemodialysis (HD) patients. It is associated with increased morbidity and mortality. Assessment of subjective cognition may provide an easier way of implementing cognitive testing in routine clinical practice. Accordingly, we assessed beliefs about one's cognition using the metacognition questionnaire. It has two components- metamemory (5Q) and metaconcentration (4Q). The questions have no specific age focus and are applicable to the HD population.

Methods: In a cross-sectional, multi-centre study (BASIC-HHD) cohort (n=313), patients receiving HD were administered neuropsychometric tests and the metacognition questionnaire (99% return). Demographic and clinical variables were ascertained from records. Patients completed the Beck Depression Inventory and two objective cognition tests, Modified Mini Mental State (3MS-global cognition) and TMT B (executive function).

Results: Both metamemory and metaconcentration scales have significant relationships with the cognitive impairment outcome variable (3MS≤80 or 3MS>80) at the 5% significance level (N=244, with exclusion of missing data). In a linear regression model that adjusts for age, gender, education, BDI score, stroke and number of weekly dialysis sessions, the p-value is **0.002** (metamemory scale) and **0.04** (metaconcentration scale). Adjusted OR (95% CI) is 0.80 (CI 0.70, 0.92) for metamemory and 0.82 (CI 0.68, 0.99) for metaconcentration suggesting that, an increase in metamemory score or the metaconcentration score by one, reduces the likelihood of being cognitively impaired by 20% and 18% respectively, adjusting for other variables. Both scales did not have a significant relationship with the TMT B outcome variable.

Conclusions: Subjective cognition assessment of HD patients periodically, may provide an indication of the change in global cognitive status of HD patients and is relatively easily employed. The twin components of the metacognition questionnaire should be validated as a determinant of neurocognitive performance in patients with chronic kidney disease across all stages.

SA-PO966

The Effect of the Interdialytic Interval on Cognitive Functioning in Hemodialysis Patients Shayna L. Henry,[2] Larry D. Jamner,[2] Sarah E. Choi,[3] Madeleine V. Pahl.[1] *[1]Nephrology, Univ of California, Irvine, CA; [2]Psychology and Social Behavior, Univ of California, Irvine, CA; [3]Nursing, Univ of California, Irvine, CA.*

Background: Cognitive problems are common among hemodialysis (HD) patients and may be associated with a variety of factors including fluid and electrolyte abnormalities, effect of uremic toxins, and the HD procedure. The long interdialytic interval (IDI) may be particularly challenging for patients as compared to short IDIs. The aim of the present study was to examine the relationship between cognitive dysfunction, social support and IDI length.

Methods: Stable patients maintained on HD for > 90 days were administered a neuropsychological battery of tests to address treatment adherence, affect, personality traits, health locus of control, social support and cognitive function before the short and long IDI. Cognitive function measures included the Mini-Mental Status Exam, Digit Span, California Verbal Learning, Benton Visual Retention and Trail-Making Tests. Patients were engaged in one week of smartphone-based monitoring in which 5 times a day they were prompted to report on their activities, social context, diet, cognitive function, and perceived support.

Results: 22 HD patients (mean age 39.5 yrs, 13 women) completed the study. CD was minimal, and diary reports of perceived support did not appear to differ significantly between HD days and between long and short IDIs. During the long IDI, patients reported CD in 12% of smartphone entries, compared to 26% during the short IDIs, and CD was significantly lower on long IDI than short IDIs for all diary measures of CD, including reaction time (M_{Long}=.11, *SD*=.36; M_{Short}=.38, *SD*=.88; *t*=-3.16, *p*=.002), trouble thinking (M_{Long}=.02, *SD*=.13; M_{Short}=.26, *SD*=.59; *t*=-4.66, *p*<.0001), and confusion (M_{Long}=.04, *SD*=.19; M_{Short}=.14, *SD*=.42; *t*=-2.52, *p*=.013).

Conclusions: We conclude that CD is mild in stable, young ESRD patients. CD is significantly worse after the HD treatment during the short IDI as measured by self-reported entries, reaction times, trouble thinking and confusion. These abnormalities improve during the long IDI. These findings suggest the HD procedure may exacerbate CD in ESRD patients.

SA-PO967

Cognitive Depression and Functional Impairment Status Are Associated Factors of Malnutrition in Elderly Patients in Maintenance Hemodialysis Nasser Abdel Polanco Flores, Erika Lopez, Belen Meltiz, Manolo Ramos Gordillo, Jose C. Pena. *CEDIASA, México, D.F., Mexico.*

Background: The relationship between cognitive depression, functional status and malnutrition in an elderly population in maintenance hemodialysis is very complex and not yet fully understood. Currently, there are no studies to establish this association. We evaluated cognitive depression and quality of life (QOL), with malnutrition in elderly chronic hemodialysis patients.

Methods: We evaluated cognitive depression, anxiety and depression and quality of life (QOL), with malnutrition in elderly chronic hemodialysis patients. A cross-sectional study was conducted in 107 patients, 55 men (51.4%) and 52 women (48.6%), mean age 70.05±4.6 for men and 71.26±5.7 for women (p=0.234). They received 3 to 4 hours high flux hemodialysis 3 times per week. Cognitive impairment was classified as, severe, moderate and mild with the mini-mental state examination score (MMSE); for emotional state was used the Hospital Anxiety and Depression scale (HADS) and for QOL the short term-12 (SF-12) Karnofsky index (KI). Nutritional status was classified also as severe, moderate and mild with, Subjective Global Assesment (SGA), body mass index (BMI) and biochemical parameters that included (sodium, potassium, cholesterol, triglycerides, albumin, uric acid, intact parathyroid hormone (iPTH) and KT/V.

Results: A severe cognitive impairment was found in 49.7% patients, moderate in 39.8%; mild in 6.9% and 3.4% showed no cognitive impairment. Severe malnutrition was present in 4.7 %, moderate in 65.4% and mild in 29.9%. The statistical analysis displayed a significant correlation between; nutrition status and MMSE r= 0.428 (p<0.001), and between QOL and nutrition r=0.361 (p<.001).

Conclusions: In our population elderly patients in maintenance hemodialysis showed a significant correlation between cognitive impairment, QOL and malnutrition. However, this association is very complex and more studies are needed to support this contention. We also were unable to demonstrate if cognitive impairment is the cause of malnutrition or viceversa.

SA-PO968

Comparison of Common Screening Tools for Depression in Haemodialysis Patients Ayman Guirguis,[1,2] Karin Friedli,[2] Clara Day,[3] Naomi Fineberg,[2,4] Michael K. Almond,[5] Andrew Davenport,[6] Maria Da Silva-Gane,[1] David Wellsted,[2] Joseph Chilcot,[7] Ken Farrington.[1,2] *[1]East and North Hertfordshire NHS Trust, United Kingdom; [2]Univ of Hertfordshire, United Kingdom; [3]Univ Hospitals Birmingham NHS Foundation Trust, United Kingdom; [4]Hertfordshire Partnership Univ NHS Foundation Trust, United Kingdom; [5]Southend Univ Hospital NHS Foundation Trust, United Kingdom; [6]Royal Free London NHS Foundation Trust, United Kingdom; [7]King's College London, United Kingdom.*

Background: Depression is common in haemodialysis (HD), its diagnosis is complicated by overlapping symptoms.The Beck Depression Inventory-II (BDI-II) is a useful screening tool with good psychometric properties. Cut-off score ≥ 16 indicates probable depression in this setting,with few data on other commonly used tools.We determined cut-off values for the Patient Health Questionnaire 9 (PHQ-9) and Patient Health Questionnaire 2 (PHQ-2), corresponding to BDI-II ≥ 16 in this setting.

Methods: HD patients at 3 UK renal centres. Inclusion criteria:dialysis vintage >3 months, aged >18 years and English proficiency.Patients screened for depression with the BDI-II and PHQ-9. We used ROC analysis to determine the cut-off points for the PHQ-9 and PHQ-2 corresponding to a BDI-II cut-off ≥ 16. We also determined levels of agreement.

Results: 494 patients (61% males) median interquartile range for the BDI-II, PHQ-9 and PHQ-2 were 10(5-19),5(2-11) and 1(0-2) respectively. Using the BDI-II cut-off, area under the curve in the ROC analysis for the PHQ-9 and PHQ-2 were 0.94 (CI 0.92-0.96) and 0.89 (CI 0.86-0.93) respectively optimal cut-off points of ≥ 8 for PHQ-9 and ≥2 for PHQ2 (sensitivity 87% and 84% and specificity 88% and 86% respectively).Proportion of patients with BDI ≥16 was 34%, with PHQ-9 ≥8 was 38% and PHQ-2 ≥ 2 was 38%. Levels of agreement of PHQ-9 ≥ 8 and PHQ-2 ≥2 with BDI-II ≥ 16 were substantial (κ = 0.724 and 0.678 respectively).

Conclusions: The PHQ-9 and PHQ-2 are acceptable screening tools compared to the BDI-II in dialysis patients. Cut-off scores for PHQ-9 ≥ 8 and PHQ-2 ≥2 compare well to a BDI-II cut-off ≥ 16. Use of simple screening tools may help to detect depression and improves clinical outcomes in HD patients.

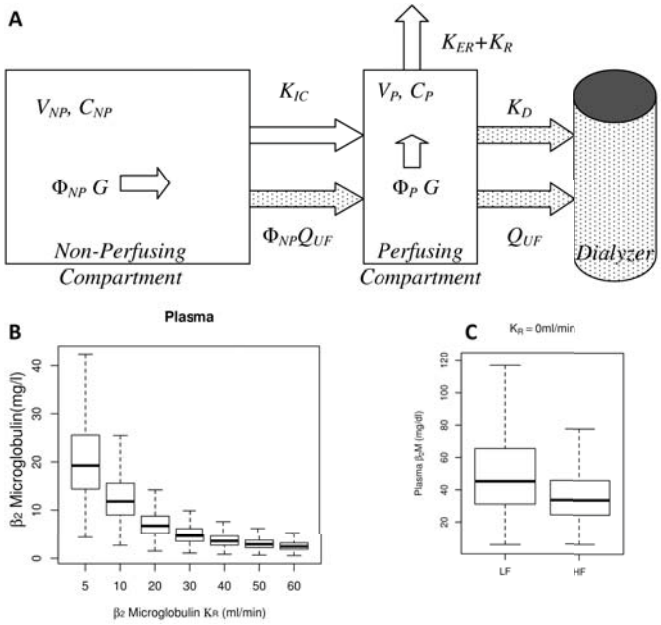
Systematic Review of Beta 2 Microglobulin Population Kinetics Christos Argyropoulos,[1] Maria-Eleni Roumelioti,[1] Thomas D. Nolin,[2] Mark L. Unruh.[1] *[1]UNM, Albuquerque, NM; [2]Univ of Pittsburgh, Pittsburgh, PA.*

Background: Beta 2 Microglobulin (β_2M) is a middle molecule associated with a higher risk of death in hemodialysis (HD) and chronic kidney disease (CKD) patients. We lack a quantitative understanding of β_2M at the population level.

Methods: We did a meta-analysis of studies with patient level data about β_2M generation, distribution and elimination and we developed a population kinetic bicompartmental model (PM) for β_2M in CKD and HD



[A].

Results: Ten papers reporting 9 separate studies fulfilled the criteria for inclusion. Most of the patients (74/106) were on HD with minimal residual renal function (RRF). Renal function is the major determinant of total body β_2M clearance and the estimated median value was 90.4 versus 2.9 ml/min for HD patients. In the table we summarize estimates for the population distribution values (median, upper, Q95 and lower, Q025, 2.5% tail). In simulations from the PM, β_2M increased as renal function declined [B]. In anuric HD pts, β_2M was higher in those on low flux dialysis, but there was substantial overlap [C].

			Population Distribution Values		
Kinetic Parameter	**Number (studies)**	**Number measurements/ patients**	**Median**	**Q025**	**Q975**
Generation Rate (mg/kgr/day)	8	146/96	3	1.6	5.8
Intracompartmental Rate Transfer (ml/min)	6	73/63	68.5	39.4	119.3
Extrarenal Clearance, Cl (ml/min)	6	59/56	2.9	1.4	6.25
Total Body Clearance in controls (ml/min)	3	19/19	90.4	62.1	131.7
Total Volume Distribution, TVD (L)	6	79/69	11.1	6.6	18.9
TVD (BW%)	5	69/59	17.7	11.1	28.2
Perfusing Compartment Volume, PCV (BW%)	5	69/59	4.7	3.5	6.3
Ratio of Non-perfusing to PCV	5	69/59	2.7	1.8	4.15

Conclusions: A PM β_2M based on estimable parameters of generation, distribution and clearance, highlights the importance of RRF and may allow personalization of HD prescription.

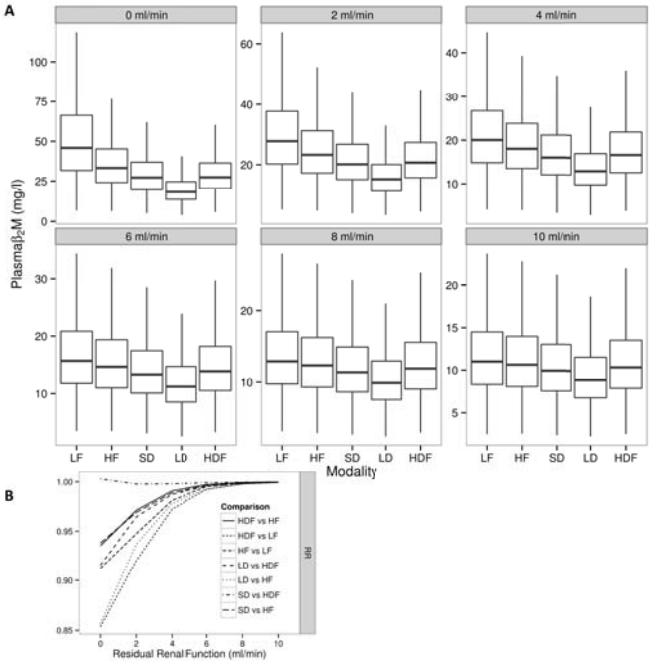
SA-PO970

Large Scale Modeling of Beta 2 Microglobulin Population Kinetics Biomarker for In-Silico Hemodialysis Trials Christos Argyropoulos,[1] Maria-Eleni Roumelioti,[1] Kamyar Kalantar-Zadeh,[3] Thomas D. Nolin,[2] Mark L. Unruh.[1] *[1]Renal Div, Univ of New Mexico, Albuquerque, NM; [2]Pharmacy and Therapeutics, Univ of Pittsburgh, Pittsburgh, PA; [3]Univ of California Irvine, School of Medicine, Orange, CA.*

Background: Beta 2 Microglobulin (β2M) is a middle molecule uremic toxin associated with a higher risk of death in hemodialysis (HD) patients. Nevertheless, a quantitative understanding of the relative role of residual renal function (RRF) and dialytic clearance on β2M levels is lacking.

Methods: We adopted a population kinetic model (PKM) for the generation, distribution, extrarenal, renal and dialytic removal of β2M. Predialysis concentration was related to survival using the observed relation in the HEMO trial. Subsequently we used the PKM model to simulate β2M concentrations and relative survival in a population of ESRD patients with different levels of RRF. In these simulations we evaluated the intervention protocols utilized in randomized controlled trials (RCTs) of HD patients: low flux (LF) and high flux (HF) membranes in conventional thrice weekly HD, and HFHD in short (SD) and long daily (LD) sessions and on-line hemodiafiltration (HDF).

Results: Only when RRF was <2 ml/min, higher dialytic removal materially affected β_2M exposures



[A]. In patients initiating conventional HFHD total loss of RRF was associated with a relative risk (RR) of >20%. HDF and daily HD may decrease this RR by 10%[B]. Only frequent long sessions consistently reduced mortality risk by 15% in anuric pts[B].

Conclusions: These assessments highlight the potential importance of individualizing treatment regimes based on RRF in this era of cost-utility consciousness. Preservation of RRF may be an important treatment goal when managing HD patients, since RRF is a very important determinant of β2M concentration in HD patients. RCTs of interventions to preserve RRF are needed.

SA-PO971

Accuracy of Point of Care Glucometer in Stable Hemodialysis Patients Using Different Blood Samples Eng Kuang Lim,[1] Lee Ying Yeoh,[2] Yan Zhang,[3] Fei Fu,[4] Si Chanjuan.[5] *[1]Renal Medicine, Khoo Teck Puat Hospital, Singapore; [2]Renal Medicine, Khoo Teck Puat Hospital, Singapore; [3]Renal Center, Khoo Teck Puat Hospital, Singapore; [4]Renal Center, Khoo Teck Puat Hospital, Singapore; [5]Renal Center, Khoo Teck Puat Hospital, Singapore.*

Background: Samples for glucose monitoring in hemodialysis(HD) population is often obtained interchangeably from HD bloodline (BL) and capillary prick(CP). However, use of BL sample in Point Of Care Glucometer (POCG) has not been validated. ISO 15197 guideline requires 95% of POCG measurements to be within ±15 mg/dl margins of reference results at glucose concentrations < 75 mg/dl and within ±20% if glucose concentration ≥ 75 mg/dl. The purpose of this study was to determine the reliability of CP and BL glucose measurement using POCG compared to standard laboratory measurement.

Methods: This was a prospective observational study of consecutive inpatient HD sessions for stable diabetic ESRD patient. Patients dialysed using temporary dialysis catheter, or unable to provide consent are excluded. Haematocrit (HCT), Mean Arterial Pressure (MAP), Ejection fraction (EF), Serum Albumin and finger oedema were recorded. Paired Sample of blood obtained from CP and BL will be tested on POCG concurrently. Concurrent bloodline sample is sent to laboratory as control.

Results: A total of 53 patients with 149 dialysis sessions were included in the study. Mean laboratory plasma glucose, POCG CP, and POCG BL were 132.6±34.8mg/dl, 134.2±35.1mg/dl and 133.5±33.2mg/dl respectively. 19.5% of patients were septic, 4 % have Congestive Cardiac Failure but none has finger oedema or on vasopressor. Mean haematocrit was 30.4%. Bland Altman plot showed that POCG CP and POCG BL have good agreement with laboratory glucose although both have imprecision of 6.8% respectively. POCG BL will give 93% of result within the ISO 15197 margin whereas POCG CP, 86%. Regression analyses showed that CP glucose was not influence by HCT, MAP, EF, or Serum Albumin.

Conclusions: POCG glucose measurement using hemodialysis bloodline sample gave better precision and less bias compare to capillary prick sample in stable hemodialysis patients. We recommend that POCG measurement to be carried out using hemodialysis bloodline sample.

SA-PO972

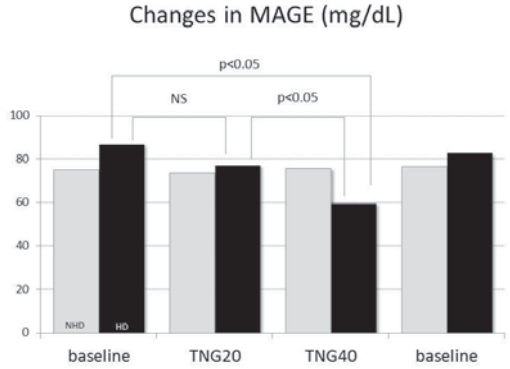
Dose-Dependent Glycemic Control with Teneligliptin, a Novel DPP-4 Inhibitor, in Diabetic Hemodialysis (HD) Patients Assessed by Continuous Glucose Monitoring (CGM)

Takashi Harada,[1] Jyunichiro Hashiguchi,[1] Yoshiaki Lee,[1] Kenji Sawase,[1] Hiroshi Ichinose,[1] Osamu Sasaki,[1] Rica Etoh,[1] Masatoshi Hayashida,[1] Yoko Obata,[2] Tomoya Nishino,[2] Satoshi Funakoshi.[1]
[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Univ, Nagasaki, Japan.

Background: Teneligliptin (TNG) is a novel DPP-4 inhibitor that does not require dose adjustment for HD patients. We conducted a prospective study to assess the efficacy of TNG in controlling glycemic variability, and the dose-dependency of this agent on DM patients on HD.

Methods: Ten relatively well-controlled (GA<25) DM patients on HD were enrolled in this study. All the subjects were already treated with various types of DPP-4 inhibitors not including TNG (alogliptin, vildagliptin or linagliptin) monotherapy as the baseline treatment. Subjects were switched to 20mg/day of TNG for 2 weeks, 40mg/day of TNG for 2 weeks, then baseline treatment one by one. Plasma glucose, GA and the mean amplitude of glycemic excursions (MAGE) were measured at the end time point of each arm including baseline-treatment on both HD-days and HD-free days.

Results: As shown in Figure 1, the average MAGE on HD days in 40mg TNG treatment group was significantly reduced compared with the baseline treatment (86.4±26.3 mg/dL versus 59.5±20.0 mg/dL).



Notably, significant decrease in average MAGE on HD days in 40mg of TNG compared to 20mg of TNG from 77.5±16.7 mg/dL to 59.5±20.0 mg/dL. It is of importance that MAGE was the same after switching back to baseline therapy, indicating these changes in MAGE were not due to physical or environmental factors, but the pharmacological effect of each agent. No symptomatic hypoglycemia was observed.

Conclusions: In our study, monotherapy of TNG at 40 mg/day as was superior to 20 mg/day in controlling glucose variation on HD-days in the treatment for diabetic HD patients. This is the first report to demonstrate clinical dose-dependency of DPP-4 inhibitor.

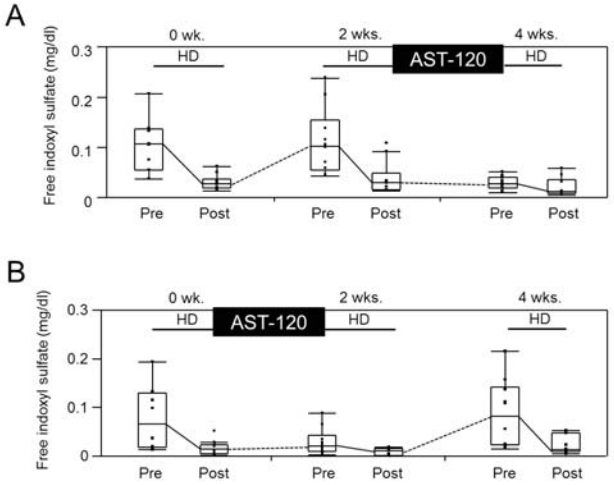
Continuous Reduction of Protein-Bound Uremic Toxins with Improved Oxidative Stress by Oral Charcoal Adsorbent in Maintenance Hemodialysis Patients; an Additional Blood Purification Therapy

Suguru Yamamoto,[1] Kentaro Omori,[2] Koji Matsuo,[1] Kazuko Kawamura,[1] Hiroki Maruyama,[1] Hiroshi Watanabe,[3] Toru Maruyama,[3] Junichiro J. Kazama,[1] Ichiei Narita.[1]
[1]Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Omori Clinic, Niigata, Japan; [3]Kumamoto Univ Graduate School of Pharmaceutical Sciences, Kumamoto, Japan.

Background: An accumulation of protein-bound uremic toxins is one of the causes for the development of uremia-related complications. We examined whether oral charcoal adsorbent, AST-120, shows an additional effect on removal of protein-bound uremic toxins in patients undergoing maintenance hemodialysis treatment.

Methods: A crossover trial was conducted with AST-120, 6 g/day, for 2 weeks and non-treatment for 2 weeks in maintenance hemodialysis patients (n=20). Serum level of total and protein unbound, free, indoxyl sulfate at pre/post dialysis session before and after the AST-120 treatment were measured. Oxidative stress markers, such as oxidized albumin and 8-isoprostane, were also measured. Data were presented as medians (interquartile range), and Wilcoxon signed- rank test was used for the statistical analysis.

Results: Use of AST-120 6 g/day for two weeks induced dramatic reduction both of total and free indoxyl sulfate [total 45.7 (33.2-50.5)%, p<0.001, and free 70.4 (44.8-79.8)%, p<0.001.



In addition, use of AST-120 induced significant reduction of oxidized albumin [63.4 (60.3-69.0)% versus 68.5 (63.0-74.3)% in before AST-120 treatment, p=0.041] as well as 8-isoprostane [458.1 (380.7-615.6) versus 642.4 (450.7-880.6) pg/ml in before AST-120 treatment, p=0.035].

Conclusions: Oral charcoal adsorbent induced a continuous removal of protein-bound uremic toxins with improvement of oxidative stress in patients undergoing maintenance hemodialysis treatment. This adsorption will be an additional blood purification of regular dialysis treatment.

SA-PO974

Increasing the Dialytic Clearance of the Protein-Bound Solute P-Cresol Sulfate Does Not Achieve a Proportional Reduction in Plasma P-Cresol Sulfate Levels

Maria Carmela N. Rosales,[1] Tammy L. Sirich,[1] Natalie Plummer,[1] Thomas H. Hostetter,[2] Timothy W. Meyer.[1]
[1]Stanford and VA, Palo Alto, CA; [2]Case Western, Cleveland, OH.

Background: The dialytic clearance of protein-bound solutes can be increased out of proportion to that of urea by increasing the dialysate flow (Q_d) and the dialyzer mass transfer area coefficient (K_oA). This study tested whether increasing the clearance of the bound solute p-cresol sulfate (PCS) by these means would reduce its plasma levels.

Methods: Studies were performed in patients on nocturnal hemodialysis so that Q_d and K_oA could be manipulated over a wide range while maintaining adequate Kt/Vurea. Six patients were studied during two periods of two weeks duration. The prescriptions for these periods were designed to provide similar urea clearances but widely different bound solute clearances. The *Low* K_oA-Q_d period used a small dialyzer, Q_d of 300 ml/min, and blood flow of 350 ml/min. The *High* K_oA-Q_d period used a larger dialyzer, Q_d of 800 ml/min, and blood flow of 270 ml/min. At the end of each period PCS and ureaN were measured in plasma and spent dialysate. PCS clearances were calculated in terms of the free unbound PCS concentration.

Results: Results (mean±sd; [a] p<0.05)

		Low K_oA-Q_d	*High* K_oA-Q_d
UreaN	Clearance (ml/min)	200 ± 20	219 ± 18 [a]
	plasma predialysis (mg/dl)	43 ± 11	47 ± 12
	Removed in dialysate (g)	18 ± 3	20 ± 3
PCS	Clearance (ml/min)	234 ± 32	535 ± 76 [a]
	plasma predialysis (mg/dl)	0.19 ± 0.12	0.18 ± 0.09
	Removed in dialysate (mg)	142 ± 84	236 ± 135 [a]

The *High* K_oA-Q_d prescription increased ureaN clearance by an average of only 10 percent so that plasma ureaN levels as well as the amounts of ureaN removed in the dialysate at the end of the periods remained similar. In contrast, the *High* K_oA-Q_d prescription more than doubled the clearance of free PCS. This large increase in clearance was accompanied by a marked increase in the amount of PCS removed in the dialysate but the plasma PCS level was not significantly reduced.

Conclusions: An increase in PCS production may prevent plasma PCS levels from falling in proportion to increases in PCS clearance achieved by changing the dialysis prescription.

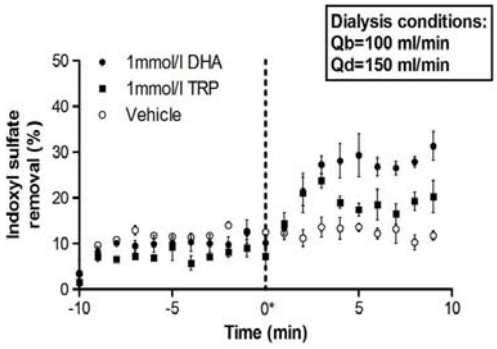
Enhanced Indoxyl Sulfate Dialyzer Clearance with Use of Binding Competitors: An *In Vitro* Proof-Of-Concept Study Xia Tao,[1] Stephan Thijssen,[2] Nathan W. Levin,[2] Peter Kotanko,[2] Garry J. Handelman.[1] *[1]Clinical Laboratory and Nutritional Sciences, Univ of Massachusetts Lowell, Lowell, MA; [2]Renal Research Inst, NY, NY.*

Background: Indoxyl sulfate (IS) is a uremic toxin that accumulates in chronic kidney disease patients and is associated with multiple-organ toxicity. Because of its high-affinity binding to human serum albumin (HSA), the dialytic clearance of IS is comparatively low. Here we propose a method for increasing the dialytic clearance of IS by using competitors of its binding to albumin.

Methods: Potential displacers of IS on HSA were tested in rapid equilibrium dialysis (RED) cartridges. The ability of 1mM tryptophan (TRP) and docosahexaenoic acid (DHA) to increase IS removal was evaluated with an *in vitro* dialysis model. HSA preloaded with 100uM IS, was circulated on the blood side (100 ml/min) of a F40S dialyzer with single-pass counter-current dialysate flow (150 ml/min). After a 10-min baseline test of clearance, 1mM TRP or DHA were infused into the blood-side circuit upstream of the dialyzer for 10 min, and the effects on IS removal were determined by HPLC.

Results: The free fraction of IS increased 1.4 fold with addition of TRP and 3 fold with DHA in RED device, while no significant change was seen with addition of antipyrine. Baseline IS removal in the in vitro dialysis model was 10.0±0.3 % ml/min (mean ± SEM), which increased to 19.5 ± 0.8 % with infusion of TRP and 27.3±1.0% ml/min with infusion of DHA.



* Start of displacer infusion, Mea ± SEM, N=3

Conclusions: This study shows that TRP and DHA effectively displace IS from albumin and increase its removal when evaluated in an *in vitro* dialysis model. The results suggest that the concept of using binding competitors to enhance the dialytic clearance of protein-bound uremic toxins is a potential therapeutic approach that can be applied to current hemodialysis technology.

Oxidative Stress in Maintenance Hemodialysis Patients Siren Sezer,[1] Mehtap Erkmen Uyar,[1] Ayse Zeynep Bal,[1] Nilüfer Bayraktar,[2] Bahar Gurlekdemirci,[1] Burak Sayin.[1] *[1]Dept of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [2]Dept of Biochemistry, Baskent Univ Faculty of Medicine, Ankara, Turkey.*

Background: Advanced glycation end products (AGEs) are a group of highly oxidant compounds with pathogenic significance in diabetes and in several other chronic diseases. Various antioxidant enzymes superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and catalase. The aim of this study is to evaluate the association between the levels of the components of the oxidative stress process and clinical and biochemical parameters including pulse wave velocity in maintenance hemodialysis (MHD) patients.

Methods: One hundred thirty six maintenance hemodialysis patients (MHD) (59 female, 51.8±14.3 years) were enrolled into the study. Monthly assessed biochemical parameters were recorded.Office systolic and diastolic blood pressure levels and dry weights were also recorded. Pulse wave velocity (PWv) was determined from pressure tracing over carotid and femoral arteries using the SphygmoCor system and change in PWv levels through 1 year was evaluated with ΔPWV. Serum AGE, malondialdehyde and SOD levels were determined by ELISA method.

Results: Patients were divided into two groups from the median value of serum AGE; group 1, n:68, mean AGE 2.76 u/mL and group 2, n:68, mean AGE 6.21 u/mL. Groups were similar in means of demographic characteristics but group 2 patients had longer dialysis duration (p:.0026).Patients with higher serum AGE levels had significantly higher systolic (p:.046) and diastolic (p:.041) BP than group 1 patients. Group 2 patients had also lower dry weights (p:.013) and serum bicarbonate levels (p:.005) and; higher comorbidity scores (p:.038) and serum CRP levels (p:.003). Both PWv levels and ΔPWV were significantly higher in group 2 patients than group 1 patients (p:.001 and 0.001 respectively). Serum AGE levels were positively correlated with serum CRP (r:.164, p:.046) and negatively correlated with serum SOD (p:.008, r:-.212) levels.

Conclusions: We suggest that increased AGE levels appear to be associated with arterial stiffness and hypertension; and could be a potential biomarker that can be assessed as a cardiovascular risk in MHD patients.

SA-PO977

Dietary Fiber Intake: Its Relation with Glycation End Products and Arterial Stiffness Siren Sezer,[1] Bahar Gurlekdemirci,[1] Burak Sayin,[1] Irem Olcay Eminsoy,[2] Emre Tutal,[1] Eyup Kulah.[3] *[1]Dept of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [2]Dept of Nutrition, Baskent Univ Faculty of Medicine, Ankara, Turkey; [3]Dept of Nephrology, Baskent Univ Faculty of Medicine, Istanbul, Turkey.*

Background: Dietary fiber intake is associated with protection against cardiovascular diseases as well as anti-inflammatory and metabolic effects that were pointed out in recent studies. Advanced glycation end products (AGEs) are a group of highly oxidant compounds. The pathologic effects of AGEs are related to oxidative stress and inflammation. The aim of this study is to evaluate the association between the dietary fiber intake and the components of oxidative stress and inflammation as CRP, superoxide dismutase (SOD) and AGEs accompanied by pulse wave analysis.

Methods: One hundred thirty maintenance hemodialysis patients (73 male, 51.9±14.3 years with 9.1±5.4 years dialysis duration) were enrolled into the study. Daily dietary fiber intake was assessed using a validated food frequency questionnaire for 6 consequence days. Monthly assessed biochemical parameters were recorded. Serum AGEs and SOD levels were determined by ELISA method. Pulse wave velocity (PWv) was determined from carotid and femoral arteries using the SphygmoCor system. Patients were divided into 2 groups according to mean value of dietary fiber intake.

Results: Mean dietary fiber intake were 16.5±3.0 g/day in patients with group 1 (n: 64) and 8.8 ± 2.1 g/day in group 2 (n: 66). However, mean values of dietary water, carbohydrates, lipids and protein deals were similar in both groups. Patients in group 1 had significantly lower CRP (p: 0.002) and AGE (p: 0.001) and higher SOD (p: 0.04) levels when compared with group 2. PWv levels were higher in patients with group 2 ($p<0.05$). In regression analysis dietary fiber intake and SOD levels were the detected as the predictors of AGE.

Conclusions: We conclude thatdietary fiber intake is independently correlated with CRP and AGEs, in addition decreased fiber intake is resulted in improved arterial stiffness. Thus, adequate fiber intake could prevent cardiovascular events and inflammatory processes in patients ongoing hemodialysis.

Expanding the List of Uremic Solutes Using an Established Metabolomics Platform Hisae Tanaka,[1] Tammy L. Sirich,[1] Daniel S. Weaver,[2] Timothy W. Meyer.[1] *[1]Dept of Medicine, Stanford and VA, Palo Alto, CA; [2]SRI International, Menlo Park, CA.*

Background: Metabolomic studies using mass spectrometry have increased the number of solutes known to accumulate when the kidneys fail. The current study was designed to identify additional uremic solutes using an established metabolomics platform.

Methods: Samples of plasma and plasma ultrafiltrate from 6 maintenance hemodialysis patients (HD) and 6 normal subjects (NL) were analyzed on a platform capable of detecting more than 3000 known compounds by the combination of liquid and gas chromatography with mass spectrometry. Solutes were classified as uremic based on the finding of significant differences between their concentration in HD and NL with a false discovery rate <0.05 and an HD/NL concentration ratio greater than 2.5 or detection of the solute in at least 5 of 6 HD patients but no more than 1 normal subject. Solutes were classified as novel uremic solutes when reports of their accumulation in humans with CKD or ESRD could not be found in PubMed or the EUTox database. Potential microbial contributions to uremic solute production were identified by searching the BioCyc collection of databases for microbial metabolic pathways capable of producing each solute.

Results:

459	solutes detected in the plasma and/or plasma ultrafiltrate of HD patients
126	of these solutes classified as uremic
60	of the uremic solutes classified as novel based on the lack of prior reports in PubMed or EUTox
66	of the uremic solutes potentially produced by microbes, including 54 by known colon microbes

Solutes which had not been previously identified as uremic included 14 amino acids which had undergone N-acetylation or other chemical modification and 6 phenyl compounds with had undergone sulfate conjugation.

Conclusions: These results add significantly to the number of known uremic solutes. A significant portion of uremic solutes may be produced by microbes. Increased knowledge of uremic solutes and their sources should help improve treatment for renal failure patients.

SA-PO979

Steady State Kinetic Analysis of Low Molecular Weight Protein Removal Using Only Intradialytic Concentration Measurements Baris U. Agar,[1] Richard A. Ward,[2] Werner Beck,[3] Markus Storr,[3] J. Ken Leypoldt.[1] *[1]Baxter Healthcare Corporation, Deerfield, IL; [2]Univ of Louisville, Louisville, KY; [3]Gambro (Subsidiary of Baxter International, Inc), Hechingen, Germany.*

Background: Evaluation of low molecular weight protein kinetics during extracorporeal treatments is optimal when both intradialytic and postdialytic changes in protein concentrations and the protein concentration before the next treatment are

determined. Such study designs are often impractical due to excessive time commitments by patients and clinical staff. We evaluated the effect of more limited sampling schedules on the accuracy of kinetic parameters for protein removal.

Methods: Kinetic parameters for beta-2-microglobulin (b2m) were determined using 3 different methods: 1) an optimal method using concentrations measured over a complete intra- and interdialytic cycle (Optimal Model); 2) a steady state method not requiring a concentration before the next treatment (SS Model); and, 3) a steady state method using only intradialytic concentrations (ID Model). Kinetic data from 10 patients treated for 240 min by thrice weekly hemodiafiltration were analyzed using a two-compartment kinetic model containing 4 unknown parameters: generation rate (G); total distribution volume (V_T); central distribution volume (V_C); and intercompartmental clearance (K_{12}).

Results:

Model	G (mg/min)	V_T (L)	V_C (L)	K_{12} (mL/min)
Optimal	0.129 ± 0.026	18.7 ± 4.3	5.7 ± 1.0	73.5 ± 18.9
SS	0.129 ± 0.033	19.0 ± 3.8	5.8 ± 0.9	72.0 ± 19.3
ID	0.131 ± 0.035	20.6 ± 5.3	5.3 ± 1.9	72.2 ± 40.3

There is little loss of accuracy when using the SS model (median absolute differences between the Optimal and SS models were 0.022 mg/min for G, 1.0 L for V_T, 0.3 L for V_C and 4.0 mL/min for K_{12}). Similar overall accuracy is obtained using the ID Model except for higher variability in V_T and K_{12} (median absolute differences between Optimal and ID models were 0.024 mg/min for G, 1.8 L for V_T, 0.4 L for V_C and 13.8 mL/min for K_{12}).

Conclusions: Steady state kinetic parameters for low molecular weight protein removal during extracorporeal treatments can be obtained using only intradialytic concentration measurements.

SA-PO980

The Role of Uremic Toxin Accumulation in Adipose Tissues in Lipodystrophic Phenotype in Mild Chronic Kidney Disease

Hitoshi Minakuchi, Shu Wakino, Keiko Fujimura, Koichi Hayashi, Hiroshi Itoh. *Internal Medicine, Keio Univ, Tokyo, Japan.*

Background: Lipodystrophic phenotype has been described in early chronic kidney disease (CKD) that includes adipose tissue atrophy, systemic insulin resistance (IR), dyslipidemia and ectopic lipid accumulation. To elucidate its pathogenesis, we investigated the role of an endogenous nitric oxide synthase inhibitor, asymmetric dimethyarginine (ADMA) and indoxyl sulfate (IS) that are among uremic toxins and affect insulin sensitivity.

Methods: We rendered six-week old SD rats CKD by 5/6th nephrectomy (Nx) and compared various phenotypes between Nx and sham-operated rats. Cultured 3T3L1-fibroblasts were differentiated into mature adipocytes with or without ADMA. Transgenic (TG) mice overexpressing each isoform of ADMA degrading enzyme, dimethylarginine dimethylaminohydrolase (DDAH)-1 and DDAH-2 were subject to Nx and their phenotypes were investigated. By using our cohort with non-diabetic G1-G3a CKD patients, associations between eGFR and various clinical parameters were examined.

Results: OGTT and ITT revealed that IR was evident in Nx. Insulin stimulation failed to activate downstream molecules of insulin receptor, PDK and Akt in adipose tissues in Nx. As a consequence of IR, adipose tissue weight, adipocyte size and adipocyte differentiation marker expressions decreased in Nx. Tissue lipid content in the liver and muscle increased in Nx. Tissue levels of ADMA, IS and oxidative stress increased in the adipose tissue of Nx. Both DDAH1 and DDAH2 expressions decreased and a putative IS receptor, arylhydrocarbon receptor (AhR) expression increased in the adipose tissue of Nx. ADMA inhibited adipocyte differentiation, triglyceride accumulation and insulin signaling, which were reversed by pretreatment with cGMP. Both in DDAH1 and DDAH2 TG mice with Nx, all the lipodystrophic phenotypes were reversed. In our CKD cohort, eGFR levels were significantly associated both with serum ALT and triglyceride levels.

Conclusions: In mild CKD, uremic toxin accumulations in the adipose tissue trigger lipodystrophic changes including ectopic fat depositions, which might explain the recently-recognized clinical association between CKD and fatty liver.

Chronic Kidney Disease (CKD) Disruption of Macrophage Lipid and Inflammatory Handling and Effects of Liver X Receptor (LXR) Agonism

Ryohei Kaseda, T. Alp Ikizler, Sergio Fazio, Valentina Kon. *Vanderbilt.*

Background: Macrophage foam cell formation, a key feature of atherosclerotic cardiovascular disease (CVD), reflects an imbalance between uptake and efflux of cellular cholesterol. Advanced CKD requiring dialysis disrupts efflux, but little is known about foam cell formation in moderate CKD which has increased CVD risk. We evaluated cellular lipid handling as well as inflammatory response to lipoproteins from CKD patients and assessed potential benefits of activating cellular cholesterol transporters by LXR agonism.

Methods: LDL and HDL were isolated by sequential density ultracentrifugation of blood specimens from CKD patients (stage 3-4, N=50) and normal controls (N=20). Human THP-1 cells were used to measure uptake of LDL and efflux to HDL with gas chromatography which determined cellular lipid content. HDL effects on cytokines (MCP-1, *TNF-α, IL-1b)*, Toll like receptor-2 (TLR-2), and cholesterol transporters (ABCA1) were assessed by RT-PCR and western blot.

Results: There was no difference in macrophage uptake of $LDL^{Control}$ versus LDL^{CKD}. By contrast, compared to $HDL^{Control}$, cholesterol efflux to HDL^{CKD} was reduced (24.6±1.7 versus 19.8±0.8, p=0.008) and macrophage inflammatory cytokine response was enhanced (IL-1ß 1.09±0.06 versus 1.60±0.09 p<0.001, TNF-α 1.11±0.10 versus 1.55±0.09 p=0.001, MCP-1 0.98±0.05 versus 1.18±0.06 p=0.021). Cellular exposure to LXR agonist (T0901317) significantly increased macrophage ABCA1 gene and protein expression and improved efflux not only to $HDL^{Control}$ but also to HDL^{CKD} (24.6±1.7 versus 28.7±1.3, 19.8±0.8 versus 22.8±0.8, both p<0.001). However, LXR agonist further amplified the cytokine response and increasedHDL^{CKD} effect on TLR-2 (1.07±0.06 versus 1.28±0.13 p=0.008).

Conclusions: CKD-induced potentiation in macrophage foam cell formation does not reflect increased LDL uptake, and instead denotes reduced efflux due to impairment in cholesterol acceptor function of HDL^{CKD}. LXR activation in cellular cholesterol transporters improves efflux to HDL^{CKD}. Thus, even in the face of dysfunctional HDL, activation of cellular transporters can abrogate pro-atherogenic lipid handling, a benefit offset by heightened pro-inflammatory effect of HDL^{CKD}.

Evaluating Observed versus Expected Mortality Rates in U.S. Dialysis Patients Amid Secular Declines

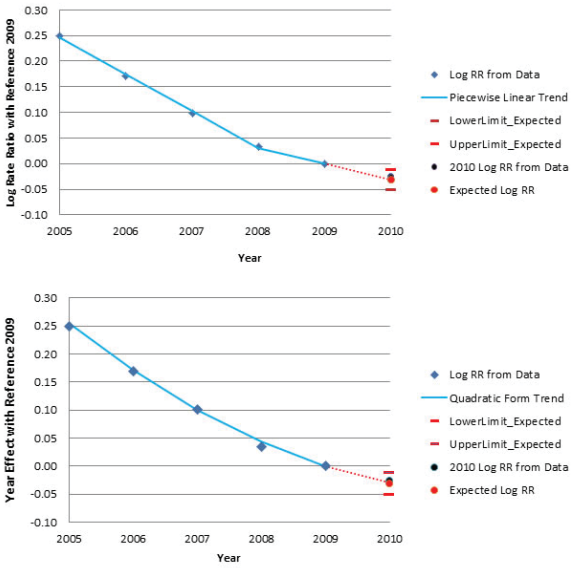
Jiannong Liu,[1] Keri Monda,[2] Charles A. Herzog,[1] M. Alan Brookhart,[3] Til Stürmer,[3] Brian D. Bradbury,[2] Kenneth J. Rothman,[4] Glenn M. Chertow.[5] *[1]Chronic Disease Research Group, Mpls, MN; [2]Amgen, Inc., Thousand Oaks, CA; [3]UNC-CH, Chapel Hill, NC; [4]Research Triangle Inst, Raleigh, NC; [5]Stanford Univ, Palo Alto, CA.*

Background: Effects on mortality and CV events in dialysis patients (pts) of the 2011 ESA label and reimbursement changes have not been carefully examined. We modelled recent mortality trends in U.S. dialysis pts, as a first step in a before/after comparison.

Methods: Using the CMS ESRD database, we included all adult (≥18) pts on dialysis for ≥9 mos, 2005-2010, with Medicare as primary payer (MPP) for ≥6 mos. Pts were followed from Jan 1 or day 1 of the first calendar mo after criteria were met, each yr, to the earliest of death, loss of MPP, modality change, transplant, or yr end. Time trends were modeled using Poisson regression with log link for 2005-2009, adjusted for pt characteristics. We used a piecewise linear function of yr with 2008 as the node, and a quadratic polynomial function for the time trend. The linear trend from 2008-2009 and the quadratic function were extrapolated to 2010; we used bootstrapping to estimate the standard error and 95% CI. The expected 2010 mortality rate was calculated using the extrapolation and 2010 cohort characteristics, and compared with the observed rate.

Results: Both the piecewise linear and quadratic functions fit the 2005-2009 trend fairly well and predicted the 2010 death rate accurately. The expected 2010 death rate was 20.0 per 100 pt-yrs from both functions; the observed rate was 19.9.

Figure. Observed, Fitted, and Expected Log Rate Ratios



Conclusions: Accurately predicting temporal mortality trends in dialysis pts is possible. This sets the groundwork for analyses examining deviance of observed 2011/2012 mortality rates from rates expected based on complete 2005-2010 data in a context of secular decline.

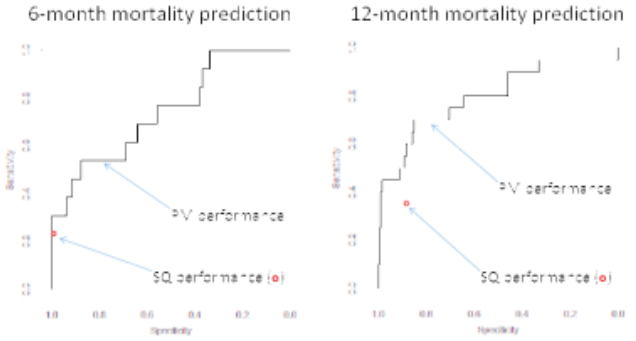
Performance of Surprise Question Compared to Prediction Models in Hemodialysis Patients Stephan Thijssen,[1] Yuedong Wang,[2] Rebecca H. Apruzzese,[1] Paul Balter,[3] Qingqing Xiao,[1] Len A. Usvyat,[3] Peter Kotanko.[1] *[1]Renal Research Inst, New York, NY; [2]Statistics and Applied Probability, Univ of California, Santa Barbara, CA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: The surprise question (SQ) ("Would you be surprised if this patient were still alive in X months?") is a significant predictor of patient survival on hemodialysis (HD). We compared the SQ with novel statistical prediction models (PM) for mortality prediction.

Methods: We developed a set of 2 statistical models (with different sets of predictor variables to cover the majority of patients) for 6- and 12-month mortality prediction in a large cohort of U.S. chronic HD patients (1/2 for training, 1/4 for parameter selection, 1/4 for validation). 6- and 12-mo SQ survey responses were obtained from attending nephrologists for 215 prevalent HD patients from 5 U.S. clinics. Patients were prospectively followed for 12 mo and their survival compared to model predictions using ROC analysis.

Results: The SQ's sensitivity and specificity were 0.2308 and 0.9897 @ 6 mo and 0.35 and 0.8817 @ 12 mo. The PM's area under the ROC curve was 0.75 and 0.8 for 6- and 12-mo prediction, resp. The PM outperformed the SQ for both 6- and 12-mo mortality prediction (greater sensitivity @ the same specificity, and vice versa; see figure: SQ well below PM's ROC curve).



Conclusions: The SQ has a low sensitivity for mortality prediction in HD patients and is not well suited for identifying patients at risk. Statistical PM can deliver superior sensitivity and specificity compared to the SQ. Further, they provide a death probability and, thus, more detailed information than the binary SQ. With adequately chosen cutoffs for PM, the tradeoff between sensitivity and specificity can be optimized to suit the clinical need in the context of HD patient care.

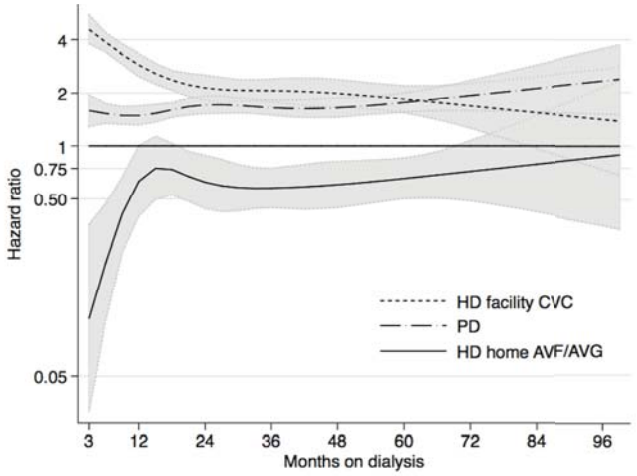
Dialysis Modality and Mortality: Applying Marginal Structural Models to Data from Australian and New Zealand Dialysis and Transplant (ANZDATA) Registry Kevan Polkinghorne,[1,3] Jessica Kasza,[1] Rory Wolfe,[1] Mark R. Marshall,[2,3] Stephen P. McDonald.[3] *[1]Epidemiology and Preventative Medicine, Monash Univ, Melbourne, Victoria, Australia; [2]Nephrology, Middlemore Hospital, Auckland, New Zealand; [3]ANZDATA Registry, Royal Adelaide Hospital, Adelaide, South Australia, Australia.*

Background: The optimal dialysis modality for patients with end stage kidney disease remains unclear. Without adequate randomized studies, sophisticated analyses of observational data must inform decision-making. Previous analyses comparing dialysis modalities have failed to account for vascular access (VA) type in the hemodialysis patients.

Methods: All incident adult patients who commenced dialysis between October 1, 2003 and December 31, 2011 were assessed. The exposure of interest was time-varying dialysis modality (PD, facility HD, or home HD), with facility and home HD sub-classified by VA type (CVC, or AVF/AVG). Discrete-time Cox proportional hazards marginal structural models for death were fit. Each patient's observation at each period was weighted using stabilized inverse probability of treatment and censoring weights, estimated using propensity score models, which account for exposure and censoring history.

Results: 20,191 patients with mean 2.5 years follow-up were included. 30% of patients had at least one change in dialysis modality. Relative to facility HD AVF/AVG (HR=1, figure) the risk of death for patients treated with home HD with AVF/AVG was much lower early, waning over the first year and stabilizing around 0.75 from 24 months. HD CVC and (to a lesser extent) PD were associated with an ongoing higher risk of death.



Conclusions: Relative to facility HD with permanent VA, home HD has improved survival while facility CVC has the highest risk. PD has a lower risk of death compared to facility CVC but was consistently higher than facility HD.

SA-PO985

Vascular Access and Survival in a Large Catheter-Dominant Dialysis Program Damien Ashby, Neill D. Duncan, Albert J. Power, Sophie Kathirgamanathan. *Renal and Transplant, Imperial College London, London, United Kingdom.*

Background: Compared to other forms of access, arteriovenous fistulae are associated with improved survival in haemodialysis patients, and are widely believed to be superior, but the evidence base is entirely observational, and therefore subject to bias. Centre level data avoids some of this bias, so the outcome in centres with unusual practice patterns can be informative.

Methods: The largest UK dialysis centre(currently 1390 haemodialysis patients) is also an extreme outlier in terms of access practice with 80% of prevalent patients dialysing on tunneled catheters. This retrospective study examined survival after 90 days, in a cohort of patients who started dialysis during a 3 year period, with respect to vascular access.

Results: Between 01.12.2005 and 01.12.2008, 746 incident haemodialysis patients (aged 18–91, 60.1% male, 47.2% caucasian) were included. The dominant form of access was a pair of single-lumen tunneled catheters, used in 85.4% of patients at 90 days. Over a mean observation period of 1178 days 34.7% of patients died, with fistula access associated with longer survival (median 2721 versus 2298 days, p=0.019). In a Cox regression model, the independent predictors of survival were age, ethnicity, comorbidity and renal diagnosis, with fistula access only weakly associated with outcome (HR 0.717, p=0.116). In the catheter group, one year(after 90 day) survival was 91.5%, after adjustment to age 60.This compares favourably with the UK age adjusted average of 89.0% for the whole 2008 incident cohort (all access types).

Conclusions: The advantage of fistula access is diminished in this catheter-dominant program, where outcome in catheter patients is at least equivalent to the national average. This could be because catheter outcomes are improved incentres where they are more frequently used, or because a substantial fraction of the fistula "advantage" is actually a result of selection bias.

SA-PO986

Association between Catheter Anatomy and Fatal Cardiac Arrest in Hemodialysis Kevin Chan, Ann Mooney, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care - NA, Waltham, MA.*

Background: Mortality risk doubles for ESRD patients who dialyze through a catheter vascular access when compared to patients who dialyze through an arteriovenous fistula(Chan et al., 2011). The pathophysiological mechanism for this catheter-related excess mortality remains unclear. As the tip of the catheter sits in the right atrium where the outflow of blood is deposited, we hypothesized the tip's proximal location is pro-arrhythmogenic because it directly exposes the heart to electrolyte shifts.

Methods: Case-control study of all hemodialysis patients with a catheter vascular access discharged from the Fresenius Medical Care North America (FMCNA) Dialysis Network from January 1997 to April 2014. The patient outcome was determined by the reason for the patient's discharge: death versus other (transfer of care, recovery of renal function, or transplantation). The exposure variable was the anatomical location of the catheter: upper body (internal-jugular or subclavian) or femoral. Logistic regression was used to determine the association of catheter location with cardiac mortality.

Results: We identified 310,801 hemodialysis patients with a catheter vascular access who were discharged from the FMCNA Dialysis Network. 3.5% of these patients were discharged with a femoral vascular access. Using logistic regression, we found patients with a femoral catheter associated with a significant 18% increased risk of fatal cardiac arrest when compared to patients with an internal-jugular or subclavian vascular access (Table 1). Femoral catheter patients were at even greater risk of dying from sepsis.

	Events (%)		OR (95% CI)
	Femoral	Upper Body	
Cardiac Arrest	19.8%	17.3%	1.18 (1.13-1.23)
Intra-dialytic cardiac arrest	1.36%	1.40%	0.97 (0.85-1.19)
Sepsis	7.7%	4.8%	1.67 (1.57-1.78)

Conclusions: Given significantly greater risk of cardiac arrests and sepsis episodes, femoral catheters should be the vascular access of last resort.

SA-PO987

High-Flux versus Low-Flux Hemodialysis in Patients with Higher Dialysis Dose: Insights From the MPO Trial Martin Wagner,[1,2] Franziska Koenigsbauer,[1,3] Navdeep Tangri,[4] Jan Beyersmann,[3] David M. Kent,[5] Peter U. Heuschmann,[2] Christoph Wanner,[1] Francesco Locatelli.[6] *[1]Div. of Nephrology, Univ Hospital Wuerzburg, Germany; [2]Inst of Clinical Epidemiology and Biometry, Comprehensive Heart Failure Center, Univ of Wuerzburg, Germany; [3]Inst of Statistics, Univ of Ulm, Germany; [4]Div. of Nephrology, Univ of Manitoba, Winnipeg, Canada; [5]Center for Predictive Medicine Research, Tufts Medical Center, Boston, MA; [6]Dept of Nephrology, Allessandro Manzoni Hospital, Lecco, Italy.*

Background: Mortality risk varies among hemodialysis (HD) patients. High-flux membranes were thought to improve survival, but evidence remains unclear. We investigated the effect of high-flux versus low-flux HD on mortality in patients of the MPO trial with higher versus lower dialysis dose, considering individual's baseline mortality risk.

Methods: Incident HD patients of 9 European countries were randomized to high-flux versus low-flux and followed for up to 7.5 yrs if they achieved a single-pool Kt/V >1.2 after a 4-12 wks run-in phase. Primary endpoint was death of all causes. Baseline mortality risk was determined by a novel clinical score that we developed in the UK Renal Registry and validated in DOPPS. Dialysis dose was classified as Kt/V≥1.4 or <1.4.

Results: As determined by the score, patient characteristics (n=637) varied across risk quartiles (age, BMI, residual renal function, vascular access, diabetes, CVD, hematocrit, albumin, creatinine, all p<0.05). In patients with Kt/V≥1.4 (n=221), high-flux was associated with a beneficial effect on mortality (HR 0.59, p=0.058) independent from baseline risk (HR 1.07, p<0.01). We detected evidence suggestive for variation of treatment effect by high-flux according to baseline risk, but the interaction of risk*flux was not statistically significant (p=0.1). No effect was found for high flux (HR 1.05, p=0.8) in the Kt/V<1.4 group (n=416) while baseline risk was associated with increased risk of mortality (HR 1.09, p<0.01).

Conclusions: Our clinical risk score accurately stratified incident HD patients according to mortality risk. The results suggest that high-flux HD may prolong survival in patients treated with higher dialysis doses, independent from baseline mortality risk.

SA-PO988

Different Impact of Hemodialysis Vintage on Cause-Specific Mortality in Long-Term Hemodialysis Patients in Japan Keiichi Sumida,[1] Kunihiro Yamagata,[2] Kunitoshi Iseki,[2] Yoshiharu Tsubakihara.[2] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan; [2]Renal Data Registry Committee, Japanese Society for Dilysis Therapy, Tokyo, Japan.*

Background: Along with the improvement of hemodialysis care, the proportion of patients with a longer hemodialysis (HD) vintage has been increasing. Several studies have shown that the HD vintage is associated with increased mortality risk in patients receiving HD. However, no significant effect of HD vintage on cause-specific mortality in HD patients has been shown, especially among long-term HD survivors.

Methods: To elucidate the effect of HD vintage on cause-specific mortality, we used the standard analysis file (JRDR-12002) and conducted a nationwide registry-based retrospective cohort study of 192,760 maintenance HD patients who had been on hemodialysis more than one year and who could be followed for a year between 2008 and 2009. The HD vintage was divided into eight subgroups: 1–<2, 2–<5, 5–<10, 10–<15, 15–<20, 20–<25, 25–<30, and ≥30 years.The study outcomes were 1-year all-cause and cause-specific mortality.

Results: The mean age and hemodialysis vintage of study participants were 66.2 ± 12.4 and 8.3 ± 6.9 years. During the study period, 15,998 deaths occurred from all causes, which included 6302, 3019, and 1459 deaths, respectively, from CVD, infection-related, and cancer causes. In multivariate analysis (vintage 1–<2 years as referent), there was a significant association between the HD vintage and the odds ratio (OR) of all-cause mortality with an increasing trend of OR in each vintage (vintage ≥30, OR = 1.84, 95% CI 1.50–2.27). A similar association was observed between the HD vintage and infection-related mortality (vintage ≥30, OR = 3.11, 95% CI 2.10–4.61). The OR of CVD mortality remained significant and fairly constant up to 20–<25 years of category (OR = 1.14 to 1.37) followed by reductions in OR to 1.28 (95% CI 0.94–1.75) and 1.13 (95% CI 0.78–1.65) for HD vintages of 25–<30 and ≥30 years, respectively. No significant association was found between the HD vintage and cancer mortality.

Conclusions: The HD vintage has a different impact on cause-specific mortality in HD patients. This impact was more pronounced among long-term HD patients.

SA-PO989

Inflammation and Oxidative Stress in Hemodialysis Patients with Sleep Apnea Syndrome Olga Nikitidou,[1] Vassilios Liakopoulos,[1] Euphemia Daskalopoulou,[2] Nicholas V. Dombros,[1] Aikaterini A. Papagianni.[3] *[1]Nephrology and Hypertension, 1st Dept of Internal Medicine, AHEPA Univ Hospital, Medical School, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; [2]Sleep Laboratory, Dept of Internal Medicine, St. Paul General Hospital, Thessaloniki, Greece; [3]Nephrology Dept, Hippokration General Hospital, Medical School, Aristotle Univ of Thessaloniki, Thessaloniki, Greece.*

Background: Sleep apnea syndrome (SAS) is an established cardiovascular risk factor in the general population related to inflammation and oxidative stress and is very common among hemodialysis patients. The aim of the present study was to investigate the role of SAS in the promotion of inflammation and oxidative stress in hemodialysis patients.

Methods: 37 hemodialysis patients (23 males) participated in the study. The night between two consecutive midweek hemodialysis sessions, they underwent an overnight polysomnography study with a "SOMNOscreen™" device. The following morning blood samples were obtained for TNF-α, IL-6, MPO and oxLDL.

Results: We investigated the correlation of patients' markers of inflammation and oxidative stress with their characteristics (age, BMI, duration of hemodialysis) and their sleep parameters (total sleep time, AHI–Apnea-Hypopnea Index, RDI-Respiratory Disturbance Index, DI-Desaturation Index, mean and minimum SpO_2 and percentage of sleep time with SpO_2<90%). TNF-αcorrelated positively with BMI (r=0.510, p<0.0001) and total sleep time(r=0.370, p=0.027). IL-6 correlated positively with age (r=0.363, p= 0.027), AHI (r=0.385, p=0.018), DI (r=0.336, p=0.042) and percentage of sleep time with SpO_2<90% (r=0.415, p=0.012) and negatively with mean SpO_2 (r=-0.364, p=0.027). MPO correlated positively with AHI (r=0.385, p=0.018), DI (r=0.380, p=0.02) and percentage of sleep time with SpO_2<90%(r=0.388, p=0.019). Finally, oxLDL correlated positively with BMI (r=0.443, p=0.007), AHI (r=0.395, p=0.015), RDI (r=0.328, p=0.048) and total sleep time with SpO_2<90%(r=0.389, p=0.019).

Conclusions: These results indicate that, in hemodialysis patients, the severity of SAS and nocturnal hypoxia correlate with markers of inflammation and oxidative stress and may contribute to their augmented cardiovascular risk.

Dental Health and Mortality in People with End-Stage Kidney Disease Treated with Hemodialysis: A Multinational Cohort Study Giovanni F.M. Strippoli.[1,2,3,4] *[1]On Behalf of the ORAL-D Study Investigators; [2]Diaverum; [3]Univ of Sydney; [4]Amedeo Avogadro Univ of Eastern Piedmont.*

Background: Clinical outcomes for adults treated with hemodialysis are poor and have not substantially improved, with typical mortality rates of 15% per annum. Interventions evaluated to date have largely been ineffective so novel, testable determinants of health outcomes for dialysis patients are needed.

Methods: We did a prospective multinational cohort study (the ORAL-D study) conducted from 2010 to 2012 **t**o investigate whether dental disease and health practices are associated with early mortality in adults with end-stage kidney disease on hemodialysis. We included 4205 patients in Europe and Argentina. We assessed edentulousness (complete tooth loss), dental disease (number of decayed, filled and missing teeth), frequency of teeth brushing and changing a toothbrush, use of dental floss and mouthwash, time spent on oral hygiene, age at first dental visit and time elapsed since last dental visit. The outcomes were all-cause and cardiovascular mortality.

Results: Over an average of 22.1 months (7737 person-years) follow-up, 942 deaths occurred including 477 from cardiovascular causes. Edentulousness (adjusted hazard ratio [HR] 1.28, 95% CI 1.11–1.48) and decayed, missing, or filled teeth score ≥ 14 (1.67, 1.33–2.10) were associated with early all-cause mortality whilst dental flossing (0.52, 0.33–0.82), brushing teeth daily (0.77, 0.60–0.97), spending at least two minutes oral hygiene daily (0.82, 0.70–0.96), changing a toothbrush at least every three months (0.79, 0.67–0.95), and visiting a dentist within the past six months (0.79, 0.65–0.95) were all associated with better survival. Results for cardiovascular mortality were similar, although associations with brushing teeth and time elapsed since a recent dental visit were not significant. These associations were independent of socioeconomic and clinical prognostic factors.

Conclusions: In adults with end-stage kidney disease treated with long-term hemodialysis, poorer dental health was associated with higher risk of death, including cardiovascular mortality, whereas preventive dental health practices were associated with better survival.

SA-PO991

Periodontitis and Early Mortality in Adults with End-Stage Kidney Disease treated with Hemodialysis Giovanni F.M. Strippoli.[1,2,3,4] *[1]On Behalf of the Oral Diseases in Dialysis (ORAL-D) Study Investigators; [2]Diaverum; [3]Univ of Sydney; [4]Amedeo Avogadro Univ of Eastern Piedmont.*

Background: Periodontitis is associated with cardiovascular events in the general population and represents a testable health determinant of dialysis patient outcomes. We aimed to evaluate whether periodontitis is associated with early mortality and cardiovascular death in adults treated with hemodialysis.

Methods: The ORAL-D study is a prospective multinational cohort study of oral health in adult hemodialysis patients in Europe and Argentina treated between 2010-2012.

We included 4205 patients who underwent a standardized oral examination at baseline. We assessed for periodontitis according to World Health Organization and Centers for Disease Control definitions. We calculated the hazards of all-cause and cardiovascular mortality using a random-effects Cox proportional hazards analysis fitted using a shared frailty model to account for clustering within countries and adjusted for sociodemographic and clinical variables.

Results: During 6150 person-years of follow-up, 650 deaths occurred of which 325 were cardiovascular. Periodontitis was evaluable in 3338 dentate participants of which 1355 (40.6%) had moderate to severe periodontitis. In crude analyses, moderate to severe periodontitis was associated with lower risks of all-cause (HR 0.78, 95% confidence interval 0.67 to 0.92) and cardiovascular mortality (0.70, 0.56 to 0.89). There was evidence of decreasing mortality risk with more severe periodontal disease (P=0.02 for trend). However, when analyses were clustered by country and adjusted for other prognostic clinical and socio-demographic factors, periodontitis was not associated with all-cause (0.86, 0.71 to 1.05) or cardiovascular mortality (0.77, 0.59 to 1.02). Similar results were observed when the Centers for Disease Control (CDC) definition for periodontitis was used.

Conclusions: Unlike in other settings, periodontitis is not an independent risk factor for early mortality or cardiovascular death for adults treated with hemodialysis.

SA-PO992

Geriatric Nutritional Risk Index Predicts Quality of Life and Clinical Outcome in Hemodialysis Patients No Better Than Its Individual Components Ilia Beberashvili,[1] Ada Azar,[2] Inna Sinuani,[3] Gregory Shapiro,[1] Leonid Feldman,[1] Zhan Averbukh.[1] *[1]Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel; [3]Pathology, Assaf Harofeh Medical Center, Zerifin, Israel.*

Background: Geriatric Nutritional Risk Index (GNRI) has been reported as a predictor of clinical outcomes in maintenance hemodialysis (MHD) patients. The aim of our study was to test whether GNRI provides an improved specificity for adverse prognosis in this population than its individual components.

Methods: Atwo-year prospective observational study performed on 261 MHD outpatients (38.7% women) with a mean age of 68.6±13.6 years. Prospective all-cause and cardiovascular (CV) hospitalization and mortality, geriatric nutritional risk index (GNRI) and short form 36 (SF-36) quality-of-life (QoL) scores were measured.

Results: For each one unit increase in baseline GNRI levels, the first hospitalization hazard ratio (HR), after adjustments for confounders, was 0.98 (95% confidence interval (CI), 0.97 to 0.99) and first CV event HR was 0.96 (95% CI, 0.93 to 0.99); all-cause death HR was 0.96 (95% CI, 0.93 to 0.98) and CV death HR was 0.95 (95% CI, 0.92-0.99). Adjusted HRs for each 0.1 g/dl increase in baseline albumin levels were 0.94 (95% CI, 0.91 to 0.98), 0.89 (95% CI, 0.82 to 0.97), 0.86 (95% CI, 0.80 to 0.91) and 0.87 (95% CI, 0.79 to 0.95), respectively. The accuracy of albumin was also stronger than GNRI in predicting of above clinical outcomes according to the receiver operating characteristic (ROC) curve analysis. Albumin was related to self-reported QoL with higher strength and magnitude than GNRI. This difference was prominent in total score (r=0.24, P<0.001 versus r=0.15, P=0.01), mental health (r=0.23, P<0.003 versus r=0.15, P=0.02) and physical health (r=0.23, P<0.001 versus r=0.16, P=0.02) dimensions, and in most scales of the SF-36. Body weight/ ideal body weight, another component of GNRI, performed worse than GNRI as a predictor of clinical outcomes and QoL.

Conclusions: Despite the strong relationship with clinical outcomes and QOL, GNRI doesn't improve or even worsens performance of albumin. This questions the clinical value of GNRI as a prognostic tool in MHD population.

SA-PO993

A Pilot Evaluation of ZS-9 as a Potential Emergency Treatment for Hyperkalemia William Peacock,[1] Zubaid Rafique,[1] Alex Yang,[2] Philip T. Lavin,[3] Henrik S. Rasmussen,[4] Phillip D. Levy.[5] *[1]Baylor College of Medicine, Houston, TX; [2]Xelay Acumen, Inc., Belmont, CA; [3]Boston Biostatistics Research Foundation, Framingham, MA; [4]ZS Pharma, Inc., Coppell, TX; [5]Wayne State Univ, Detroit, MI.*

Background: Hyperkalemia is a common problem, with higher levels requiring emergent intervention. Non-invasive treatments are limited by a slower rate of potassium (K+) reduction, with more rapid therapy (i.e., renal replacement therapy [RRT]) being both invasive and expensive, with estimated costs of up to $140,000 per episode. ZS-9, an orally dosed zirconium-based potassium (K^+) trapping agent, may lower serum K^+ at a sufficient rate to avoid the need for emergent RRT in selected pts. Our purpose was to evaluate the rate of reduction and dose relationships of ZS-9 as a potential therapy for pts with baseline K^+ >6.0 mEq/L.

Methods: Data from a large prospective phase 3 study, designed to evaluate different doses of ZS-9 for acute and chronic treatment of moderate hyperkalemia, are abstracted. Pts were included if they had a baseline K^+ >6.0 and repeated K^+ measurements.

Results: Thirteen pts met entry criteria, of whom 54% were male, 31% black and 69% white. Mean age (SD) was 69.7 (10.7) yrs in the 5g group and 67.0 (5.2) yrs in the 10g group. Comorbidities included 46% chronic kidney disease, 46% congestive heart failure, and 69% diabetes mellitus. 9 pts (69.9%) had a K^+<6.0 by 4 hrs (Table) with an effect on K^+ that was dependent upon ZS-9 dosing.

Potassium, mEq/L	ZS-9 dosage	
	5g (n=7)	10g (n=6)
K^+ at baseline, mean (SD)	6.1 (0.07)	6.2 (0.2)
K^+ at 4 hrs post-treatment, mean (SD)	5.6 (0.5)	5.3 (0.9)
K^+ change over 4 hrs, mean (SD)	-0.5 (0.5)	-0.8 (0.8)
No. (%) pts with K^+ <6.0 mEq/L by 4 hrs	5 (71.4%)	4 (66.7%)

Conclusions: ZS-9 may be an effective emergency treatment for hyperkalemia and can potentially be used to avoid acute RRT, translating to substantial cost savings. This should be further evaluated in a randomized prospective trial.

Insulin Resistance Is Associated with New-Onset Cardiovascular Events in Non-Diabetic Peritoneal Dialysis Patients Chang-Yun Yoon, Young Su Joo, Eunyoung Lee, Jung Tak Park, Seung Hyeok Han, Tae-Hyun Yoo. *Dept of Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

Background: Chronic exposure to high glucose-containing peritoneal dialysis (PD) solution and consequent abdominal obesity are potential sources of insulin resistance (IR) in prevalent PD patients. The aim of this study was to elucidate the prognostic values of IR on new-onset cardiovascular (CV) events in non-diabetic prevalent PD patients.

Methods: A total of 201 non-diabetic prevalent PD patients were recruited. IR was assessed by homeostatic model assessment of IR (HOMA-IR) using fasting plasma insulin and glucose levels. The primary outcome was new-onset CV events during the follow-up period. Cox proportional hazard analysis was performed to ascertain the independent prognostic value of HOMA-IR for the primary outcome.

Results: The mean age was 53.1 years and male was 49.3% (n=99). The mean HOMA-IR was 2.6±2.1. HOMA-IR was positively associated with body mass index (BMI) and serum concentrations of triglyceride (TG) and calcium, whereas negatively associated with high-density lipoprotein cholesterol. Moreover, previous CV diseases were significantly more prevalent in the high HOMA-IR group. In multivariate linear regression, BMI (β=0.222, P=0.002), TG (β=0.421, P<0.001), and previous CV diseases (β=0.151, P=0.032) were still significantly associated with HOMA-IR. During a mean follow-up duration of 40.2 months, the primary outcome was observed in 36 patients (17.9%). When patients were divided into tertiles according to HOMA-IR, the highest tertile group showed significantly higher incidence rates of new-onset CV events compared to the lower two-third group (P=0.029). Furthermore, multivariate Cox analysis revealed that HOMA-IR was a significant independent predictor of the primary outcome (hazard ratio=1.18, 95% confidence interval=1.03-1.35, P=0.014).

Conclusions: IR measured by HOMA-IR was an independent risk factor for new-onset CV events in non-diabetic prevalent PD patients.

SA-PO995

Glycated Albumin Has a Stronger Association Than Hemoglobin A1C with Mortality in ESRD Patients in the 4D Trial Christina Chen,[1] Christiane Drechsler,[2] Christoph Wanner,[2] S. Ananth Karumanchi,[1] Anders H. Berg.[1] *[1]Beth Israel Deaconess Medical Center; [2]Univ Hospital Würzburg.*

Background: Hemoglobin $A1_c$ (Hb $A1_c$) may not be an accurate index of glycemic control in patients with renal insufficiency due to factors such as uremia and epogen that affect the lifespan of red cells, and these effects may confound the relationship between Hb $A1_c$ and prediction of outcomes. This study compares the risk of death associated with glycated albumin (GA) versus Hb $A1_c$ in ESRD patients.

Methods: The Deutsche Diabetes und Dialyse Studie (4D study) was a prospective, randomized control trial (RCT) involving 178 dialysis centers in Germany that investigated the cardiovascular benefit of atorvastatin use in 1255 patients with ESRD with median time of follow up of 4 years. Hb $A1_c$ and GA were measured in samples obtained at month 6. Cox regressionanalysis was used to determine the hazard ratio (HR) for all-cause mortality over 42 months for GA as well as Hb $A1_c$.

Results: GA was studied as a continuous variable using univariate Cox proportional HR and found to be significant (HR 1.274; 95% CI 1.009-1.610, P-value 0.042). It remained significant after using multivariate analysis to adjust for age, sex, atorvastatin treatment, systolic relative risk, body mass index, coronary artery disease, heart failure, peripheral artery disease, duration of diabetes, hemoglobin, phosphate, and c-reactive protein (HR 1.291; 95% CI 1.004-1.659, P-value 0.046). In contrast, univariate analysis of Hb $A1_c$ values found no significant risk(HR 1.007; CI 0.937-1.082, P-value 0.954) and was also not significant when using multivariate analysis of the above variables (HR 1.029; 95% CI 0.951-1.114, P-value 0.474).

Conclusions: This is the largest study to date comparing the prediction of risk by GA and Hb $A1_c$ tests for glycemic control in patients on hemodialysis.These results suggest that GA is more closely associated to mortality than Hb $A1_c$, in agreement with previous smaller studies. Additional studies are necessary to confirm that targeting lower GA levels improves survival.

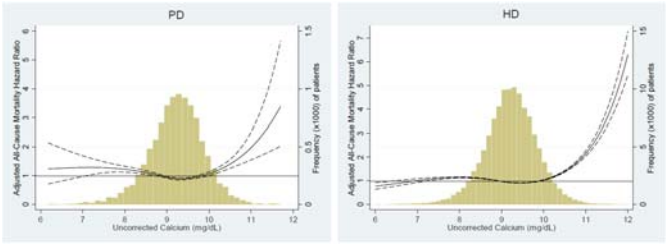
SA-PO996

Time-Averaged Uncorrected Serum Calcium: Relationship with Dialysis Modality and Cause-Specific Mortality Matthew B. Rivara,[1] Vanessa A. Ravel,[2] Kamyar Kalantar-Zadeh,[2,3] Elani Streja,[2] Wei Ling Lau,[3] Allen R. Nissenson,[4,5] Bryan R. Kestenbaum,[1] Ian H. de Boer,[1] Jonathan Himmelfarb,[1] Rajnish Mehrotra.[1] *[1]Kidney Research Inst, Seattle, WA; [2]Harold Simmons Ctr for Chronic Dis Research and Epi, UC Irvine Med Ctr, Irvine, CA; [3]Nephrology, UC Irvine Med Ctr, Orange, CA; [4]DaVita, Inc., El Segundo, CA; [5]David Geffen Sch of Med at UCLA, Los Angeles, CA.*

Background: Uncorrected serum calcium concentration is the first mineral metabolism metric planned for use as a quality measure in the U.S. dialysis population. Few studies in patients undergoing peritoneal dialysis (PD) or hemodialysis (HD) have assessed the association of uncorrected serum calcium with outcomes.

Methods: This observational cohort study uses data from 129,076 dialysis patients (PD 10,066; HD 119,010) treated in a large dialysis organization from 2001-2006. We performed Cox proportional hazards survival analyses to determine the relationship of time-averaged uncorrected serum calcium with all-cause, cardiovascular, and infection-related mortality.

Results: Following adjustment for potential confounders, uncorrected calcium <8.5 and ≥10.2 mg/dl was associated with excess all-cause mortality in both PD and HD patients (comparison group: calcium 9.0 to <9.5 mg/dl). Further adjustment for serum albumin attenuated the all-cause mortality hazard ratios (HRs) associated with calcium <8.5 mg/dl (HR 1.29: 95% CI 1.16, 1.44 for PD; HR 1.17: 95% CI 1.13, 1.20 for HD), and amplified the HRs associated with calcium ≥10.2 mg/dl (HR 1.65: 95% CI 1.42, 1.91 for PD; HR 1.59: 95% CI 1.53, 1.65 for HD). Calcium ≥10.2 mg/dl was also associated with increased risk for cardiovascular mortality (HR 1.45: 95% CI 1.15, 1.84 for PD; HR 1.64: 95% CI 1.55, 1.73 for HD).



Conclusions: In a large nationally representative cohort of dialysis patients, high concentrations of uncorrected serum calcium were associated with increased mortality risk, irrespective of dialysis modality.

SA-PO997

High Dialysate Calcium Concentration Promotes Low Parathyroid Hormone Status, which Is an Independent Risk Factor for Short-Term Cardiovascular Mortality in Hemodialysis Eric Daugas,[1,2] Emilie Merle,[1,2] Hubert Roth,[2] Gerard M. London,[2] Guillaume Jean,[2] Thierry P. Hannedouche,[2] Jean-Louis Bouchet,[2] Tilman B. Drueke,[2] Denis Fouque.[2,3] *[1]Nephrology, APHP, Bichat Hospital, Paris, France; [2]French Calcium and Phosphate Observatory, France; [3]Nephrology, Hospices Civils de Lyon, France.*

Background: To detail low parathyroid hormone (PTH) status and mortality association in incident patients on hemodialysis.

Methods: Multicenter prospective cohort study including 2164 incident hemodialysis patients at M0 in October 2010, prospectively followed until M24. Patients were classified according to their K/DIGO PTH status at M0 or M12 or both. M12 to M24 all-cause mortality, cardiovascular (CV) mortality and non-CV mortality were evaluated for each PTH status using adjusted Cox analysis. Factors of M0 to M12 PTH variability were analyzed by multivariate logistic regression.

Results: A decrease of PTH to a low status between M0 and M12 was independently and strongly associated with M12-M24 CV mortality (HR 2.01; 95%CI: 1.2-3.37; p =0.008; respectively). Among patients with a high or normal PTH status at M0, M6 independent predictive factors for a decreased PTH to a low status at M12 were hypoalbuminemia (OR: 0.96; 95%CI: 0.93 -0.99; p=0.01), a high dialysate calcium concentration use (1.75 mmol/L) (OR:2.02; 95%CI :1.37 to 2.99; p<0.0001) and to a lesser extent the use of native vitamin D (OR:1.02, 1.01-1.03, p = 0.014), whereas non calcium-based phosphate binders were protective (OR: 0.92, 95%CI: 0;86 to 0.99; p=0.031 for sevelamer and OR: 0.97, 95%CI: 0.95 to 0.99; p=0.04 for lanthanum). In the high CV mortality risk subgroup with an acquired low PTH status at M12, M12 independent factors associated with M12-M24 cardiovascular mortality were age, a C-reactive protein higher than 10mg/L and again a high dialysate calcium concentration (OR:5,43; 95%CI: 2.17-13.62; p<0.0001).

Conclusions: Patients with decreased PTH levels to a low status one year after hemodialysis initiation are at high risk of short-term CV mortality. High dialysate calcium concentration use is an important contributor of PTH decrease and its continuation is a major predictor of CV mortality the year after. Therefore, use of high dialysate calcium concentration should be restricted in hemodialysis patients.

SA-PO998

Non-Oxidized PTH (n-oxPTH) Is Associated with Cardiovascular Events and All-Cause Mortality in Patients with Secondary Hyperparathyroidism Undergoing Hemodialysis Who Participated in the EVOLVE Trial Berthold Hocher,[1] Michael Godes,[1] Christoph Reichetzeder,[1] Oleg Tsuprykov,[1] Glenn M. Chertow,[2] Patrick S. Parfrey,[3] Jürgen Floege,[4] Yumi Kubo,[5] Bastian Dehmel,[5] Tilman B. Drueke.[6] *[1]Univ of Potsdam; [2]Stanford Univ School of Medicine; [3]Memorial Univ; [4]RWTH Univ of Aachen; [5]Amgen Inc.; [6]Inserm Unité 1088.*

Background: Oxidized PTH (oxPTH) has no PTH/PTHrp receptor (PTH1R)-stimulating properties, whereas non-oxidized PTH (n-oxPTH) is an agonist at PTH1R. However, PTH oxidation has been ignored in the development of PTH assays: the intact PTH (iPTH) assays currently used, recognize both n-oxPTH and oxPTH. We recently developed an assay that separately measures oxPTH and n-oxPTH.

Methods: To test the hypothesis that n-oxPTH, but not oxPTH or iPTH, has predictive value for cardiovascular events and all-cause mortality, we analyzed baseline plasma samples from 2867 participants of the EVOLVE trial (ClinicalTrials.gov: NCT00345839). The patients were followed for up to 64 months. The primary composite end point (PCEP) was the time until death, myocardial infarction, hospitalization for unstable angina, heart failure, or a peripheral vascular event.

Results: Median (10^{th} and 90^{th} percentiles) baseline iPTH was 497 (247, 1246) pg/mL, oxPTH was 438 (215, 1111) pg/mL and n-oxPTH was 58 (27, 151) pg/mL. Pearson's correlation analyses showed a strong relationship between iPTH and oxPTH (r=0.996; p<0.001) and a weaker relationship between iPTH and n-oxPTH (r=0.82; p<0.001). A multivariate Cox regression model adjusted for patient characteristics, cardiovascular comorbidities and baseline labs on PCEP revealed that n-oxPTH, but not oxPTH or iPTH, was associated with the PCEP (hazard ratio: 1.078; 95%CI: 1.012, 1.148; p=0.020), cardiovascular mortality (hazard ratio: 1.111; 95%CI: 1.014, 1.218; p=0.024), and all-cause mortality (hazard ratio: 1.113; 95%CI: 1.038, 1.193; p=0.003).

Conclusions: Only n-oxPTH, but not iPTH or oxPTH, was associated with cardiovascular events and mortality as well as all-cause mortality in the baseline samples of the EVOLVE trial.

SA-PO999

The Effect of Cinacalcet on Calciphylaxis Events in Haemodialysis Patients in the EVOLVE Clinical Trial Jürgen Floege,[1] Yumi Kubo,[2] Glenn M. Chertow,[3] Patrick S. Parfrey.[4] *[1]RWTH Univ of Aachen, Germany; [2]Amgen Inc., Thousand Oaks, CA; [3]Stanford Univ School of Medicine, Palo Alto, CA; [4]Memorial Univ, St. John's, NF, Canada.*

Background: Uncontrolled secondary hyperparathyroidism (sHPT) in hemodialysis (HD) patients is a well recognized risk factor for calciphylaxis (calcific uremic arteriolopathy). The effect of calcimimetics on the incidence of calciphylaxis is unknown. Non-adjudicated, adverse events collected during the Evaluation of Cinacalcet HCl Therapy to Lower Cardiovascular Events (EVOLVE) Trial were used to define the frequency of calciphylaxis events in HD-patients with sHPT receiving cinacalcet or placebo.

Methods: A multicenter, global, randomized, double-blind, placebo-controlled clinical trial assessing mortality and non-fatal cardiovascular events in 3883 HD patients with secondary hyperparathyroidism (baseline median parathyroid hormone (iPTH) concentration 693 pg/mL (10%, 90% range 363 - 1694 pg/mL). Calciphylaxis adverse events were collected while patients were receiving study drug.

Results: Within the study safety analysis set (n= 3861) 24 patients developed calciphylaxis, 18 in the placebo group and 6 in the cinacalcet group (hazard ratio 0.30, 95% confidence interval [CI] 0.12-0.76; log-rank, p=0.007). In a multivariate model, predictors associated with an increased risk of calciphylaxis included treatment with placebo, female sex, higher body mass index, higher diastolic blood pressure, history of peripheral vascular disease, history of parathyroidectomy, as well as current and former tobacco use at baseline. The cumulative event rates (95% CI) at year 4 were 1.5% (0.9%, 2.6%) in placebo patients and 0.7% (0.3%, 1.5%) in cinacalcet patients. Median (10%, 90% range) plasma iPTH at the time of calciphylaxis was 796 (225, 2093) pg/mL in placebo patients and 410 (71, 4957) in cinacalcet patients. Calcium was within the KDIGO target range in most patients. Immediately prior to calciphylaxis, vitamin K antagonists were used by 9/18 placebo patients and 2/6 cinacalcet patients.

Conclusions: In the EVOLVE trial, treatment of sHPT with cinacalcet led to a decreased risk of calciphylaxis. ClinicalTrials.gov number: NCT00345839.

SA-PO1000

Effect of Paricalcitol and Atorvastatin Combined Treatment on Inflammatory and Oxidative Stress Markers in Chronic Hemodialysis (hD) Patients with Permanent Subcutaneous Catheter (psc). NCT1820767

Ricardo Mouzo,[1] Valter Ruggero Maria Lombardi,[2] Jose Carlos Diez Baylon,[3] Herless Rodrigo Avellaneda Campos,[1] Jose Paniagua De la Riva,[1] Carmen Perez Nieto,[1] Fernando Simal,[1] Benjamin De Leon Gomez,[4] Mario Prieto Velasco1.[4] *[1]Nephrology, Hospital El Bierzo, Ponferrada, Spain; [2]Biotechnology, EBIOTEC, La Coruna, Spain; [3]Hemodialysis, PONFEDIAL, Ponferrada, Spain; [4]Nephrology, Hospital Leon, Leon, Spain.*

Background: Cardiovascular disease remains the most common cause of morbidity and mortality in CKD patients related to oxidative stress, inflammation and endothelial dysfunction. In addition, PSC is an inflammatory stimulus in these patients. The aim of the current study was to evaluate the effect of different oral treatments, paricalcitol (P), paricalcitol plus atorvastatin (P+A), and atorvastatin (A) alone on the release of pro-inflammatory cytokines and oxidative stress.

Methods: 30 patients age 71.21 ±16.88 in HD treatment 3 times per week for 33.93 months ± 35, were randomized into a 12 weeks period study. Group 1 (n=10) was treated with P; Group 2 (n=11) was treated with P+A; Group 3 (n=9) received A alone. Blood samples were collected two weeks before treatment (T-2), at baseline (T0), 6 weeks (T6) and 12 weeks after treatment (T12) and 2 weeks post treatment (T14). CD3, CD4, CD8, CD19, CD25, CD56, CD69 and CD95 lymphocytes blood markers and serum levels of IL-2. IL-4, IL-5, IL-6, IL-8, IL-10, IL-12p70, IL-1β, TNF-β, TNF-α, and IFN-γ were analyzed by flow cytometry. Serum levels of PEG-2, COX-2, iNOS and FGF-23 were analyzed by ELISA.

Results: Treatment with P+A significantly reduced the expression of CD25, CD56, CD25/CD56 double positive, and CD69 compared with the treatment with P and A alone. A reduction in the release of IFNγ, IL-1β, IL-2 and IL-5 was also observed, mainly in Gr. 1 and 2; and a reduction in COX-2 p<0.012 in T0 versus T12.Moreover treatment with P+A significantly reduced the plasma level of FGF23 (T0 versus T12: p=0.044).

Conclusions: The combined treatment with P+A elicits an early and significant decrease of inflammation and oxidative stress in HD patients. These effects could have a considerable impact in reducing the risk of progressive atherosclerotic cardiovascular disease in patients using psc.

SA-PO1001

Beneficial Effects of Parathyroidectomy on Proximal Aortic Stiffness in Hemodialysis Patients with Secondary Hyperparathyroidism: A Pilot Study

Haiming Li, Shensen Li, Chuanming Hao, Yong Gu, Jing Chen. *Nephrology, Huashan Hospital Fudan Univ, Shanghai, China.*

Background: Aortic pulse wave velocity is a strong predictor of all--cause and cardiovascular mortality in chronic dialysis patients. Increased PWV is associated with both traditional and nontraditional factors in dialysis patients. The effects of parathyroidectomy (PTX) on aortic stiffness remains unclear.Our aim was to evaluate the specific changes of proximal aortic stiffness after successful PTX.

Methods: Forty five patients undergoing PTX were studied at baseline and during a follow-up period of 12 months regarding changes of proximal aortic stiffness using echocardiographic methods(PTX group). We evaluated the pulse wave velocity (PWV) in the region of aortic arch. The clinical data was also recorded at baseline and one year's follow up. 45 age, sex and dialysis vintage matched hemodialysis patients were enrolled as control group. Both the PWV and the clinical data were also recorded in control group. ΔPWV is calculated by PWV(one year after PTX) minus PWV at baseline.

Results: Thirty nine patients in PTX group were analyzed while six patients were excluded (5 due to poor image of echocardiography, 1 due to relapse of hyperparathyroidism within one year). 37 patients were finally analyzed in control group. The pre-dialysis blood pressure in PTX group was dramatically decreased from 158±16 mmHg to 124±13 mmHg in systolic BP and from 92±11 mmHg to 71±12 mmHg in diastolic BP with reduced numbers of anti- hypertension drugs at one year's follow up. The pre-dialysis BP remained similar in the control group after one year's follow up. None of the patients was prescribed Vit D in the PTX group while 31 patients were taking vit D in control group. ΔPWV is significantly lower in the PTX group (0.2±0.03 m/s versus 0.89 ± 0.16 m/s, p<0.001) than in the control group. No difference was observed in both groups when considering the ejection fraction and LVMI.

Conclusions: Parathyroidectomy might slow the progress of aortic stiffness in hemodialysis patients with hyperparathyroidism. The benefits of PTX may be due to decreased serum calcium, iPTH level,blood pressure and prescription of active vit D.

Sevelemar Decreases Serum Uric Acid Levels and Improves Arterial Stiffness in Hemodialysis Patients

Siren Sezer,[1] Bahar Gurlekdemirci,[1] Emre Tutal,[1] Ayse Zeynep Bal,[1] Mehtap Erkmen Uyar,[1] Fatma Nurhan Ozdemir Acar.[2] *[1]Dept of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [2]Dept of Nephrology, Baskent Univ Faculty of Medicine, Istanbul, Turkey.*

Background: Sevelamer has an unique effect as a resine that can act as a prebiothic. Avoiding calcium intake, there might be a differential influence of sevelamer in terms of cardiovascular risk profile. The aim of this study was to evaluate the effects of phosphorus binders on serum uric acid, HbA1c and lipid profile levels and the progression of arterial stiffness.

Methods: A total of 151 patients (mean age: 53.0 ± 14.4 years; mean duration of dialysis: 9.5 ± 1.2 years) undergoing maintenance hemodialysis and using the same phosphorus binders under three years follow-up were enrolled into the study. Patients were divided into two groups according to usage of phosphate binders (PB) as sevelamer based PB (group 1; n: 99) and calcium based PB (group 2; n.52). Biochemical parameters were assessed from monthly clinical visits in three year follow up period. Arterial stiffness determined at the initial and at the end of the 3rd year by aortic pulse wave velocity (PWV) (Sphygmo-Cor).

Results: : Serum calcium, phosphorus, parathyroid hormone, CRP and URR levels were similar in two groups. Serum LDL-C levels and PWv values were significantly lower in group 1 (p<0.005). Mean üric acid levels had significantly decreased in group 1 where remained stable in group 2 in three years follow up period. 22.4% of patients in group 1 and 3.8% of patients in group 2 showed a reduction more than 2 mg/dl in mean üric acid levels. Fasting plasma glucose (p:0.001) and HbA1c (p<0.005) levels were significantly lower in diabetic group 1 patients than group 2. PWv values were similar in both groups at the inital of the study. PWv values of group 1 patients were significantly lower than group 2 at the 3rd year of the study (p<0.005).

Conclusions: Despite similar phosphorus levels and dialysis adequency, sevelamer improves the cardiovascular risk by pleiotropic effects through lowing uric acid, LDL-C and HbA1c concentrations Thus, sevelamer improves the cardiovascular risk profile of hemodialysis patients and prevents the progression of arterial stiffness.

SA-PO1003

Changes in Serum Uric Acid Level in Chronic Dialysis Patients prior to Death

Dalia Elrashid M. Yousif,[1] Rasha Hassan Hussein,[1] Bernard J. Canaud,[2] Daniele Marcelli,[2] Len A. Usvyat,[3,4] Peter Kotanko,[3] Roberto Pecoits-Filho.[1] *[1]Pontificia Univ Catolica do Parana, Curitiba, PR, Brazil; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Renal Research Inst, New York, NY; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: Hemodialysis (HD) patients are subjected to enhanced oxidative damage as a result of reduced anti-oxidant systems and increased pro-oxidant activity. Uric acid has important antioxidant properties.We hypothesized that uric acid levels change prior to death in HD patients.

Methods: In this retrospective cohort study we analyzed a subset of the international MONitoring Dialysis Outcomes (MONDO) initiative (Usvyat, Blood Purification 2013). HD patients from the Fresenius Medical Care (FMC) clinics in Europe who died between 1/1/ 2006 and 12/31/2012 were identified. Only patients with more than one serum uric acid measurement in the 24 months prior to death during the study period were selected. Penalized b-splines were constructed to track the trajectories of uric acid levels in patients before death.

Results: A total of 11,433 incident HD patients (58 % males) were enrolled. Mean serum uric acid was <5.9 mg/dl before death. Males showed higher levels of serum uric acids compared to females. Serum uric acid levels dropped significantly between months 24 and 4 before death, followed by a notable increase in the 3 months prior to death.

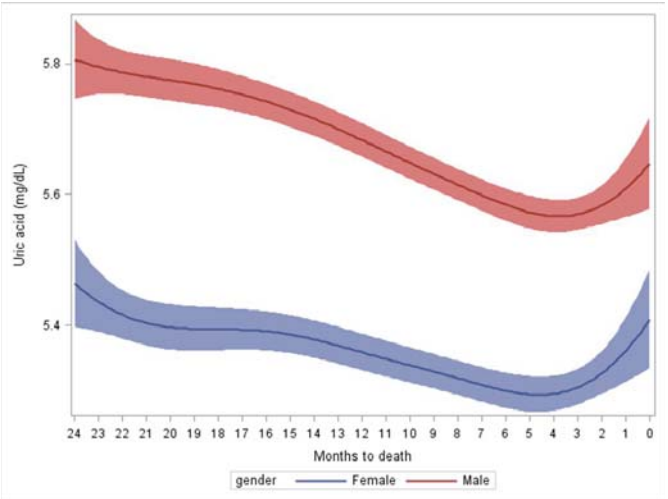

Figure 1: Mean (95% CI) uric acid levels before death.

Conclusions: Our study indicates that uric acid levels present a reverse J-shaped pattern prior to death in incident HD patients, with a significant increase during the last 3 months of life. Additional studies are required to define the biology underlying this dynamic.

SA-PO1004

Tumor Necrosis Factor-Related Apoptosis-Inducing Ligand (TRAIL) as an Independent Predictor of Cardiovascular Events in Hemodialysis Patients

Katsuhito Mori,[1] Tetsuo Shoji,[2] Akinobu Ochi,[1] Yujiro Okute,[1] Mika Sonoda,[1] Mitsuru Ichii,[1] Yoshihiro Tsujimoto,[3] Tsutomu Tabata,[3] Masanori Emoto,[1] Masaaki Inaba.[1] *[1]Dept of Metabolism, Endocrinology and Molecular Medicine, Osaka City Univ Graduate School of Medicine, Japan; [2]Dept of Geriatrics and Vascular Medicine, Osaka City Univ Graduate School of Medicine, Japan; [3]Div of Internal Medicine, Inoue Hospital, Japan.*

Background: Tumor necrosis factor (TNF)-related apoptosis-inducing ligand (TRAIL), which belongs to TNF ligand superfamily, is inversely associated with the severity of atherosclerosis and the prognosis of patients with advanced atherosclerosis. Recent clinical studies have shown that low TRAIL levels were associated with increased mortality in peritoneal and hemodialysis patients. Therefore, we focused on the association between serum TRAIL levels and cardiovascular disease (CVD) events in hemodialysis patients.

Methods: The hemodialysis patients in this study were selected from our prospective observational cohort. Five hundred and sixteen patients were divided into quartile 1(Q1) (lowest) to Q4 (highest) according to their baseline TRAIL level measured by ELISA. The main outcomes were CVD events including ischemic heart disease, stroke, peripheral artery disease, pulmonary edema, and valve disease.

Results: The median (IQR) TRAIL levels were 85.9 (67.7-108.5) pg/mL and did not differ significantly between male and female. During follow-up, 189 CVD events were recorded. A decrease from Q4 to Q1 of TRAIL was associated with a significant increase in CVD events. TRAIL was also associated significantly and inversely with CVD in Cox models adjusted for age and confounding variables including sex, diabetic nephropathy, dialysis vintage, and pre-existing CVD in Q1 versus Q4 of TRAIL (HR 1.79, 95% CI 1.17-2.80, p = 0.007).

Conclusions: Serum TRAIL may be a novel biomarker for predicting CVD events in hemodialysis patients.

SA-PO1005

Association of Oxidized Low-Density Lipoprotein/Low-Density Lipoprotein Cholesterol Ratio, Not Superoxide Dismutase Level, with Cardiovascular Disease and Coronary Artery Calcification in Hemodialysis Patients

Yukari Asamiya, Ken Tsuchiya, Kosaku Nitta. *Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Japan.*

Background: and Aims: Serum malondialdehyde-modified low-density lipoprotein (MDA-LDL)/LDL-cholesterol (LDL-c) ratio, a marker for the degree of LDL oxidation, has been shown to be a risk factor for cardiovascular disease (CVD) and metabolic syndrome in non-hemodialysis (HD) subjects. However, little information is available on the association of this ratio with antioxidant level ([high-density lipoprotein-cholesterol [HDL-c] and superoxide dismutase [SOD]), the presence of CVD, and coronary artery calcification (CAC) in HD patients.

Methods: One hundred and two HD patients and 26 healthy subjects (controls) were enrolled in this cross-sectional study. Serum MDA-LDL/LDL-c ratio and SOD level were examined in all study participants. The CAC scores and their possible associations with clinical/laboratory data, including the presence of CVD, MDA-LDL level, MDA-LDL/LDL-c ratio, HDL-c level, LDL-c level, as well as the mean values of the most recent 3-year levels of phosphate, calcium, and intact parathyroid hormone, were examined in 57 HD patients (CAC group).

Results: Both the all HD patients and CAC group had significantly higher MDA-LDL/LDL-c ratios than the controls. The MDA-LDL/LDL-c ratios were significantly and positively correlated with CAC scores, associated with the frequency of CVD, and significantly and negatively correlated with HDL-c levels, but not with SOD levels in the CAC group. The multivariate logistic regression analysis showed that MDA-LDL/LDL-c ratio (odds ratio [OR], 1.04; 95% confidence interval [CI], 1.01–1.07; P = 0.003), and HD duration (OR, 1.17; 95% CI, 1.04–1.36; P = 0.007) were independently associated with CAC score in CAC group.

Conclusions: The MDA-LDL/LDL-c ratio rather than the SOD level of HD patients could reflect the degree of LDL oxidation, and therefore, could be an important factor for CVD and CAC in HD patients.

SA-PO1006

Hemodialysis and Peritoneal Dialysis Equally Impact Endothelial Function in Patients with End-Stage Renal Disease

Huaying Pei, Zhe Li, Lihua Wang, Xiaowen Yin, Jianzhao Duan, Shaomei Li, Huibin Tan, Shuxia Fu. *Div of Nephrology, The 2nd Hospital of Hebei Medical Univ, Shijiazhuang, China.*

Background: Cardiovascular disease (CVD) is the major cause of disability and death in dialysis patients with end-stage renal disease (ESRD) while endothelial dysfunction is a major pathogenesis of CVD. It has been shown that hemodialysis improves endothelial function by removing dialysable endothelial toxins but not peritoneal dialysis. Here we investigated the factors affecting the ET-1/NO system in ESRD patients receiving dialysis to compare the effects of hemodialysis (HD) and peritoneal dialysis (PD) on the endothelial dysfunction.

Methods: Forty HD and 80 PD patients without diabetes and 12 normal healthy adults were enrolled. Radioimmunoassay was adopted to assay the concentration of ET-1. Colorimetric nitrate reductase assay was conducted to measure the activities of endothelial nitric oxide synthase (eNOS). Clinical characteristics of patients were recorded following standard procedure.

Results: Higher systolic blood pressure (SBP), Uric Acid (UA) and incidence of CVD while lower cholesterol (TC) and LDL were found in HD group (P<0.05). However, more patients with residual renal function (RRF) ≥1ml/min were found in PD than in HD group (50% versus 20%, P<0.05). Circulating ET-1 levels increased significantly in both HD and PD patients compared to that in controls (138.92±31.65pg/ml, 140.89 ±29.5pg/ml and 16.11±1.24pg/ml respectively, P<0.05) but no difference was found between HD and PD groups (P>0.05). eNOS activities, decreased dramatically in both dialysis groups (12.65±2.36U/ml in HD,12.34±1.60U/ml in PD and 14.74±1.60U/ml in control respectively, P<0.05) but without difference between HD and PD patients. Multiple linear regression analysis showed that SBP, UA and LDL were the independent risk factors for decreased eNOS activities while SBP and TG for increased ET-1 levels.

Conclusions: Our results suggest both hemodialysis and peritoneal dialysis have equal effects regarding improving endothelial function given that both groups had same levels of eNOS activities and ET-1, which is probably due to the facts that the HD patients had higher SBP and UA while peritoneal patients had better RRF.

SA-PO1007

Association between Inflammatory Markers, Left Ventricular Systo – Diastolic Dysfunction and Right Heart Involvement in CKD Patients

Luca Di Lullo,[1] Antonio Bellasi,[2] Domenico Russo,[3] Alberto Santoboni.[1] *[1]Nephrology and Dialysis, L. Parodi - Delfino Hospital, Colleferro, Roma, Italy; [2]Nephrology and Dialysis, S. Anna Hospital, Como, Italy; [3]Nephrology and Dialysis, Univ of Napoli "Federico II", Napoli, Italy.*

Background: Chronic kidney disease (CKD) is characterized by an increased mortality and morbidity due to cardiovascular involvement. Both left ventricular systolic and diastolic function are affected since CKD early stages. Pathophysiology of heart failure in CKD patients involves left ventricular hyperthophy, dilated cardiomiopathy, arrythmias and cardiac fibrosis together with widespread inflammatory status accountable for early atheroembolic disease.

Methods: We have enrolled 146 patients (96 males and 50 females aged 68 ± 9 years with mean dialytic age of 18 ± 0.4 months) on hemodialysis treatment and 120 patients (72 males and 48 females aged 57 ± 8 years) on stage III – V CKD. They underwent trans – thoracic ecocardiography and screened for inflammatory markers (CRP, IL-6, TNF-α).

Results: Hemodialysis patients showed significant correlations between IL – 6, CRP and TNF-α blood levels and systo - diastolic dysfunction parameters such as E/E' ratio. Therefore, they also showed strong and significant correlation between IL-6, CRP levels and right ventricular dysfunction indexes, such as TAPSE (tricuspid annulus plane systolic excursion) and systolic pulmonary artery pressure (PAPs). On the other hand, CKD patients showed no correlations between inflammatory asset and right heart dysfunction.

Conclusions: Our data confirm close correlation between systolic dysfunction and inflammatory markers in CKD and hemodialysis patients. Therefore, our findings underline close relationships between inflammatory markers and right heart dysfunction parameters in hemodialysis patients such as TAPSE and PAPs reflecting right heart involvement in the development of cardio – renal syndrome.

SA-PO1008

Factors Associated with Intradialytic Hypotension in HD Patients with Pre-Dialysis BP >140/90

A. Harford,[1] D. Miskulin,[2] Cynthia A. Kendrick,[3] Manisha Jhamb,[4] Lavinia A. Negrea,[5] Jennifer J. Gassman,[3] Philip Zager.[1] *[1]Univ New Mexico; [2]Tufts Med Ctr; [3]Cleveland Clinic; [4]Univ Pitt Med Ctr; [5]CWRU.*

Background: Intradialytic hypotension(IDH) can precipitate ischemic events, cardiac stunning and death. Patients with a low BP at the start of dialysis are prone to IDH. We examine factors associated with IDH in patients with normal-to-elevated BP at dialysis start (SBP >140 mm Hg).

Methods: The study is based on HD patients enrolled in baseline of the Blood Pressure in Dialysis Study, a RCT assessing 2 levels of BP control. During weekly study visits, treatment sheets were reviewed and patients were questioned about symptoms during dialysis. IDH was defined as symptoms (e.g. dizziness) or a drop in systolic BP to <90 mm Hg requiring intervention. Cramps were excluded as they may be due to different factors than reduced effective circulating volume (ECFV). Cardiac MRI was performed at end of baseline.

Results: There were 170 episodes of IDH (excluding cramps) requiring intervention over 8 weeks in 95 patients. Selected factors across groups by IDH frequency are shown in the table.

% or Mean	No IDH or cramps only (n=50)	1-3 IDH Episodes (n=28)	4+ IDH Episodes (n=19)
Interdialytic Weight Gain (% EDW)	4.3	4.1	4.5
Ultrafiltration Rate (UFR) mls/kg/h	9.3	10.1	9.4
Delivered Time (h)	3.8	3.6	3.6
Dialysate-Serum Na Gradient	2.0	2.8	1.8
Pre-dialysis SBP (mm Hg)	148	153	151
Pre-dialysis DBP (mm Hg)	80	77	73 *
Pulse Pressure (mm Hg)	68	76	79 *
Hx Coronary Artery Disease (CAD)	4%	4%	27%
LV Mass Index (g/m2)	36	33	32
Ejection Fraction	54	58	57
IVC diameter (mm)	23	19	24

*p ≤ 0.05

Conclusions: Among patients with normal to elevated pre-dialysis BP and preserved EFs, we find that that lower diastolic BP relates to IDH. This association may reflect cardiac ischemia, with DBP dropping below a level at which there is adequate coronary perfusion. In keeping with this, we find a higher prevalence of CAD in patients most prone to IDH. Alternatively, a lower diastolic pressure, which equates to a higher pulse pressure, may reflect arterial non-compliance and inability to autoregulate with declining ECFV. More attention should be paid to diastolic BP when considering BP goals in HD patients, especially those with CAD.

Funding: NIDDK Support

SA-PO1009

Skin Autofluorescence (SAF) and Tissue–Advanced Glycation End Product Concentration (AGES) in Hemodialysis Patients. A New Tool to Detect Cardiovascular Risk (CVR) Secundino Cigarran,[1] Walter Luis López Alarcón,[1] Juan Latorre,[1] Montserrat Pousa,[1] Anna Minasyan,[3] Jesus Calvino,[2] Lourdes Gonzalez-Tabares,[2] Miguel A. Garcia-Gonzalez.[3] *[1]Nephrology, Eoxi Lugo-Cervo- Monforte, Burela, Lugo, Spain; [2]Nepphrology, Eoxi Lugo-Cervo- Monforte, Lugo, Spain; [3]Nephrology, Health Research Inst of Santiago de Compostela (IDIS), Santiago de compostela, La Coruña, Spain; [4]Nephrology, Health Research Inst of Santiago de Compostela (IDIS), Santiago de Compostela, La Coruña, Spain.*

Background: The prevalence of cardiovascular disease in patients on HD remains high,because combinations of classical and non classical risk factors. AGEs assessed by SAF as measure of cumulative metabolic stress correlates with outcomes in HD pts.Our aim is to assess and compare tissue AGEs levels with nutritional,inflammation and CVR markers in HD.

Methods: 40 caucasian, stable, HD pts were included cross transversal study (mean age 72 yo),67% men,40% diabetes status.At midd week day session blood biomarkers were drown.Anthropometric measures were obtained.Inflammation (Epo resistance index (ERI) C Reactive protein),nutritional (nPNA,Prealbumin,Albumin) and CV R markers (Fibrinogen,Troponin us) and adequacy parameters were measured. AGEs were evaluated with SAF (AGE Reader, DiagnOptic s, Groningen, The Neetherlands) by 3 consecutive measurements at slightly different skin sites on the same forearm. Arms with graft or vascular access were avoided. SAF is a validated cutaneous device using ultraviolet source at sepcific range of wavelengths (350-420 nm).

Results: 85% pts showed at high CVR by SAF. 77% had previous CV events (stroke, AMI). SAF levels had a significant positive correlation with: Charlson comorbidity index (r: 0.440, p<0.005),troponin us (r: 0.368, p=0.023), CRP (r 0.338, p= 0.033), ERI (r=0.463, p=0.03, Fibrinogen (r 0.380; p=0.038) and eKT/V (r: 0.383; p= 0.015).A significant negative correlation with:Vit D levels (r=-0.315;p=0.025) and triglycerides (r= -0.322; p= 0.042).No other significance was met.

Conclusions: AGEs´skin accumulation are directly associated with, comorbidity, inflammation, cardiovascular and coronary artery disease risk biomarkers in caucasian pts on HD. SAF becomes a non invasive novel tool to assess CVR.

Funding: Other NIH Support - Galician Health Service

SA-PO1010

Skin Autofluorescence (SAF) to Assess Advanced Glycation End Products (AGEs) and the Association with Renal and Cardiovascular Risk Factors (CVR) in Chronic Kidney Disease (CKD) Stage 1-5ND Secundino Cigarran,[1] Juan Latorre,[1] Ana Isabel Fernandez-Alonso,[1] Jesus Calvino,[2] Montserrat Pousa,[1] Emilio E. Gonzalez-Parra,[3] Saray Lopez-Prieto,[1] Lourdes Gonzalez-Tabares,[2] Miguel A. Garcia-Gonzalez.[4] *[1]Nephrology, Eoxi Lugo-Cervo-Burela, Burela, Lugo, Spain; [2]Nephrology, Eoxi Lugo- Cervo- Burela, Lugo, Spain; [3]Nephrology, Fundacion Jimenez Diaz, Madrid, Spain; [4]Nephrology, Health Research Inst of Santiago de Compostela (IDIS), Santiago de Compostela, La Coruña, Spain.*

Background: AGEs accumulation is a novel CVR and is a measure of cumulative metabolic stress. Assessment by SAF may be a useful marker of CKD progression.Aim is to compare tissue AGEs levels with nutritional,inflammation and CVR markers in CKD stage 1-5ND pts.

Methods: 259 caucasian pts were included (mean age 72 yo),61.4% men,37.1% diabetes status. Comorbidity by Charlson Index, CKD risk formula at 5 yr, CKD-EPI formula, urine and biochemistry tests, fluid overload(FO) by spectroscopic bioimpedance (BCM,Fresenius Bad Homburg, GER),Arm/branch test and carotid atheromatosis were assessed.AGEs were evaluated with SAF (arbitray units) (AGE Reader,DiagnOptics, Groningen, The Neetherlands) by mean of three readings. Data were analyzed with univariate Spearman´s rank correlation as appropiate. "p" value <0.05 was considered significant.

Results: 50.3 % showed moderate-severe CVR.Univariate analysis revealed significant correlations between SAF levels and some potential CVR and CKD progression. SAF were high in males (3.15± 0.8 versus 2.71± 0.6), PAD (3.34±0.8 versus 2.84± 0.7),Carotid atheromatosis (3.17±0.8 versus 2.5 ±0.6) SAF had a significant positive correlation with: Charlson comorbidity index (r: .337, p<0.001),CKD risk formula (r: .312, p<0.001), FO (r=.332, p<0.001),P excretion index (r=.326, p <0.001),iPTH(r= .284, p <0.001),ACR (r= .184, p=0.004).A negative significant correlation with Hb (r:- .321, p<0.001),GFR (r=- .448, p<0.001),nPNA (r=-.156, p<0.001),Albumin (r= -.249, p<0.001),Cholesterol (r= -.235, p<0.001).No significance with DM status.

Conclusions: SAF is associated with nutritional, CVR,carotid atheromatosis,peripheral artery disease,comorbidity and risk to initiate renal replacement therapy in CKD pts.SAF may be used as outcome after measures taken.

SA-PO1011

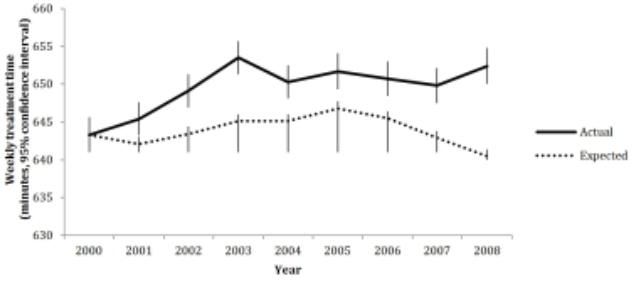
Trends in Treatment Time for In-Center Hemodialysis Susan P.Y. Wong,[1] Ann M. O'Hare.[2] *[1]Univ of Washington; [2]Univ of Washington.*

Background: The majority of patients treated for end-stage renal disease receive in-center hemodialysis, which demands substantial time commitment.

Methods: Using data from the Clinical Performance Measures Project--a Centers for Medicare and Medicaid Services quality improvement initiative conducted in Medicare-certified dialysis facilities across the U.S.--we performed an observational study to describe temporal trends and determinants of prescribed dialysis treatment time among a national sample of prevalent adults receiving chronic hemodialysis from 2000-2008. We evaluated temporal trends in actual versus expected treatment times based on 2000 practices.

Results: From 2000-2008, mean weekly treatment time increased from 643±98 to 652±110 minutes (trend, p<0.001). After adjusting for changes in patient characteristics over time, patients surveyed in 2008 received an additional 12 minutes (95% confidence interval [CI] 9, 14) of dialysis every week as compared with similar patients surveyed in 2000.

Figure 1. Actual versus expected time spent on dialysis each week based on 2000 practices



Weekly treatment times increased by more than 20 minutes for black patients, those residing in the South, those with a serum hemoglobin level <10g/dL and those prescribed ultrafiltration volumes ≥3L per treatment. There was heterogeneity in the magnitude of discrepancy between actual and expected weekly treatment times, especially across groups defined by race (black versus other racial minority groups; 24 additional versus 1 additional minutes), age (45-64 years versus≥80 years; 19 additional versus 1 fewer minutes), cause of ESRD (diabetes mellitus versus other causes; 19 additional versus 1 fewer minutes), facility ownership (for-profit versus non-profit; 3 fewer versus 15 additional minutes), census region (3 fewer in the Northeast versus 24 additional minutes in the South), dialysis sp*Kt*/*V* dose (<1.2 versus≥1.2; 15 fewer versus 13 additional minutes) and ultrafiltration volume per treatment (<3L versus≥3L; 4 fewer versus 23 additional minutes).

Conclusions: From 2000-2008, there was an increase in treatment time for patients receiving in-center hemodialysis and growing heterogeneity in treatment time across patient subgroups. In 2008, patients spent an average of 10 additional hours on dialysis as compared with similar patients in 2000.

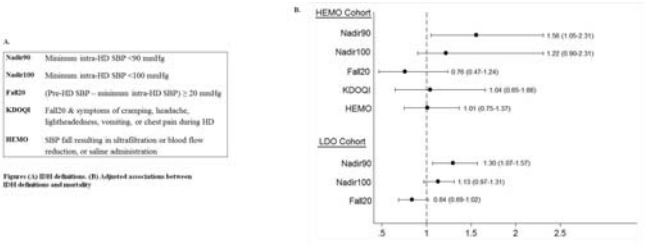
SA-PO1012

Empirically Defining the Associations of Mortality and Various Definitions of Intradialytic Hypotension Jennifer E. Flythe,[1,2] Gary C. Curhan,[2] Steven M. Brunelli.[2,3] *[1]Univ of North Carolina Kidney Center; [2]Brigham and Women's Hospital; [3]DaVita Clinical Research.*

Background: Intradialytic hypotension (IDH) is a serious and frequent complication of hemodialysis (HD); however, there is no consensus evidenced-based definition of IDH. As a result, coherent evaluation of the effects of IDH is difficult. We examined the associations of commonly employed IDH definitions and mortality in two cohorts.

Methods: We analyzed data from 1,409 HEMO study patients and 10,392 patients from a single large dialysis organization (LDO). IDH definitions (Figure A) were selected *a priori*. For each definition, patients were characterized as having IDH if they met the corresponding definition in at least 30% of baseline exposure period treatments and were characterized as control otherwise. Odds ratios (OR) for 2-year mortality (HEMO cohort) and 1-year mortality (LDO cohort) across binary IDH definitions were estimated by fitting logistic regression models. Analyses stratified by pre-HD systolic blood pressure (SBP) were performed in the LDO cohort.

Results: Overall, Nadir90-defined IDH was most potently associated with mortality (Figure B). Within the subgroup of patients with pre-HD SBP ≥160 mmHg, Nadir100 was most potently associated with mortality: adjusted OR (95% CI) 1.29 (1.07-1.56). IDH definitions that considered intra-HD SBP fall, symptoms, and interventions were not associated with outcome (Figure B) and, when added to nadir SBP, such criteria did not accentuate mortality associations (not shown).



Secondary analyses indicated a dose-response trend in the association of Nadir90-defined IDH (<5%, 6-29%, 30-49%, and ≥50% sessions with IDH) with mortality (not shown).

Conclusions: Our results suggest that nadir-based definitions best capture the association between IDH and mortality.

Interdialytic Weight Gain Has Declined over Last Decade Internationally

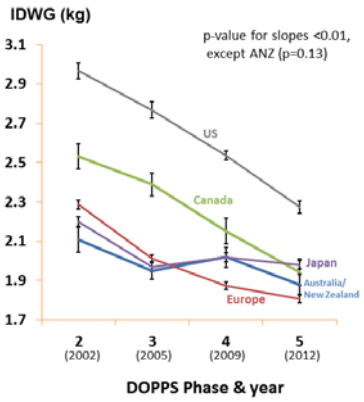
Michelle M.Y. Wong,[1] Keith McCullough,[1] Rajiv Saran,[2] Brian Bieber,[1] Francesca Tentori,[1] Ronald L. Pisoni,[1] Manfred Hecking,[3] Tadashi Tomo,[4] Bruce M. Robinson,[1] Friedrich K. Port.[1] *[1]Arbor Research Collaborative for Health; [2]Dept of Medicine, Univ of Michigan; [3]Medical Univ of Vienna; [4]Oita Univ Hospital.*

Background: High interdialytic weight gain (IDWG), high ultrafiltration rate, and short treatment time are associated with adverse outcomes in hemodialysis (HD) patients. Based on preliminary indication of a declining trend over time in IDWG, we examined this trend and evaluated facility practices that could explain it.

Methods: Data were from 25,601 patients in the Dialysis Outcomes and Practice Patterns Study (DOPPS) phase 2-5 (2002-2012), with HD vintage ≥1 year. The mean of the absolute IDWG between the 1st and 2nd session and the 2nd and 3rd session of the week was compared across U.S., Canada, Europe, Japan and Australia/New Zealand (ANZ). Linear regression was used to assess the association between IDWG and patient-level and facility-level factors.

Results: IDWG declined across regions, ranging from -0.2kg (ANZ and Japan) to -0.7kg (U.S.) (figure). The % of patients with high IDWG (>5.7% of post-HD weight) also declined. Younger age, male sex, lack of residual renal function, higher nPCR, and lower pre-HD serum sodium were significantly associated with higher IDWG. Higher facility mean dialysate sodium (DNa) was associated with higher IDWG; other facility practices (table) were not significant. DNa declined over the same time; U.S. had the largest decline (-1.9 mEq/L).

Mean IDWG, by DOPPS Phase and Region



Facility practices associated with IDWG*

	Adjusted linear association with IDWG (kg), (95% confidence interval)
Avg. dialysate sodium (per mEq/L)	0.09 (0.08, 0.11)
Avg. treatment time (per 30 min)	0.02 (-0.02, 0.06)
Target pre-HD SBP (per 5 mmHg)	0.01 (0, 0.03)
Target pre-HD DBP (per 5 mmHg)	-0.02 (-0.05, 0.01)
Dietitian consult for high IDWG (+ likely)	0.01 (-0.01, 0.03)
Diuretic use (per 20%)	-0.01 (-0.04, 0.01)

*adjusted for patient characteristics

Conclusions: The steady decline in IDWG is a provocative finding that may affect clinical outcomes. Of the facility factors analyzed, DNa had the strongest association with IDWG, accounting for ~0.1kg per 1mEq/L DNa. In the U.S., DNa explains ~0.2kg of the decline in IDWG, but future investigation needs to consider other factors such as dietary sodium restriction and achieving measured "dry weight" post-HD.

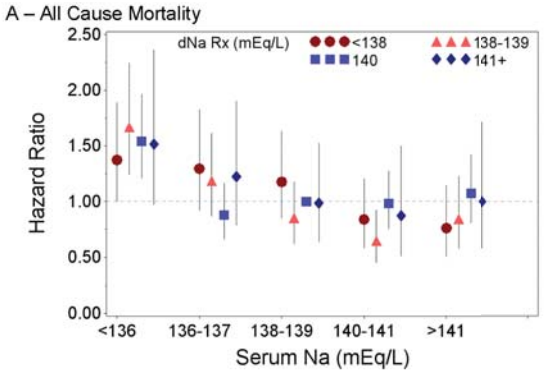
Do We Need to Reduce Dialysate Sodium Now?

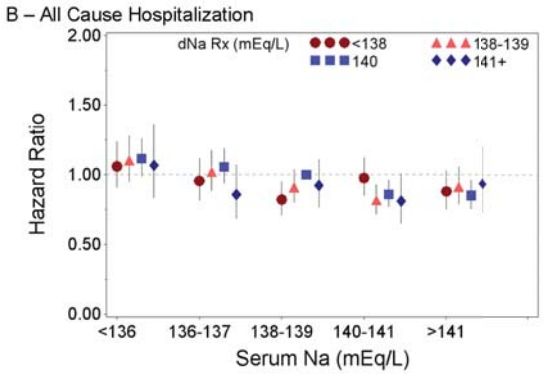
B. Horowitz,[1] A. Harford,[1] O. Myers,[3] D. Miskulin,[4] S. Paine,[2] Philip Zager.[1,2] *[1]Internal Medicine, Univ of New Mexico, Albuquerque, NM; [2]Dialysis Clinic, Inc., QM Dept, Albuquerque, NM; [3]Biostatistics, Univ of New Mexico, Albuquerque, NM; [4]Tufts Medical Center, Boston, MA.*

Background: There is controversy surrounding the optimal dialysate sodium (DNa). Several dialysis providers have urged their medical directors to reduce dNa to 134 to 138 mEq/L to reduce interdialytic weight gain (IDWG; [% EDW]) and BP. However, recent DOPPS data suggests that the impact of DNa on IDWG and BP is modest and that calls for reductions in DNa may be premature. Therefore, we assessed the relationships of DNa to predialysis serum sodium (SNa), systolic BP (SBP), ΔSBP during dialysis, IDWG, hospitalization and mortality in DCI.

Methods: We studied HD patients who dialyzed in 2013 with a stable DNa for ≥ 90 days (n=9350). We computed least square means for SNa, IDWG, SBP and ΔSBP. In a second analysis, we and constructed Cox models to assess the relationships of SNa, DNa and DNa-SNa (NaG) to mortality and hospitalization in prevalent patients in 2009-2012 (n = 12,728). We adjusted for age, sex and race in both analyses.

Results: SNa were similar at DNa ranging from ≤ 136 mEq/L (137.4 mEq/L) to ≥141 mEq/L (138.6 mEq/L). IDWG was 2.8%, 3.4%, 3.0% and 2.9% at DNa ≤ 136, 139, 140, and ≥141 mEq/L, respectively. Predialysis SBP did not differ by DNa. The ΔSBP (mm Hg) was similar at DNa concentrations of ≤ 136 (10), 137 (9.5), 138 (10.5), 139 (9.6), 140 (8.3) and ≥141 mEq/L (9.3). Hyponatremia and a NaG >6 mEq/L were associated with increased mortality. However, DNa, when stratified by SNa, was not associated with changes in mortality or hospitalization.





Conclusions: The apparent impact of DNa on IDWG, SBP, and ΔSBP was modest. Differences in DNa were not associated with differences in mortality or hospitalization. Until we have trial data it may be premature to further reduce DNa.

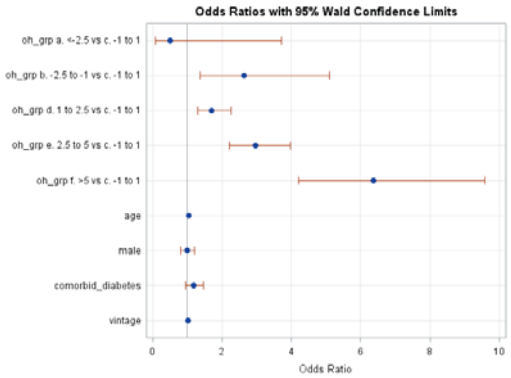
Hydration Status and Mortality: Results From a Large International Study

Marijke J.E. Dekker,[1,2] Len A. Usvyat,[3,6] Peter Kotanko,[3] Frank van der Sande,[1] Constantijn Konings,[2] Daniele Marcelli,[4] Yuedong Wang,[5] Nathan W. Levin,[3] Bernard J. Canaud,[4] Karel M. Leunissen,[1] Jeroen Kooman.[1] *[1]Dept of Internal Medicine, Div of Nephrology, Univ Hospital, Maastricht, Netherlands; [2]Dept of Internal Medicine, Catharina Hospital, Eindhoven, Netherlands; [3]Renal Research Inst, New York; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Univ of California, Santa Barbara; [6]Fresenius Medical Care, Waltham.*

Background: In hemodialysis (HD) patients fluid overload (FO) is a strong predictor for all-cause mortality. Fluid depletion (FD) can lead to intradialytic hypotension, associated with increased mortality. The relation of different levels of FO and chronic FD on outcome has not yet been studied. In this study we evaluated the effect of both FO and FD on patients outcome.

Methods: We studied all prevalent HD patients from the European Fresenius network (17 countries). Hydration status was assessed by Body Composition Meter (BCM) measurements. We included patients with ≥ 1 BCM measurement between 1/2011 and12/2011 and recorded their survival between 1/2012 and 6/2012 (follow up). Logistic regression was constructed to evaluate the association between FO/FD and survival.

Results: We included 9,463 patients (mean age 63 years, 57.4% male, mean dialysis vintage 5.1 months). During follow up, 476 patients (5.03%) died. FO was associated with an incrementally elevated risk of mortality, OR 1.71 (95% CI 1.29-2.26) with 1.0-2.5L FO and OR 2.96 (95% CI 2.20-3.98) with 2.5L-5.0L FO. Also FD (pre-dialytic -2.5 to -1.0L) was associated with mortality (OR 2.64 (95% CI 1.36-5.11)).



Conclusions: Our data indicate that FO and FD are associated with an increased mortality risk in a dose-dependent fashion. This study showed for the first time that FD is associated with an increased risk of death. Achieving euvolemia may improve outcomes in chronic HD patients.

SA-PO1016

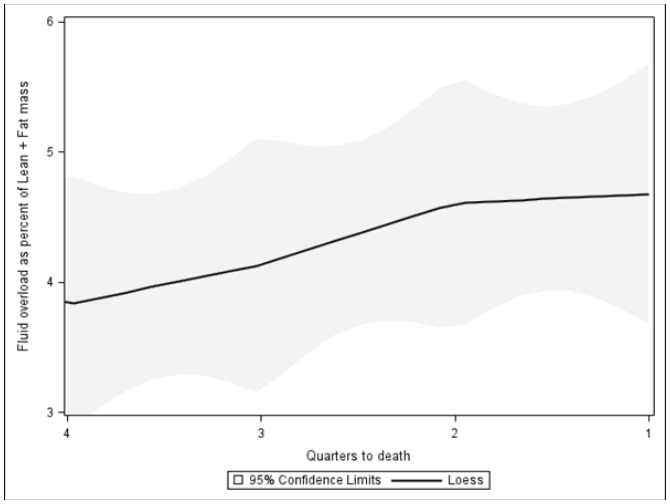
Body Composition in Hemodialysis Patients in the Final Year before Death: Results from the International MONDO Initiative Adrian M. Guinsburg,[1] Marcelo D. Ferder,[1] Aileen Grassmann,[2] Xiaoqi Xu,[3] Len A. Usvyat,[4,5,6] Jeroen Kooman,[5] Frank van der Sande,[5] Peter Kotanko,[6] Franklin W. Maddux,[4] Michael Etter,[3] Daniele Marcelli,[2] Cristina Marelli,[1] Bernard Canaud.[2] *[1]Fresenius Medical Care, Buenos Aires, Argentina; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Fresenius Medical Care, Hong Kong, Hong Kong; [4]Fresenius Medical Care, Waltham, MA; [5]Maastricht Univ Medical Centre, Maastricht, Netherlands; [6]Renal Research Inst, New York, NY.*

Background: Lean tissue mass (LTM), fat mass (FM), and fluid overload (FO) have been linked to survival in hemodialysis (HD) patients. Here we describe changes in body composition (BC) in the final year of life in a large HD cohort.

Methods: This analysis was conducted in a subset of MONitoring Dialysis Outcomes (MONDO) database [Usvyat, Blood Purif 2013]. Patients treated in Europe(E), Asia(A) and South America(SA) who died between Jan06-Dec12 with at least one BC measurement each in the 1-3 months and 9-12 months before death were enrolled. BC was assessed by bioimpedance spectroscopy (BCM, Fresenius Medical Care).

Results: Data from 1,141 patients were available (E 885,SA 195,A 61). Age 70.1±13, male 59%, diabetic 35%. Post-dialysis weight (W), LTM and FM declined significantly in the final year of life, while FO increased.

	9-12 months before death (MBD)	1-3 MBD	Diff (mean/95CI)
W(kg)	68.2 (16.0)	66.0 (16.1)	-2.2 (-2.5/-2.0)
LTM(kg)	30.8 (8.8)	30.0 (8.7)	-0.8 (-1.1/-0.4)
FM(kg)	26.6 (11.4)	25.2 (11.5)	-1.4 (-1.7/-1.0)
FO(kg)	2.1 (1.9)	2.5 (2.1)	+0.3 (0.2/0.4)
FO% of LTM+FM	4.0 (3.5)	4.8 (3.8)	+0.8 (0.6/1.0)



Conclusions: This is the first international research to assess BC in final year before death. Data indicate a clinically relevant decrease in LTM and FM, and a concurrent increase in FO. These findings might aid in earlier identification and design of interventional strategies for patients at high risk for adverse outcome.

SA-PO1017

Urea Kinetic Parameters Confounded by Volume Overload in HD Patients Richard Amerling,[1] Len A. Usvyat,[3] Qingqing Xiao,[2] James F. Winchester,[1] Peter Kotanko,[2] Nikolas B. Harbord.[1] *[1]Nephrology and Hypertension, Mount Sinai Beth Israel, New York, NY; [2]Renal Research Inst, New York, NY; [3]Fresenius Medical Care, Waltham, MA.*

Background: Low KT/V urea and urea reduction ratio (URR) have been linked to poor outcomes in HD patients in observational trials. Both parameters are affected by the patients' volume status. We conducted a retrospective data analysis to explore this relationship.

Methods: We analyzed data from 5,162 Renal Research Institute in-center HD patients who had at least one in-center treatment in August 2010 (study month). Treatment parameters: post-dialysis weight (PW) was computed as average for the study month. URR and kt/V, were obtained from monthly urea kinetic modeling. Target weight (TW) is weight prescribed by the patients' physicians. As surrogate for pre-dialysis volume status, we used the difference between the achieved post-dialysis weight and the estimated target weight (PW-TW).

Results: Patients with KT/V <1.2 (Fig. 1), and URR <65% had significantly greater values of PW-TW, suggesting they were volume overloaded.

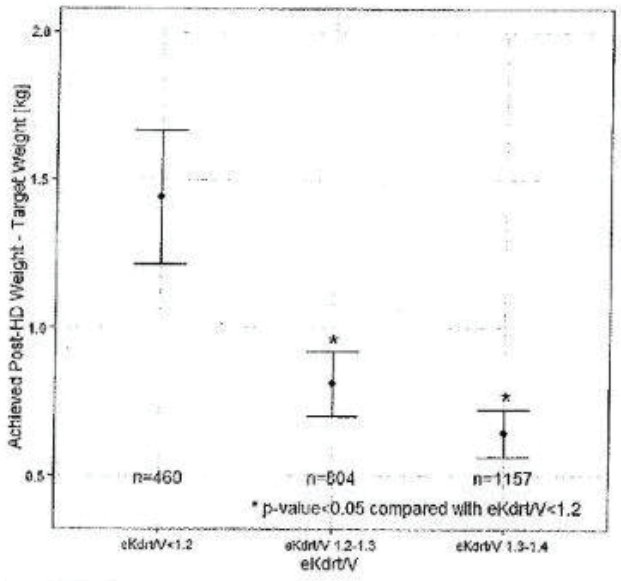


Figure 1. Relationship between Urea Kinetics and PW-TW

Conclusions: Low KT/V and URR could reflect volume overload, as opposed to decreased small solute clearance. Since volume overload is a known cause of morbidity and mortality in HD patients, this observation calls into question the use of small solute kinetics to guide dialysis prescriptions. Greater attention to volume removal and control, via longer and/or more frequent treatments, might be preferred.

SA-PO1018

Missing Hemodialysis (HD) Treatments: International Variation and Associations with Predictors and Outcomes in the DOPPS
Issa A.L. Salmi,[1] Maria Larkina,[2] Lalita Subramanian,[2] Hal Morgenstern,[3] Stefan H. Jacobson,[4] Raymond M. Hakim,[5] Francesca Tentori,[2] Rajiv Saran,[3] Takashi Akiba,[6] Natalia A. Tomilina,[7] Friedrich K. Port,[2] Bruce M. Robinson,[2] Ronald L. Pisoni.[2] *[1]Royal Hosp, Oman; [2]Arbor Research; [3]Univ MI; [4]Danderyd Hosp, Sweden; [5]Vanderbuilt Univ; [6]Tokyo Women's Med. Univ, Japan; [7]Moscow St. Univ, Russian Federation.*

Background: Missed HD treatments (MT) are known to be associated with mortality and hospitalization. Here we report new DOPPS results on frequency of MT in 20 countries and associations with patient (pt) predictors and outcomes.

Methods: Data were from 8,667 DOPPS 5(2012-14) pts on dialysis >120 days and prescribed 3X/week HD. Logistic and linear regression were used to estimate associations (adjusted odds ratios [OR] or differences [Δ], with p<0.05 shown) for pts with ≥1 MT versus no MT in 1st 4 study months (excluding hospitalizations), adjusting for case mix and country.

Results: MT prevalence varied >10 fold across countries (Table). MT was more likely in younger pts(OR=1.19 per 10 yrs younger), had a depression symptom score (CESD)>10 (OR=1.48), or travel >1 hour to HD unit (OR=2.35). MT was not strongly linked with CV-related comorbidities. MT pts had poorer control of serum phosphorus (OR=1.27 for P>5.5mg/dl), PTH (OR=1.26 for PTH> 300 pg/mL), and hemoglobin (OR=1.52 for Hb<10g/dL). With the KDQOL, MT pts reported higher perceived burden of kidney disease (Δ=4.35), worse general health (Δ=5.73), and worse physical component score (Δ=1.25, p=0.06).

Conclusions: Our findings support prior studies, highlighting that longer travel times, higher perceived disease burden and lower self-reported physical wellness relate to HD adherence. While MT is most common in the U.S., the tremendous variation across DOPPS countries implies that MT may be modifiable. Focus on strategies to lessen MT in the U.S. and elsewhere is needed. Improvement in MT could be one metric to assess impact of efforts, such as renal ACOs, to coordinate care in the U.S.

Country	N Patients[A]	Percent of HD Patients Missing ≥1 HD treatments

What Treatment Benefits Are Important to Patients with ESRD on Hemodialysis?
Mona L. Martin,[1] Matthew J. Wolfe,[1] Anna Ryden.[2] *[1]Health Research Associates Inc., Seattle, WA; [2]AstraZeneca R&D, Mölndal, Sweden.*

Background: There are no published data on patient perceptions of condition-specific treatment success in individuals with end-stage renal disease on hemodialysis (ESRD-HD). Results from qualitative interviews helped to identify concepts important to this patient group in defining treatment success.

Methods: Semi-structured interviews were conducted by telephone as part of a phase 2 clinical trial of tenapanor (AZD1722; a minimally absorbed inhibitor of the Na^+/H^+ exchanger NHE3) for patients with ESRD-HD and chronic fluid overload (NCT01764854). Interviews were conducted prior to treatment initiation and at the end of treatment, in order to document patients' experiences and capture their thoughts on what constitutes a successful treatment. Patients responded to open-ended questions such as "Can you describe your current thoughts about what makes a treatment successful?", followed by questions probing into the changes in symptoms and impacts on daily life that they would like to experience as a result of treatment. The data reported below are from patient responses to the above questions during pre-treatment interviews.

Results: Twenty-one patients from eight sites across the U.S.A. completed the pre- and post-treatment interviews and are included in this analysis. The main emergent themes for treatment success arising from the initial open-ended questions were: reduction in the amount of fluid removed during dialysis and less fluid retention between dialysis sessions, fewer side effects following dialysis, and feeling better after dialysis. When asked which changes in symptoms would define treatment success, fluid retention was the most frequently discussed theme. Other themes included relief from constipation and thirst, and increased energy. When asked about impact on daily life, the main emergent theme was regarding activity levels (e.g. the ability to travel and perform everyday tasks).

Conclusions: Patients with ESRD-HD considered that a key element of a successful treatment should be reducing the amount of fluid removed during dialysis. Therapies able to reduce chronic fluid overload may have a role to play achieving this outcome.

Funding: Pharmaceutical Company Support - AstraZeneca

SA-PO1020

Weight Gain after Starting Peritoneal Dialysis: Prevalence, Possible Causes and Prognostic Significance
Shin Man Choy, Cheuk-Chun Szeto. *Div of Nephrology, Prince of Wales Hospital, Hong Kong, Hong Kong.*

Background: Observational studies suggested that high body mass index is associated with improved survival in dialysis population. Weight gain is common amongst patients newly put on peritoneal dialysis (PD). However, the prevalence, risk factors and long term implications of body weight gain in patients newly started on PD have not been explored.

Methods: We studied 444 consecutive patients with end stage renal disease newly started on PD therapy. Body weight, measured when the patient was clinically euvolemic, at the time of initiation of PD and 1 year later were reviewed. Clinical factors affecting weight changes were explored.

Results: Patients were followed up for 60.9 ± 32.8 months. The mean weight change after one year of PD was 1.34± 3.27 kg. Patients without any peritonitis episodes during the first year of PD had significantly more weight gain than those who had peritonitis (1.58 ± 3.17 versus 0.16 ± 3.56 kg, P = 0.001). The number of peritonitis episodes during the first year of PD had inverse correlation with weight gain during this period (r = -0.174, P = 0.0002). Moreover, weight change had a modest but statistically significant correlation with the concomitant change in residual renal function (r = 0.137, P = 0.004). However, there were no significant relations between body weight change and glucose load, peritoneal transport characteristics, fasting plasma glucose, HbA1c, dialysis adequacy, or baseline residual renal function. Patients with weight gain >3.0 kg had similar overall survival, technique survival and peritonitis-free survival as compared to those with stable body weight. On the other hand, patients with weight loss >0.5 kg had worse technique survival (P = 0.03) and peritonitis-free survival (P = 0.005) than the others.

Conclusions: Weight gain is common among Chinese patients during the first year of PD. Weight change is related to peritonitis and decline of residual renal function during the same period. Weight gain within the first year of PD is not associated with any adverse clinical outcomes, while weight loss more than 0.5 kg is associated with worse technique survival and peritonitis-free survival subsequently.

SA-PO1021

Variation in Focus of Treatment Outcome Preferences According to Renal Replacement Therapy Modality
Zoe C.L. Pittman,[1] Chris W. McIntyre.[1,2] *[1]Royal Derby Hospital; [2]Univ of Nottingham.*

Background: Individual patient preferences for treatment outcomes vary between symptom control and survival, but the relationship with treatment modality in renal replacement therapy (RRT) has not been previously investigated. We systematically explored RRT patients' outcome preferences, utilising established methodology to compare and quantify the subconscious trade off in decision making.

Methods: Prevalent haemodialysis (HD), peritoneal dialysis (PD) and transplant (Tx) patients completed an outcome preference set comprising 25 possible treatment outcome profiles each scored for overall acceptability. All profiles contained the same 6 attributes (pain, tiredness, breathing, depression, survival and treatment burden (TB)), spread across 4 severity levels. Standard full profile conjoint analysis was used to derive importance weights for each attribute, allowing their relative contribution to be determined for every individual. Patient demographics and treatment history were collected.

Results: 44 patients were studied (HD 24 PD 19 Tx 11), mean age HD 63.3±14.6, PD 60.1±9.9, Tx 61.6±9.1yrs (p=0.800), % male HD 62.5, PD 66.7, Tx 54.5 (p=0.855). Overall importance weights (%) were highest for survival (24.1) and lowest for TB (11.2). The balance varied with modality; HD patients ascribed highest weights to pain (19.9) and breathing (19.6), PD rated survival (21.9) and breathing (19.6) and Tx survival (36.1) and depression (16.9). TB rated least for both HD and PD patients. There was a significant difference between all groups for pain (p=0.006), and between Tx and HD for survival (p=0.049). 7 patients completed 1 year follow up with no significant change in preference distribution. At patient level there was a clear separation in preference patterns; either predominant preference for survival, or aversion to symptoms and indifference to survival ± indifference to increased TB.

Conclusions: We have demonstrated that the balance of outcome preferences change by modality irrespective of age or gender suggesting that the modality itself may influence the focus. Understanding these preferences and how they change with time and modality may lead to additional targets for improving the quality of life of our patients.

SA-PO1022

Patient Characteristics and Outcomes by Glomerulonephritis (GN) Subtype in End-Stage Renal Disease (ESRD) Michelle M. O'Shaughnessy, Maria E. Montez-Rath, Richard A. Lafayette, Wolfgang C. Winkelmayer. *Stanford Univ School of Medicine, Palo Alto, CA.*

Background: Patients with ESRD due to GN have rarely been the focus of outcomes based research. We examined patient characteristics by GN subtype in a national ESRD cohort and identified independent associations between GN subtype and post-ESRD mortality.

Methods: Data on patients with ESRD attributed to 6 major GN subtypes [focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), IgA nephropathy (IgAN), lupus nephritis (LN), membranoproliferative GN (MPGN), vasculitis] who initiated ESRD therapy from 1996 to 2011 were extracted from the U.S. Renal Database System. Demographic variables were tabulated. Mortality hazard ratios were compared using Cox regression.

Results: In this national ESRD cohort (n=83,740), demographic variables differed considerably among GN subtypes.

	FSGS, n=34,071	LN, n=16,385	IgAN, n=12,912	MN, n=7,121	MPGN, n=5,148	Vasculitis, n=8,103
Age, mean	51.4	40.7	45.9	58.0	52.6	63.1
Male sex, %	61.7	18.3	67.6	66.0	60.2	52.4
Race, %						
- White	59.0	43.5	75.1	69.5	74.6	88.8
- Black	36.1	48.6	6.6	26.0	17.9	7.5
- Other	4.9	7.9	18.3	4.5	7.4	3.7
Hispanic, %	8.7	16.3	12.5	10.1	10.7	9.0
Medicaid eligible, %	18.5	32.0	13.5	16.6	20.4	12.0
Geographic region, %						
- Northeast	19.6	15.8	19.3	20.1	20.6	19.2
- Mid-west	23.4	18.5	23.1	23.6	24.8	27.2
- South	39.7	44.2	30.4	38.1	33.0	33.2
- West	16.7	20.4	26.7	17.0	20.7	20.0
Incident ESRD therapy, %						
- Hemodialysis	79.0	85.9	70.6	82.6	81.6	91.8
- PD	14.6	10.8	17.0	12.9	11.7	6.5
- Transplant	6.0	3.1	11.8	4.2	6.3	1.5
Mortality HR (95% CI)						
- Unadjusted	2.0 (1.9-2.1)	2.1 (2.0-2.2)	1.0 (referent)	2.5 (2.4-2.7)	2.3 (2.2-2.5)	4.0 (3.8-4.2)
- Demographics-adjusted	1.4 (1.3-1.5)	2.3 (2.2-2.5)	1.0 (referent)	1.3 (1.3-1.4)	1.6 (1.5-1.7)	1.7 (1.6-1.8)

Mean age ranged from 40.7 (LN) to 63.1 (vasculitis), % male from 18.3 (LN) to 67.6 (IgAN), % black from 6.6 (IgAN) to 48.6 (LN), % peritoneal dialysis (PD) as initial modality from 6.5 (vasculitis) to 17.0 (IgAN). Adjusted mortality referent to IgAN was highest for LN (HR 2.3, 95% CI 2.2-2.5).

Conclusions: These preliminary data demonstrate substantial heterogeneity among GN subtypes even after ESRD development, both in patient characteristics at presentation to ESRD therapy and in subsequent patient survival.

Funding: Private Foundation Support

SA-PO1023

Glycemic Markers and 1-Year Hemodialysis Outcomes in Non-Diabetic Patients from the GIDE Study Neal Mittman,[1] Lin Ma,[2] Brinda Desiraju,[1] Mark E. Williams,[3] Julia I. Brennan,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[2] Eduardo K. Lacson.[2] *[1]Kidney Care of Brooklyn and Queens, Brooklyn, NY; [2]Fresenius Medical Care, North America, Waltham, MA; [3]Joslin Diabetes Center, Boston, MA; [4]Spectra Laboratories, Rockleigh, NJ.*

Background: We previously reported elevated glycemic indices, fructosamine (F) and glycated albumin (GA), in non-diabetic (NDM) ESRD patients, as confirmed by hemoglobin A1c (HgbA1c) <6.5%. From the multi-year prospective observational Glycemic Indices in Dialysis Evaluation (GIDE) Study, we report 1st year outcomes in NDM HD patients exceeding hyperglycemic thresholds for these alternative glycemic markers per the literature and/or manufacturer recommendation.

Methods: As of April 1, 2013, 946 active NDM-HD patients from 26 FMCNA facilities with glycemic markers from Jan-Mar 2013 were followed until Mar 31, 2014. Baseline albumin-adjusted and unadjusted fructosamine (AlbF; F) and glycated albumin (GA) or percent GA (%GA) divided patients into high/low glycemia by thresholds of: AlbF≥974 µmol/g, F>285 µmol/L, %GA>15.7%, and GA>300 µmol/L. Cox models with and without adjustment for age, sex, race, ethnicity, vintage (log), BMI, HD catheter, and baseline comorbidity were utilized to determine associations between each dichotomized glycemic index to death and to hospitalization.

Results: Elevated glycemia was indicated in 4% (AlbF), 60% (F), 29% (%GA) and 16% (GA) of NDM cohort patients. Only high AlbF was significantly associated with both 1-year death risk (HR=2.3, p=0.04; adjusted HR=2.6, p=0.04) and hospitalization risk (HR=1.5, p<0.05; adjusted HR=1.6, p=0.03). A paradoxical association with lower death risk was noted with elevated F (HR=0.5, p=0.005) and GA (HR=0.4, p=0.04).

Conclusions: Preliminary findings in HgbA1c-confirmed NDM HD patients indicated an association between poor glycemic control determined from AlbF with 1-year survival and hospitalization risk. Elevated F and GA were both associated with better survival. To our knowledge, this is the first prospective indication that NDM glycemic status may have prognostic implications in HD patients. The GIDE study is ongoing; more detailed evaluation and longer term follow-up is planned.

SA-PO1024

Glycemic Control and Mortality in Diabetic Patients on Dialysis: Effect of Age and Dialysis Type Ji In Park,[1,2] Kyung Don Yoo,[1,2] Seung Seok Han,[1,2] Jung Pyo Lee,[1,2] Dong Ki Kim,[1,2] Kwon Wook Joo,[1,2] Yon Su Kim,[1,2] Yong-Lim Kim,[2] Shin-Wook Kang,[2] Chul Woo Yang,[2] Hajeong Lee.[1,2] *[1]Seoul National Univ Hospital; [2]Clinical Research Center of End Stage Renal Disease in Korea.*

Background: Though the improved glycemic control prevents diabetic nephropathy progression and lowers mortality in the chronic kidney disease, it remains unclear whether glycemic control is beneficial in the ESRD. In this study, we evaluate the effect of HbA1c on mortality in the diabetic patients on dialysis according to the age and dialysis types.

Methods: Among 3,302 patients with ESRD enrolled in Clinical Research Center for End Stage Renal Disease in Korea between 2008 and 2013, we included patients with underlying diabetes mellitus or initial HbA1c>6.5%. Age was categorized as <55(young), 55-64(middle) and ≥65(old) years old. We adjusted in proportional hazards models for age, sex, MCCI, hemoglobin, primary renal disease, BMI, and dialysis duration.

Results: Among a total of 1,239 patients, 873 patients received HD, and 366 did PD. During the mean follow-up of 19.1 months, 141 patients (11.4%) died. HbA1c≥8% group showed worse survival than <8 % groups (HR 2.2, 95% CI 1.48-3.29, P<0.001). In the subgroup analysis, same results were shown in HD (HR 1.9, 95% CI 1.08-3.21, P=0.025) and PD group (HR 2.7, 95% CI 1.38-5.20, P=0.004). However, in the age groups, HbA1c≥8% was a significant predictor in the young (HR 4.3, 95% CI 1.78-10.41, P=0.001) and middle group (HR 3.3, 95% CI 0.81-2.69, P=0.002), but not in the old group. Further analysis was carried out on age subgroups of each dialysis modalities. It revealed that among HD patients, HbA1c≥8% was a significant factor only in the young group, while among PD, it was in the young and middle groups. Mortality rates due to infection were higher in PD group than in HD (32.2, 20.1/1000-patient-year, respectively) and among PD patients, deaths from infection were significantly higher in HbA1c≥8% group than in <8% group (P=0.024).

Conclusions: In this study, we elucidated that target of glucose control should be individualized according to age and dialysis type in diabetic patients on dialysis. Improving glycemic control is beneficial only in young dialysis patients and middle aged PD patients.

SA-PO1025

Use of Insulin Pump in Patients with End Stage Renal Disease on Dialysis Hossein Ghofrani, Elaine Kaptein. *Nephrology, LAC/USC Medical Center, Los Angeles, CA.*

Background: Among patients with end stage renal disease (ESRD) on hemodialysis (HD) or peritoneal Dialysis (PD), about 5-10% have diabetes mellitus type 1. Prolonged insulin half-life as well as insulin resistance alters insulin dosing in diabetics with ESRD. Although use of insulin pumps in type 1 diabetics leads to more favorable metabolic control and less hypoglycemic events, there are no data or guidelines on insulin dosing in dialysis patients.

Methods: We retrospectively report diabetes control, insulin dosing and dose adjustments in a series of 5 ESRD patients (4 on HD or 1 on PD) who are currently using insulin pump, compared to the same patients prior to pump use. We recorded and compared periodic HgA1C and incidence of hypoglycemia episodes before and after pump use, the initial basal insulin dose estimated from standard formulas to estimates for our ESRD patients to avoid hypoglycemia and hyperglycemia, and actual total daily dose (TDD) of insulin to achieve acceptable glycemic control with TDD calculated with the formula used for general diabetic population (based on pre-pump insulin amount).

Results: The initial basal dose of insulin required to start the pump was only 10-15% of the recommended dose for general insulin pump users. Average TDD of insulin was lower while using the pump compared to pre-pump dosing (32.9±6.5 units versus 38.3 ± 4.7 units; not statistically significant). After dose adjustment, the actual TDD to achieve an acceptable glycemic control was on average 16% less than calculated TDD. HgA1C level did not show significant change before and after pump use. Average monthly number of recorded hypoglycemia episodes decreased significantly (3.1±0.9 on pump versus 5.8±1.6 pre-pump, p=0.04).

Conclusions: We have successfully used insulin pumps in five dialysis-dependent patients, and found that the initial basal dose was about 10% of recommended, although total daily dose was 90% of expected.Experience in our ESRD patients may provide some guidance for calculating initial, maintenance, basal and bolus dosing of insulin while using an insulin pump in ESRD patients.

SA-PO1026

Monthly Variability in Serum Bicarbonate in Hemodialysis Patients

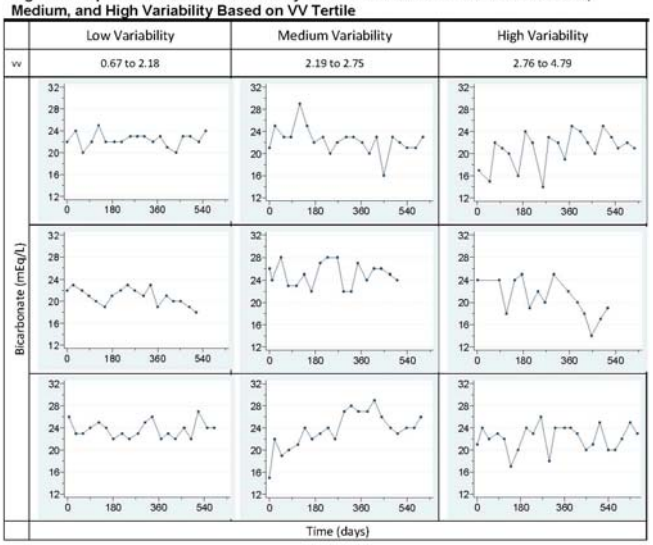
Ravi Patel,[1] Mark Abi Nader,[2] William Paredes,[1] Charles B. Hall,[1] Vaughn W. Folkert,[1,3] Matthew K. Abramowitz.[1,3] *[1]Albert Einstein College of Medicine; [2]Georgetown Univ Medical Center; [3]Montefiore Medical Center.*

Background: The optimal management of acid-base status in hemodialysis (HD) patients remains unclear. Previous studies have associated both low and high serum bicarbonate with adverse outcomes. However, a standardized approach to individualizing therapy does not exist. An important yet overlooked factor is the month-to-month variability in serum bicarbonate.

Methods: We retrospectively studied consecutive patients initiating HD from 1/2008–6/2012 at a single dialysis center with a uniform dialysate bicarbonate concentration. Clinical cutpoints were used to classify each serum bicarbonate as low (<22), normal (22-26), or high (>26 mEq/L). Each monthly observation *i* was assigned a Variability Value (VV): $VV = \sqrt{(([HCO_3]_i - [HCO_3]_{i-1})^2 + ([HCO_3]_i - [HCO_3]_{i+1})^2)/2)}$. VV tertiles were used to define low, medium, and high variability. Factors associated with VV over time were examined using linear mixed models.

Results: 181 patients were included, with mean serum bicarbonate 22.6±3.0 mEq/L and mean VV 2.50±1.60. VV distinguished low versus high month-to-month variability.

Figure 1. Representative Plots of Monthly Serum Bicarbonate in Patients with Low, Medium, and High Variability Based on VV Tertile



Among low bicarbonate values, 41% returned to normal the subsequent month. Among high values, 60% returned to normal. Compared with normal bicarbonate levels, both low and high serum bicarbonate were associated with higher VV (0.50 (0.39-0.61) and 0.92 (0.74-1.09), respectively) after multivariable adjustment including medication use, protein intake, dialysis adequacy, and interdialytic weight gain.

Conclusions: Substantial month-to-month bicarbonate variability exists in a subset of HD patients. Even if clinicians take no action, a bicarbonate value outside the normal range has approximately a 50% chance of returning to normal the following month. There is little utility to basing treatment decisions on a single monthly bicarbonate level.

Serum Potassium and All-Cause Mortality in Dialysis Patients: A Nationwide Prospective Observational Cohort Study in Korea

Sunhwa Lee,[1] Hajeong Lee,[1] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yong-Lim Kim,[2] Shin-Wook Kang,[3] Chul Woo Yang,[4] Yon Su Kim.[1] *[1]Internal Medicine, Seoul National Univ Hospital; [2]Kyungpook National Univ Hospital; [3]Yonsei Univ College of Medicine; [4]Seoul St. Mary's Hospital.*

Background: Abnormalities of serum potassium concentration has been suggested to be a risk factor of mortality in chronic kidney disease or dialysis patients. We investigated the impact of serum potassium level on survival according to dialysis modalities.

Methods: A nationwide prospective observational cohort study for end stage renal disease patients has been ongoing since August 2008. Among the participants, patients had been selected who checked serum potassium level at least twice between 3 and 18 months. Time-averaged potassium level was calculated by an arithmetic mean, and its relationship with mortality was analyzed using Cox proportional hazard model.

Results: A total of 1,686 patients (hemodialysis (HD) 62.3%, peritoneal dialysis (PD) 37.7%) were included in the final analysis. Serum potassium levels were significantly lower in PD than in HD patients (4.31±1.06 versus 4.79±1.05 mg/dL, $P<0.001$). During the mean 2.2-year of follow up, 142 patients died of mainly cardiac arrest (n=39) and infection (n=46). In survival analysis, hypokalemia was a significant predictor of mortality. Moreover, hypokalemic PD patients showed higher mortality even after adjustment of age, history of congestive heart failure, diabetes, hypoalbuminemia, and hypouricemia (Hazard ratio 2.98, 95% confidence interval 1.68–5.28, $P<0.001$). However, serum potassium did not show any association with mortality in HD patients. Hypokalemic PD patients died more due to cardiovascular events than normo~hyperkalemic PD patients ($P<0.001$). Subgroup analysis showed that hypokalemic PD patients had still higher mortality rate than others regardless of sex or presence of diabetes.

Conclusions: Hypokalemic PD patients have higher mortality risk. Cardiovascular death is the major cause of mortality in PD patients with hypokalemia. However in HD patients, serum potassium level was not associated with mortality.

SA-PO1028

Continuous Glucose Monitoring System in Glucose Profile Assessment and Insulin Pumps in Diabetic Nephropathy Patients with Hemodialysis

Shuangxin Liu, Wei Shi, Li Zhang, Xinling Liang, Zhiming Ye, Bin Zhang, Wenjian Wang, Lixia Xu, Zhonglin Feng, Jianchao Ma, Zhilian Li, Yuanhan Chen, Lifen Wang. *Dept of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Good glycemic control is often difficult to maintain in diabetic patients treated with hemodialysis. However, recent studies have suggested that diabetic patients who use insulin pump has been shown to reduce glycated hemoglobin levels without an increased risk of hypoglycemia, as compared with a regimen of multiple daily insulin injections, but results in diabetic nephropathy patients with hemodialysis have not been reported. The continuous blood glucose monitor (CGMS) has recently offered an opportunity to monitor blood glucose at 5-minute intervals for 72 continuous hours in diabetic patients.

Methods: There were 14 diabetic patients on hemodialysis using free glucose dialysate in the study. All participants underwent 72-hour CGMS and HbA1c evaluation. Continuous subcutaneous insulin pump insulin intensive therapy group for the ultra-short effect of human insulin analogues - insulin lispro, conventional subcutaneous insulin Humalog before meals program for the Addition 21:00 Novolin N treatment. There was the whole area under the curve (AUC) of each 24-hour glucose profile. Glucose area above high limit is 10mmol/L, and glucose area below low limit is 3.9mmol/L.

Results: Diabetic nephropathy patients with hemodialysis 12 cases with first use of continuous subcutaneous insulin pump therapy to strengthen, then the routine use of subcutaneous insulin program. Duration above high glucose limits are 34% ± 12%, duration within limits are 65 ± 23%, and duration below limit are 1% ± 1% in continuous subcutaneous insulin pump therapy group, while duration above high glucose limits are 65% ± 32%, duration within limits are 35% ± 12% in the conventional subcutaneous insulin program, $p< 0.05$.

Conclusions: In diabetic nephropathy with hemodialysis in insulin pump therapy compared with conventional subcutaneous insulin therapy, blood glucose is more stable standard. CGMS technology can effectively evaluate the patient's blood glucose with hemodialysis.

SA-PO1029

Higher Alkaline Phosphatase Level as an Independent Risk Factor for All Clinical Fractures in Hemodialysis Patients: A Prospective Cohort Study

Yasuhiro Yamashita,[1] Tatsunori Toida,[1] Yuji Sato,[1] Kazuo Kitamura,[1] Shouichi Fujimoto.[2] *[1]First Dept of Internal Medicine, Univ of Miyazaki Hospital, Miyazaki, Japan; [2]Dept of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan.*

Background: Risk factors of bone fracture in hemodialysis (HD) patients have not been fully clarified. Recently, higher alkaline phosphatase (ALP) level was reported as a predictor of hip fractures in a Japanese cohort study (Maruyama et al. Nephrol Dial Transplant 2014); however, its follow-up period was short (one year) and incidence was examined retrospectively. Using prospective cohort data, we investigated the relationship between ALP level and all clinical fractures in HD patients.

Methods: We examined data of 1,551 HD patients (mean age 67±13 years, males 57.8%, diabetes 24.0%, and median HD vintage 74 months) in the Miyazaki Dialysis Cohort Study (MID study), and evaluated ALP level and the incidence of all clinical fractures during the 48-month follow-up using multivariate Cox regression analysis.

Results: During the follow-up, 157 (10.1%) patients were newly diagnosed with clinical fractures (hip fracture 27.4%, vertebral fracture 19.7%, and other fractures 52.9%). The higher ALP tertile group was older, more likely female, had a longer HD vintage, and had more past hip fractures. Patients in the higher ALP tertile were more likely to have lower levels of albumin, calcium, and phosphate, and a higher level of intact parathyroid hormone (iPTH). Multivariate Cox regression analysis showed that being in the highest ALP tertile (269 to 1180 IU/L) was a significant risk factor for all clinical fractures, even when the middle tertile (196 to 268 IU/L) was set as a reference [hazard ratio (HR) 2.02, 95% confidence interval (CI) 1.06 to 3.85] after adjustment for age, sex, primary disease, calcium carbonate, oral vitamin D, corticosteroid, statin, past hip fracture, hemoglobin, albumin, calcium, phosphate, and iPTH.

Conclusions: In this cohort study, higher ALP level was an independent risk factor for all clinical fractures in HD patients.

SA-PO1030

The Relationship between the Spine Deformity Index Biochemical Parameters of Bone Metabolism and Vascular Calcifications: Results from the Epidemiological Vertebral Fractures Italian Study in Dialysis Patients (EVERFRACT Study) Maria Fusaro,[1] Marianna Noale,[1] Giovanni Tripepi,[2] Claudia Torino,[2] Marianna Alessi,[3] Luciana Bonfante,[3] Antonio Piccoli,[3] Rosalba Cristofaro,[3] Maurizio Gallieni.[4] *[1]CNR, Padua, Italy; [2]CNR IFC, Reggio Calabria, Italy; [3]Nephrology Unit, Padua, Italy; [4]Nephrology Unit, Milan, Italy.*

Background: The Spine Deformity Index (SDI) is a summary measure of the VFs. The aim of this study was to evaluate the relationships SDI, laboratory parameters (EVERFRACT study).

Methods: 387 hemodialysis patients, aged 64.2 ± 14.1 years, we determined: 25(OH) vitamin D, total Bone Gla Protein (BGP), undercarboxylated BGP (ucBGP) and total Matrix Gla Protein (MGP). We performed L-L x-Rays of the spine (T5 to L4) to evaluate VFs and aortic (AoVC) and iliac (IaVC). We divided the SDI score by the number of fractures, to obtain a more precise index of fracture severity (corrected-SDI: c-SDI).

Results: 55.3% VFs. SDI was 1.4 ± 1.74 while c-SDI was 0.74 ± 0.75. VFs had a grade of severity higher through T11-L3. The severity of VFs was highlighted only by c-SDI (see Table).80.6% AAoC and 55.6% IAC. SDI was significantly associated with AAoC (OR=1.15, p=0.023). A SDI >1 was significantly associated with: sex (male OR 1.86, p=0.007), age (OR 1.03, p=0.0003) and albumin ≥ 3.5 g/dL (OR 0.54, p=0.026). c-SDI score was significantly associated with AAoC (OR=1.48, p=0.0009) and with IAC (OR=1.54, p=0.025). c-SDI >1 was significantly associated with: age (OR 1.05, p<0.0001), LDL Cholesterol ≥ 90 mg/dL (OR 1.74, p=0.0354) and ucBGP ≥ 17.2 mcg/L (OR 0.35, p=0.0025).

Vertebra	Mild VF	Moderate VF	Severe VF	SDI	c-SDI
T5	24 (6.0%)	7 (1.7%)	0 (0.0%)	38	1.23
T6	33 (8.3%)	14 (3.5%)	1 (0.2%)	64	1.33
T7	38 (9.6%)	12 (3.0%)	0 (0.0%)	62	1.24
T8	35 (8.8%)	10 (2.5%)	0 (0.0%)	55	1.22
T9	26 (6.5%)	8 (2.0%)	1 (0.2%)	45	1.29
T10	19 (4.7%)	8 (2.0%)	0 (0.0%)	35	1.30
T11	30 (7.5%)	14 (3.5%)	3 (0.7%)	67	1.43
T12	35 (8.8%)	17 (4.2%)	2 (0.5%)	75	1.39
L1	19 (4.7%)	12 (3.0%)	2 (0.5%)	49	1.48
L2	4 (1.0%)	3 (0.7%)	2 (0.5%)	16	1.78
L3	2 (0.5%)	3 (0.7%)	0 (0.0%)	8	1.60
L4	13 (3.2%)	4 (1.0%)	0 (0.0%)	21	1.24
Tot	278	112	11	Sum 535	Average 1.38

Conclusions: Only c-SDI score performed the grade of VFs severity and it showed a stronger association with vascular markers. This is the first time that the association of SDI with biochemical parameters and VC.

SA-PO1031

Epidemiology of Hip Fracture in ESRD Dialysis Patients: Taiwan National Cohort Study Chih-Chiang Chien. *Dept of Nephrology, Chi-Mei Medical Center, Tainan City, Taiwan.*

Background: Chronic kidney disease increases the risk for hip fractures. Hip fractures are associated with increased mortality, decreased quality of life, and higher economic burden. To determine whether dialysis modality is associated with a higher incidence of hip fractures in end-stage renal disease (ESRD) dialysis patients.

Methods: In the Taiwan National Health Insurance Research Database, we examined records of ESRD patients who initiated dialysis between 1999 and 2005. Patients were followed until death, transplant, dialysis withdrawal or 31 December 2008. The cumulative incidence rate of hip fracture was calculated using Kaplan-Meier methods. Predictors of hip fracture was calculated using Cox models.

Results: A total 51,473 dialysis patients were examined in this study. During the study period, 1903 patients had hip fracture. The overall incidence rate of hip fracture was 89.21 per 10,000 patient-years. Patients' age was 67.91±10.45 and 59.27±14.08, and they included 60.6% and 51.8% women in patients with and without hip fracture, respectively. Female gender, old age, receiving hemodialysis, a prior history of hip fracture and having baseline comorbidities were risk factors for hip fracture in the dialysis patients. Patients on hemodialysis had a 31% higher incidence of hip fracture than those on peritoneal dialysis (HR 1.31, 95% CI: 1.01-1.70). Patients ≥ 65 years had a more than 13-fold increased risk of hip fracture compared to those aged 18-44 years old (HR 13.65, 95% CI: 10.12-18.40). The overall in-hospital mortality rate was 3.2%. The cumulative survival rates after a hip fracture were 74.6% at one year and only 29.6 % at seven years.

Conclusions: Our findings supported the notion that being on HD is a risk for hip fracture. Additionally, age was also a significant risk for a hip fracture in patients with ESRD and undergoing dialysis.

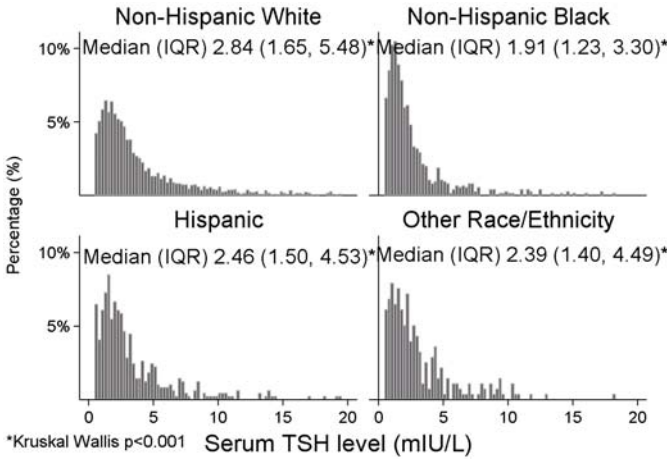
SA-PO1032

Thyroid Function Patterns across Race/Ethnicity in a National Incident Hemodialysis Cohort Connie Rhee,[1] Jiaxi Wang,[1] Bahattin T. Oztan,[1] Steven B. Kim,[1] Daniel L. Gillen,[1] Rajnish Mehrotra,[2] Elani Streja,[1] Steven M. Brunelli,[3] Csaba P. Kovesdy,[4] Gregory Brent,[5] Kamyar Kalantar-Zadeh.[1] *[1]UCI, Irvine, CA; [2]Univ of Washington, Seattle, WA; [3]DaVita Clinical Research, Minneapolis, MN; [4]Memphis VAMC, Memphis, TN; [5]UCLA, Los Angeles, CA.*

Background: Nearly one-quarter of hemodialysis (HD) patients have hypothyroidism (HT), defined by an elevated serum thyrotropin (TSH). Given racial/ethnic differences in TSH distribution in the general population, we compared the baseline distribution and longitudinal trajectory of TSH levels across race/ethnicity in HD patients from a large national dialysis organization.

Methods: Among a 5-year cohort (1/2007-12/2011) of adult incident HD patients with ≥3 TSH levels, we examined the TSH distribution in non-Hispanic whites, non-Hispanic blacks, Hispanics, versus other race/ethnicities (former 2 groups referred to as whites and blacks). We then examined the longitudinal trajectory of TSH across racial/ethnic subgroups using unadjusted and multivariable linear mixed models adjusted for age, sex, and diabetes.

Results: Among 3946 patients, the baseline median (IQR) of serum TSH was 2.54 (1.49, 4.80) mIU/L. Compared to whites, blacks and Hispanics had lower median (IQR) baseline TSH. In unadjusted linear mixed models, blacks and Hispanics had significantly lower baseline serum TSH versus whites (Δ=-0.90 and -1.15mIU/L), which were attenuated in adjusted models. In unadjusted and adjusted linear mixed models, TSH decreased over time in whites (-0.38mIU/L per year in both models), with similar rates of decline observed in blacks, Hispanics, and other race/ethnicities.



Conclusions: Black and Hispanic HD patients have lower TSH distributions versus whites, but similar rates of TSH decline over time. Further studies are needed to determine the genetic, autoimmune (i.e. thyroid autoantibodies), and environmental factors for differential TSH distributions across race/ethnicity.

Funding: NIDDK Support

SA-PO1033

Sex Steroid Levels in Chronic Kidney Disease, Dialysis and Kidney Transplant Recipients: Associations with Disease Severity and Prediction of Mortality Matthew Allan Roberts,[1] Francesco L. Ierino,[2] Rudolf Hoermann,[3] Mark Ng Tang Fui.[3] *[1]Eastern Health Clinical School, Monash Univ, Australia; [2]Nephrology, Austin Health, Australia; [3]Medicine, Univ of Melbourne, Australia.*

Background: Levels of circulating sex steroids change with stages of chronic kidney disease (CKD) and may be associated with clinical outcome.

Methods: We prospectively recruited patients with (a) CKD III-IV, (b) undergoing chronic dialysis and (c) kidney transplant recipients (KTR) from a single centre in 2003 and 2004. Two stored samples taken 3 months apart were analyzed for serum testosterone and other sex hormones using liquid chromatography/tandem mass spectrometry and the mean of the two was used for analysis. We also measured novel cardiac biomarkers troponin T and NT-BNP. Patients were followed until death, transplant or June 30, 2013, and survival analysis performed.

Results: Sex hormones were measured in 49 patients with CKD III-IV, 102 patients receiving dialysis and 70 KTR. In males, median (IQR) testosterone levels were lowest in dialysis patients and highest in KTR, whereas in females, testosterone was lowest in KTR. Over a median follow up of 8.5 years 52 men (36%) died.

Testosterone ng/dL	CKD III-IV	Dialysis	KTR	P
Male	309 (242-372); n=38	277 (193-398); n=61	372 (274-467); n=44	0.005
Female	7.5 (6.3-21.1); n=11	7.5 (4.9-12.1); n=41	4.9 (1.2-10.1); n=26	0.04

In Cox proportional hazard regression models, testosterone predicted mortality independent of baseline age, body mass index, stage of renal disease, and circulating levels of brain

natriuretic peptides or cardiac troponin T. An increase in testosterone by 29ng/dL (1 nmol/L) was associated with a 9.8% (95% confidence interval 3.1-16.3%) decrease in mortality. By contrast, sex steroid levels were not associated with mortality in females.

Conclusions: Levels of testosterone vary by CKD stage and in males, predict mortality independent of established and novel predictors.

Funding: Clinical Revenue Support, Government Support - Non-U.S.

SA-PO1034

The Soluble Urokinase Receptor (suPAR) Predicts Mortality in End-Stage Renal Disease Bjorn Meijers,[1] Ruben Poesen,[1] Markus Storr,[2] Kathleen Claes,[1] Pieter Evenepoel,[1] Bert Bammens,[1] Dirk R. Kuypers.[1] *[1]Nephrology, Univ Hospitals Leuven, Leuven, Belgium; [2]Gambro Dialysatoren GmbH, Hechingen, Germany.*

Background: The soluble urokinase receptor (suPAR) is a candidate biomarker for focal segmental glomerulosclerosis (FSGS). The clinical usefulness however is questioned as suPAR accumulates parallel to loss of kidney function. In non-FSGS CKD patients suPAR is an independent predictor of cardiovascular disease. Whether suPAR is associated with outcome in dialysis patients has not been studied to date.

Methods: We measured suPAR concentrations in patients with end-stage renal disease using the human uPAR enzyme-linked immune sorbent assay (R&D systems™). Associations with overall mortality were explored using Kaplan-Meier estimates and multivariate Cox proportional hazards analyses.

Results: We determined suPAR concentrations in 186 prevalent patients with end-stage renal disease (hemodialysis patients (HD) n=125; peritoneal dialysis patients (PD) n=61). suPAR concentrations in HD and PD were similar (median 5918 versus 6372 ng/mL, Wilcoxon P NS). suPAR concentrations were associated with overall mortality (P 0.001). In multivariate analysis, after correction for age, sex, albumin, c-reactive protein, haemoglobin and PTH, suPAR remained independently associated with mortality (P 0.01).

Conclusions: suPAR is directly and gradually associated with overall mortality in patients with end-stage renal disease. This extends observations in patients with mild-to-moderate CKD. These observations question whether suPAR is a selective biomarker for FSGS and suggest a role for the urokinase receptor signalling pathway in CKD.

SA-PO1035

Major Bleeding in Incident Hemodialysis Patients Suzanne H. Forbes, Neil Ashman. *Dept of Nephrology and Transplantation, Royal London Hospital, London, United Kingdom.*

Background: End-stage renal disease (ESRD) is associated with increased risk of bleeding related to uremia, platelet dysfunction, hypergastrinemia and dialysis anticoagulation. In prevalent hemodialysis (HD) patients in our centre the rate of major bleeding is 3.3 per 100 patient years (comparable to North American data at 2.5). All published analyses looking at bleeding risk in HD, however, exclude incident (<90day) patients. We hypothesized the risk of major bleeding at this time of maximal biochemical disturbance would be elevated.

Methods: We performed an observational retrospective study of all HD new starters of any cause over a 74 month period ending March 2013. Those dialysing for <1week, for delayed graft function, or transfers already established on HD were excluded. Bleeding was defined as 'major' using International Society on Thrombosis and Haemostasis criteria, or as any bleed requiring admission. Minor bleeds were also captured.

Results: 1540 patients were analysed. The majority dialysed for a minimum 90 days, equalling 364 patient-at-risk years. All patients were anticoagulated on HD with tinzaparin. The median age was 57 with a pre-HD eGFR of 6.5ml/min/1.73m^2. 973 were male and 517 diabetic. Starting access was a catheter in 1256 patients and 730 were on at least one antiplatelet agent. Within the first 90 days of HD there were 188 bleeding events across 177 patients; 95 were major, 3 fatal. The overall rate for a major bleed was 26.1 per 100 patient years. Contrary to published prevalent data, gastrointestinal bleeds constituted just 60% of the major bleeds, with intracranial, intraocular and retroperitoneal bleeds also significant. Analysis of time from initiation of HD to major bleeding event showed the risk to be maximal in the first 2 weeks, falling quickly thereafter to that seen in the prevalent population.

Conclusions: In comparison with prevalent patients, we demonstrate that incident HD patients have an 8-fold increase in major bleeding events, exaggerated particularly in the first 2 weeks. This data should prompt increased caution with antiplatelets and dialysis anticoagulation at this time. Furthermore this data forms a proposal to examine registry-wide incident bleeding across the UK.

SA-PO1036

Outcomes of Warfarin Use in Haemodialysis Suzanne H. Forbes, Emma O'lone, Neil Ashman. *Nephrology and Transplantation, Royal London Hospital, United Kingdom.*

Background: Haemodialysis (HD) patients have increased bleeding risk. There is debate about warfarin use in these patients. A 4-fold increased risk of major bleeding in prevalent HD patients taking warfarin is published. Non-renal patients taking warfarin are closely monitored in anticoagulation clinics whereas HD patients engaging with renal services thrice weekly are more likely to have their warfarin dosed there. In a population with elevated bleeding risk, tight INR control is key. We examined whether this was achieved.

Methods: We examined all patients known to our services taking warfarin for any reason whilst on HD and calculated combined time on HD and warfarin, examining bleeding outcomes, death and calciphylaxis. For patients with >3 INR results available we used the Rosendaal linear interpolation formula to calculate time in the therapeutic range (TTR, based on target INR). We also expanded this to a wider therapeutic window (INR 1.5-4), outwith which a thrombotic or bleeding event is known to be more likely, and noted peak INR results.

Results: We identified 214 HD patients taking warfarin, totalling 510 patient years. Reasons for warfarin are shown.

Indication	n (%)
AF	61 (29)
DVT	55 (26)
Valve	42 (19)
PE	26 (12)
Thrombus	10 (5)
Access	8 (4)
Other	12 (5)

There were 81 bleeding events, overall bleed rate of 15.9 per 100 patient years (versus published 3.57 in non-HD patients). 6 patients developed calciphylaxis (4 fatal). TTR was 36.5% days (37.9% tests) in range for target INR. Expanding the range to 1.5–4 gave 68.7% days (70% tests) in range. 40% of patients had at least one INR>5, and 10%>10. Of those with a bleed, median peak INR was 7.4 versus 5 in those without and TTR correlated with outcome.

Conclusions: We show significant bleeding in HD patients taking warfarin. We also show INR control in these patients is suboptimal compared with standards expected in haematology clinics, with significant time spent outwith a safe INR range. There are few indications for warfarin in HD that have a solid evidence base. This data reinforces that HD patients should avoid warfarin. When it is absolutely indicated, INR control should be rigorously monitored and there may be a role for a joint anticoagulation service for these patients.

SA-PO1037

Clinical Characteristics Associated with High Post-Dialysis Hemoglobin in Chronic Hemodialysis Patients Linda H. Ficociello,[1] Paul Balter,[1,2] Dong (Winnie) Hua,[1] Claudy Mullon,[1] Paul M. Zabetakis,[2] Jose A. Diaz-Buxo.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Inst, NYC, NY.*

Background: Hematocrit-derived hemoglobin (hb) was captured during a quality improvement project on fluid management across multiple dialysis (DL) units, including beginning (pre-DL) and end (post-dL) of DL. Post-DL hb is not routinely measured, so its clinical utility has not been fully explored.

Methods: Hb was captured via Crit-Line Monitors (CLM) in over 41,000 treatments from 1099 patients (pts) during 2 years. Pre-DL hb is measured after saline prime, post-DL hb before rinse-back, and measurements include multiple observations/pt.

Results: 66% of treatments (n=27,285) had post-DL hb<12, 29% (n=11,834) had a post-DL hb between (b/t) 12-13.9, and 5% (n=2,131) had post-DL hb ≥14g/dL [2.9% b/t 14-14.9, 1.4% b/t 15-15.9, 0.7% b/t 16-16.9, and 0.2% 17+g/dL]. Table categorizes pts based on highest post-DL hb. On average, pts with post-DL hb ≥14g/dL had higher pre-DL hb, steeper % change in blood volume, lower pre and post-DL SBP, greater pre and post-DL weight, and lower epo doses.

	Post-DL hb<12	Post-DL hb 12-13.9	Post-DL hb≥14	p-value
Number of pts (n,%)	253 (23%)	578 (53%)	268 (24%)	
Cause of ESRD (%): Diabetes Hypertension Polycystic Kidney %Other	36 35 2 27	41 32 3 24	34 34 2 30	0.24
Monthly/Bi-weekly Pre-DL hb (g/dL)	10.3	11.5	12.5	<0.0001*
CLM Pre-DL hb (g/dL)	10.0	11.7	13.0	<0.0001*
CLM Post-DL hb (g/dL)	10.7	13.0	15.0	by design
%Change Blood Volume	-6.3	-10.0	-13.5	<0.0001*
Pre-DL SBP (mmHg)	145.7	145.8	139.0	0.003**
Post-DL SBP (mmHg)	138.7	134.8	125.5	<0.0001*
Pre-DL Wt (kg)	78.2	80.7	86.6	<0.0001**
Post-DL Wt (kg)	76.0	78.1	83.3	0.003**
% administered Epo	77.5	62.5	31.7	<0.0001
Epo per Epo treatment (units)	6604	4231	4541	<0.0001*
Epo per treatment (units)	5108	2523	1343	<0.0001*

* All group means differ
** ≥14 group means differ from other groups

Conclusions: Clinical characteristics of pts with post-DL hb≥14 differ from pts with lower post-DL hb. Clinical relevance of high ending hb should be further explored, such as cardio and cerebrovascular hospitalizations. Future projects may consider inter-dialytic hb changes in addition to intra-dialytic changes.

Cancer Incidence Among U.S. Medicare End-Stage Renal Disease Patients on Hemodialysis, 1996-2009 Anne Mobley Butler, A. V. Kshirsagar, M. Alan Brookhart. *Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Patients with end-stage renal disease (ESRD) receiving dialysis have increased risk of cancer. Yet, contemporary cancer burden estimates in this population are sparse, and estimates that account for the high competing risk of death in this population are non-existent.The objective of this study is to quantify the burden of incident cancer among U.S. ESRD patients, overall and among subgroups.

Methods: Using data from the United States Renal Data System (USRDS), a national registry of patients in the Medicare ESRD program, we identified patients ≥ 18 years receiving dialysis between April 1995 and December 2010 with Medicare as primary payer and parts A and D coverage. Site-specific cancers required ≥ 2 ICD-9-CM diagnosis codes within 6 months. For overall and site-specific cancers, we calculated 5-year cumulative incidence since dialysis initiation using competing risk methods and standardized mortality ratio (SMR)-weighted annual incidence rates.

Results: Between 1996-2009, we observed constant rates of incident cancers for all sites combined, from 3923 to 3860 cases per 100,000 person years [annual percentage change, 0.1; 95% confidence interval (CI), -0.4, 0.6], but identified increasing and decreasing rates for some common site-specific cancers. Of 482,510 patients in the cumulative incidence analysis, 37,128 patients were diagnosed with cancer within 5 years after dialysis initiation. The 5-year cumulative incidence of any cancer was substantially lower in the analysis that did not censor deaths (9.48%; 95% CI, 9.39% to 9.57%) compared to the analysis that censored deaths (13.86%; 95% CI, 13.71% to 14.01%). Accounting for case-mix characteristics and the competing risk of death, the 5-year standardized cumulative incidence of any cancer was higher among the following subgroups: older age; males; non-whites; non-Hispanics; primary ESRD cause other than diabetes; recent dialysis initiation; and history of kidney transplant evaluation.

Conclusions: These results suggest a high burden of cancer in the dialysis population, with varying patterns of cancer incidence in subgroups.

Physican Bias in Initiating Chronic Hemodialysis in Major Psychiatric Illness Roshni Upputalla, Andi Qipo, Siddhartha Yedla, Vivek Reddy, Njideka Oragunye, Kisra Anis. *Nephrology, Jacobi Medical Center, Bronx, NY.*

Background: Patients with major psychiatric illnesses are a challenging population in the initiation and maintenance of chronic hemodialysis (HD). These patients require frequent care and need more allocation of resources due to their underlying psychiatric diagnosis. There is a lack of literature addressing the many issues related to initiation of chronic HD treatment in this group.

Methods: We retrospectively looked at 503 patients, who started dialysis at Jacobi Medical Center from 1998 to 2012. There were 41 patients with diagnosis of major depression, bipolar disorder and schizophrenia (study group), and 462 patients with no mental illness (control group).The prevalence of patients with mental illnesses in our group (8.8%) reflected the prevalence of the same diagnosis in general population (9-10%). Data included age, gender, smoking, alcohol, drug history, eGFR (MDRD), BUN, creatinine, albumin, and type of dialysis access used at first HD session.

Results: Control group had a higher percentage of males (53%) compared to study group (28%).The study group started on HD at a higher level of GFR of 9.4 versus 7 (p=0.012), lower BUN 65 versus 92 mg/dL (p<0.0001) and creatinine 5.3 versus 7.3 mg/dL (p<0.0001), and higher albumin 3.6 versus 3.4 g/dL (p=0.05). At initiation of HD the study group had higher percentages of AVF 17% versus 9.5%, AVG 4.8% versus 1.5%,and TDC 60% versus 56% compared to controls but none was statistically significant possibly due to small sample size. There was a statistically significant lower percentage of non-tunneled dialysis catheters in the study group compared to control group 17% versus 32.5% (p=0.041) at HD initiation.

Conclusions: Possible explanations for our findings are that patients with mental illness received medical interventions earlier due to closer follow up. In 20% of cases the decision for HD initiation in the study group was made due to altered mental status, ranging from agitation to lethargy, believed to be due to uremia. Diagnosis of altered mental status due to uremia might represent a challenge in these patients as the underlying mental illness or side effects of medications could affect mental status.

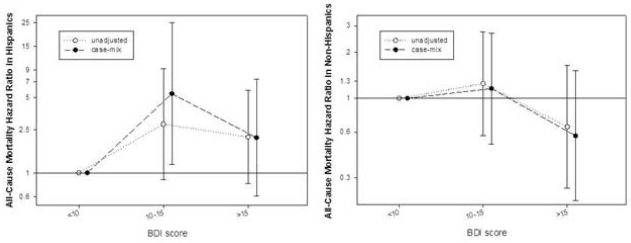
SA-PO1040

Association of Depression and Ethnicity with Survival in Hemodialysis Patients: Findings from the MADRAD Study Melissa Soohoo,[1] Elani Streja,[1] Connie Rhee,[1] Tracy Nakata,[1] Jennie Jing,[1] Csaba P. Kovesdy,[2] Daniel L. Gillen,[1] Kamyar Kalantar-Zadeh.[1] *[1]UCI, Irvine, CA; [2]Memphis VAMC, Memphis, TN.*

Background: Hemodialysis (HD) patients have a disproportionately higher risk of both depression and mortality, but prior studies examining the relationship between depression and mortality have been inconsistent. It remains unknown as to whether there is a differential depression—mortality association among ethnic minority HD patients.

Methods: We conducted a prospective study examining the association between depression and all-cause mortality in 490 HD patients from 13 large dialysis organization centers from the Malnutrition, Diet and Racial Disparities in Chronic Kidney Disease (MADRAD) cohort (entry period starting October 2011 with follow-up through March 2014). Associations between depression, defined by baseline Beck Depression Inventory (BDI) score, and mortality were examined in the overall cohort and within ethnic subgroups (Hispanic versus non-Hispanic) using case-mix-adjusted Cox proportional hazards models.

Results: Among 490 HD patients, the mean age was 54.5±15 years; 44% were Hispanic; and 19% and 29% of patients had mild (BDI 10-15) and moderate-severe depression (BDI>15), respectively. We did not observe a significant association between BDI score and mortality in the overall cohort (ref.: BDI <10): adjusted HRs (aHRs) (95%CI) 1.60 (0.81-3.16) and 1.03 (0.52-2.02) for mild and moderate-severe depression, respectively. However, when stratified by ethnicity, we observed a significant association between mild depression and mortality in Hispanic patients only: aHR (95%CI) 5.45 (1.20-24.8) (Figure).



Conclusions: We observed a 5.5-fold higher risk of death with mild depression among Hispanic HD patients. Further studies are needed to confirm these findings, and to determine if depression may be a potential factor for racial and ethnic survival disparities in HD patients.

SA-PO1041

The Prevalence of Depressive Affect and Associations in Increased Hospitalization Rates in Incident Hemodialysis Patients Kathryn A. McDougall,[1] John W. Larkin,[1] Rebecca L. Wingard,[1] Lin Ma,[1] Mikhail Artemyev,[2] Len A. Usvyat,[1] Eduardo K. Lacson,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America (FMCNA); [2]Renal Research Inst.*

Background: Depression is common in hemodialysis (HD) patients (Pts), but not well defined in the incident HD (iHD) population. We investigated the prevalence of and associated hospitalization rates for depressive affect (DA) during 1-30 and 121-150 days after initiating HD.

Methods: From Jan-Jul 2013, among 108 randomly selected FMCNA HD clinics, 577 and 543 iHD Pts at 1-30 and 121-150 days after initiating HD were attempted to be contacted by telephone for depression screening using the Patient Health Questionnaire 2 (PHQ2). The PHQ2 has two questions that determine presence of depressed mood and anhedonia in the prior two weeks. PHQ2 scores range from 0-6; a positive DA score is ≥3. Clinical and lab parameters were collected for up to the first 30 and 150 days of HD, respectively. Analyses included Poisson regression and t-test comparisons.

Results: Of 1,120 attempts to perform DA screening, 306 PHQ2 assessments were completed. Responders (30.4%) were: 40.5% females; mean age 64.3±14.8 years; 66.4% diabetic; and 49.0% and 20.0% utilized catheters at the end of 30 and 150 days respectively. PHQ2 indicated DA prevalence at 20.1% and 15.0% for Pts at 1-30 and 121-150 days after starting HD (p=0.24). DA screening was performed at both time points in 35 Pts with 7 and 2 Pts found positive at 1-30 and 121-150 days respectively (p=0.076). Pts with DA had 0.66 more admissions and 4.9 additional hospital days per Pt year when compared to Pts without DA (p<0.001).

Conclusions: The prevalence of DA in iHD Pts is consistently high throughout the incident period, with a trend to be lower after the first 30 days. Increased hospitalization rates were significantly associated with DA in iHD Pts. In a small number of paired Pts screened for DA at both the initiation of and end of the incident period, the occurrence of DA was slightly reduced; while adjustment to HD and Pt selection might have contributed to this finding, early identification of DA and subsequent Pt care interventions could be a factor. Further investigation is needed to evaluate this hypothesis.

SA-PO1042

Faith, Religion and Mental Health in a Sample of Brazilian Hemodialysis Patients Gildete Barreto Lopes,[1] Gentil Luz Junior,[1] Barbara De Alencar Costa,[1] Jean M. Monteiro,[1] Lucas Resende,[1] Sherman A. James,[2] Antonio Alberto Lopes.[1] *[1]Univ Federal da Bahia, Salvador, Brazil; [2]Duke Univ, Durham, NC.*

Background: Religiosity and faith/spirituality are associated with clinical presentation and outcomes in patients with chronic diseases. We assessed associations between self-declared faith and mental health in a sample of Brazilian patients on maintenance hemodialysis (MHD) from a population of predominantly African descent with a variety of religious orientations.

Methods: We conducted a cross-sectional analysis of data from 784 MHD patients (60.2% males, mean age = 48.9±18.1 yrs; 87% non-White) enrolled in the PROHEMO cohort in Salvador (Bahia), Brazil, during Jan 2010-Jan 2011. Patients were asked to state their religious affiliation (e.g., Catholic, Protestant, other) and how much their faith/spirituality has helped in their adjustment to chronic kidney disease: not helpful; helpful, but not so much; and very helpful. The SF-36 was used to measure mental health on a

scale of 0 (lowest) to 100 (highest). Linear regression was used to assess associations between faith/spirituality and mental health scores, controlling for religious affiliation and several other covariates.

Results: Patients' religious affiliations were: 55.8% Catholic, 33.8% Protestant, 2.0% Spiritism, 0.8% Candomblé, 0.1% Mormon, and 7.4% No Religion. 81.5% indicated that faith was "very helpful" in their adjustment to kidney disease. The "very helpful" response was endorsed by 93.9% of Protestants, 77.8% of Catholics, 69.6% of patients affiliated with other religions, and 56.9% of patients with no religious affiliation. In the statistical models adjusting for religious affiliation, comorbidities, and standard covariates, mental health score was approximately 10 points higher (P<0.001) in patients reporting faith to be "very helpful". In stratified analyses, Catholics endorsing the "very helpful" response scored 12.75 points higher than other Catholics (P<0.001) and Protestants endorsing this response scored 15.48 points higher than other Protestants (P=0.009).

Conclusions: This study provides additional evidence for an important role for spirituality/religious faith in the mental health of MHD patients.

SA-PO1043

Risk Factors Associated with Depressive Affect in Incident Hemodialysis Patients John W. Larkin,[1] Kathryn A. McDougall,[1] Rebecca L. Wingard,[1] Mikhail Artemyev,[2] Lin Ma,[1] Len A. Usvyat,[1] Eduardo K. Lacson,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America (FMCNA); [2]Renal Research Inst.*

Background: Depression and depressive symptoms in hemodialysis (HD) patients (Pts) are common, yet not well characterized in the incident population. FMCNA is performing initiatives to identify depressive affect (DA) in incident HD (iHD) Pts. This study is an enlarged cohort built upon initial results that investigated the risk factors associated with DA in iHD Pts.

Methods: From Jan-Jul 2013, 577 Pts in their first month of HD at 108 randomly selected clinics were attempted to be contacted for telephonic DA screening using the Patient Health Questionnaire 2 (PHQ2). DA is defined as a PHQ2 score ≥3 out of a range of 0-6. PHQ2 is validated to determine presence of depressed mood and anhedonia during the previous two weeks. Clinical and lab parameters were captured during the 1st month of HD and associations were studied using logistic regression.

Results: In 577 attempts to screen iHD Pts for DA, 214 PHQ2 assessments were performed. Responders were: 39.2% females; mean age 67.2±15.4 years; 65.6% diabetic; and 49.0% utilized dialysis catheters at the end of 30 days. The prevalence of DA was 20.1% in Pts in the first month of HD. Male Pts were observed to have lower risk of DA (OR=0.30, p=0.0089). Higher levels of online dialytic clearance were associated with a tendency for lower risk of DA (OR=0.33, p=0.1172). Although higher log of creatinine (Cr) levels were observed to tend towards greater risk of DA in the original Pt cohort studied; this association was not observed in this analysis with a sufficiently increased sample size. No associations were identified between DA and age, diabetes, access type, ethnicity, race, body mass index, residual renal function, albumin, or interdialytic weight gain.

Conclusions: In this study, DA was observed to have a prevalence of 20.1% in Pts in the first month of dialysis. Males were identified to have a lower risk for DA. Higher Cr levels were not associated with DA, in contrast to previous findings in a smaller cohort. Lower online dialytic clearance may be linked to DA, but further investigation is needed to determine if higher dialytic clearance may ameliorate DA.

SA-PO1044

Prevalence and Associated Factors of Chronic Itch in Hemodialysis Patients – Results of GEHIS, a Representative Cross Sectional Study in Germany Melanie Weiß,[1] Thomas Mettang,[2] Ulrich Tschulena,[3] Elke Weisshaar.[1] *[1]Dept of Clinical Social Medicine, Univ Hospital Heidelberg, Germany; [2]Clinic for Nephrology, German Clinic for Diagnostics, Germany; [3]Fresenius Medical Care Germany GmbH, Germany.*

Background: Chronic Itch (CI) is an often underestimated symptom in hemodialysis (HD) patients and appears to be a frequently neglected problem. Aiming to investigate the prevalence of CI and associated factors, a representative cross-sectional study was conducted in 25 randomly selected dialysis units in Germany.

Methods: Prevalence of CI was investigated in all participants as well as clinical data, dialysis parameters and the generic health related Quality of Life (HRQOL) (SF12). Characteristics of CI were assessed in HD patients with CI. A visual analogue scale (VAS) was used to assess severity of CI.

Results: 860 patients were included, 42.8% were female. Mean age was 67.2 years (SD: 13.4). Point prevalence of CI was 25.2% with a 95% confidence interval (95%-CI) of 22.4-28.1%. 27.2% (95% CI 24.1-30.3%) experienced CI within the past 12 months, lifetime prevalence was 35.2% (95%-CI 31.9-38.3%). 60.4% of the patients with CI had been suffering from CI up to 10 years, 11.8% since more than 10 years. Patients aged <70 years suffered significantly more frequently of CI than older patients. Though men were more frequently affected by CI (26.2 versus 23.9%), sex was not a significant association. The top 3 localizations were lower limbs (54.6%), back (52.0%) and scalp (43.2%). The shuntarm was affected in 26.6%. Worst severity of CI (VAS) was 6.5, mean severity 4.1. HD patients with CI showed significantly worse values both for the SF-12 physical and mental component summaries. Top 3 dialyzer membranes were polysulfone (59.5%), polyarylethersulfone (24.3%) and polyethersulfon (9.9%). Patients treated with polysulfon membrane showed significantly less CI, whilst polyarylethersulfon was significantly associated with a higher number of affected.

Conclusions: The 1st epidemiological study on the prevalence of CI in HD patients indicates CI to cause a high impairment in HRQOL in affected patients. Though suffering for years and leading to substantial burden, CI still seems to be a medical challenge in HD patients.

SA-PO1045

Psychiatric Illness and Mortality in ESRD HD Patients Paul L. Kimmel,[1] Chyng-Wen Fwu,[2] Kevin C. Abbott,[3] Marva M. Moxey-Mims,[1] Paul W. Eggers.[1] *[1]Div of Kidney, Urologic and Hematologic Diseases, NIDDK, NIH, Bethesda, MD; [2]Social and Scientific Systems, Inc., Silver Spring, MD; [3]Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Only limited epidemiologic data exist on psychiatric illness in ESRD patients, and none on pediatric patients.

Methods: We used 1991-2010 incident ESRD patients from USRDS to describe numbers of patients with psychiatric illness having at least 1 hospitalization within a year after starting dialysis. ICD9 codes were identified in Medicare billing data for depression and affective disorders, organic disorders and dementias, drug and alcohol-related disorders, schizophrenia and other psychoses, anxiety, personality and other disorders. We calculated 1-year survival rate from 1st day of hospitalization in adult patients with or without primary psychiatric diagnosis, using Kaplan-Meier analyses.

Results: 1,596 patients with ESRD before age 20 (of 3570, 45%) and 899,869 of 1,448,720 patients (62%) who started ESRD therapy after age 20 were hospitalized within a year after ESRD therapy. 24% of adults and 23% of children had an admission with a secondary psychiatric diagnosis. 2% of adults and 3% of children admitted had a primary psychiatric diagnosis. The most common primary pediatric psychiatric hospitalization was depression/affective disorder. The most common primary adult psychiatric hospitalization was organic disorder/dementia, closely followed by depression/affective disorder. Patients over 65 years were the most likely adults to have a primary psychiatric hospitalization. Although adults with a primary psychiatric hospitalization were younger than patients without (63.0±15.2 versus 67.3±13.4, P<0.001), their 1-year survival rate was worse (56% versus 63%, P<0.001).

Conclusions: Medicare billing data allows identification of comorbid psychiatric illness in ESRD. Primary psychiatric admissions comprise 2-3% of hospitalizations, with dementia and organic disorders in adults and depression and affective disorders in children the most common diagnoses. Greater mortality risk of patients with a psychiatric diagnosis may be related to the disease, poor adherence or concomitant medications.

Funding: NIDDK Support, Other U.S. Government Support

SA-PO1046

HIV Infection in U.S. ESRD Patients Paul L. Kimmel,[1] Chyng-Wen Fwu,[2] Kevin C. Abbott,[3] Paul W. Eggers.[1] *[1]Div of Kidney, Urologic and Hematologic Diseases, NIDDK, NIH, Bethesda, MD; [2]Social and Scientific Systems, Inc., Silver Spring, MD; [3]Walter Reed National Military Medical Center, Bethesda, MD.*

Background: HIV infection has affected primarily African-American men in the ESRD program. We previously showed the incidence of HIV infection in ESRD patients plateaued by 2000, but the prevalence had increased monotonically.

Methods: We used data from 1995-2011 USRDS to describe recent trends of numbers of HIV-infected ESRD patients using two identification methods. Method 1: AIDS nephropathy listed as the primary cause of ESRD in CMS Form 2728. Method 2: Method 1 patients plus patients with at least one hospitalization and/or two outpatient encounters in a one-year observation period with an HIV/AIDS diagnosis (ICD9 codes 042, 043, 044, 07953, and V08) identified from Medicare billing data. Patients ascertained by Method 1 were followed from the date of 1st ESRD service. Patients ascertained by billing data were followed from the date of 1st hospitalization for HIV/AIDS diagnosis or the 2nd HIV/AIDS outpatient encounter after ESRD service, until death or December 31, 2011. Annual mortality rate was calculated for period prevalent HIV/AIDS ESRD patients.

Results: 13,255 and 31,116 patients were identified by Methods 1 and 2, respectively. The number of AIDS nephropathy patients recorded was relatively stable from 810 in 1995 to 813 in 2007, but decreased 34% to 535 in 2011. In contrast, the number of period prevalent HIV/AIDS patients (Method 2) increased linearly almost 3 fold from 3,208 in 1995 to 9,508 in 2011. The mean age of 41.3±10.1 (SD) in 1995 prevalent patients increased to 50.2±11.0 in 2011 prevalent patients. Annual mortality rate in period prevalent HIV/AIDS patients decreased from 547 per 1,000 patient years at risk in 1995 to 146 in 2011. Mortality rates in HIV/AIDS ESRD patients however were higher than general ESRD patients of comparable age.

Conclusions: Medicare billing data enhances identification of HIV infected ESRD patients. The incidence of HIV infection in the ESRD program has decreased, but prevalence has increased as patient mortality has decreased. These findings are likely a result of access to antiretroviral therapy.

Funding: NIDDK Support, Other U.S. Government Support

SA-PO1047

Prospective Memory Is Impaired in Patients with End Stage Renal Disease (ESRD) Daniel J.W. Jones,[1] Laurie T. Butler,[1] John P. Harris,[1] Emma C. Vaux.[2] *[1]School of Psychology and Clinical Language Sciences, Univ of Reading, Reading, United Kingdom; [2]Renal, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom.*

Background: Cognition is known to be impaired in End Stage Renal Disease (ESRD); numerous areas of retrospective memory have been explored in patients with ESRD, suggesting impairments in verbal, visual and episodic memory. Another type of memory,involved with the formation of future intentions and, at present, yet to be explored in ESRD, is that of prospective memory (PM). PM is considered to be essential in the successful completion of day-to-day activities and vital for independent living. It is particularly important for ESRD patients due to the strict diet, medication and treatment programmes thatpatients must follow. It is crucial to determine if patients are cognitively impaired in this area due to the potentially fatal consequences that could arise if strict schedules are not fulfilled.

Methods: In the present study, 18 ESRD patients (Kt/V>1.4) were compared with 18 age and education-matched controls on the Virtual Week task, a measure of PM that emulates typical tasks an individual is likely to carry out on a daily basis (e.g. taking medication). Tasks are irregular (non-repeated), but use prompts to cue an individual as to when to complete a specific task (event-based tasks). The exercise involves patients reading cards aloud whilst making their way around a board with a dice (one loop of a board simulates one day); each day involves remembering to complete a certain number of tasks which must be communicated to the experimenter. Each patient completed the Virtual Week immediately before a haemodialysis treatment session in a quiet room located on the renal ward.

Results: Patients remembered significantly fewer events than the control group, suggesting patients' PM to be impaired in comparison to typical-functioning adults.

Conclusions: This study provides the first piece of evidence to suggest a PM impairment in ESRD, highlighting potential implications that may arise in terms of patients' well-being and quality of life, especially relating to their functional independence whilst away from the dialysis centre. Further work is required to fully understand the extent of this PM impairment.

SA-PO1048

Cognitive Decline in Maintenance Hemodialysis Patients David A. Drew, Daniel E. Weiner, Hocine Tighiouart, Urvi Ajay Shah, Amy Kantor, Tammy Scott, Mark J. Sarnak. *Tufts Medical Center, Boston, MA.*

Background: Cognitive impairment is common among dialysis patients, but little information exists on cognitive decline in hemodialysis patients.

Methods: In the Boston Dialysis Study, cognitive function was assessed at baseline in 314 patients using a comprehensive battery of cognitive tests. Using principal component analysis, individual test results were reduced into two domain scores, representing memory and executive function, which have a mean of zero and standard deviation of one. The cognitive battery was re-administered yearly whenever possible from 2005 until 2012. Linear mixed models and joint mixed models (accounting for death, transplant and drop-out) were used to explore the change in cognitive performance over time.

Results: The mean age of study participants at enrollment was 63 years, 53% were men, 22% were African American and 90% had at least a high school education. During median follow up of 1.8 years (25^{th}-75^{th}: 1.1-3.2), 196 had at least one follow up test (median number of tests = 3), 141 deaths occurred, and 40 underwent kidney transplantation. We observed statistically significant declines in multiple cognitive tests (Table). The greatest declines were seen in tests of executive function (-0.09 SD per year [-0.05, -0.12]). Similar results were seen when using joint mixed models accounting for the potential competing risks of death and kidney transplantation.

Table 1. Slope in Tests of Cognitive Function (Change Per Year)*

Test	MMSE	Recall Total	Recognition	Digit Symbol	Trails A (seconds)	Trails B (seconds)	PCA Memory	PCA Executive Function
Linear Mixed Model	**-0.43 (-0.28, -0.58)**	-0.20 (0.10, -0.49)	-0.11 (0.02,-0.24,)	**-0.70 (-0.14, -1.26)**	**6.4 (3.0, 9.7)**	**5.9 (2.5, 9.3)**	0.03 (0.07, -0.01)	**-0.09 (-0.05, -0.12)**
Joint Mixed Model	**-0.46 (-0.30, -0.62)**	-0.22 (0.08, -0.53)	-0.12 (0.01, -0.26)	**-0.73 (-0.14, -1.33)**	**7.6 (4.1, 11.1)**	**6.2 (2.7, 9.8)**	0.03 (0.07, -0.01)	**-0.09 (-0.05, -0.14)**

*Average slope (linear rate of change of the test per year). Linear mixed model includes time, random intercept and slope. For joint model, dropout was accounted for when estimating the slope. A negative coefficient indicates worsening performance for all tests except for Trails A&B, where a positive coefficient indicates worsening performance. Significant results are highlighted in bold.

Conclusions: Hemodialysis patients have significant declines in cognitive performance over time, particularly within tests of executive function. Future studies should evaluate predictors of decline and strategies to maintain cognitive function.

Funding: NIDDK Support, Private Foundation Support

SA-PO1049

Frailty and Cognitive Function in Incident Hemodialysis Patients Mara Mcadams-DeMarco,[1] Jingwen Tan,[1] Megan Salter,[1] Andrew Law,[1] Lucy A. Meoni,[1] Bernard G. Jaar,[1] Wen Hong Linda Kao,[1] Rulan S. Parekh,[2] Dorry L. Segev,[1] Stephen M. Sozio.[1] *[1]Johns Hopkins; [2]Univ of Toronto.*

Background: Cognitive impairment is an important outcome in hemodialysis (HD) patients. While frail older adults without kidney disease are at risk for poor cognitive function, it is unclear whether frail HD initiates are more likely to develop poor cognitive function.

Methods: At cohort entry 323 adult HD patients from PACE were classified into 3 groups (frail, intermediately frail, and nonfrail [Fried *et al*]). Global cognitive function (3MS) and executive function (Trail Making Tests A (TMTA) and B (TMTB)) were assessed at cohort entry and 1-year follow-up. All tests were performed on a non-dialysis day. Associations between frailty and cognitive function were evaluated in adjusted (for sex, age, race, BMI, education, depression and comorbidity at baseline) linear (3MS, TMTA) and tobit (TMTB) regression models.

Results: At baseline, mean age was 55 (SD=13), with 57% male, 73% AA, 22% prior CVD, and 18% prior stroke. Prevalence of frailty was 34.2% and 37.3% intermediate frailty; mean (SD) of 3MS was 89.6 (8.2), of TMTA was 55.6 (30) and of TMTB was 161 (83). Frailty was independently associated with worse cognitive function at baseline and 3MS at 1-year follow-up.

Table: Adjusted Association of Frailty at Hemodialysis Initiation and Cognitive Function

Baseline	Non-Frail	Intermediately Frail	Frail	P for Trend
3MS (n=319)	Ref	-0.97 (-2,89, 0.95)	**-3.01 (-5.00, -1.02)**	**0.003**
Trail Making Test A (n=323)	Ref	5.98 (-1.20, 13.17)	**12.62 (5.09, 20.14)**	**0.001**
Trail Making Test B (n=316)	Ref	19.78 (-2.49, 42.04)	**33.74 (10.34, 57.14)**	**0.005**
1-year follow-up				
3MS (n=155)	Ref	-1.54 (-4.15, 1.08)	**-4.02 (-6.70, -1.33)**	**0.003**
Trail Making Test A (n=174)	Ref	2.74 (-8.44, 13.92)	3.41 (-8.42, 15.23)	0.57
Trail Making Test B (n=170)	Ref	7.15 (-24.16, 38.46)	16.32 (-17.05, 49.68)	0.33

3MS: lower is worse
TMTA and TMTB: higher is worse
Bold is statistically significant (P<0.05)

Conclusions: In adults HD patients, frailty is associated with decrements in cognitive function, particularly global cognitive function. Frail HD patients should be screened for cognitive function and potentially targeted for interventions to improve cognitive function.

Associations of Different Definitions of Frailty with Adverse Outcomes among Prevalent Hemodialysis Patients Kirsten L. Johansen, Lorien S. Dalrymple, Glenn M. Chertow, George A. Kaysen, John Kornak, Barbara A. Grimes, Cynthia Delgado. *USRDS Nutrition Special Studies Center, UCSF, San Francisco, CA.*

Background: Frailty is a state of impaired homeostatic reserve that is associated with vulnerability to adverse health outcomes. Many definitions have been applied among patients with ESRD, and their relative value has not been explored.

Methods: We defined frailty using criteria developed and validated by Fried and colleagues: three or more of weight loss, exhaustion, weakness, slow gait speed, and low physical activity. We compared this "performance-based" definition to one that substituted low self-reported physical function (score <75 on the Physical Function scale of the SF-36) for the performance criteria (weak grip and slow walking) among 709 participants in the USRDS ACTIVE/ADIPOSE cohort study. We used multivariable time-dependent Cox proportional hazards modeling (adjusting for demographics, comorbidity, and type of vascular access) to compare the degree to which each definition served as an independent predictor of mortality. We also evaluated a step-wise approach using both definitions, dividing patients into three groups: not frail, frail by self-report only, and frail by self-report and performance-based definitions.

Results: 33% of patients met the performance-based definition of frailty, and 54% met the self-report-based definition at baseline. Median follow-up was 1.7 (IQR 1.4-2.4) years, and there were 92 deaths. Both definitions of frailty predicted mortality (HR 1.74 [95% CI 1.07 – 2.80] for self-report and HR 2.20 [95% CI 1.42 – 3.40] for performance-based). Considering both definitions together, there was a graded association across the three categories that persisted after multivariable adjustment (HR 1.51 [0.82 – 2.80] for self-report only and 2.40 [1.38 – 4.00] for the group meeting both definitions) compared with the non-frail group.

Conclusions: Our findings suggest that a frailty definition based on self-report measures, most of which are already collected in dialysis facilities, was associated with higher mortality. Testing physical performance among those meeting the self-report-based definition could identify patients at even higher risk.

SA-PO1051

Feasibility of Clinical Studies in Haemodialysis Patients - Influence of Cognition and Frailty Osasuyi A. Iyasere,[1] Graham D. Cole,[2] Jordan Abdi,[2] David Andrew Williams,[2] Megan Griffith,[1] Neill D. Duncan.[1] *[1]Imperial College Renal and Transplant Centre, United Kingdom; [2]Imperial College, London.*

Background: Studies have reported better outcomes in patients who participate in clinical research, but the underlying risk factors are unclear. Cognitive impairment and frailty, common in haemodialysis (HD) patients, often preclude recruitment into clinical studies. The outcomes from such studies may therefore not be generalizable. This observational study evaluated the relationship between the 2 variables, research interest and short term clinical outcomes.

Methods: HD patients were evaluated from a single UK centre. Executive function and frailty were assessed using the CLOX 1 test and the Canadian Study of Health and Aging Frailty scale respectively. An independent assessor evaluated their willingness to take part in research. They were thus classified into three groups- interested in research (IR), not interested (NR) and could not consent due to language barrier or lack of capacity (CC). Hospitalisation and mortality data were collected over 6 months. Regression analysis was used to evaluate the relationship between cognition, frailty and outcomes.

Results: 102 patients (median age - 71 years) were assessed. 57.8%, 31.4% and 10.8% were in the IR, NR and CC groups respectively. There was no significant difference in the prevalence of executive dysfunction (47% IR, 40% NR, 83.3% CC,p=0.16) or frailty (46% IR, 47% NR, 73% CC,p=0.25) between the groups. Multinomial logistic regression analysis showed higher CLOX1 scores where associated with a lower risk of being in the CC group (OR-0.691, p=0.014).Age, sex, comorbidity, dialysis vintage and frailty were not influential. There was no difference in admission rates (p=0.54), length of stay (p=0.92) and time to first admission (p=0.56). There were no deaths in this cohort.

Conclusions: Frailty and executive function did not influence the willingness to participate in research but lower CLOX1 scores were associated with incapacity and language barrier. There were no differences in short term outcomes between those interested in research and those who were not.

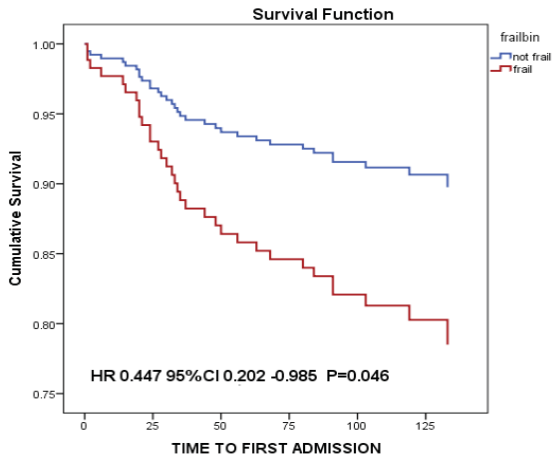
SA-PO1052

Executive Dysfunction and Frailty in a Dialysis Population - Correlates and Outcomes Osasuyi A. Iyasere,[1] Graham D. Cole,[2] Jordan Abdi,[2] David Andrew Williams,[2] Megan Griffith,[1] Neill D. Duncan.[1] *[1]Imperial College Renal and Transplant Centre, London, United Kingdom; [2]Imperial College, London, United Kingdom.*

Background: Cognitive impairment and frailty are common in the haemodialysis (HD) population. They have been linked to mortality and hospitalisation. Executive function is the most affected cognitive domain in HD patients. Little is known about the impact of executive dysfunction on clinical outcomes. We report the results of a 6 month observational study evaluating the risk factors and outcomes associated with executive dysfunction and frailty in HD patients.

Methods: Adult HD patients from a single UK centre, were assessed for executive dysfunction and frailty using the CLOX1 test and Canadian Study for Health and Aging Frailty scale, respectively. Clinical data were collected over 6 months from medical records. Logistic and Cox regression analysis were used to evaluate risk factors and outcomes. Survival and hospitalisation were the clinical outcomes evaluated.

Results: 213 HD patients were evaluated [median age(IQR) 69(22) years, 55% Asian]. 43% had executive dysfunction (CLOX 1 <10) and 53% were frail. Age (OR-1.032,p=0.037) and dialysis vintage (OR- 1.011, p=0.031) were associated with executive dysfunction. Admission rates were higher in the frail group (17%) than in the non frail group (7%, p=0.019). The frail group were less likely to be admission free in a Cox regression model adjusting for age, sex, ethnicity, dialysis vintage and comorbidities.



There was no difference in mortality between the groups but event rates were low (n=3). Executive dysfunction did not affect clinical outcomes.

Conclusions: Age and dialysis vintage were associated with executive dysfunction in HD patients. Frailty was associated with a higher risk of hospitalisation over 6 months, but not executive dysfunction. Event rates were too low to evaluate their influence on mortality.

SA-PO1053

Frail Elderly Patient Outcomes on Dialysis (FEPOD) - A Cross Sectional Comparison of Assisted Peritoneal Dialysis with Haemodialysis Osasuyi A. Iyasere, Lina Johansson, Edwina A. Brown. *Imperial College Renal and Transplant Centre, London, United Kingdom.*

Background: Assisted peritoneal dialysis (aPD) is an emerging alternative to haemodialysis (HD), the prevalent modality for older UK patients. But its use is limited by lack of patient reported outcome (PRO) data. FEPOD part 1, a multicentre cross-sectional study, compared quality of life and physical function on aPD and HD in older patients. It showed that frailty and not dialysis modality, determined outcomes. FEPOD part 2 is an on-going 2 year longitudinal study measuring trajectories of these outcomes .We report the baseline results from the combined group (FEPOD 1 and 2), to evaluate the consistency of our initial findings.

Methods: Patients >60 years old, on dialysis for >3 months were recruited from 23 centres. HD patients (needing hospital transport) were matched to aPD patients (needing assistance to perform PD) by age, sex, diabetes status, dialysis vintage, ethnicity and index of deprivation. Frailty was assessed using the Canadian Study of Health and Aging Frailty scale. PRO assessments included Hospital Anxiety and Depression Scale (HADS), SF-12, Palliative Outcomes Symptom scale (renal), Illness Intrusiveness Rating Scale (IIRS) and Barthel's score.Outcome predictors were determined by regression analysis with p values adjusted for multiplicity.

Results: We recruited 250 patients (129 aPD, median age 75years; 121 HD, median age 76years). Frailty was more common in aPD patients (51.9%) than in HD patients (42.6%). Univariate analysis showed possible depression (HADS >8) was more common in the aPD group (38.8%) compared to HD (23.8%, p=0.051), with no differences in other PROs. Frailty was the predominant predictor of PROs after multivariate analysis using a generalised linear model (SF 12 MCS p=0.0015, p =0.0008 for SF12 PCS, IIRS, Symptom score, HADS, Barthel score respectively). It was also associated with possible depression in logistic regression analysis (p < 0.001).Dialysis mode was not influential.

Conclusions: The results confirm that frailty determines outcomes in older and frail patients, not dialysis modality. Assisted PD should therefore be made more available, allowing patients to choose their optimal dialysis modality.

SA-PO1054

Frail Elderly Patient Outcomes on Dialysis (FEPOD) Study: A Baseline Analysis of Secondary Outcomes Osasuyi A. Iyasere, Lina Johansson, Edwina A. Brown. *Imperial College Renal and Transplant Centre, London, United Kingdom.*

Background: Assisted peritoneal dialysis (aPD) is an emerging alternative to haemodialysis (HD) for frail older patients in the UK. A lack of outcome data has limited its use. FEPOD study part 1, a multicentre cross-sectional observational study showed a high falls and hospitalisation burden regardless of modality. FEPOD part 2 is the ongoing longitudinal study evaluating the trajectory of these outcomes. We report on the secondary outcomes of falls, hospitalisation and patient satisfaction for the combined cohort (FEPOD 1 and 2) at baseline.

Methods: Patients >60 years old, on dialysis for >3 months were recruited from 23 centres. HD patients (requiring hospital transport) were matched to aPD patients (requiring assistance to perform PD) by age, sex, diabetes status, dialysis vintage, ethnicity and Index of Deprivation. Frailty was assessed using the Canadian Study of Health and Aging Frailty scale. Patients were given a falls questionnaire, the Renal Treatment Satisfaction questionnaire (RTSQ) and a health use proforma to evaluate secondary outcomes.

Results: 250 (129aPD; 121HD) patients were recruited at baseline. 33 % of the entire cohort sustained at least one fall in the preceding 6 months (34% aPD, 32% aPD, p=0.717). 11 patients had subsequent fracture (14% of falls). 46% of all patients were admitted to hospital in the preceding 3 months with 42% being dialysis related admissions. There was no significant difference in admission rates between aPD and HD. The median RTSQ score was higher in the aPD group (55) than in the HD group (51, p= 0.012). Dialysis modality was the only predictor of RTSQ in multivariate analysis (p=0.029).But over 90% of the study group, regardless of modality, would recommend their treatment to others.

Conclusions: These results confirm the high falls, fracture and hospitalisation rates in older patients on dialysis, regardless of modality. The morbidity burden associated with dialysis in this group should be highlighted when discussing renal replacement therapy. Treatment satisfaction was higher in the aPD group, but this did not influence recommendation rates.

SA-PO1055

Frailty and Mortality in Dialysis: Evaluation of a Clinical Frailty Scale Talal A. Alfaadhel, Karthik K. Tennankore. *Dept of Medicine, Div of Nephrology, Dalhousie Univ, Halifax, NS, Canada.*

Background: Frailty is associated with poor outcomes for dialysis patients; however, the severity of frailty is not captured by previous measurement tools. The purpose of this study was to assess if frailty (as defined by a clinical frailty scale) was associated with mortality among incident dialysis patients.

Methods: We conducted a prospective cohort study of incident, chronic dialysis patients between January 2009 and June 2013, (last follow-up December 2013). Based on overall clinical impression, the Canadian Society of Health and Aging Clinical Frailty Scale (CFS) score, was determined for patients at the start of dialysis by their primary nephrologist. The CFS allocates a single point to different states of frailty (1:very fit, 2: well, 3: managing well, 4: vulnerable, 5: mildly frail, 6: moderately frail, 7: severely frail or terminally ill) based on physical, functional and cognitive status. The primary outcome was time to death. Patients were censored at the time of transplantation.

Results: The cohort consisted of 390 patients with completed CFS scores (mean age 63±15 years). The majority were Caucasian (89%) and male (67%) and 30% had end stage renal disease (ESRD) due to diabetic nephropathy. The median Charlson Comorbidity Index (CCI) score was 4 (IQR 3-6) and the median CFS score was 4 (IQR 2-5). There were 96 deaths over 750 patient-years at risk. Using an adjusted multivariable Cox survival analysis

the HR associated with each one-point increase in the CFS was 1.24 (95% confidence interval 1.06-1.46), p=0.009.

Model	Number exposed / Events	HR	95% CI	P
Unadjusted	390 / 96	1.42	1.25-1.61	<0.001
Model 1[a]	390 / 96	1.32	1.15-1.52	<0.001
Model 2[b]	390 / 96	1.30	1.12-1.51	<0.001
Model 3[c]	390 / 96	1.24	1.06-1.46	0.009

a: adjusted for age, race and sex
b: adjusted for variables in a, CCI ≥ 5 and diabetic ESRD
c: adjusted for variables in b, GFR, albumin, BMI and dialysis modality

Conclusions: Frailty as defined by the CFS is associated with mortality in dialysis. The CFS is easy to implement in routine clinical practice and may be a novel prognostic tool for incident dialysis patients.

SA-PO1056

A Comparison of Stroke Incidence between Patients Initiating Hemodialysis and Peritoneal Dialysis in Korea Dong-Ryeol Ryu,[1] Hyunwook Kim,[2] Hee Sung Ko,[1] Shina Lee,[1] Jung-Hwa Ryu,[1] Mina Yu,[1] Seung-Jung Kim,[1] Duk-Hee Kang,[1] Kyu Bok Choi.[1] *[1]Dept of Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Korea; [2]Dept of Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gunpo, Korea.*

Background: We aimed to compare the stroke incidence between incident hemodialysis (HD) patients and peritoneal dialysis (PD) patients using the Korean Health Insurance Review and Assessment Service database, which enabled us to perform a population-based complete survey.

Methods: We initially identified all of the incident dialysis patients who had started HD or PD and whose age was 18 years or older between January 1, 2005 and December 31, 2008 in Korea. Among them, the patients who were dead or developed any kind of strokes within 90 days from the date of dialysis were excluded; the remaining eligible 30,828 patients were included in the final analyses. Patients who underwent kidney transplantation, who were dead during follow-up period, or who survived until December 31, 2009 were censored.

Results: During the median follow-up period of 24.7 months, incidence rates of total stroke (P=0.0014), hemorrhagic stroke (P=0.0017), and ischemic stroke (P=0.0341) were significant higher in HD patients than those in PD patients by log-rank test. In addition, after adjustments with baseline characteristics in multivariate Cox analysis, hazard ratio of hemorrhagic stroke in HD patients was significantly higher than that in PD patients (HR, 1.217; 95% CI, 1.032-1.434; P=0.0194), while there were no significant differences in hazard ratios of total stroke and ischemic stroke between HD and PD patients.

Conclusions: The risk of hemorrhagic stroke in Korean HD patients was increased compared to PD patients. The possible causes should be evaluated and a countermeasure will be needed.

SA-PO1057

Serum Sodium, Cognition and Mortality in Hemodialysis (HD) Patients Urvi Ajay Shah, Amy Kantor, Hocine Tighiouart, Daniel E. Weiner, Tammy Scott, David A. Drew, Mark J. Sarnak. *Dept of Nephrology, Tufts Medical Center, Boston, MA.*

Background: Cognitive impairment is highly prevalent in HD patients. Hyponatremia has been associated with cognitive impairment in the general population and may be associated with mortality in HD patients.

Methods: The mean of 3 serum sodium (Na) measurements, approximating the timing of cognitive testing, was ascertained in 323 patients. All patients underwent a battery of previously validated cognitive tests. Principal factor analysis (PFA) was used to derive two summary factors representing memory and executive function. Multivariable linear models were used to assess the relation of Na to each PFA score in cross sectional analysis, and multivariable cox models were used to evaluate the association of Na with all-cause mortality.

Results: Mean (SD) age was 62.3 (16.5) years, 46% were women and 22% were blacks. Median (interquartile range) Na was 139.3 (137.3-140.7) mEq/L. Median length of follow up was 2.1 years and there were 154 deaths. There was no significant association between serum Na and cognitive function (p>0.1 for all analyses). Lower Na was however independently associated with higher mortality.

Association of serum sodium with all-cause mortality

	Unadjusted HR (95% CI)	Demographic adjusted* HR (95% CI)	Risk factor adjusted** HR (95% CI)	Adjusted for † HR (95% CI)
Sodium Linear (per 1 SD = 2.6 mEq/L ↑)	0.81 (0.68-0.96)	0.79 (0.67-0.93)	0.77 (0.65-0.92)	0.80 (0.67-0.96)
Quartiles median (p25, p75)				
Q1 136.3 (135.0, 136.7)	1.57 (1.00-2.45)	1.61 (1.03-2.52)	1.65 (1.03-2.64)	1.59 (0.99-2.58)
Q2 138.3 (138.0, 139.3)	0.83 (0.52-1.32)	1.00 (0.63-1.60)	0.83 (0.51-1.36)	0.77 (0.47-1.26)
Q3 140.3 (140.0, 140.7)	1.22 (0.76-1.95)	1.02 (0.63-1.64)	1.04 (0.64-1.68)	1.03 (0.64-1.67)
Q4 142.0 (141.3, 142.7)	1.00 (ref)	1.00 (ref)	1.00 (ref)	1.00 (ref)

*Adjusted for age, gender and race
**further adjusted for dialysis vintage, cause of ESRD (diabetes vs rest), dialysis access (fistula vs rest), PVD/CAD/stroke/HF and smoking
†further adjusted for Kt/V, albumin and CRP

Conclusions: Serum Na is not associated with cognitive impairment in HD patients, but lower Na values, even within the normal range, are associated with higher mortality.

Funding: NIDDK Support

SA-PO1058

Rates of Infection in Patients Treated with Dialysis Seth Wright,[1] Mark J. Sarnak,[1] Klemens B. Meyer,[1] David Richard Snydman,[1] Vladimir Ladik,[2] Hocine Tighiouart,[1] Doug Johnson,[2] Daniel E. Weiner.[1] *[1]Tufts Medical Center, Boston; [2]Dialysis Clinic, Inc., Nashville.*

Background: Infections in patients treated with dialysis are associated with substantial morbidity and mortality, but their incidence rates, patterns and potential risk factors are poorly described.

Methods: Infections (defined as a positive blood culture or peritonitis; ≥5 days of in-center antibiotics or an out-of-center oral, IV, or intraperitoneal (IP) antibiotic order; or hospitalization or death with an infection-related code) were evaluated in all patients treated by a large U.S. dialysis provider (DCI) from Oct 2009-Dec 2012. Dialysis modality and vascular access were defined by those in use at the time of an event. Cox regression was used to evaluate risk factors for infection.

Results: A total of 27,394 patients contributed 42,798 pt-years of data. In the study period, 30% of patients died with 13% of the deaths listing infection as a primary or secondary cause. The most common infections causing hospitalization were pneumonia (30%), bacteremia/sepsis (17%), and cellulitis/soft tissue (15%).

Outcome	Catheter	Fistula	Graft	Peritoneal
Antibiotic course	13.07 (12.85-13.28)	5.84 (5.75-6.08)	6.77 (6.61-6.94)	8.49 (7.74-9.28)
Parenteral only	7.92 (7.75-8.09)	2.10 (2.05-2.16)	2.74 (2.64-2.85)	6.23 (6.00-6.46)
Hospitalization-infection	3.44 (3.33-3.55)	1.58 (1.53-1.63)	1.77 (1.69-1.86)	2.38 (2.24-2.53)
Positive blood culture	5.90 (5.75-6.10)	0.66 (0.63-0.69)	0.96 (0.90-1.03)	
Peritonitis				3.23 (3.06-3.39)
Death-infection	0.50 (0.46-0.54)	0.18 (0.17-0.20)	0.25 (0.22-0.28)	0.22 (0.18-0.27)

Rates of infectious outcomes by modality per 100 pt-months (95% CI). For each outcome, rates differed between dialysis modalities (p<0.001). Rates were similar when limited to incident patients only (44%). In multivariable analysis, risk factors for infection (as a composite of the above outcomes; antibiotics limited to IV/IP) included: HD catheter [HR 2.83 (2.73-2.94)] or PD [HR 2.09 (1.98-2.19)] versus fistula; ESRD from diabetes [HR 1.23 (1.19-1.28)] versus hypertension; and white race [HR 1.16 (1.12-1.20)] versus black.

Conclusions: These detailed, modality-specific data provide background information on the rate and type of fatal and non-fatal infections in dialysis patients. Pneumonias and cellulitis made up nearly half of the infectious admissions. Exploring risk factors associated with these specific infections may be of interest.

Funding: NIDDK Support, Pharmaceutical Company Support - Dialysis Clinic, Inc.

SA-PO1059

Efficacy of Interferon Therapy in HCV Positive Patients on Haemodialysis Fizza Kazmi,[1] Hafiz I. Ahmad,[1] Syed Rizwan Bokhari,[1] Arif Asif.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College, Lahore, Pakistan; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: In Pakistan, the prevalence of hepatitis C is very high in dialysis patients than the general population, 38% weighted average (23.7-68%). Pegylated interferon in combination with ribavirin is recommended treatment for most patients with chronic hepatitis C infection without renal dysfunction. Because ribavirin and pegylated interferon are not removed adequately by hemodialysis, only standard non-pegylated interferon alfa (IFNa) is used in ESRD patients. However, limited data are available regarding the efficacy of this approach. We studied the IFNa alone therapy in our chronic hepatitis C patients receiving maintenance hemodialysis.

Methods: All 22 Hepatitis C positive patients undergoing maintenance hemodialysis in our center were included in this study. PCR revealed that 14 patients were positive

for hepatitis C viral RNA. Of these, two were excluded on clinical grounds and 12 were considered suitable for treatment. IFNa in a dose of 3 million i.u. thrice weekly was given to these patients.

Results: Of the 12 patients who received treatment, 2 were dropped out due to treatment side effects mainly pancytopenia and thrombocytopenia, and 3 developed decompensated liver disease during therapy and hence their treatment was stopped. Seven patients completed the treatment. Four patients became PCR negative as an early response and completed 6 months therapy. Three patients received an extended course of IFNa for 8 months and became PCR negative.

Conclusions: Interferon therapy in hepatitis C positive hemodialysis patients is effective. However, the number of patients who are unfit for therapy and the dropout rate due to intercurent illnesses and side effects is quite high.

SA-PO1060

Combination Pegylated Interferon Alpha-2A and Ribavirin in the Treatment of Hepatitis C in End Stage Renal Disease Patients - A Single Centre Experience Sai Krishna Duraisingham,[1] Richard Marley,[2] Raj C. Thuraisingham,[1] Mark Blunden.[1] *[1]Dept of Nephrology, Barts Health NHS Trust, London, United Kingdom; [2]Hepatology, Barts Health NHS Trust, United Kingdom.*

Background: Hepatitis C is a leading cause of liver disease in patients with ESRD with associated morbidity and mortality. Outcomes of renal transplantation in such patients are improved if patients are rendered RNA negative pre-transplant. Historically, treatment with pegylated Interferon (IFN) and Ribavirin (Rib) has been discouraged due to concerns regarding reduced clearance on haemodialysis and the side effect profile. The primary purpose of this study was to assess the success of IFN/Rib in achieving sustained viral remission when treatment was supervised in a joint Renal/Hepatology clinic. Successful renal transplantation was examined as a secondary outcome.

Methods: 39 Patients with HCV were identified from our hospital database. Demographic, dialysis modality, virology, treatment regime, side effect profile and transplantation data were recorded. All patients were followed-up by a hepatitis nurse specialist and supervised by the joint liver-renal clinic. Dose of ribavarin was titrated up to maximal tolerated dose and full blood count was measured weekly. EPO/iron treatment was modified accordingly.

Results: 22 dialysis patients were identified as having been treated, 17 were not treated due to not needing treatment (eg not transplantable or pre-dialysis) or unable to undergo treatment (compliance issues or patient choice). Sustained viral response was achieved in 14 patients which when broken down by genotype were comparable to general population results for interferon and ribavarin regimes. 8 of these patients underwent successful transplantation as did 1 patient who had failed treatment, after a biopsy showed no fibrosis.

Conclusions: With close monitoring ribavirin is safe to use in the ESRD population and allows comparable sustained viral response rates to non-ESRD population. At present newer agents are yet to be fully studied in this group and as yet their promise is mainly in genotype 1 hepatitis C. These agents hold promise of interferon free treatments and will allow post transplant treatment too in a selected sub-group.

SA-PO1061

Positive HBV and HCV Status Exhibit Pronounced Iron Metabolism Disturbances and Higher Phosphate Levels Jolanta Malyszko,[1] Andrzej Milkowski,[2] Teresa Rydzynska.[2] *[1]2 Dept Nephrology, Medical Univ, Bialystok, Poland; [2]Fresenius Medical Care, Poznan, Poland.*

Background: Iron status in patients on dialysis is disturbed. Iron metabolism is regulated by number of factors including inflammation, hepcidin, liver function, diet etc. Viral infection i.e. hepatitis, still present in dialyzed patients may affect liver function. In animal model hepatectomy is related to hypophosphatemia. The aim of the study was to find out whether iron status, phosphate levels and hemoglobin are affected by presence of viral hepatitis in hemodialyzed patients.

Methods: Biochemical parameters and viral status were assessed by standard laboratory methods.

Results: The study was performed on 5058 patients dialyzed in Fresenius Medical Care facilities in Poland. 55 patients were hepatitis B antigen positive, 150 had antibodies against HCV and 6 patients were positive for both viruses. We analysed serum haemoglobin, TSAT, ferritin, albumin, phosphate in prevalent patients. HCV and HBV positive patients were the youngest among studied groups (mean age 42), HBV (mean age 52) and HCV positive patients (mean age 55) were also significantly younger than negative patients (mean age 66 years). HBV and HCV positive patients have significantly higher ferritin (median 883 ng/mL, TSAT (mean 47%), albumin (4.11 g/dL) and phosphate (5.87 mg/dL) relative to negative patients and HBV or HCV positive subjects. HCV positive patients have higher significantly phosphate and haemoglobin levels than negative patients (5.20±1.58 mg/dL versus 4.71±1.56 mg/dL, $p<0.01$ and 11.05±1.45 g/dL versus 10.80±1.91 g/dL, $p<0.05$, respectively), while HBV positive patients had higher albumin than negative patients 4.1±0.5 g/dL versus 3.9±0.4 g/dL, $p<0.05$). TSAT were similar in patients with HBV, HCV and negative for both viruses.

Conclusions: Prevalence of viral hepatitis is very low (below 4%) in total HD population studied, mainly found in younger patients. However, patients with HCV and HBV infection showed a very different pattern of iron metabolism and phosphate levels. Hyperferritinemia in this population may be due to previous blood transfusions and/or enhanced chronic inflammatory process in the liver.

SA-PO1062

Cystatin C and Risk of Sepsis T. Clark Powell,[4] Orlando M. Gutierrez,[1] Russell Griffin,[2] John P. Donnelly,[4] Monika M. Safford,[3] Henry E. Wang.[4] *[1]Div of Nephrology, Univ of Alabama School of Medicine; [2]Dept of Epidemiology, Univ of Alabama School of Medicine; [3]Div of Preventive Medicine, Univ of Alabama School of Medicine; [4]Dept of Emergency Medicine, Univ of Alabama School of Medicine, Birmingham, AL.*

Background: Chronic kidney disease (CKD) and systemic inflammation are risk factors for sepsis. While often viewed as a marker of chronic kidney disease, Cystatin-C (Cyst-C) may also reflect systemic inflammation. We sought to determine the association between baseline Cyst-C and long-term rates of community-acquired sepsis, and to determine if this relationship is influenced by traditional markers of CKD (eGFR, ACR) and inflammation (hsCRP).

Methods: We used 10 years of data on 30,239 adults ≥45 years old from the REasons for Geographic and Racial Differences in Stroke (REGARDS) cohort, identifying sepsis events through hospital records. Using multivariable Cox regression, we examined the independent association of increased Cyst-C with long-term rates of sepsis, adjusting for sociodemographics, health behaviors, and chronic medical conditions. We also evaluated the influence of eGFR, ACR and hsCRP upon the association between Cyst-C and sepsis rates.

Results: Among 28,095 individuals, mean Cyst-C were: sepsis 1.24±0.72 mg/dL, non-sepsis 1.03±0.45 mg/dL. Over a median follow-up of 6.7 years (IQR 5.2-8.2), 1,405 participants experienced a sepsis hospitalization. Cyst-C≥1.11 mg/dL was independently associated with increased sepsis rates (adjusted HR 1.79; 95% CI: 1.59-2.03). The addition of eGFR<60 mg/min/1.73m^2 (HR 1.53; 95% CI: 1.32-1.77), ACR≥30 mg/dL (1.47; 1.29-1.67), and hsCRP>3.0mg/dL (1.55; 1.38-1.74) only partially influenced the association between Cyst-C≥1.11 mg/dL and sepsis (1.52; 1.32-1.74).

Conclusions: Cyst-C is associated with long-term rates of sepsis, independent of eGFR, ACR or hsCRP. Cyst-C may provide a strategy for long-term sepsis risk prediction and prevention.

SA-PO1063

Senior Patients on Hemodialysis - Are They an Economic Burden? Teresa M. Jeronimo, Anabela M. Guedes, Ana Pocinho Pimentel, André Fragoso, Ana Cabrita, Ana Paula Silva, Viriato J.V. Santos, Idalecio Bernardo, Pedro Neves. *CHA.*

Background: With a longer life expectancy older patients face dialysis. A trend for guarantying only conservative treatment has been advocated, not only due to health care related issues, but also due to financial contingencies. Do these patients portent a higher economic burden? The aim of this study was to evaluate and compare the hemodialysis(HD) related expenditure of a senior population during the first year of treatment.

Methods: This study considered incident HD patients at our Centre, between 2008 and 2011. Serial laboratory data were collected at dialysis initiation and monthly until 12 months of follow-up. Costs were calculated based on the Portuguese capitation system. T-test for variable comparison and Kaplan-Meier for survival were used in the statistical analysis.

Results: A total of 201 patients(77 females,124 males), with mean age of 65.0 years, previous nephrology follow-up time of 32.5 months and one-year survival on HD were included. Group I(n=61), which included patients with 75 years or older, started HD earlier(eGFR 9.7 versus 8.0 mL/min/1.73m2,p=0.003) and presented initial lower PTH levels(525.6 versus 796.1 pg/mL,p=0.011). There were no differences on hemoglobin, phosphorus or albumin levels. This group presented lower global expenditure at 6 and 12 months evaluations(3849.3 versus 4791.6 euros/patient, p=0.045 and 6511.2 versus 8230.0 euros/patient,p=0.031), respectively. These differences result mainly from the mineral metabolism related medication(818.7 versus 1511.4 euros/patient/year,p=0.005), for an equal control of PTH and lower phosphorus levels(3.9 versus 4.1 mg/dL,p=0.007). Anemia related costs are similar and both groups evolved with similar hemoglobin. Lower albumin levels were detected in the group I(3.8 versus 4.1 g/dL,p=0.001). Despite survival being higher in group II(n=124) which included patients younger than 75 years old(log rank=3.9,p=0.049), there were no differences in hospitalization rate or duration.

Conclusions: In conclusion, older patients start dialysis sooner, with lower PTH levels. Through the first year on HD exhibit lower medication cost(mainly due to mineral bone disease related medication) and equal hospital related expenses and morbidity.

SA-PO1064

Diagnostic Utility of Gait Speed for Predicting Hemodialysis Patient Outcomes Nancy G. Kutner,[1,2] Rebecca H. Zhang,[1,3] Yijian Huang.[1,3] *[1]USRDS Rehabilitation/QoL Special Studies Center, Emory Univ, Atlanta, GA; [2]Rehabilitation Medicine, Emory Univ, Atlanta, GA; [3]Biostatistics/Bioinformatics, Emory Univ, Atlanta, GA.*

Background: Impaired mobility has personal and social burdens, and increased mortality risk with gait speed <0.8 meters/second (m/s) has been shown among individuals with chronic kidney disease. In clinical care for older persons, routinely measuring usual walk speed is increasingly advocated, and dismobility defined by gait speed of <0.6 m/s, <0.8 m/s, and <1.0 m/s has been shown to predict a variety of adverse outcomes. Information is needed about the predictive utility of gait speed for dialysis patient outcomes.

Methods: In the USRDS special study ACTIVE-ADIPOSE, we assessed baseline gait speed 2009-2011 in a multi-center cohort of 752 prevalent patients aged 20-92 undergoing maintenance hemodialysis (HD). Baseline gait speed and mortality over a median follow-up of 703 days were investigated in a Cox proportional hazards model, and associations with

hospitalization, need for ADL assistance, and SF-36 Physical Functioning (PF) score at a 12-month follow-up were estimated in multivariable logistic or linear regression models, adjusting for age, sex, and baseline value of the outcome.

Results: Slow gait speed prevalence increases with age and is higher among women, but the difference between HD patients and the general population in prevalence of slow gait speed is much greater at younger ages. Compared with study participants whose walk speed was 0.6 m/s or faster, participants with walk speed <0.6 m/s (n=94) were almost twice as likely to die, and those who were unable to perform the walk test (n=83) were over five times more likely to die. Risks for hospitalization, ADL difficulty, and lower SF-36 PF score after 12 months were greater for those with walk speed 0.6 to <1.0 m/s compared with participants whose walk speed was 1.0 m/s or faster.

Conclusions: Walking places demands on the heart, lungs, circulatory, nervous, and musculoskeletal systems, and gait speed can provide a validated, easily measured and informative marker of dialysis patients' health. The predictive utility of gait speed warrants continued study in this population.

SA-PO1065

Right TraC Is Associated with Improved Patient Experience of Care during Care Transitions Rebecca L. Wingard,[1] Kathryn A. McDougall,[1] Billie Axley,[1] Andrew D. Howard,[2] Janice B. Sitzlar,[1] Sharon Deluca,[1] John W. Larkin,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America (FMCNA), Waltham, MA; [2]Metropolitan Nephrology Associates, Clinton, MD.*

Background: Patient-centered care requires strategies to improve patient (pt) activation. The ongoing Right TraC™ Care Transitions Program includes such strategies aimed at reducing hospital readmissions. This is an interim analysis of Phase I data of the Right TraC Patient Experience Survey.

Methods: As of Apr 2013, 28 HD clinics in the U.S. participate in Right TraC, Phase I. Staff use hospital admit and post-hospitalization checklists, which include enhanced exchange of pt information, rapid anemia management, nutrition supplements, target weight assessment, medication review, pt counseling for attending appointments, "red flag" symptoms of illness and readmission prevention strategies for the same diagnosis. Teach-back technique is used to review why pts were hospitalized and their role after discharge. Clinic secretaries were trained to administer the survey on the third outpatient treatment after discharge. We compared results from Q2 2013 to Q1 2014 using ANOVA.

Results: Pts responded to each question with "yes", "somewhat", or "no." These responses were converted to a scale of 0-100% and summarized by calendar quarter (yes=100%, somewhat=50%, no-0%). Approximately 350 surveys were completed per quarter with an average response rate of 30%.

Question	Q2, 2013	Q3, 2013	Q4, 2013	Q1, 2014	Change from Q2 2013 to Q1 2014	p-value for difference between Q2 2013 and Q1 2014
Can you explain why in hospital?	88.2	95.2	96.3	97.0	9.95%	<.0001
Did nurse teach about new meds in a way you could understand?	81.3	89.0	89.8	91.8	12.90%	<.0001
Know what your meds do for you?	74.3	82.1	83.3	82.4	10.91%	0.005
Can act on Red Flag symptoms?	76.8	84.9	85.6	75.0	-2.29%	NS
Can follow discharge instructions?	85.8	96.4	95.1	95.3	10.98%	<.0001
Can ask questions of healthcare team?	91.6	99.3	98.9	98.9	7.88%	<.0001
Feel well-cared for by staff after hospital stay?	97.5	98.5	98.9	99.2	1.83%	0.056

Conclusions: Ratings of pt experience improved during Right TraC, particularly for medications and discharge instructions. Ratings varied by quarter for Red Flags. Further modification of interventions is needed for continued improvement.

SA-PO1066

Successful Multidisciplinary Quality Initiative to Preserve Arm Veins in CKD/ESRD Populations at a Tertiary Care Center Gauri Bhutani,[1] Mireille El Ters,[4] Sami Safadi,[1] Amy Mahon,[3] Joe L. Klunder,[2] Sandra J. Taler,[1] Amy W. Williams,[1] Andrew Stockland,[2] Marie C. Hogan.[1] *[1]Nephrology, Mayo Clinic; [2]Radiology, Mayo Clinic; [3]Nursing, Mayo Clinic, Rochester, MN; [4]Nephrology, Univ of Kansas, Kansas City, KS.*

Background: Peripherally inserted central venous catheters (PICCs) are associated with higher rates of venous thrombosis and lower rates of functioning AV fistulas (AVFs). Small bore tunnelled central venous catheters (STCCs) may be a safer alternative to help improve rates of successful AVFs.

Methods: Interventions (2011 - 2014): 1. Electronic alert discouraging provider orders for PICC placement if eGFR<30ml/min/1.73m^2 and providing rationale for PICC avoidance 2. Interventional Radiology collaboration to facilitate/ substitute STCCs instead of PICCs. 3. Education of providers (didactics) and CKD patients (onsite patient education, brochures, posters and CKD education classes). We compared number of cases with eGFR<30 who received PICCs before [Jan 2010 (Period 1)], during [Mar - Apr 2013 (Period 2)] and after interventions [Feb-Mar 2014 (Period 3)]. We also evaluated the trends in STCC use in CKD/ESRD. Fisher's exact test was used for statistical analysis.

Results: PICCs placed in ESRD patients declined in Periods (Pds) 2 and 3 compared to Pd 1 ($^{\times,\alpha}p<0.01$). Fewer PICCs were also placed in patients with eGFR<30 (Not ESRD) in Pd 3 ($^{\#}p = 0.015$). This reflects the reduced PICC placement in CKD 4-5 ($^{\#}p <0.01$). We did not detect any change in PICC placement rates in AKI patients.

PICC (by group)	Period 1 (Jan 2010) n = 275	Period 2 (Mar - Apr 2013) n = 580	Period 3 (Feb-Mar 2014) n = 580
ESRD	11 (4%) $^{\alpha,\times}$	**6 (1.03%)** $^{\times}$	**1 (0.01%)** $^{\alpha}$
eGFR <30 ml/min/1.73m^2 (Not ESRD)	35 (12.7%)*	62 (10.7%)	**43 (7.4%)***
-CKD 4 and 5	17 (6.2%)$^{\#}$	36 (6.2%)	**9 (1.5%)**$^{\#}$
-Acute kidney injury (AKI)	18 (6.5%)	26 (4.5%)	34 (5.8%)

STCC use at our center has increased 17 fold (2010-14). Prevalent ESRD cases among all STCCs placed increased from 22.6% in 2010-2012 to 42% by August 2013 (p = 0.04).

Conclusions: A targeted multidisciplinary strategy reduced PICC use in CKD and ESRD patients at our center. STCC use increased, especially in ESRD patients. Future studies will determine if these efforts translate to improved AVF rates.

SA-PO1067

A Multidisciplinary Approach Is Successful in Improving Vascular Access Outcomes in an Underserved Dialysis Population in a Large Indigent-Care Public Hospital Arshad Ali, Ravi R. Rajani, Susan M. Shafii, Vandana Niyyar. *Emory Univ School of Medicine, Atlanta, GA.*

Background: The three basic kinds of vascular access for hemodialysis(HD) are an arteriovenous fistula (AVF), AV graft (AVG),and a central venous catheter (CVC).National Kidney Foundation Kidney Disease Outcomes Quality Initiative recommends AVF and AVG for vascular access and avoidance of CVC if possible.The Fistula First Catheter Last recommends an AVF prevalence rate of 68%. However, 80% of ESRD patients initiate HD with a CVC and 52% dialyze with a CVC at >90 days.In a retrospective review, we studied patient,physician and socio-economic factors as they relate to a specific underserved and uninsured ESRD population at Grady Memorial Hospital–"the undocumented immigrants" who do not have legal access to the U.S. medical system.

Methods: We conducted a retrospective review of the medical records from 11/01/2010 to 04/7/2014 of this patient population. A multipronged approach led by the renal fellows included detailed counseling,emphasizing compliance and involvement of their families. Social workers and interpreters were extensively involved to overcome the socio-economic,cultural and language barriers.There were concerted efforts made for placement of AV access during intermittent admissions for HD.

Results: There were a total of 35 patients in this cohort on 04/07/2014.The average age was 47.8 +/-13.9 years,with a male to female ratio of 1.2:1.They were predominantly Hispanic(74%),African(23%), and Asian(3%).The etiology of the renal failure was HTN(51%), Diabetes(31%),glomerulonephritis(6%),HIVAN(3%) and others(9%).All were initiated on HD with CVC.We found a 77% conversion rate of CVC to AV access,of which 33% were radiocephalic AVF,37% brachiocephalic AVF,26% brachiobasilic AVF and 4% AVG.The average time of conversion from CVC to AV access was 6.3 months +/- 255 days with 48% placed within 90 days of HD initiation. Primary AVF failure rate was 3.7%.

Conclusions: This retrospective review indicates that it is possible to achieve optimal dialysis vascular access in an underserved and uninsured patient population by using a multidisciplinary approach.Renal physicians should take the lead and assume the role of team leaders.

SA-PO1068

Can an Active Intervention Increase Vascular Access Outcome? Marco Oliveira Mendes,[1] David Navarro,[1] Ana Azevedo,[2] Patricia Veigas,[1] Ana Carina Ferreira,[2] Patrícia Matias,[1] Tiago Amaral,[2] Bruno Costa Pinto,[1] Cristina Jorge,[1] Fernanda Gomes,[1] Célia Gil,[1] Manuel A. Ferreira.[1] *[1]Nefrologia, Nephrocare de Vila Franca de Xira, Vila Franca de Xira, Lisboa, Portugal; [2]Nefrologia, Dialverca, Alverca, Lisboa, Portugal.*

Background: Programs of monitoring vascular access (VA), followed by angiographic and/or surgical intervention, have been performed in order to improve VA outcome. Our goal is to assess the impact of an immediate response from a specialized vascular access center (VAC) on the VA of patients (pts) from a large hemodialysis center.

Methods: A retrospective analysis of the VA patency and VA interventions in 2 periods (20 months each), before and after the implementation of an immediate response from VAC, was performed. Both populations were equivalent. 218 pts were included, with mean age ±SD) 67,2±15,4 years, 50% female, 37,2% diabetics, with mean HD time of 61,5±58,4 months. Monthly determinations of VA flow (Qa) using the BTM-Blood Temperature Monitor-Fresenius Medical Care, were performed. Predefined indications for angiography were: A-V fistula (AVF) Qa < 400 ml/min; PTFE graft Qa < 600 ml/min or a Qa drop > 50% in 2 consecutive months; significant high venous pressure (VP), edema of VA limb or thrombosis of the VA.

Results:

	Pre CAV	POS CAV	p value
VA in use			
Central venous catheter (CVC) (%)	28.58	25.7	NS
AVF (%)	42.86	48.2	NS
AVF patency (months)	58,26±59,69	56,57±59,15	NS
PTFE patency (months)	27,50±25,09	34,63±25,56	P <0.01
Kt/v	1.57 (±0.27)	1.94 (±0.35)	P <0.01
Intervention			
Angioplasty without stent (%)	13.47	24.76	NS
Surgical review (%)	18.37	26.98	NS
Outcome			
Failure due to thrombosis (%)	19.42	8.97	NS
Hospitalization related to the VA (%)	11.02	3.17	P <0.01

Conclusions: Introduction of VAC represented a decrease of thrombosis rate (50%), hospitalizations related to the AV (71%), use of CVC and a significant increase in Kt/V. The role of VAC appears to be particularly important in preserving the PTFE patency. In our opinion, these major clinical advantages justify the increased number of VA interventions and the costs associated.

SA-PO1069

Timing of Dialysis Access Creation: A Single Centre Experience Post-Initiating Dialysis Early and Late (IDEAL) Study and following the Creation of a Dedicated Vascular Access Nurse Position Jonathan Eng Ho Ling, Gail Theresa Read, Lisa Shelverton, Elizabeth Nguyen, Richard Yu, Geoffrey S. Kirkland. *Nephrology, Royal Hobart Hospital, Hobart, Tasmania, Australia.*

Background: The Initiating Dialysis Early and Late(IDEAL) study, published in 2010, showed that starting dialysis later in patients with well-controlled chronic kidney disease(CKD) was not associated with a significantly worse mortality rate. In our dialysis service following this publication, we observed an increased time from arteriovenous fistula(AVF) creation to dialysis initiation, decreased primary access failure rates and a lower estimated glomerular filtration rate(eGFR) on starting dialysis.

Methods: A Vascular Access Nurse position was created in 2010 to improve access to surgical AVF creation. Standard practice in our unit is an eGFR of 15 or less is used as a trigger for AVF creation. We analysed data on patients with CKD 5 progressing to dialysis during 2008 to 2013. Data was routinely collected during this period and included dates and eGFR at the time of AVF creation and commencement of dialysis, eGFRs at 1,2 and 5 years before initiation of dialysis, cause of renal disease and co-morbidities. Patients who required emergency initiation of dialysis were excluded from this review.

Results: Results show an increase in average time to dialysis from eGFR of 15 from 5.5 months to 10.8 months and a decrease in the mean eGFR on commencement of dialysis was 9 ml/min to 5 ml/min across the 5 year period. The mean eGFR at AVF creation was 13 in 2008 and 16 in 2013. Despite the wider gap between AVF creation and dialysis commencement post-IDEAL, AVF failure rates decreased from 10 episodes in 2010 to 4 episodes in 2013.

Conclusions: In summary we have shown a significant change in our unit's pattern of access creation and initiation of dialysis resulting in an average patient gaining an extra 5 dialysis-free months with no increased risk of AVF failure.

SA-PO1070

Clinical Utility of Far-Infrared Therapy to Improve Access Blood Flow and Pain Control in Hemodialysis Patients Soo Jeong Choi, Moo Yong Park, Jin Kuk Kim, Seung Duk Hwang. *Internal Medicine, Soonchunhyang Univ Bucheon Hospital, Bucheon, Gyunggi-do, Korea.*

Background: A well-functioning vascular access and minimal needling pain are important goals for achieving adequate dialysis and improving the quality of life for hemodialysis (HD) patients. Far-infrared (FIR) therapy has been used for various medical conditions, including chronic pain control and the treatment of some cardiovascular diseases. Recently, Taiwan researchers reported that FIR therapy improved endothelial function and increased access blood flow and patency in HD patients.The aim of this study is to evaluate the effects of FIR therapy on access blood flow and needling pain in Korean HD patients.

Methods: This prospective clinical trial was conducted at Soonchunhyang University's Bucheon Hospital in Korea between June 2013 and January 2014. A total of 31 HD patients were enrolled in the study. FIR therapy was administered for 40 min during HD three times per week and continued for 3 months. The access blood flow was measured by the ultrasound dilution method, while pain was measured by the numeric rating scale (NRS) at baseline, then once per month.

Results: One patient was transferred to another facility and six patients stopped FIR therapy due to increased body temperature and discomfort, though none of them experienced a burn episode.While hemostasis improved after the first month of FIR therapy, itching sensation of patients did not change. Pain score (4.7 ± 0.5 to 1.5 ± 0.3, $p < 0.001$) and anxiety score (4.4 ± 0.6 to 1.6 ± 0.3, $p < 0.001$) decreased after three months. However, the access blood flow did not increase significantly after a single HD session (878.1 ± 108.1 ml/min to 923.9 ± 102.3 ml/min, $p = 0.317$) nor after 3 months (827.9 ± 139.3 ml/min to 924.2 ± 153.7 ml/min, $p = 0.160$). Patients with an initial access flow under 500mL/min experienced a great increase in flow after FIR therapy than those with an initial flow over 500ml/min (p=0.010, Figure 1).

Conclusions: This study shows that FIR is safe and can improve access flow and needling pain in hemodialysis patients. Future studies with large populations and long-term follow-up are needed to further investigate these findings.

SA-PO1071

Reducing Adverse Effects of Arteriovenous Fistula Cannulation with Doppler Ultrasound Fabiana Dias Carneiro, Ana C.M.S. Ramos, Bruna Gomes Barbeiro, Ewerton Soares Dias, Erika B. Rangel, Maria C.C. Andreoli, Adriano Luiz Ammirati, Nadia K. Guimaraes, Thais Nemoto Matsui, Bento C. Santos. *Centro de Diálise Einstein, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: Vascular access function and patency are essential for optimal management of hemodialysis (HD) patients. Failure to detect access dysfunction has consequences on morbidity and mortality. To note, only a small number of studies has been performed prospectively to assess the impact of vascular access surveillance on outcome. Objective: We aimed to report the use of Doppler ultrasound (DU) for guiding arteriovenous fistula (AVF) cannulation in HD patients.

Methods: AVF cannulations were guided by DU and clinical adverse effects related to cannulations were assessed (hematoma and more than two cannulations attempts) from 2004-2014. Surveillance DU was repeated when physical examination detected abnormalities. One-way Anova was used and $P<0.05$ was considered significant.

Results: Demographic data of 157 HD patients comprised 75.2% male patients, with average age of 65,9± 15,6 yo, and 39% diabetic. HD treatment was delivered 3 times per week, average duration of 4h, blood flow of 300 to 350 ml/min, dialysate flow of 500 ml/min, and polysulphone dialyzers were used. Average time of follow-up was 32±28 months (range, 2 to 120 months). Median time from AVF confection to first use was 32 days (range, 20-730 days). DU-guided AVF cannulation reduced the occurrence of AVF hematoma from 2.63 to 1.71 episodes/patient.year (P=0.054) and the requirement for more than two cannulations from 4 to 1.78 episodes/patient.year (P=0.0014).

Conclusions: Doppler ultrasound is a helpful tool in association with physical assessment to minimize adverse effects of AVF cannulation, as well as to detect vascular accesses at risk and to track access complication rates. Furthermore, DU may be implemented to maximize access longevity in HD patients.

SA-PO1072

Real-Time Imaging of Vascular Access to Optimize Cannulation Practice and Education: Role of the Access Procedure Station Rosa M. Marticorena,[1] Latha Kumar,[1] Gurpreet Dhillon,[1] Jo-Ann Tria,[1] Darya Zevart, Sanjeev Sirpal,[1] Ian Smith,[2] Sumeet Suneja,[1] Xi Shan,[1] Sahar Kajbaf,[1] Abdul Aziz Walele,[1] Jasdip S. Sachdeva,[1] Hitesh K. Mehta,[1] Bajinder S. Reen,[1] Sandra M. Donnelly.[1] *[1]Medicine/Nephrology, William Osler Health System, Brampton, ON; [2]Surgery/Vascular Surgery, William Osler Health System, Brampton, ON.*

Background: The Access Procedure Station (APS), a novel healthcare delivery system, was established to optimize the management of vascular access (VA) in CKD patients on hemodialysis. The APS consolidates the management of new accesses, complicated accesses or accesses difficult to cannulate (defined as the use of more than 2 needles for hemodialysis at least once per week), in a controlled environment.

Methods: Eighty-five patients were enrolled in APS; 35 females and 50 males. Patients received a complete evaluation with bedside ultrasound and real-time ultrasound-guided needle insertions by nurses with specialized training in ultrasound use. Admission criteria for APS include, but are not limited to: assessment and cannulation of new and/or complicated accesses, cannulation post procedures, troubleshooting during HD (needle reposition or re-cannulation), assisting with CVC insertions and removals, local thrombolysis and other access procedures.

Results: A total of 516 access procedures were performed in 85 patients admitted in APS over a period of 5 weeks. Of the 85 patients, 25 had a history of multiple needle insertions at least once per week over the 5 weeks prior to admissions. Compared to 125 events of multiple needle insertions reported in the medical chart prior to APS enrollment, during the first 5 weeks of operation of the APS, there were 7 events (*p=0.0001*[/italic][/italic]); 3 cases of a second needle insertion at one of the cannulation sites, 2 episodes of blood extravasation - intramural bleed- during the first needle insertion, and 2 events of flow limiting severe venous spasm after cannulation.

Conclusions: The implementation of the APS has improved access care in our Unit, reduced morbidity, and has streamlined the delivery of cost effective patient care. The APS has also served as an educational opportunity for advanced training in imaging in the specialty of Vascular Access for Nursing Staff.

SA-PO1073

Patency and Complications of Arteriovenous Fistulation in Upper Arm of Hemodialysis Patients with Multiple Comorbidities Xueqin Bian, Hong Ye. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: In clinical settings, arteriovenous fistula, also called lifeline of dialysis patients, is the preferred access in hemodialysis; however, incidence of fistula dysfunction is extremely high in maintenance hemodialysis patients with multiple comorbidities.

Fistulation in upper arm was recommended in several recent investigations to reduce the occurrence of fistula dysfunction of these patients. Here, the patency of upper arm fistula and complication after fistulation in upper arm of maintenance hemodialysis patients with multiple comorbidities were analysis in this study.

Methods: From January 2009 to December 2012, maintenance hemodialysis patients with multiple comorbidities underwent upper arm fistulation in our hospital were enrolled in this study. Patency of fistula was examined at 6 and 12 months after fistulation by ultrasonography. Complications, including bleeding, infection, steal syndrome, aneurysm, thrombosis and central venous stenosis were evaluated at 12 months after fistulation. Cox proportional hazard models were used for statistic analysis.

Results: A total of 195 times upper arm fistulation were performed in 183 hemodialysis patients with multiple comorbidities. The primary patencies were approximately 90% and 86% at 6 and 12 months, respectively. The cumulative patencies were 95% and 89% at 6 and 12 months, respectively. The incidence of all complications was 13.1% (24 of 183) at 12 month, among which bleeding was 41.6% (10 of 24), infection was 4.1% (1 of 24), steal syndrome was 8.2% (2 of 24), aneurysm was 8.2% (2 of 24), thrombosis was 16.4% (4 of 24), central venous stenosis was 20.8% (5 of 24). In all kinds of comorbidities, diabetes (HR: 2.73; 95% CI: 1.19 to 6.32) and fistulation history (HR: 1.45; 95% CI: 1.06 to 1.97) were responsible for reduction of primary patency.

Conclusions: Arteriovenous fistulation in upper arm of hemodialysis patients with multiple comorbidities had excellent patency and few complications. Diabetes and fistulation history were detrimental factors for patency of upper arm fistula.

SA-PO1074

Pre-Operative Examination for Arteriovenous Access in Hemodialysis: An Insight into Clinical Practice Guidelines Deirdre B. Cassidy,[1] Aurangzaib Khawaja,[2] Javaad Ayub,[3] Nicholas Inston,[2] Eric G. Lancelot,[3] Shona Matthew,[1] John Graeme Houston.[1] *[1]Univ of Dundee, United Kingdom; [2]Queen Elizabeth Hospital, Birmingham, United Kingdom; [3]Guerbet, Paris, France.*

Background: Arteriovenous fistulas (AVF) are the preferred vascular access (VA) for hemodialysis but have a high incidence of primary failure, particularly at the radiocephalic site. Recent studies have shown routine pre-operative vascular ultrasound (US) in addition to clinical assessment improves the AVF patency rates. This study aims to assess the content and consistency of international clinical practice guidelines in terms of pre-operative recommendations.

Methods: Guideline databases and nephrology societies' websites were used to search for VA practice guidelines that included recommendations on pre-operative assessment (up to April 2014). Key guidelines (NDOQI, ERBP, CARI, CNS) were identified and compared using the Appraisal of Guidelines for Research Evaluation (AGREE) II instrument by three observers (DC, AK, JA). All scores were calculated as scaled domain score and between group differences calculated using analysis of variance. Inter rater reliability was assessed by intraclass correlation coefficient (ICC).

Results: Overall, guideline recommendations for pre-operative assessment include physical examination (4/4) and US for planning (3/4). Venography was recommended in suspected cases of central venous stenosis (2/4). The application of magnetic resonance angiography (MRA) and computed tomographic angiography (CTA) have been mentioned in suggestion to care (2/4). Guideline methodology rigour was variable between the guidelines ($p<0.02$). This may be due to different search strategies and different methods of updating guidelines. Agreement was found between observers in overall ranking of the guidelines and inter rater reliability was found to be significant (ICC, $p<0.005$).

Conclusions: Physical examination, US mapping and venography are the main methods available for pre-operative assessment. Further work will include a systematic review of recent preoperative imaging studies with MRA or CTA in order to see if these modalities can offer additional information as compared to the conventional methods recommended in the guidelines.

Time to Get Off the Button-Hole Bandwagon? - A Single Center Experience of Staph Aureus Infection and Vascular Access Type Luxme Nadarajah, Neil Ashman, Ravindra Rajakariar, Mark Blunden. *Renal Unit, Royal London Hospital, London, United Kingdom.*

Background: There has been increasing interest /use in the "button - hole " method of A-V fistula cannulation, with apparent benefits of less pain and bleeding. Concerns have been raised about infectious complications. After a number of serious infections in our institution we reviewed staph Aureus bacteriemia cases in haemodiallysis over a 2 year period and access type, as well as other complications asscociated with access such as bleeding.

Methods: Using our database we analysed all postive blood cultures and bleeding episodes on haemodialysis program over a two year period - accounting for approx 1900 patient years of haemodialysis. All positive cultures for staph Aureus were analysed as to access, complications of the sepsis, inpatient days and co-morbities. Major bleeding was defined as requiring admission and transfusion.

Results: 11 cases of staph aureas sepsis were felt due to staph infection introduced via button hole AVF, 40 cases due to tunnel line, one in a PTFE graft and none due to rope ladder cannulation. 3 button patients had endocarditis and 1 had a mycotic aoritc aneurysm. Mortality was 18%. In a seperate review of bleeding from vascular access over a 8 year period, there were no major bleeding episodes assocaited with button hole, with most bleeding coming from infected PTFE grafts or anuersymal (and often stenotic proximally) native AVFs. Average length of stay was 13.5 days with button hole asscoiated sepsis compared to 14 days for line sepsis.

Conclusions: Button hole cannulation was apparently assoctiated with increased severe infection but not other major complications related to access such as bleeding. Patient selection may have been an issue with infections more likley to happen in diabetics (5 patients) and immuno-compromised patients (2 patients were HIV positive). Button-hole can probably be safely used on a select subgroup but not all patients especially with underlying conditions associated with increased skin infections.

SA-PO1076

Haemodialysis Arteriovenous Autogenous and Prosthetic Angioaccess in 80 Years and Older Patients: Single Centre Study Dinith Prasanna Galabada,[1] Maggi Steele,[1] Mohamed Morsy,[2] Abbas Ghazanfar,[2] Rebecca Suckling,[1] Atul Bagul.[2] *[1]South West Thames Renal Unit, St. Helier Hospital, Carshalton, United Kingdom; [2]Vascular Unit, St. George's Hospital, London, United Kingdom.*

Background: The number of patients over 80 years with end stage kidney disease requiring chronic haemodialysis has been steadily increasing. Autogenous angioaccess is widely considered as the preferred vascular access due to its high patency and low complication rates. Aim of this study was to analyze the primary patency,assisted primary patency and secondary patency rates of autogenous and prosthetic angioaccess in the elderly population over 80 years of age in the South West Thames Renal unit.

Methods: This is a retrosepective observational study, assessing all angioaccess procedures performed between January 2006 and March 2013. Demographic data,Cause of renal failure,Type of angioaccess and Co-morbidities were collected. Primary patency, assisted primary patency and secondary patency rates at 6,12,24 and 36 months were calculated using Kaplan-Meier Survival method.

Results: There were 277 Autogenous (No=263;95%) and prosthetic(brachioaxillary bypass graft) angioaccesses. Among fistulae,50% were radiocephalic,41% brachiocephalics. Mean age at creation of access was 83.7 years (Range 80-95 yrs), 68.8% were males, 55% had a Davies Co-morbidity score of 2 and 75% were de-novo (first angioaccess). More than half of the angioaccess procedures were pre-emptive. primary patency rates were 71.5%,62.5%,46% and 43% at 6,12,24 and 36 month respectively. Assisted primary patency rates were 76%,68.5%,55% and 48.5% at same time points. Secondary patency rates were 78.5%,70%,56.2% and 51% at the respective time points post creation. Functional secondary patency rates were 83.8%,79%,66% and 58% for the same durations. Primary failure of angioaccess rate was 25%,30% died with a functioning access. Thrombosis rate was 0.123 per patient- year. There was no statistical difference between autogenous and prosthetic angioaccess patencies.

Conclusions: Elderly patients aged 80 or over with end stage renal failure should be considered for angioaccess as first line for haemodialysis. Autogenous angioaccess is recommended as a priority in the elderly patients over 80 years.

SA-PO1077

The Economic Burden of Initiating Dialysis with the Wrong Foot – A Matter of Vascular Access Anabela M. Guedes, Teresa M. Jeronimo, Ana Pocinho Pimentel, André Fragoso, Ana Cabrita, Ana Paula Silva, Viriato J.V. Santos, Idalecio Bernardo, Pedro Neves. *Serviço Nefrologia, Hospital de Faro, Portugal.*

Background: Vascular access is primordial in timely preparation for hemodialysis (HD) start for a number of reasons, namely dialysis efficacy, morbidity and mortality. Nonetheless economic reasons should also be ascertained. Is anticipated construction of a definitive blood access cost beneficial? The aim of this study was to compare different initial vascular access related expenditure during the first year on dialysis.

Methods: This study considered incident haemodialysis patients at our Centre, between 2008 and 2011. Serial laboratory data were collected at baseline and monthly until 12 months of follow-up. Costs were calculated based on the Portuguese capitation system. T-test for variable comparison and Kaplan-Meier for survival were used in the statistical analysis.

Results: A total of 176 patients (70 females, 106 males), with mean age of 67.4 years and previous nephrology follow-up time of 43.0 months were included. Group I (n=38 patiens) started HD by catheter and presented higher C reactive protein (54.9 versus 24.5 mg/L, p=0.016), lower albumin (3.5 versus 3.8 g/dL, p= 0.013) and lower eGFR (8.1 versus 9.9 mL/min/1.73m2, p= 0.014) by the time of HD initiation. Both groups had similar demographic and other considered biochemical characteristics. They evolved without significant analytical differences. Group II (n=138), which started HD with a functioning arteriovenous fistula or graft, exhibited lower cumulative cost after 6 months (3920.2 versus 5369.3 euros/patient, p=0.010), mainly due to lower expenditure with anemia related medication (3152.9 versus 4529.1 euros/patient, p=0.007). These disparities fade after 12 months on HD. Higher hospitalization rate and duration was observed in group I (13.9 versus 6.0 days/patient, p=0.002). Survival was higher in group II (log rank = 4.5, p=0.035).

Conclusions: In conclusion, patients presenting with definitive blood access start dialysis sooner, with better albumin levels, probably reflecting the lower grade of inflammation, measured by CRP. These features result in lower medication cost (mainly anemia related medication) and lower hospital related expenses and morbidity.

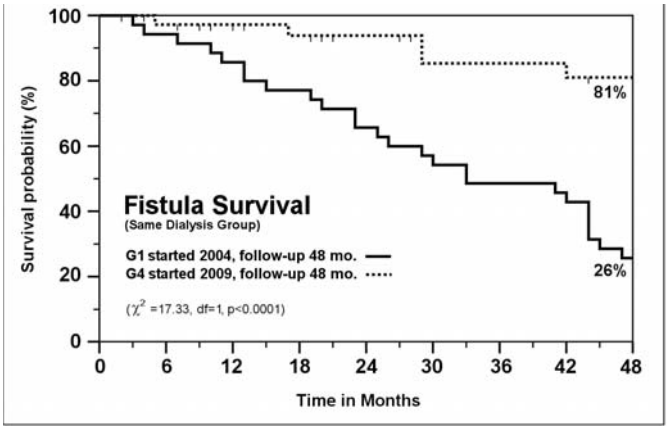
SA-PO1078

A New Method for Vascular Access Life Table Analysis Chaim Charytan,[1] Stephen R. Ash,[2] Anatole Besarab,[3] Farhanah Yousaf,[1] Stanley Frinak,[4] Joan E. Arslanian,[1] Kim Hirschman.[5] *[1]Nephrology, NYH Queens, New York, NY; [2]Nephrology, Indiana U., Lafayette, IN; [3]Nephrology, UCSF, San Francisco, CA; [4]Nephrology, Henry Ford HS, Detroit, MI; [5]QA, Vasc-Alert, Lafayette, IN.*

Background: Dialysis centers are required to have an access surveillance program (ASP), but do ASPs improve outcomes? One way to measure efficacy is to assess the effect of ASPs on access longevity. We describe a new method of survival analyses for AV accesses based on dialysis treatment data (DTD). Rules for extracting life table data from DTD are given. Access survival analysis is then used to assess efficacy of the ASP by comparing the 1st and 5th year of ASP use.

Methods: NY Hospital Queens initiated an ASP in 2003/4 using the Vasc-Alert device to identify patients at risk for access complications. Our method of analysis used first and last dates of access use in DTD to approximate access initial use and loss, confirmed by review of patient records. Fistula (AVF) data in two time periods was analyzed and compared: AVFs first used in the 1st yr of the ASP use, (group G1, 6/1/04 to 5/31/05, N=35), and AVFs first used five yrs later, (group G4, 1/1/09 to 12/31/09, N=42).

Results: Results of Kaplan-Meier analysis of DTD survival data are shown in the figure below. The number of patients in G1 ranged from 35 to 9 at 48 mo, with survival=26%. For G4, patients ranged from 42 to 18 at 48 mo, with survival=81%. There was a significant difference in the survival curves ($p < 0.0001$).



Conclusions: Results show that extracting access survival data from DTD is an excellent approximation of access survival. Kaplan-Meier analysis of DTD can be used as a tool to evaluate the success of an ASP or to compare different ASPs. The data in the figure indicate that an ASP in concert with a vascular access management program can extend the patency of fistulas.

SA-PO1079

Vascular Access and Patient Values: Fistula Refusal May Be Rational and Non-Modifiable Damien Ashby, Azara Janmohamed, Jeremy Crane, Neill D. Duncan, Lina Johansson. *Imperial College Kidney and Transplant Centre, Imperial College, London, United Kingdom.*

Background: Arteriovenous fistulae are associated with improved survival, but some patients refuse to have a fistula. These patients may be better understood by analysis of the decision process, which is influenced by (1) circumstance: factors specific to the decision, including the patient's understanding of it; and (2) disposition: stable patient factors, such as personality or values, which are independent of the decision being made, and largely non-modifiable. The role of values in access preference has not been studied.

Methods: Healthcare values were determined using structured interviews in prevalent haemodialysis patients, with subjects unaware of the vascular access focus of the study. Values were determined by weighted analysis of discrete trade-off decisions relating to a set of non-renal healthcare scenarios, designed to test the following value attributes: (1) survival, (2) pain, (3) appearance, and (4) treatment burden.

Results: Thirty patients were interviewed, with one incomplete, leaving 29 (aged 19–76, 67% male) with completed interviews for analysis. Fourteen patients had a fistula, and 15 were patients with a tunnelled catheter who had refused fistula formation. Compared to the fistula group, patients from the catheter group gave pain a higher priority (mean score 19.1 versus 13.2, p=0.025) and tended to give survival a lower priority (mean score 12.1 versus 16.2, p=0.127). These differences led to altered attribute rankings: pain was the lowest ranked attribute in the fistula group, whereas for the catheter group, survival had the lowest rank. Values were predictive of access grouping: of patients who prioritised pain over survival, 71% were from the catheter group, as opposed to only 33% of those who prioritised survival over pain (p=0.046).

Conclusions: Healthcare values have a significant effect on vascular access decisions, with patients who prioritise pain over survival being more likely to refuse fistula formation. Fistula refusal of this type may be a non-modifiable rational choice, arising from and consistent with a distinct set of healthcare values. The proportion of fistula refusal which is of this type is unknown.

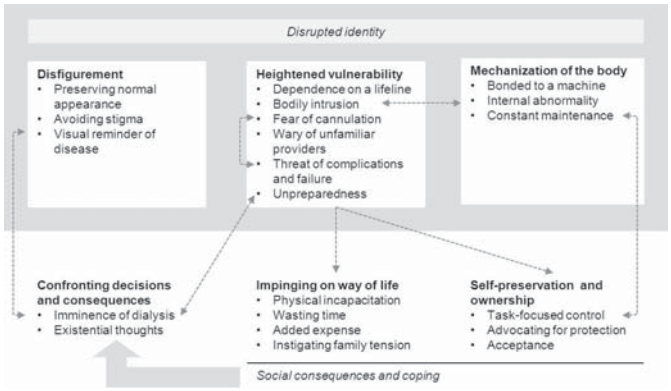
Anything but a Simple Surgical Procedure: Patients' Perspectives of Vascular Access for Hemodialysis Jordan R. Casey,[1,2] Camilla Sara Hanson,[1,2] Wolfgang C. Winkelmayer,[3] Jonathan C. Craig,[1,2] Suetonia Palmer,[4] Giovanni F.M. Strippoli,[1] Allison Tong.[1,2] *[1]School of Public Health, Univ of Sydney; [2]Centre for Kidney Research, The Children's Hospital at Westmead; [3]Div of Nephrology, Stanford Univ; [4]Univ of Otago.*

Background: Delayed creation of vascular access may be partly due to patient refusal and is associated with adverse outcomes. Concerns about vascular access are prevailing treatment-related stressors for patients on hemodialysis (HD). We aimed to describe patients' perspectives on vascular access initiation and maintenance.

Methods: In this systematic review, electronic databases were searched to December 2013. Thematic synthesis was used to analyze the findings.

Results: From 46 studies (n=1034 patients) we identified six themes: heightened vulnerability (bodily intrusion, fear of cannulation, threat of complications and failure, unpreparedness, dependence on a lifeline, wary of unfamiliar providers); disfigurement (preserving normal appearance, visual reminder of disease, avoiding stigma); mechanization of the body (bonded to a machine, internal abnormality, constant maintenance); impinging on way of life (physical incapacitation, instigating family tension, wasting time, added expense); self-preservation and ownership (task-focused control, advocating for protection, acceptance); and confronting decisions and consequences (imminence of dialysis, existential thoughts).



Conclusions: Initiation of vascular access signifies kidney failure and imminent dialysis which is emotionally confronting. Patients strive to preserve their vascular access for survival; but describe it as an agonizing reminder of their body's failings and "abnormality" of being attached to a machine disrupting their identity and lifestyle. Timely counseling and building patients' trust in healthcare providers may improve the quality of dialysis and outcomes for patients with CKD requiring HD.

SA-PO1081

Avoiding the Need for Dialysis Lines: Outcomes of Pre-Emptive AVF Formation – A Single Centre Retrospective Analysis Raja Mohammed Kaja Kamal, Nelomi Anandagoda, Ankan Mittal, Maggi Steele, Bhrigu Raj Sood, David Makanjuola. *South West Thames Renal Unit, St. Heliers Univ Hospital NHS Trust, Carshalton, Surrey, United Kingdom.*

Background: The native arteriovenous fistula (AVF) remains the preferred choice, with better outcomes. UK guidelines recommend creation of dialysis access atleast 6 months before the anticipated start of dialysis and that 65% of all incident HD patients should commence dialysis with an AVF.

Methods: This single centre retrospective study analyses outcomes of patient undergoing pre-emptive AVF/graft surgery between Jan 2006 and Oct 2012. Data were collected from our renal and pathology department database. Outcomes were analysed for successful use, need for surgical or radiological intervention prior to use of the AVF/graft and the impact of eGFR at the time of AVF/graft creation.

Results: Number of pre-emptive AVF/graft procedures (N) = 741

Outcome			N (%ge)
AVF successfully used for 1st HD without intervention			**186 (25%)**
AVF successfully used for 1st HD after intervention			**62 (8%)**
AVF became usable after intervention, but after starting dialysis with alternative access			**117 (24%)**
AVF never used (reasons given below)			**310 (42%)**
Excluded due to transfer			**4 (1%)**
Reasons for not using AVF			
AVF/Graft failure			191 (26%)
Patient died before starting dialysis			46 (6%)
Not yet started dialysis			49(6.8%)
Transplanted before starting dialysis			12(1.6%)
Change in modality (Conservative management)			12(1.6%)
eGFR (ml/min) at time of creation of AVF			
	Mean	**Median**	**Range**
AVF used successfully with or without intervention	12.1	12	3-48
AVF never used	14.6	14	4-60

Conclusions: This large single centre study shows that only 33% of AVF/graft were used successfully for first HD, further 24% used, had to start dialysis with a line. 42% were not used and over half of these were due to AVF/graft failure. The eGFR at time of creation of the AVF/graft did not affect outcome.Timely planning is necessary as only 25% of **AVF/graft** were usable at start of dialysis without any intervention, which is comparable to other published literature.The groups who died or switched to conservative management needs to be looked at in greater detail, as it suggests that they may have had an unnecessary procedure performed.

SA-PO1082

Catheter Removal Is Associated with Reduced Blood Stream Infections, All-Cause Hospital Admissions and Myocardial Infarctions

Kathryn Taylor,[3] Jerry W. Jackson,[1] Qingqing Xiao,[2] Julia I. Brennan,[1] John W. Larkin,[1] Len A. Usvyat,[1] Norma J. Ofsthun,[1] Kevin Chan,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Inst, New York, NY; [3]Johns Hopkins Medicine Armstrong Inst for Patient Safety and Quality, Baltimore, MD.*

Background: It is known that hemodialysis (HD) dependent end stage renal disease patients with central venous catheter (CVC) vascular accesses are at an increased risk for infection, hospitalization, and death compared to patients with arteriovenous fistulas (AVFs) or arteriovenous grafts (AVGs). Additionally, CVCs have been suggested to contribute to a state of chronic inflammation in HD patients. We investigated the short-term impact on several key outcomes for conversion from a CVC to an AVF/AVG vascular access in HD patients.

Methods: We studied all in-center HD patients that converted from CVCs to AVFs/AVGs between Jan 1, 2013 and Dec 31, 2013. For every patient, we computed rates for all-cause hospital admissions, hospital admissions related to myocardial infarctions, and number of positive blood cultures for 90 days prior to and 90 days after vascular access conversion. Only patients with treatments in the 90 days before and after periods were selected. Comparisons of admission rates and positive blood culture rates between before and after periods were performed using Poisson regression.

Results: We studied 3,543 patients. All-cause hospital admissions decreased by 37%, admissions related to myocardial infarctions decreased by 28% and positive blood culture events decreased by 62% upon transition from CVCs to AVFs/AVGs.

Table 1:	90 days before	90 days after	Percent change	p-value
Number of patients	3543			
All-cause hospital admissions ppy	3.03	1.92	-37%	<0.001
Admissions related to myocardial infarctions	0.012	0.008	-28%	<0.001
Positive blood cultures ppy	0.48	0.18	-62%	<0.001

Conclusions: Among in-center HD patients, transition from a CVC to an AVF/AVG access was associated with significant benefits of reductions in blood stream infection rates, all-cause hospitalization rates and myocardial infarction related hospitalizations. These results emphasize the imperative need for reducing the prevalence of CVCs in this population.

A Retrospective Analysis of Tunnelled Femoral Vein Catheter Outcomes in Haemodialysis Patients

Robin Ramphul, Raja Mohammed Kaja Kamal, Rebecca Suckling, Pauline A. Swift. *Renal Unit, South West Thames Renal and Transplantation Unit, Carshalton, Surrey, United Kingdom.*

Background: Permanent vascular access (VA) for haemodialysis can be challenging for some patients and may require the use of tunnelled femoral venous catheters (TFVC), usually as a last resort. Published literature on TFVCs for dialysis is scarce and study populations have been small. Our aim was to examine the clinical outcomes of TFVCs inserted in our unit over a 2 year period.

Methods: In this retrospective case series study we have identified and collected data on all TFVCs inserted between February 2011 and September 2013. Prior to TFVC insertion all patients were referred for consideration of arterio-venous fistula or graft, peritoneal dialysis, and were deemed unsuitable for tunnelled venous catheters in neck veins. Patients without contraindications were started on warfarin anticoagulation therapy at the time of TFVC insertion. Indications, complications and outcomes of TFVCs were obtained from patient records.

Results: 98 TFVCs were inserted in 59 patients during the study period. The median catheter survival was 49 days (range 0 – 771 days). When censored for elective removal and death with catheter in-situ, catheter patency at 2, 6 and 12 months was 70%, 40% and 25% respectively. The indications for catheter removal are shown in table 1. Elective catheter removal after establishing alternative VA was the most common indication for removal (32%). Catheter related blood stream infection contributed to catheter removal in 7% cases. Organisms were predominantly staphylococcus aureus and epidermidis species. One of these patients (who was colonised with a methicillin resistant strain) died as a result of their bacteraemia. 1 patient receiving warfarin therapy died of a spontaneous gastrointestinal bleed. There were no incidences of deep vein thrombosis (DVT) in this study.

Indication for Removal	Number (n)	%	n per 1000 catheter days
No longer required	30	32	3.0
Poor flow	26	27	2.6
Retracted	14	15	1.4
Infection	7	7	0.7
Death with catheter in-situ	6	6	0.6
Bleeding	1	1	0.1

Conclusions: TFVCs can be used as an effective and relatively safe option when there is either no other access options or whilst definitive access is created.

SA-PO1084

Complications and Outcomes of Tunneled Cuffed Catheters in Elderly Hemodialysis Patients

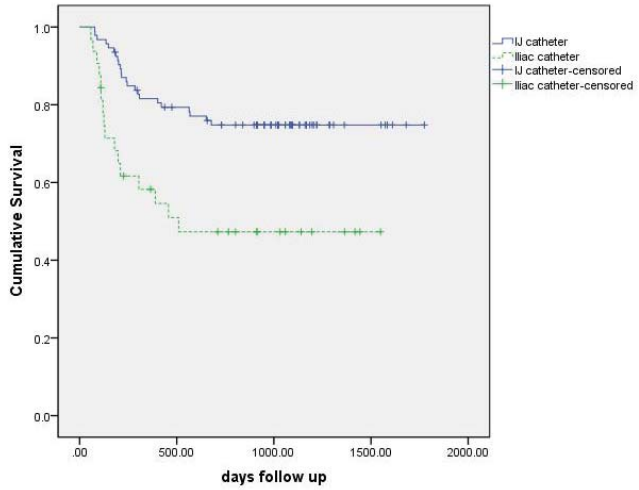
Li Hua Wang,[1] Ai Li Jiang,[2] Fang Wei.[3] *[1]Dept of Kidney Disease and Blood Purification Centre, Inst of Urology and Key Laboratory of Tianjin, 2nd Affiliated Hospital of Tian jin Medical Univ, Tianjin, China; [2]Dept of Kidney Disease and Blood Purification Centre, Inst of Urology and Key Laboratory of Tianjin, 2nd Affiliated Hospital of Tian jin Medical Univ, Tianjin, China; [3]Dept of Kidney Disease and Blood Purification Centre, Inst of Urology and Key Laboratory of Tianjin, 2nd Affiliated Hospital of Tian jin Medical Univ, Tianjin, China.*

Background: To investigate complications and outcomes of TCCs in elderly patients.

Methods: We reviewed the clinical parameters of 127 patients aged over 65 years with 207 new TCC placements and measured complications and survival of TCCs.

Parameter	IJ TCCs	Iliac TCCs	*P* value
N catheters	155	52	
N pts	94	33	
Age	69±7	70±6	0.527
Sex N (% male)	51(54%)	19(58%)	0.741
Diabetes N (%)	39(41%)	15(45%)	0.157
Hypertension N (%)	23(24%)	7(21%)	0.705
Coronary heart disease N (%)	49(52%)	15(45%)	0.435
Glomerulonephritis N (%)	24(26%)	8(24%)	0.883
Peripheral vascular disease N (%)	34(36%)	11(33%)	0.769
Previous catheter placement	17(18%)	16(48%)	0.001
Complactions			
malnutrition	16(17%)	11(33%)	0.049
tumors	5(5%)	6(18%)	0.024
hypotension	17(18%)	12(36%)	0.031
Kt/V	1.1±0.17	1±0.19	0.006

Results: The average primary catheter patency was shorter in iliac vein TCCs. Patients with iliac vein TCCs underwent frequent exchanges than those with internal jugular vein TCCs. Infection-free survival was similar for both groups, but dysfunction-free survival was significantly poorer in iliac vein TCC. Age, peripheral vascular disease and previous catheter placement were the independent risk factors for TCCs.



Conclusions: There is a high incidence of catheter related infection for elder hemodialysis patients with TCCs. The iliac vein tunneled cuffed catheter is associated with an increased risk of dysfunciton.

SA-PO1085

Nosocomial Acute Dialysis Catheter Related Events in Relation to Size and Site: Mayo Clinic ICU Experience in CRRT Patients Pramod Kumar Guru,[1] Abbasali Akhoundi,[2] Kianoush Banaei-Kashani.[3] *[1]Pulmonary and Critical Care, Mayo Clinic, Rochester; [2]Mayo Clinic; [3]Mayo Clinic.*

Background: Optimal size and site of dialysis catheter for proper delivery of CRRT in ICU patients remains a debatable issue. Practices vary according to provider's preferences and patient characteristics. Literature gap is significant to allow appropriate decision making.

Methods: This is a retrospective analysis of adult ICU patients, spanned over 3 year, regarding our CRRT patient outcomes in relation to catheter size and site. We hypothesized that catheter related complications and patient outcomes do not depend on the size or specific site of the catheter in acutely ill ICU patients.

Results: Right internal jugular (IJ) catheter of ≤ 15 cm and Left IJ of ≤ 20 cm are classified as short length; Right IJ ≥ 20 cm and Left IJ ≥ 24 cm as long length group. The baseline characteristics were similar, except higher SOFA score in short length group. The cause of AKI, need for MV, and coagulation parameters didn't differ between the two groups.

Characters	Short length cathters, N= 190, n(%)	Long length catheters, N=137,n(%)	p value
Areterial puncture	1(0.5)	2(1.4)	0.5
Hematoma	2(1)	2(1.4)	1
Minor bleeding	23(12)	29(21)	0.027†
Major bleeding(RBC transfusion)	75(39)	44(32)	0.17
New Anemia	44(23)	54(39)	0.001†
Significant arrhythmia	11(6)	10(7)	0.6
Others	11(6)	10(7)	0.6
No complication	152(80)	95(69)	0.027†
ICU mortality	68(25)	47(34)	0.8
Hospital mortality	89(46)	64(46)	1
Hospital days,median(IQR)	22(11-35)	21.3(11-43.5)	0.63
ICU days,median(IQR)	9 (5-16.6)	10(5-17)	0.8
CRRT time,hours,median(IQR)	103(43-171)	107(43-173)	0.72
Catheter time, hours,median(IQR)	136(63-256)	144(63-254)	0.6

Patients with long catheters had more complications (31%) in comparison to patients with short catheter (20%), p<0.05. None of the other in-hospital patient outcomes were statistically significant. There was no catheter related infection. Analysis for catheters at right IJ, left IJ and femoral site didn't show any difference, except more transfusion requirement on left IJ group.

Conclusions: In this large cohort of ICU patients, our analysis showed that mortality and major complications were unrelated to dialysis catheter size and site.

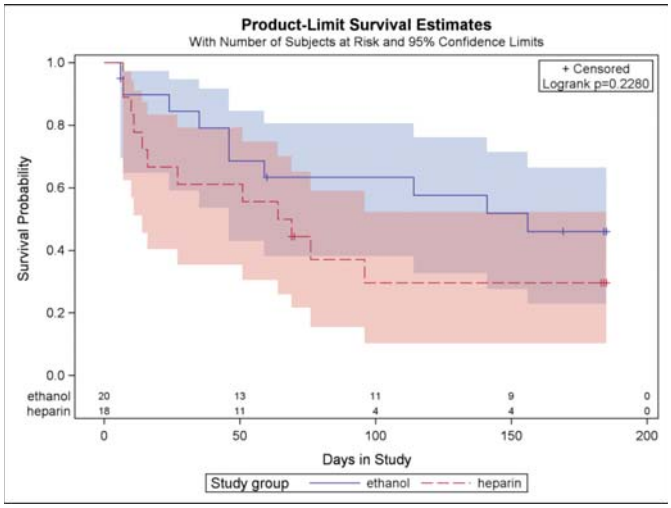
SA-PO1086

Safety and Efficacy of a 30% Ethanol / 4% Sodium Citrate Locking Solution Compared to Heparin to Prevent Hemodialysis Catheter-Related Infections: A Pilot Study Lavern M. Vercaigne,[1,3] Sean Armstrong,[2,3] Don Allan,[2,3] James M. Zacharias,[2,3] Lisa M. Miller.[2,3] *[1]Faculty of Pharmacy, Univ of Manitoba, Winnipeg, MB, Canada; [2]Section of Nephrology, Faculty of Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [3]Manitoba Renal Program, Winnipeg, MB, Canada.*

Background: Catheter-related blood stream infections (CRBSI) are problematic in the hemodialysis population. The reduction of CRBSI and catheter thrombosis can improve patient outcomes. The objective of this pilot study was to collect preliminary data on the safety and efficacy of a 30% ethanol / 4% sodium citrate catheter locking solution versus heparin 1000 units / ml to prevent CRBSI and thrombosis.

Methods: A prospective, randomized, comparative design was used in chronic hemodialysis patients with incident catheters. Forty patients were followed prospectively until they developed a CRBSI, evidence of catheter dysfunction, were censored due to unrelated issues, or reached the full study duration without an endpoint.

Results: There were no serious adverse events directly related to the catheter locking solutions. The rate of CRBSI in the heparin and ethanol / sodium citrate groups were 0.76/1000 and 0/1000 catheter days, respectively. The median time to the first catheter endpoint was 67 days in the heparin group and 156 days in the ethanol / sodium citrate group. Kaplan Meier curves are shown in Figure 1.



The rate of alteplase use was 1.51 / 1000 catheters days in the heparin group and 2.78 / 1000 catheter days in the ethanol / sodium citrate group.

Conclusions: The 30% ethanol / 4% sodium citrate catheter locking solution was safely used in this pilot study. It was effective in eliminating CRBSI and prolonging catheter survival compared to heparin. The pilot study is limited by sample size and a larger appropriately powered RCT is required to confirm these promising results.

Ethanol Locks for the Prevention of Catheter-Related Bloodstream Infections: A Systematic Review and Meta-Analysis Lisa M. Miller,[1,2] Lavern M. Vercaigne,[3] Sherri Vokey,[1] Rasheda Rabbani,[4] Ahmed Abou-Setta,[4] Ryan Zarychanski.[1,4,5] *[1]Faculty of Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Manitoba Renal Program, Winnipeg, MB, Canada; [3]Faculty of Pharmacy, Univ of Manitoba, Winnipeg, MB, Canada; [4]George and Fay Yee Center for Healthcare Innovation, Univ of Manitoba/WRHA, Winnipeg, MB, Canada; [5]Dept of Haematology and Medical Oncology, Cancer Care Manitoba, Winnipeg, MB, Canada.*

Background: Catheter-related bloodstream infections (CRBSIs) are a serious complication of central venous catheters (CVCs), associated with increased hospitalization and death. The purpose of this systematic review is to examine whether ethanol locking solutions reduce CRBSIs in patients with CVCs.

Methods: Randomized controlled trials (RCTs) from MEDLINE, EMBASE, Cochrane Library, and IPA databases were searched from inception to March 2014. We also searched the World Health Organization's International Clinical Trials Registry Platform, relevant conference proceedings from 2009-2013, and reference lists of relevant articles, and performed Forward searches in Scopus and Web of Science. Two reviewers independently identified RCTs comparing ethanol lock solutions to other locking solutions in the prevention of CRBSIs in patients with a CVC, assessed studies for inclusion/exclusion, and extracted trial level data including population characteristics, interventions, and outcomes. Risk of bias was assessed using the Cochrane Collaboration risk of bias assessment tool.

Results: Three studies with a total of 485 patients, constituting 34 047 catheter days were included. Fixed-effects models were used to estimate pooled rate ratios for outcomes. CRBSIs ranged from 0.28 to 31.2 per 1000 catheter days. The rate ratio comparing ethanol

locks to controls was low in all studies ranging between 0.17 (95% CI 0.02-1.62) and 0.83 (95% CI 0.46-1.49). Ethanol locks did not significantly decrease CRBSI (pooled rate ratio 0.60, 95% CI 0.35-1.00). There was no difference in catheter removal rates between the ethanol and the control groups (pooled rate ratio 0.58, 95% CI 0.26-1.29).

Conclusions: There is insufficient evidence to support the routine use of ethanol locking solutions in the prevention of CRBSIs in patients with central venous catheters.

SA-PO1088

Benefits and Harms of Citrate Locking Solutions for Dialysis Catheters: A Systematic Review and Meta-Analysis Alexa L. Grudzinski,[1] Arnav Agarwal,[2] Gihad E. Nesrallah.[1,3] *[1]Nephrology Program, Humber River Hospital, Toronto, ON, Canada; [2]Dept of Health Sciences, McMaster Univ, Hamilton, ON, Canada; [3]Keenan Research Centre, Li Ka Shing Knowledge Inst, Toronto, ON, Canada.*

Background: Citrate-based locking solutions may be a cost-effective alternative to heparin for hemodialysis catheters. We conducted a systematic review and meta-analysis to compare benefits and harms of these interventions.

Methods: We searched CENTRAL, MEDLINE, EMBASE, and CINAHL. We included randomized, parallel arm clinical trials that enrolled adult patients (>18 years) receiving chronic hemodialysis through central venous catheters using a citrate locking solution. We excluded studies in which citrate was combined with other agents, such as antibiotics. Two reviewers performed data extraction independently and in duplicate with standard data extraction forms. We pooled count data using generic inverse variance with random-effects models, but used fixed-effect models when combining only two studies. Subgroups included low (4% or lower) versus higher (>30%) citrate.

Results: We screened 600 citations. Forty-one proceeded to full-text screen; 5 met inclusion criteria. Studies included between 19 and 291 participants (Median N = 61) followed for a total of 174.6 catheter-years; 2 were multi-centred trials. Three studies assessed all-cause mortality; the pooled relative risk was 0.71 (95% CI=0.42-1.24; p=0.21; I^2=0%). The rate ratio for bacteremic episodes was 0.54 (95% CI=0.23-1.29; p=0.16; I^2=65%) while the rate ratio for bleeding was 0.48 (95% CI=0.3-0.75; p=0.001;I^2=5%), favouring citrate. Pooled rates of catheter exchange/replacement and in-situ thromboslysis were not significantly different between groups. Risk of bias within pooled studies was low; however, imprecision due to small sample sizes and low event rates reduce our overall confidence in the pooled effect estimates.

Conclusions: Compared with heparin, citrate-based locking solutions for dialysis catheters had more favourable effects on rates of bacteremia and bleeding; however, larger trials are needed to confirm these findings. Given its lower unit cost, citrate may represent a dominant treatment strategy over heparin.

SA-PO1089

Outcome of AVF/Graft Formation in Patients Who Started Dialysis with Central Venous Catheter – A Single Centre Retrospective Analysis Nelomi Anandagoda, Raja Mohammed Kaja Kamal, Ankan Mittal, Maggi Steele, Bhrigu Raj Sood, David Makanjuola. *SW Thames Renal Unit, St. Helier Hospital, Carshalton, Surrey, United Kingdom.*

Background: Access related complications cause significant morbidity, therefore, good dialysis access is a key priority. Native arteriovenous fistula(AVF) remains the preferred choice with significantly better outcomes. UK guidelines suggest that 85% of all prevalent patients on haemodialysis should receive dialysis via a functioning AVF and central venous catheters(CVC) should be employed as a method of last resort, to reduce the overall risk of infectious complications.

Methods: This single centre retrospective study analysed outcomes of AVF/grafts created from January 2006 to September 2012 in patients already established on dialysis through CVC. Data was collected from renal and pathology department databases on successful use of AVF/graft and reasons for failure.

Results: Number of access procedures (N)-786;AVF/AVG used for HD–614(78%);AVF/AVG used without need for intervention–487(62%);AVF/AVG used after surgical or radiological intervention-122(16%);AVF/AVG never used–172(22%).

Reason for AVF/Graft never used (172)			
Renal Transplant	0.9%		
Death	3.9%		
Patient Choice	0.3%		
AVF/Graft Failure prior to use (reasons below)	16.7%		
Recovered Function	n=1		
Reason for AVF/Graft Failure (131)			
Bleeding	2.3%		
Thrombosis within AVF/Graft	55.0%		
Failure to mature	13.7%		
Infection	3.8%		
Vascular Compromise	21.4%		
Steal Syndrome	3.8%		
Age(years) at time of creation of AVF/graft			
	Mean	**Median**	**Range**
AVF/graft successfully used for HD	63.1	66	18.9-94.6
AVF/graft not used for HD	63.7	65.7	18.6-95.4

Conclusions: Our data demonstrate that in the majority of patients, the AVF/graft was used successfully but 16% required surgical/radiological intervention to facilitate this. Age at time of creation did not affect success/failure to use the AVF/graft. 16.7% of all AVF/grafts created were never used due to primary failure. In this group and the subgroup of patients who died prior to use of the AVF/graft further analysis is required to see whether there were any factors which would identify them, as they might be a group in whom long-term dialysis through a line would be appropriate.

SA-PO1090

Resistance Index in Ultrasound Vessel Mapping Predicts Successful Maturation of Arteriovenous Fistula without Interventional Assistance Hyeon Seok Hwang,[1] Se Young Kim,[1] Suk Young Kim,[1] Yong-Soo Kim.[2] *[1]Section of Interventional Nephrology, Div of Nephrology, College of Medicine, The Catholic Univ of Korea, Daejeon, Korea; [2]Section of Interventional Nephrology, Div of Nephrology, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Arteriovenous fistula (AVF) is the most preferred vascular access for hemodialysis and it frequently needs interventional assistance to facilitate maturation. However, there is no reliable indicator for the prediction of unassisted AVF maturation.

Methods: In 175 patients, who had matured AVF with and without interventional assistance, parameters of duplex ultrasonography were analyzed to evaluate whether preoperative mapping predicts unassisted AVF maturation.

Results: Successful AVF maturation without interventional assistance was observed in 142 (81.1%) patients. The area under the receiver-operating characteristic curve used to predict unassisted AVF maturation was 0.620 of resistance index (RI) (P = 0.034) and 0.615 of end diastolic velocity (P = 0.027). The best cutoff value of RI was 0.80 (sensitivity, 0.56; specificity 0.70). However, the peak systolic velocity, arterial and venous diameter did not predict unassisted AVF maturation. The patients with RI ≤0.8 showed faster AVF maturation and received less interventional procedure than those with RI >0.8 (all P < 0.05). In multivariable logistic regression, female gender and history of previous access reduced the odds ratio (OR) for unassisted AVF maturation, but patients with RI ≤0.8 (OR 3.07; P = 0.021) were independently increased the OR of unassisted AVF maturation.

Conclusions: RI value in preoperative ultrasound vessel mapping is an independent predictor for unassisted AVF maturation, and patients with higher RI value should be closely monitored for the necessity of intervention to promote maturation.

PUB001

Role of MRN Complex in DNA Damage of Cisplatin-Induced Acute Renal Failure Youngjung Kim, Tae Won Kim, Sora Park, Hyun Tae Kim, Si Yun Ryu, Ju Young Jung. *Veterinary Medicine and Institute of Veterinary Science, Chungnam National Univ, Daejeon, Korea.*

Background: The cisplatin-induced acute renal failure is a major side effect which limits cisplatin long-term chemotherapy. Mre11, Rad50, and Nbs1 (MRN) complex play critical roles in the pathways involved in the early phase of the cellular response to the DNA double strands breaks (DSBs) and DNA damage repair. The aim of the present study was to explore whether the MRN complex is associated with DNA repair mechanisms in cisplatin-induced ARF.

Methods: The rats were randomly allocated into three groups as follows; control group (sacrificed 10 d after saline intraperitoneal injection), 5D group (sacrificed 5 d after cisplatin injection) and 10D group (sacrificed 10 d after cisplatin injection).

Results: In the 5D group, the level of blood urine nitrogen and creatinine were increased seven times compared to the control group with increased apoptotic cells. In the 10D group, cisplatin-induced histopathological alterations in kidney were ameliorated together with decreased apoptotic cells if compared to that of 5D group. The expression of MRN complex was increased and localized in the nucleus of proximal tubule after cisplatin injection and these increased expressions was reduced in 10D group. As in MRN complex expression, increased DNA repair related signals (ATM, RPA2, H2AX, p53) in 5D group were reduced in 10D group.

Conclusions: Taken together, cisplatin-induced damage might trigger the MRN complex expression which is followed by the DNA repair related proteins expression.

PUB002

Direct Effect of LPS on Glomerular Renin Angiotensin System in Extracorporeal Renal Perfusion Luciane Gomes Santana, Waldemar S. Almeida, Nestor Schor. *Medicine, EPM/UNIFESP, São Paulo, SP, Brazil.*

Background: Experimental observations suggest that, at least in the early phases of septic acute kidney injury, changes involving the glomerular hemodynamics results in the loss of glomerular filtration rate (GFR), leading to accented mutate in local renin angiotensin system(RAS). In our laboratory demonstrated the inhibition of enzymatic activity of renin by the direct effect of lipopolysaccharide (LPS) in immortalized human mesangial cell. If reproducible *in vivo*, inhibition of the RAS site by LPS have clinical importance given the role usually played by AngII on glomerular cells and autoregulation of glomerular hemodynamics.

Methods: FITC-LPS were infused into the aorta above the renal arteries of male Wistar rats weighing approximately 250g. 1-2 hours after systemic injection, cortical glomerular cells were isolated through sieving technique. To exclude systemic effects of LPS on the kidneys did the extracorporeal perfusion for 1-2 hours with Krebs Henseleit buffer (KH) and solution KH+LPS of *E. coli* (0.10 mg/ml) and stored at -80°C for determination of AngI/II and renin activity in high performance liquid chromatography (HPLC). Furthermore, fragments of kidney tissue will be fixed and analyzed by immunohistochemistry (IHC) for RAS.

Results: The evaluation of the blades showed absence of blood circulating cells in glomerular homogenate, n=8. The fluorescence in flow cytometry showed a higher mean fluorescence intensity of glomerular cells in the renal cortex from animals treated with FITC-LPS, n=4, compared with animals control groups, n=4. Histological evaluation by light microscopy performed in the control group underwent extracorporeal perfusion showed that tubules and glomeruli had maintained its integrity. Groups exposed to LPS in extracorporeal perfusion for 1h and 2h showed a decrease of 70% (AngII=150ng/mg versus control group 600ng/mg, $P<0.001$, $n=4$).

Conclusions: So far we proved that circulating LPS-FITC is retained in renal glomerular tissue and that LPS isolated on extracorporeal renal perfusion significantly blocked the SRA in glomerular renal tissue. We suggest that reduced levels of AngII may contribute for changes in glomerular microcirculation and GRF decline in severe sepsis.

A Combination of Delayed Ischemic Preconditioning and Galectin-9 Protects against Renal Ischemic Injury through a Regulatory T Cell-Dependent Mechanism Bingying Zhang, Yi Fang, Hui Zhang, Sheng Wu. *Nephrology, Zhangshan Hospital, Fudan Univ, Shanghai, China.*

Background: To investigates the protective mechanisms of a combination of delayed ischemic preconditioning (IPC) and galectin-9 against kidney injury caused by ischemia/reperfusion (IR).

Methods: The male mice were randomly divided into 4 groups: IR, IPC-IR, IPC-Gal9-IR and sham-sham groups (n=5). IR was introduced by clamping bilateral renal pedicles for 35 min. 18-min ischemia preconditioning was induced 4 days before renal IR, and a daily injection of 5μg galectin-9 or PBS was subcutaneously administered during the 4 days between IPC and IR. The mice were sacrificed after 35min/24h IR. Renal function was assessed based on the serum creatinine (Scr) and renal pathology. The peripheral blood and the spleen were also collected to evaluate the Treg expression by flow cytometric analysis.

Results: A 18-min renal ischemic preconditioning significantly attenuated ischemia-reperfusion injury induced 4 days later (Scr: 47.06±12.06mml/L versus 60.13±4.42mml/L, $P<0.05$; histology score: 2.12±0.13 versus 3.3±0.21, $P<0.05$), while IPC in combination with galectin-9 treatment further improved the renal protection effects(Scr: 47.06±12.06mml/L versus 60.13±4.42mml/L, $P<0.05$; histology score:1.54±0.15 versus 2.12±0.13, $P<0.05$). A reduced infiltration of macrophages and DC in renal tubulointerstitium was also identified in the IPC-Gal9-IR group. Flow cytometric analysis revealed that percent of Treg in peripheral blood, renal tissue and spleen in the IPC-Gal9-IR group increased markedly, compared with the IR or IPC-IR group ($P<0.05$). PC61 treatment, used to decrease Treg cell levels, reduced the renoprotective effects of Galectin-9.

Conclusions: Delayed IPC in combination with galectin-9 administration substantially attenuates IR injury through expansion of Regulatory T cells.

PUB004

Differential Susceptibility to Acute Kidney Injury in Heterogenous Stock Rats Praneil D. Mehta,[1] Sarah M. White,[1] Leah C. Solberg Woods,[2] Kevin R. Regner.[1] *[1]Nephrology, Medical College of Wisconsin; [2]Human and Molecular Genetics, Medical College of Wisconsin, Milwaukee, WI.*

Background: Variation in the susceptibility to ischemia-reperfusion injury (IRI) has been demonstrated in several rat strains indicating the presence of genes that promote resistance to acute kidney injury (AKI). Identification of these genes may lead to the discovery of novel biologic pathways that can be targeted therapeutically to treat or prevent AKI in humans. Heterogeneous stock (HS) rats are a novel resource that can be used to study the genetics of renal disease by yielding diverse phenotypes and enabling rapid fine-mapping of quantitative trait loci to small genomic regions. The aim of the present study was to evaluate the range of phenotypes in HS rats following renal IRI.

Methods: Experiments were performed in 8 week old male Sprague-Dawley (SD, n=8) and HS (n=39) rats. Rats underwent 30 min bilateral renal ischemia and 24 hrs reperfusion. Rats were euthanized at 24 hrs and measurement of serum creatinine by LC-MS/MS was performed. Kidneys were collected for histologic analysis and Western blotting. Tubular injury was determined by the proportion of tubular cross sections in the cortex and outer medulla with tubular casts, loss of brush border, flattened epithelium, or sloughing of tubular epithelial cells. Expression of neutrophil gelatinase-associated lipocalin (NGAL), a marker of tubular injury, in kidney lysates was assessed by Western blot.

Results: Survival at 24 hrs after IRI was 100% in both the SD and HS rat groups. Serum creatinine at 24 hrs was 1.89±0.12 mg/dl in HS rats and 3.8±0.38 mg/dl in SD rats ($P<0.0001$). Serum creatinine in 30 of 39 HS rats was below the 95% confidence interval of the mean serum creatinine in SD rats. In HS rats, kidney NGAL expression correlated with serum creatinine ($r=0.7$, $P<0.0001$) and with renal cortex tubular injury scores ($r=0.5$, $P<0.001$).

Conclusions: In summary, these data demonstrate that HS rats exhibit decreased severity of renal dysfunction and renal injury following IRI in comparison to SD rats. These findings indicate that HS rats may harbor resistance alleles for kidney injury and suggest that the HS model may be a useful tool for further genetic studies in AKI.

PUB005

Impact of Comorbidities on Acute Kidney Injury Harlan Sparrow,[1] Carol M. Ashton,[1,2,3] Wadi N. Suki,[1,3,4] David Putney,[1] Nelda P. Wray,[1,2,3] Linda W. Moore,[1,2] A. Osama Gaber.[1,2,3] *[1]Houston Methodist Hospital; [2]Houston Methodist Research Institute; [3]Weil Cornell Medical College; [4]Baylor College of Medicine.*

Background: Acute Kidney Injury (AKI), which occurs in up to 18% of hospitalized patients, doubles the average length of stay (LOS) and results in 12-fold increase in risk of death compared with patients who do not experience AKI. Identification of risk factors that contribute to AKI is important in arriving at strategies to reduce AKI in hospitalized patients. The purpose of this project was to examine the impact of various comorbidities on the rate of AKI.

Methods: The first hospitalization of patients admitted in 2012 to a tertiary academic medical center were included. Patients <18 years, those with preexisting AKI, stage 5 CKD, or dialysis on admission, and those with a maximum serum creatinine (SCr) <=0.4 mg/dL were excluded. Also, patients lacking 2 SCr values within a 72-hour period were excluded. In-hospital AKI was defined as an increase in SCr by >=0.3 mg/dL or >=50% or a decrease in estimated Glomerular Filtration Rate by >=25% over a 72-hour interval. ICD9 codes, either present on admission (POA) or non-POA were used to determine comorbidities.

Results: Demographic and hospital data of 13,951 unique patients were as follows: AKI 18%, 31% had one or more ICU days, 52% were female, and 64% were Caucasian. Patients with AKI were older (66 versus 61 yrs $p<0.001$) and more likely black (22% $p<0.001$). All comorbidities showed a significant increase ($p<0.001$) in the incidence of in-hospital acquired AKI compared to those without the comorbidity except hypertension (NS).

Comorbidity	% Total Population	% AKI with Comorbidity	% AKI without Comorbidity
Chronic Kidney Disease	9	47	16
Congestive Heart Failure	17	37	15
Cardiovascular Disease	18	29	16
Cirrhosis	5	27	18
Diabetes	26	26	16
Hypertension	55	18	19

Conclusions: This retrospective analysis on nearly 14,000 patients shows that five of the six comorbidities have significantly higher in-hospital acquired AKI. Further research is needed to determine if this association is causal or induced by confounders. Regardless, these patients should be targeted for potential intervention to reduce the incidence of AKI.

PUB006

N-Acetylcysteine Ameliorate Heat Stroke Induced Acute Kidney Injury
Chia-Chao Wu,[1] Chun-Chi Chen,[1] Kuo-Cheng Lu.[2] *[1]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Div of Nephrology, Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.*

Background: The heat-related illness has become more prevalent and contributed to increased morbidity/mortality in the world with global warming. Heat stroke (HS) is the most severe and fetal heat-related illness. However, specific and effective therapies are not yet available to date. ROS plays a central role in HS. We assessed the efficacy of N-acetylcysteine (NAC), a thiol-containing free radical scavenger and antioxidant,therapy for HS induced AKI.

Methods: Adult male Sprague-Dawley rats were used to induce experimental HS. The rats are allocated into four groups. Two experimental HS groups of rats pre-treated with either saline, or NAC and another two as normothermic controls. All physiological and biochemical variables are measured. Disease severity was verified by with serum and urine metabolic profiles and with renal histopathology. The expression of cytokines and oxidative stress markers, cell apoptosis, and the associated mechanisms were also determined.

Results: HS rat treated with NAC displayed a better survival rate and stable hemodynamics. NAC also significantly reduce severity of AKI based on biochemical and histopathlogical evidence. The NGAL-positive cells and TUNEL-positive apoptotic cells in the kidney were significantly reduced in the NAC-treated HS rat. Oxidative stresses markers were significantly reduced in NAC -treated HS rat. Cytokines studies indicated that NAC significantly modulate serum proinflammatory, and anti-inflammatory cytokines. The effect on other organs revealed similar pattern as kidney.

Conclusions: Our studies have demonstrated NAC significantly attenuated organ damage and enhanced survival in HS rats. These protective effects may be associated with its anti-inflammatory capacity and anti-oxidant activity. We suggests that NAC could be potentially therapeutic for HS induced AKI in the future.

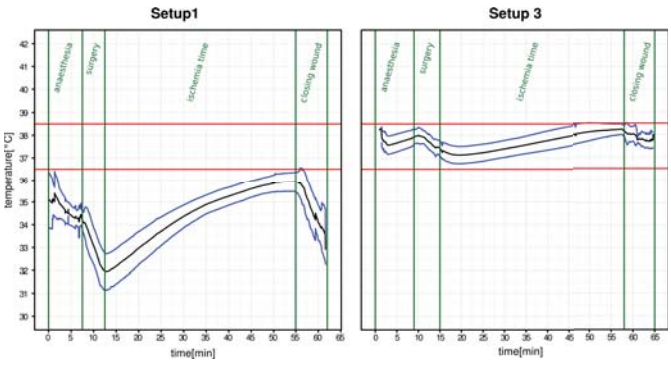
PUB007

Preoperative Heat Supply Improves Temperature Control in Experimental Ischemia Reperfusion Injury
Hannah Schaefer, Julian A. Marschner, Hans J. Anders. *Nephrologisches Zentrum, Klinikum der Univ Muenchen, Munich, Germany.*

Background: Experimental ischemia reperfusion injury (IRI) is widely used to induce AKI in mice. Beyond ischemia time body temperature (BT) is an important determinant of the severity of injury. Online body temperature monitoring (OBTM) in each mouse revealed that in our established surgery setup the BT was not constant within a target range of 36.5-38.5°C. We therefore tested various ways to improve temperature control during IR surgery based on OBTM.

Methods: Our established IRI protocol was changed stepwise. The old setup (1) provided heat supply during ischemia time by a heating pad, while setup 2 extended this also during ischemia time in a heating box. Setup 3 provided also presurgery heat supply in a 2nd heating box. Tubular injury was estimated by PAS-scoring and mRNA expression of tubular injury markers, the immune response was quantified by cytokine expression and neutrophil staining.

Results: Setup 1, 2 and 3 target range temperature readings were 0.69, 34.6 and 99.3%, respectively.



This increased the percentage number of necrotic S3 segment tubules (setup 1: 63.2%, 3: 93.3%) and neutrophil influx (setup 1: 5.7%, 3: 29.2%) as well as KIM-1 and TNFa expression. Testing various ischemia times in setup 3 for the same read-out parameters revealed that the same amount of injury is created with 20 min less ischemia time compared to setup 1. Setup 3 also allowed us to precisely modulate injury with ischemia time length since all parameters displayed significant differences for each time point.

Conclusions: As the animals BT drops quickly upon installing anaesthesia, presurgery heat supply is needed to maintain a target range temperature during IR. Optimized BT control improves the reproducible induction of IRI, as BT has a great impact on tissue injury. Vice versa, reducing BT may be a way to reduced IRI in surgical settings, such as kidney transplantation.

PUB008

Myo-Inositol Oxygenase (MIOX)-Mediated, Gentamicin-Induced Acute Tubular Injury via Oxidative and ER Stress
Ming Zhan, Yashpal S. Kanwar. *Dept of Pathology and Medicine, Northwestern Univ, Chicago, IL.*

Background: Gentamicin-induced acute kidney injury (AKI) has been recognized over decades and the clinical use of this antibiotic is thus limited. Gentamicin nephrotoxicity is associated with increased endoplasmic reticulum (ER) stress and oxidative stress, but the mechanism is still unclear. MIOX, a renal tubular enzyme, modulates tubular cellular redox in diabetes and is also upregulated in the plasma of patients with AKI. Here we investigated the potential role of MIOX in the pathogenesis of gentamicin-induced AKI.

Methods: Adult CD1 mice were injected with gentamicin intraperitoneally for different time periods. The kidney and serum samples were then obtained for the detection of targeted genes and tissue morphology analysis. In HK2 cells treated with various inhibitors, the impact of MIOX on gentamicin-induced stress signaling and mitochondrial injury was evaluated.

Results: CD1 mice with gentamicin injection for 7 days showed elevated levels of serum creatinine and blood urea nitrogen. Compared to the controls, MIOX mRNA and protein expressions were upregulated in the kidneys of gentamicin-treated mice in a dose-dependent manner, which paralleled with the increase of an AKI biomarker Kim-1. These changes were accompanied with elevated expressions of ER stress markers including GRP78, CHOP, p-JNK; as well as oxidative stress indicators Nox4, catalase, and elevated NADPH/$NADP^+$ ratio. In addition, proximal tubules from gentamicin-injected mice exhibited fragmented mitochondrial morphology and altered ER-mitochondrial contacts, along with increased Bax but decreased Bcl-2 levels, mitochondrial cytochrome C release and apoptosis. Following gentamicin treatment in vitro, HK2 cells transfected with MIOX siRNA showed reduced oxidative and ER stress. Importantly, gentamicin-induced mitochondrial dysfunction and apoptosis were partially ameliorated in HK2 cells with MIOX knockdown or cells treated with ROS scavenger or ER stress inhibitor.

Conclusions: Data suggested that ER and oxidative stress triggered by gentamicin in tubular cells is mediated by MIOX, which leads to mitochondrial dysfunction and tubular cell injury and death.

PUB009

Chymase Inhibition Ameliorates Apoptosis and Fibrosis in Hypoxic Injury of Renal Proximal Tubular Epithelial Cells
Seong Kwon Ma,[1] Chang Seong Kim,[1] Ha Yeon Kim,[1] Hoon In Choi,[1] Jung Sun Park,[1] Eun Hui Bae,[1] Jongun Lee,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea; [2]Dept of Physiology, Chonnam National Univ Medical School, Gwangju, Republic of Korea.*

Background: Chymase is an alternative pathway for angiotensin converting enzyme (ACE) in Ang II formation, and it also plays an important role in tissue remodeling through the activation of transforming growth factor (TGF)-β1 and endothelin A receptor (ET_AR). However, renoprotective effects of chymase inhibition remain elusive. We investigated the effects of chymase inhibition on the apoptosis and fibrosis induced by hypoxia in human renal proximal tubular epithelial (HK-2) cells.

Methods: HK-2 cells were cultured in hypoxic chamber in the absence or presence of chymostatin, a chymase inhibitor. The protein expressions of chymase, Ang II, Ang II type 1 receptor (AT1R), ACE, ET_AB and ET_BR were determined. We also investigated the effects of chymostatin on the expressions of pro-apoptotic and pro-fibrotic proteins.

Results: In HK-2 cells, hypoxia increased the expressions of chymase, Ang II and AT1R. However, the protein expression of ACE was not changed. The expression of ET_AR was increased while that of ET_BR was decreased. These were counteracted by the pretreatment of chymostatin. In HK-2 cells with hypoxic injury, the protein expression of Bax/Bcl-2, cleaved caspase-3 and TGF-β1 was also increased. In addition, hypoxic treatment resulted in decreased cell viability. These were also ameliorated by the pretreatment of chymostatin.

Conclusions: These findings suggest that chymase inhibition may play a protective role in the hypoxic renal tubular injury through the inhibition of apoptotic and fibrotic pathways.

PUB010

Target Specificity of PTBA Class Inhibitors
Subramaniam Sanker,[1] Nataliya Skrypnyk,[2] Mark P. De Caestecker,[2,3] Neil A. Hukriede.[1] *[1]Developmental Biology, Univ of Pittsburgh, Pittsburgh, PA; [2]Medicine, Vanderbilt Univ Medical Center, Nashville, TN; [3]Cell and Developmental Biology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Acute Kidney injury (AKI) is a rapid loss of kidney function that causes irreversible damage and fibrosis. Other than renal replacement there are no post AKI therapies. We identified the histone deacetylase (HDAC) inhibitor phenylthiobutanoic acid (PTBA) from an embryonic renal progenitor cell (RPC) proliferation screen. PTBA Analogues UPHD00025 and UPHD00186 activate proliferation of RPCs and enhance renal function after tubule injury in zebrafish and mouse AKI models. They also reduce post-injury fibrosis in mice. Since therapeutic efficiency is an outcome of target engagement, a correlation to the PTBA cognate target is essential. Using cellular thermal shift assay (CTSA) we propose to identify HDAC targets of PTBA. By pharmacokinetics we also compare PTBA, UPHD00186 and UPHD00263 to describe a mechanism of action.

Methods: Ligand induced thermal stabilization is a measure of target engagement. HEK-293 cell lysates are subjected to thermal denaturation with and without PTBA. After

pelleting the denatured proteins, the supernatants are probed on westerns with specific HDAC antibodies. For DMPK, compounds at 50mg/kg is injected IP into BALB/c mice. Metabolites in blood samples withdrawn are identified by LCMS.

Results: PTBA can stabilize all four class I HDACs from denaturation at 55°C compared to DMSO control. However class II HDACs such as HDAC5 are not stabilized by PTBA. UPHD00025 and UPHD00186 generate PTBA in plasma within 5 minutes or less after IP injections due to hydrolysis. UPHD00263 lacking the amide bond of UPHD00186 does not generate PTBA nor induce RPC proliferation.

Conclusions: Results from CTSA demonstrates that PTBA analogues target the class I HDACs. CTSA will help us to establish therapeutic targets for the PTBA class HDAC inhibitors and define which HDACs are best to target during AKI events. *In vivo* hydrolysis generates PTBA from the analogues to drive activity. Hence UPHD00025 and UPHD00186 functions as reservoirs for extended release of the PTBA. Grant support: DK069403 and DK079307.

PUB011

Role of Tight Junction Proteins in Hydrogen Peroxide-Mediated Regulation of Paracellular Permeability Angelina Voronina, Nikita Shah, Shirin Jaggi, Josephine Axis, Kurt Amsler. *Dept of Biomedical Sciences, NYIT College of Osteopathic Medicine, Old Westbury, NY.*

Background: Oxidative stress increases paracellular permeability of renal epithelia both in vitro and in vivo. Hydrogen peroxide (H_2O_2) treatment of cultured renal epithelial cells is a model for aspects of this pathogenic process. H_2O_2 treatment of MDCK cells produced a concentration-dependent collapse of domes, manifestations of transepithelial salt and water absorption.

Results: Even at concentrations that did not lead to collapse of domes, H_2O_2 produced a concentration-dependent increase in paracellular flux of calcein. In contrast, transepithelial resistance of MDCK cell populations was not affected by treatment with H_2O_2 at any of the tested concentrations. Cell death (necrosis) was observed at higher H_2O_2 concentrations but flux changes could be observed at sublethal H_2O_2 concentrations. The total cellular contents of TJ proteins, occludin, claudin-1, ZO-1 and ZO-2, were unaffected by treatment with either sublethal or lethal concentrations of H_2O_2. There were also no dramatic changes in the contents of these TJ proteins in the Triton X-100-soluble and –insoluble fractions with either sublethal or lethal H_2O_2 treatment. Lethal H_2O_2 concentrations produced altered the localization of occludin, ZO-1 and F-actin. Less dramatic alterations in the localization of ZO-2 and claudin-1 were observed. Despite increasing paracellular permeability, sublethal H_2O_2 concentrations did not markedly alter subcellular localization of any TJ proteins. Knockdown of occludin or ZO-2 increased the sensitivity of MDCK cells to H_2O_2. In contrast, overexpression of occludin or knockdown of ZO-1 diminished the sensitivity of MDCK cells to H_2O_2. Transepithelial resistance was decreased in ZO-2 knockdown cells compared to control MDCK cells but was unaffected by other manipulations.

Conclusions: These results indicate a complex interplay of multiple TJ proteins in the H_2O_2-induced regulation of paracellular permeability.

PUB012

Human Kidney-2 (HK-2) Cells Resist Hypoxic Death Emmett D. Ratigan, Alana Shigeoka, Sashi Kasimsetty, Reza Elahimehr, Dianne B. McKay. *Medicine, Univ of California San Diego, San Diego, CA.*

Background: In vitro hypoxia is an experimental method used to mimic ischemia/reperfusion injury, and is considered a valid model. To better understand the molecular mechanisms of ischemic kidney injury, immortalized renal tubular cell lines have been developed that provide a homogenous cell population allowing for in depth molecular studies of cellular stress. Amongst studies evaluating hypoxic stress, cell death assays have been commonly used as experimental end points. To test the validity of in vitro hypoxia using immortalized cell culture as a model of ischemic renal tubular injury, we subjected the well-characterized HK-2 proximal tubular cell line to severe hypoxic conditions and analyzed their ability to resist cell death.

Methods: HK-2 monolayer cell cultures were grown to 50-70% confluency and exposed to either ambient oxygen (21%) or 1% oxygenation in a Coy® hypoxic chamber for 24, 48, and 72 hours duration. The cells were grown in glucose-free DMEM to allow for aerobic respiration only. After the incubation period, HK-2 cells were harvested and cell death analyzed, using the Cellometer® Annexin V-FITC/PI Apoptosis Assay. The data represent the composite of duplicate experiments with similar results. Chi-square analysis was used with a significance level of 0.05.

Results:

Exposure	Living at 24 hours	Living at 48 hours	Living at 72 hours
Hypoxia	79%	72%	52%
Normoxia	77%	75%	53%
	P<0.01	P<0.01	P=.33

Cultures subjected to hypoxia had less cell death at 24 hours, although at 48 hours the opposite was true. Following 72 hours there was no difference between groups. Overall, the amount of excess cell death in the hypoxic group was either absent or surprisingly low, which suggests caution in interpretation of hypoxic studies using immortalized proximal tubular cell lines.

Conclusions: HK-2 cells were derived through transduction of human proximal tubule cells with HBV 16 E6 and E7 genes, which encode viral proteins acting to degrade p53 and interfere with pRB tumor suppressor activity. We propose that HK-2 cells are refractory to hypoxic cell death due to selective degradation of p53, supporting the potential of apoptotic inhibition for protection from prolonged ischemic renal injury.

PUB013

Stabilization of eEOC Autophagy in Murine Ischemic AKI Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology and Rheumatology, Univ Hospital Göttingen, Germany.*

Background: *Early Endothelial Outgrowth Cells* (eEOCs) protect mice from ischemic AKI. Autophagy, a cellular mechanism mediating endogenous protection can prolong the lifespan of cells. Thus, aim of the study was to analyze consequences of eEOC autophagy stabilization in murine ischemic AKI.

Methods: Male, 8-12 week old C57/Bl6N mice were subjected to unilateral renal ischemia (45 minutes) postuninephrectomy. Animals were systemically injected with either untreated or SAHA (SuberoylAnilide Hydroxamic Acid) or Temsirolimus pretreated syngeneic murine eEOCs at the time of reperfusion. Mice were analyzed 48 hours and 4 weeks later.

Results: Renal ischemia significantly affected renal function. Administration of SAHA pretreated cells elevated intrarenal endothelial levels of Atg8, indicating increased autophagy of the endothelium. Nevertheless, neither the administration of untreated nor SAHA or Temsirolimus pretreated cells protected mice from AKI in the short-term. Renal dysfunction still persisted at 4 weeks and cell administration did not result in any stabilization of renal function at this time.

Conclusions: Although eEOC treatment with autophagy inducers increases endothelial autophagocytic activity in the kidney, mice are nor protected from postischemic acute renal dysfunction in the short- or in the mid-term. Thus, autophagy induction in eEOCs is most likely not an effective strategy to stimulate renoprotective effects of the cells in AKI.

PUB014

Mid-Term Outcome of Murine AKI with versus without Administration of Early Endothelial Outgrowth Cells Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology and Rheumatology, Univ Hospital Göttingen, Germany.*

Background: *Early Endothelial Outgrowth Cells* (eEOCs) protect against murine ischemic AKI in the short-term. These effects can be stimulated by Angiopoietin-2 and Bone Morphogenetic Protein-5 (BMP-5). Aim of the study was to analyze mid-term consequences of eEOC treatment of murine AKI (with versus without Ang-2 / BMP-5 treatment).

Methods: Male, 8-12 weeks old C57/Bl6N mice were subjected to unilateral renal ischemia post-uninephrectomy. Untreated and Ang-2 / BMP-5 pretreated syngeneic murine eEOCs were adminstered at the time of reperfusion. Six weeks later, animals were analyzed for renal function, fibrosis and mesenchymal transdifferentiation of intrarenal endothelial cells (EnMT - Endothelial-to-Mesenchymal Transition).

Results: Renal function of postischemic mice was still significantly affected at six weeks after acute ischemia. Cell administration did not protect mice from renal dysfunction. Ang-2 treated eEOCs tended to reduce interstitial fibrosis and BMP-5 aggravated fibrosis as compared to Ang-2. EnMT remained unaffected by cell therapy.

Conclusions: Early Endothelial Outgrowth cells alone do not protect from postischemic renal damage in the mid-term. Ang-2 and BMP-5 tend to increase renoprotective effects of the cells at 6 weeks. Pharmacological preconditioning of eEOCs can result in aggravation of fibrosis, eEOC priming protocols in AKI must therefore be chosen with caution.

PUB015

Conditioned Medium (CM) from Mesenchymal Stem Cells (MSCs) Protects Human Proximal Tubular Cells (HK2) Lesions by SEPSis Jessica S. Garcia, Marcelo Andery Naves, Fernanda Teixeira Borges, Nestor Schor. *Medicine - Nephrology, UNIFESP - EPM, São Paulo, Brazil.*

Background: Recent studies emphasize the contribution of MSCs in the regeneration related to acute kidney injury (AKI). MSCs mitigate the damage and / or accelerate the repair and participate in the immunomodulation processes, probably by paracrine pathways. This protection involves the CM that contains soluble factors or microvesicles (MVs). We studied the paracrine effect of MSCs in vitro models of AKI induced by LPS in culture.

Methods: HK2 cells were cultured and incubated for 24-96 h with LPS (100mg/ml), with or without CM from MSCs. The CM was also pre-conditioned (PC) by treating MSCs with LPS (100mg/ml, PC_{LPS}) or GENTA (2 mM, PC_{GENTA}) for 48 h before the experiment and CM was also employed in frozen form ($_f$CM). Cell proliferation was evaluated by MTT assay.

Results: Increases in cell proliferation in the CM+LPS group compared with LPS alone (0.12±0.02 versus 0.10±0.02 DO, $p < 0.05$), and the major proliferation happened with the $_f$CM+LPS (0.16±0.04 DO, $p < 0.05$). Evaluating groups with PC-CM, it was observed higher proliferation in PC_{GENTA}-CM+LPS (0.16±0.05 DO, $p < 0.05$) in HK2 than in PC_{LPS}-MC+LPS (0.09±0.02 DO, $p < 0.05$). Comparing only the different CM in HK2 cells in culture, it was measured greater proliferation in PC_{LPS}-MC (0.27±0.07 DO, $p < 0.05$) when compared with CM or $_f$CM (0.21±0.03 and 0.20±0.06 DO, $p < 0.05$, respectively).

Conclusions: These preliminary results suggested that CM from MSCs exerts a protective effect by stimulating cell proliferation during the treatment with LPS. Also, it is also verified potentialization with previous PC, enhancing its effects. It is interesting that a cross-over effect in PC was observed since PC_{GENTA} was more effective than PC_{LPS}

in the isolate cell model of sepsis. Also, surprisingly ₍CM showed higher effect than the fresh form. Thus, results may indicate that it is possible to minimize AKI induced by LPS without cells transplantation but only with their CMs, avoiding potential harmful effects of cell therapy. And finally, it is also possible to stimulate the CM (PC strategy) in order to enhance its effects. Support: CNPq, FAPESP, CAPES, FOR.

Estrogens Protect against Hemorragic Shock-Induced Acute Kidney Injury in Mice Melodie Cuny,[1] Marie Buleon,[1] Julie Belliere,[1] Ivan A. Tack.[1,2] *[1]I2MC, UMR 1048, INSERM, Univ Toulouse III; [2]CHU Toulouse, France.*

Background: The protective effect of estrogens against chronic glomerular diseases is well admitted but remains unknown during Acute Kidney Injury (AKI). This study aimed to determine the impact of estrogens deprivation, replacement or acute administration during AKI, using a model of hemorrhagic shock in mice.

Methods: Four groups of C57/Bl6 female mice were submitted to a pressure-controlled hemorrhagic shock: control [C]; receiving a single acute intravenous bolus of estradiol (E2) during resuscitation [AE2]; ovariectomized [O]; ovariectomized with chronic E2 replacement [CE2]. Renal impact was studied 1 and 21 days (D1 and D21) following the shock. At D1, renal function, programmed cell death (TUNEL) and endoplasmic reticulum (ER) stress (GRP78 and CHOP expressions) were assessed. Since ER stress can induce pyroptosis, caspases 1 and 11 expressions were studied. Renal immune response was assessed using TLR4 expression and IL1β synthesis. Finally, Glomerular Filtration Rate (GFR) and renal fibrosis (collagen III deposits) were studied at D21.

Results: Mortality was higher in CE2 group. At D1, renal function was similar between groups. However, some mice, from O and CE2 groups only, showed tubular impact (assessed by cystatinuria). In control, hemorrhagic shock induced epithelial cell damages involving ER stress (increase in GRP78 and CHOP) and pyroptotic cell death (increase in caspases 1 and 11) that resulted, at D21, in secondary renal fibrosis without significant decrease in GFR. Estrogen deprivation worsened renal damages but chronic E2 replacement was not beneficial. In AE2 group renal damages were largely prevented by reduction of ER stress, pyroptosis, renal inflammation and fibrosis.

Conclusions: In this model, AKI leads to profibrotic pyropotosis that was worsened by endogenous estrogens deprivation, but not improved by chronic E2 replacement. By contrast, administration of a single bolus of E2 during resuscitation resulted in a striking protective effect, reducing both the severity of cell death related to pyroptosis, renal inflammatory response and secondary fibrosis. This result highlights the importance of studying the " bolus effect " of estradiol in situations of AKI.

PUB017

Effects of the Transplantation of Ast-hADSC in Cisplatin-Induced Acute Kidney Injury Nanmei Liu. *Dept of Nephrology, Jimin Hospital of Shanghai, Shanghai, China.*

Background: To observe the effect of the injured renal tissue and contribute to its recovery in mice with transplantation of human adipose-derived mesenchymal stem cells (hADSCs) cultured with Astragaloside IV(Ast) in cisplatin-induces acute kidney injury and explore possible mechanisms.

Methods: Male BALB/C mices were randomly divided into normal group, model group, hADSCs group and Ast-hADSCs group after establishing animal models of cisplatin-induced renal injury. hADSCs and Ast-hADSCs were injected into the transplantation group through caudal vein after 24h of cisplatin injection, and equal physiological saline was also injected into the model group. These mice were sacrificed on the 3d after transplantation. Blood samples were used to test serum creatinine (Scr) and urea nitrogen (BUN). The renal tissues were got, and HE staining was performed to observe the pathological changes, and both VEGF and PCNA staining were also observed by immunhistochemical analysis. The level of TNF-α,IL-6 and RANTES was also detected by enzyme-linked immunosorbentassay (ELISA).

Results: The levels of Scr and BUN of model groups were significantly higher than those in the normal group and intervenient group, comparing with the hADSCs group, the pathological changes in the Ast-hADSCs group was much lower. Furthermore, the Ast-hADSCs group confirmed renal tuble epithelium to be deposited by laser confocal-microscopy, as well as the expression of inflammatory cytokines, such as TNF-α, IL-6 and RANTES and the levels of apoptosis related protein, such as Caspase-3 and Bax were obviously decreased while the expression of VEGF, PCNA and Bcl-2 was increased. Among all those groups, the Ast-hADSCs had a more obviously positive effect on cisplain-induced renal damage.

Conclusions: Transplantation of hADSCs into injured kidney contributes to recovery of cisplatin-induced acute renal injury, and Ast-hADSCs is more effective in repairing acute renal injury.

PUB018

Nephrotoxicity of Ifosfamide in Adult Patients Gaël Ensergueix,[1,2] Alexandre Karras,[1] Marie Essig,[2] Eric Thervet. *[1]Nephrology, Dialysis, Hôpital Européen Georges Pompidou, Paris, France; [2]Nephrology, Dialysis, Transplantation, CHU Limoges, France.*

Background: Ifosfamide (IFO) is an alkylating agents used as an antineoplasic drug in several types of solid cancers, especially sarcomas. IFO renal side-effects have moslty been described in pediatric populations. The aim of this study was to describe, in adult patients (pts) the clinical and histological features of the IFO-associated nephrotoxicity.

Methods: We conducted an observational, retrospective study in 4 French nephrology centers. All adult pts admitted for renal failure (eGFR < 60 ml/min/1.73 m2) or tubular dysfunction after IFO therapy were included.

Results: We included 15 pts (7 men and 8 women) with a mean age at diagnosis of 54 (18-75), 93% had received IFO for sarcoma. The mean cumulative dose of IFO was 18.40 g/m². Ten pts received concomitant cisplatin treatment. In 6 pts, the renal presentation was an acute kidney injury (AKI) occurring during the first month following IFO administration, 5 pts had a slowly progressive chronic kidney disease (CKD) detected 6 to 24 months after IFO therapy and 7 pts, a proximal dysfunction (Fanconi syndrome). Three pts had several forms of nephrotoxicity. Renal biopsy was performed in 5 cases, showing marked proximal tubular mitochondrial cytopathy in 4 cases, interstitial inflammation and tubular atrophy/interstitial fibrosis in 2. After a mean follow-up of 16 months, 3 pts reached end-stage renal disease. At the last follow-up, the mean eGFR of the 12 remaining pts was 27 ml/min/1.73m². Among the 4 pts requiring initial hemodialysis only one could stop dialysis. Corticosteroids were used in 2 cases without improvement of renal function.

Conclusions: In adult pts, IFO nephrotoxicity can induce either AKI, progressive CKD diagnosed several months after discontinuation, or proximal tubulopathy. Prospective, large-scale studies are needed to precisely determine the prevalence, the pathophysiological mechanisms and the risk factors associated with this severe side-effect.

PUB019

NGAL and Urine Biochemistry for Early Detection of Acute Kidney Injury Lilian Carmo, Camila Lima, Fernando de Almeida Soares, Vivian Lumi Onusic, Liliany P. Repizo, Emmanuel A. Burdmann, Etienne Macedo. *Nephrology, USP, Sao Paulo, SP, Brazil.*

Background: Early AKI diagnosis with biomarkers of injury is promising advance for improving AKI outcomes. Association of clinical risk factors, urinary indices with these biomarkers could help to improve their performance in the clinical practice. We hypothesized that urinary neutrophil gelatinase-associated lipocalin (NGAL) in association with urinary biochemistry could be a tool to improve early AKI detection in high-risk critical ill patients.

Methods: We performed a prospective study between Jan 2012 and July 2013. We recruited patients admitted in intensive care unit (ICU) with high risk for AKI. Urinary NGAL and urine biochemistry were measured serially every 12 hours during the first two days of ICU stay. Urinary indices including strong ion difference (SIDu), potassium gradient transtubular (TTKG) and fractional excretion of sodium (FENa) were evaluated during this period.

Results: Of the 272 screened patients, 46 met the inclusion criteria. During the observation period, first 7 days of ICU stay, 30(62.5%) patients met KDIGO criteria for AKI. Urinary NGAL was higher at all points in AKI group.

	NGALu basal	NGALu 12h	NGALu 24h	NGALu 36h	NGALu 48h
No AKI	54 (21-148)	38 (22-144)	39 (21-187)	49 (12- 201)	90 (21-222)
AKI	260 (75-2649)	147 (69,7-505)	95 (54-301)	101 (52-510)	123 (57-245)

Urinary NGAL value with best sensibility and specificity to predict the development of AKI was 175 ng/ml (area under ROC curve = 0.738 - IC 95% 0,586-0.890 *p=0.011*). In patients developing AKI by sCr criteria, urinary NGAL would provide an earlier diagnosis in 10 patients (38%). Four (18%) patients with urinary NGAL levels above the cutoff did not developed AKI during the observation period. FENa was <1% in AKI and non-AKI groups. The progression of urinary SID was similar in both groups. In patients that developed AKI TTKG was not statically significantly higher.

Conclusions: Urinary NGAL was an earlier predictor of AKI in high risk patients. The association of urinary biochemistry did not improve the prediction ability of NGAL in this cohort. Further studies incorporating this indices should confirm their role in early diagnosis of AKI.

PUB020

The Risk Factors on the Prognosis of Acute Kidney Injury According to Kidney Disease: Improving Global Outcomes Definition and Staging Criteria: A Retrospective, Multicenter Study in Critically Ill Patients Jiaojiao Zhou, Lichuan Yang, Fang Liu, Ping Fu. *Div of Nephrology, Dept of Medicine, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: Despite significant advances in the medical management and therapeutics, acute kidney injury (AKI) is still a familiar and serious complication with enhanced morbidity and mortality in hospitalized patients, especially in intensive care units (ICUs). The primary purpose of this study is to apply the definition proposed by the KDIGO criteria to analyze the morbidity and risk factors on the prognosis of AKI in ICUs.

Methods: In this retrospective study, we collected the data from patients admitted in ICUs of West China Hospital of Sichuan University from July 28, 2009 to April 16, 2010. Logistic regression analysis was performed to investigate the related factors for 28-day mortality of AKI in ICU.

Results: After further exclusion, there were 1036 patients of ICU admissions enrolled in this research. We found AKI occurred in 36.9% and the mortality was 51.3%. The variables that were related to the prognosis of AKI in logistic regression analysis were as follows: sepsis (odds ratio [OR], 21.43), AKI stage 2 (OR, 17.34), severe acute pancreatitis(SAP) (OR, 11.75), AKI stage 3 (OR, 8.41), the timing of AKI in ICU (OR, 4.84), chronic obstructive pulmonary disease(COPD) (OR, 3.46), mechanical ventilation (OR = 2.76).

Conclusions: In these ICU patients, various risk factors including sepsis, SAP, AKI stage 2 and 3, the timing of AKI in ICU, COPD, and mechanical ventilation were considered as independent predictors of 28-day mortality. The KDIGO criterion is a sensitive and scientifically valid definition that provides an early warning signal for renal dysfunction in critically ill patients.

PUB021

AKIN Criteria: A Dynamic Tool Associated with Higher Odds of Hemodialysis Dependence and Death in Patients with Acute Kidney Injury Hugo Pinheiro, Gisele Vajgel Fernandes, Ederson Vidal Moura, Luis H.B.C. Sette, Lucila Maria Valente, Cintia Germana Mergulhão da Costa, Geraldo José de Amorim, André Luiz De Andrade Araújo. *Nefrologia, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Background: AKIN was planned to standardize the diagnosis and the classification of AKI allowing comparison between clinical studies worldwide and there is a linear correlation between mortality and increasing AKI stage. The aim of this study was to evaluate the association between AKIN classification in the moment of the nephrologist referral and its in-hospital progression to the patient outcomes.

Methods: We conducted a retrospective single center cohort study of in-hospital patients referred to nephrologist consult from Jan 2011 to Dec 2013. AKI was defined and classified according to the AKIN criteria, based on SCr, at the first day of nephrologist consult and consecutively during in-hospital stay. Primary endpoints were mortality and the combined outcome was defined as mortality or dialysis dependence at hospital discharge.

Results: We analysed 778 in-hospital admissions and among them 407 met AKI criteria. The mean age was 54y, 54% were female and patients were classified as follows: AKIN 1 (23.3%), AKIN 2 (25.8%) and AKIN 3 (43.7%) at the moment of nephrology referral. We found that AKIN 1, 2 or 3 needed RRT in 27.3%, 28.5% and 58.4%, respectively (P<0.0005). Worsening AKIN score from 1 or 2 to AKIN 3 was associated with higher odds of mortality and combined outcome of death and permanent need for dialysis when compared to those who maintained AKIN 1 or 2 during follow up, in unadjusted analysis (OR 2.02/CI 1.04-3.94; P= 0.038 and OR 2.22/CI 1.15-4.26; P= 0.017, respectively). Those who were referred to the nephrologist at AKIN 1 or 2 and afterwards changed AKIN to 3 during in-hospital stay had similar rates of mortality and combined outcome as those who maintained AKIN 3 (P= 0.9 and P= 0.57).

Conclusions: Patients whose AKIN rose to 3 during in-hospital stay or were referred to the nephrologist on AKIN 3 had higher rates of death or permanent need for dialysis when compared to those who remained at AKIN 1 or 2. Our results highlight the importance of nephrology referral in earlier stages of AKI.

PUB022

Acute Babesiois Presenting with AKI Ashwin Narasimhan,[1] Nishitha Cherukumalli,[2] Sravan Jasti.[3] *[1]Nephrology, Univ of Pennsylvania Hospitals, Philadelphia, PA; [2]Nephrology, Albert Einstein, Philadephia, PA.*

Background: 60 year male with hx of HepatitisB,recently diagnosed lymes disease presented to ER with sweats,chills,fatigue and fever.

Methods: Patient was diagnosed with lymes disease 1 week prior by primary who noted a target lesion on his right inner thigh and placed on 21 day course of doxycycline.Vitals on admission: BP 136/74,HR-95, RR-18 and T-103.5.Chemistries: Na-141, K-4.7,Cl-113, Co2-24,AST103, ALT78, CPK 43, Cr 2.8 and BUN58 .Hgb was 8.9, Platelets-299000, LDH 528.Micro anaplasma titres and Ehrlichiosis titres were less than assay .Peripheral smear confirmed RBC inclusions consistent with babesia with parasitic load of 6.2%. Renal consulted for AKI.Urinary sediment revealed large number of muddy brown casts and 2-3WBC casts consistent with ATN .Patient was oliguric on admission that improved with hydration. Infectious disease was consulted and given severity of parasitic burden patient underwent RBC exchange transfusion with symptoms of anemia,organ failure and fever.He was started on IV clindamycin and Quinine.His parasitic load came down to <0.01 with overall improvement in symptoms and his discharge creatinine was 1.7 and BUN of 16. He was discharged home on 10 days of atovaquone and azithromycin.

Results: Asymptomatic Babesiois occurs in only 25% of immunocompetent adult hosts. Symptomatic disease may involve multiple organ systems with respiratory distress, acute hepatitis, and AKI causing significant morbidity,including severe dialysis-requiring AKI. Kidney involvement in babesiosis is largely due to ATN from combination of underlying sepsis, hemodynamic instability,and heme pigment induced tubular injury.Rare cases of AIN have been reported.Only a few cases of babesiosis with ATN and AIN have been reported .Interstitial nephritis although not confirmed by biopsy could have existed as sediment contained WBC casts. Prompt identification,aggressive antibiotic therapy, hydration and possible redcell apheresis is treatment .In rare cases with plasma dominant AIN,prednisone may be be required.

Conclusions: Prompt identification of babesiosis with treatment in a timely manner helps avoid serious outcomes like renal failure that is dialysis dependant.

PUB023

Cell Cycle Arrest Biomarkers Accurately Predict Acute Kidney Injury in Diabetics with or without Chronic Kidney Disease Michael Heung,[1] Luis M. Ortega,[2] Lakhmir S. Chawla,[3] John A. Kellum.[4] *[1]U Michigan; [2]Temple U; [3]George Washington U; [4]U Pittsburgh.*

Background: Patients with diabetes mellitus (DM) and chronic kidney disease (CKD) are at high risk for development of acute kidney injury (AKI). However, identification of AKI can be challenging in patients with underlying chronic disease, and biomarkers often perform poorly in this population. We recently reported data from two multi-center studies of 728 (Sapphire) and 408 (Topaz) critically ill patients where a panel of urinary tissue inhibitor of metalloproteinases-2 (TIMP2) and insulin-like growth factor-binding protein 7 (IGFBP7), both markers of cell cycle arrest, were validated for risk stratification for moderate to severe AKI (KDIGO stages 2 and 3). Here we report performance characteristics of this novel biomarker panel ([TIMP2]•[IGFBP7]) in patients with DM with or without CKD.

Methods: We conducted subgroup analyses of patients with DM with and without CKD from the Sapphire and Topaz studies. Subjects were enrolled and samples obtained within 24 hours of ICU admission. We constructed receiver operating characteristic (ROC) curves using urinary [TIMP2]•[IGFBP7] for prediction of moderate to severe AKI within 12 hours. We also examined the relative risk (RR) for AKI using a pre-specified cutoff for [TIMP2]•[IGFBP7] of 0.3.

Results: There were 210 and 116 patients with DM in Sapphire and Topaz, respectively, of which 36 and 14 had CKD. Demographics for the two studies were similar. Overall, 52 patients (16%) developed moderate-severe AKI. For diabetic patients, the area under the ROC curve (AUC) was 0.83 (95%CI 0.77-0.89); the RR for AKI above the 0.3 cutoff was 13 (95%CI 4-40). When analyzed separately, the AUC and RR for diabetic patients without CKD were 0.82 (95%CI 0.75-0.88) and 9 (95%CI 3-30), respectively, and with CKD were 0.89 (95%CI 0.80-0.99) and 22 (95%CI 1-361), respectively. In the absence of AKI, neither DM nor DM with CKD resulted in [TIMP2]•[IGFBP7] distributions above the normal range.

Conclusions: For patients with DM with or without CKD, the urinary [TIMP2]•[IGFBP7] test accurately identifies patients at risk for developing AKI within 12 hours. Interquartile range for normals.

ACE - Inhibitors (ACE-I) and Angiotensin Receptor Blockers (ARB) in the Elderly: Not so Safe Andrea Guarnieri, Serena Bainotti, Elisabetta Moggia, Carmela Pino, Paola Inguaggiato, Maria Pia Giorgi di Vistarino, Alfonso Pacitti. *Nephrology and Dialysis Unit, S. Croce - Carle Hospital, Cuneo, Italy.*

Background: ACE-I and ARB are widely prescribed in any age group. The general applicability of the recommendations of the large RAAS blockade trials to especially the older CKD patient population reserves some doubts because several trials were short term studies, often enrolling younger patients with relatively few comorbid conditions and a very strict clinical control. The aim of the study was to evaluate the incidence and course of AKI due, according to clinical data and medical history, to the use of ACE-I or ARB in old patients hospitalized in our renal care unit.

Methods: Retrospective study of all old patients (age > 75 years) admitted from 1/1/2009 to 12/31/2013. 55 patients (18% of total AKI), affected by AKI due to drugs interfering with RAAS, 27 men and 28 women, mean age 82 years, treated with ACE-I (35), ARB (19), ACE-I + ARB (1). Concurrent CV disease 53%, diabete mellitus 29%, pulmonary disease 29%, multiple diseases 33%. AKIN stages: 1 29%, 2 11%, 3 60%. AKI triggered by: enteritic syndrome 49%, use of diuretic with simultaneous reduction of fluid intake 44%, pneumonia 5%, NSAID use 2%.

Results: Average days of hospitalization 8.5 +/- 4.5.

Blood chemistry.

Creatinine IN (mg/dL)	5.2 +/- 3.4
Creatinine OUT (mg/dL)	1.5 +/- 0.6
K IN (mEq/L)	5.3 +/- 1.4
K OUT (mEq/L)	4.3 +/- 0.6

Two patients needed hemodialysis with subsequent functional recovery. Two patients died with AKI without need for dialysis.

Conclusions: Our data underestimate the true incidence of the disease because not infrequently patients with such features are hospitalized in other medical departements. However some considerations are possible: 1. The incidence remained constant over the observed years without seasonal variations. 2. In 44% of cases, only a reduction in fluid intake occured, without any significant intercurrent disease. 3. After all the prognosis was benign, in 96% a functional recovery occurred and the mean length of hospitalization was comparable to the annual average. 4. No absolute controindications to RAAS blockade in old patients, but extreme caution and stop in risk of hypovolemia.

PUB025

Retroperitoneal Fibrosis: A Retrospective Descriptive Study on Clinical Features and Management Ann-Sophie Laroche, Robert Zoël Bell, Caroline Lamarche, Michel Vallee. *Nephrology, Hôpital Maisonneuve-Rosemont, Montréal, QC, Canada.*

Background: Our study was meant to describe the clinical characteristics, diagnostic methods and treatments of patients with retroperitoneal fibrosis (RPF).

Methods: We conducted a retrospective analysis of patients diagnosed with RPF at Maisonneuve-Rosemont Hospital.

Results: We identified 17 patients with RPF between 1998 and 2013. Eight patients were female (47%) and the mean age was 62 years. Eleven cases were idiopathic, four were secondary to a neoplasia, one was thought to be in the setting of an IgG4-related disease and one was caused by radiotherapy. Back pain was the most common symptom. All diagnosis were made based on the finding of a retroperitoneal mass on the computed tomography (CT) imaging. Three patients (17.6%) had histological diagnosis of RPF and seven had unspecific changes on their biopsy. There were no biopsy for 7 patients (41.1%). Ten patients needed double-J stents, 3 had a temporary percutanous nephrostomy and 2 patients had to have a nephrectomy. Only one patient required hemodialysis (5.8%). 10 patients received medical treatment including corticosteroids, tamoxifen, methotrexate and colchicine. Of the 5 patients with complete remission (29.4%), only two received treatment with prednisone, while the other three did not received any medication. There were 7 patients with partial reduction of the inflamed mass and overall improvement with treatment, 3 with prednisone only and 3 with the combination of prednisone and methotrexate. Only one did not receive any treatment. The remaining five patients were non responders – three did not receive treatment, one had one course of prednisone and another was treated with colchicine.

Conclusions: In conclusion, most of our cases of RPF were idiopathic and were diagnosed with CT scans. Most of the treated patients received prednisone and seem to respond, at least partially. There was a lot of heterogeneity in patient management, which makes it difficult to compare treatment effects. There seems to be a better outcome when treatment is adjusted based on acute-phase reactant biomarkers and CT imaging, than only CT imaging. Overall, untreated patients appear to have a worse outcome than treated patients.

Cisplatin Nephrotoxicity in Children with Solid Tumors Climaco Andres Jimenez Triana,[1] Rodolfo Rivas-Ruiz,[1] Osvaldo D. Castelan_martinez,[1] Bruce Carleton,[2] Mara Medeiros.[1] *[1]Hospital Infantil de Mexico, DF, Mexico; [2]BC Children´s Hospital, Vancouver, Canada.*

Background: Objective: To evaluate the prevalence and severity of cisplatin nephrotoxicity in Mexican children and to determine the impact of nephrotoxicity on height and weight.

Methods: Retrospective study of 54 children treated with cisplatin for solid tumors. From the medical record, the information about height, serum creatinine and electrolytes in each cisplatin cycle and after 12 months of treatment was recorded. Nephrotoxicity was graded as follows, 0: normal renal function, 1: asymptomatic electrolytes disorders in blood work, grade 2: need for electrolyte supplementation and/or increase in serum creatinine 1.5-1.9 times from baseline, grade 3: increase in serum creatinine at 12 months 2-2.9 times from baseline or need for electrolyte supplementation for more than 3 months after treatment completion, grade 4: renal replacement therapy.

Results: 41 patients had nephrotoxicity (NTX) (76%). Hypophosphatemia was found in 35 patients, hypomagnesemia in 22, hypokalemia in 20 patients. 13 patients had no nephrotoxicity, Grade 1 NTX was observed in 18, Grade 2 in 5 patients and Grade 3 in 18 patients. Patients without NTX maintained their z Score for height after 12 months of treatment, whereas those with NTX had worse z Score for height after 12 months of treatment, being more accentuated in those with NTX grade 1 than grades 2 and 3. There was no difference in z Score in weight (basal versus 12 months) in all groups (Figure 1). The cisplatin total dose had a significant negative relationship with magnesium levels at 12 months (Spearman r =-0.527, p=0.0001).

Conclusions: NTX prevalence was 76%. NTX patients were younger and received higher cisplatin doses than those with normal renal function. Patients receiving cisplatin should be monitored during each cycle of treatment for evidence of grade 1-4 nephrotoxicity. Even asymptomatic electrolyte abnormalities can cause clinically significant effects on height. Serum magnesium is likely to fall with increasing cisplatin dose and should be specifically monitored as cumulative cisplatin exposure increases. Hypomagnesemia can cause significant neurological effects.

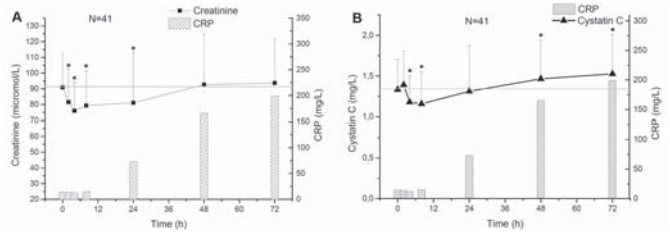
PUB027

Serum Cystatin C as Diagnostic Marker of Acute Kidney Injury after Cardiopulmonary Bypass: A Word of Caution Anders Svensson,[1] Csaba P. Kovesdy,[2,3] John-Peder Escobar Kvitting,[4] Ingemar R. Cederholm,[4] Zoltan Szabo.[4] *[1]Ostergotland Heart Centre Univ Hospital; [2]Memphis VAMC; [3]Univ of Tennessee; [4]Linkoping Univ Hospital.*

Background: Serum cystatin C may be an alternative to serum creatinine to estimate glomerular filtration rate and to diagnose post-operative acute kidney injury (AKI) after cardiac surgery. Serum creatinine and cystatin C may, however, have different postoperative dynamics the reasons for which are unclear.

Methods: Post-operative changes in serum creatinine and cystatin C were followed in 41 patients with normal pre-operative kidney function undergoing cardiac surgery using cardiopulmonary bypass (CPB). Inflammation and AKI were examined by measuring pre- and post-CPB C-reactive protein (CRP) and neutrophil gelatinase associated lipocalin (NGAL), respectively. Intra-individual differences in creatinine and cystatin C were examined using repeated measures ANOVA and Tukey's HSD. The effect of inflammation on intra-individual changes was examined using mixed effects regression.

Results: Both serum creatinine and cystatin C decreased significantly in the first 24 hours post-operatively (p<0.001). Serum creatinine levels returned to pre-operative levels (Figure, Panel A), whereas serum cystatin C continued to rise and were significantly elevated at 48 and 72 hours post-CPB compared to pre-operative levels (Figure, Panel B). CRP levels increased significantly post-CPB and were significantly associated with increases in both serum creatinine and cystatin C in mixed models (p<0.001). AKI occurred in two patients, and their exclusion did not affect the results.



Conclusions: Serum creatinine and cystatin C have different post-CPB dynamics. The reasons for this are unclear, but may include processes unrelated to changes in kidney function.

PUB028

Incidence of Acute Kidney Injury in Critically Ill Patients at an Urban Community Hospital Jiandong Wei, David Kau, Spiro Demetis, Reynaldo G. Tan. *Medicine, Lutheran Medical Center, Brooklyn, NY.*

Background: Acute kidney injury (AKI) is a common condition in critically ill patients and is often associated with poor prognosis. More accurate data about the incidence and early recognition of risk factors for AKI will improve awareness and early prevention of AKI in community-based hospitals.

Methods: Patients who were admitted to the intensive care units (ICUs) at Lutheran Medical Center, an urban community hospital from July 2013 to May 2014 were screened for development of AKI from first ICU day to 7 consecutive days. Patient demographics, co-morbidity and survival status at hospital discharge were compared in patients with or without AKI. Pearson Chi-Square was used for data analysis.

Results: 360 were enrolled in the study. 46 (12.8%) patients developed AKI, 63 (17.5%) did not have AKI, 251 (69.7%) patients did not complete screening due to being transferred out of the ICUs. Patients with age ≥ 75 have higher incidence of AKI than those under age of 75 (18.0% versus 9.0%, p = 0.025). AKI has the highest incidence in medical ICU when compared to surgical ICU and cardiac ICU (16.7%, 7.6% and 11.1% respectively, p = 0.003). There was no difference of AKI incidence in patients among different race, with or without type 2 diabetes mellitus, chronic liver disease or morbid obesity. Hospital mortality was 47.8% in critically ill patients with AKI, 15.9% in those without AKI abd 9.2% in patients who were transferred out of the ICUs in less than 7 days (p < 0.001).

Conclusions: This single-centered prospective observational study shows that AKI is commonly encountered and is associated with high mortality in critically ill patients in an urban community hospital. Patients with advanced age and admitted to the medical ICU have higher risk for developing AKI. Prevention of AKI starts in the community with prompt assessment of those at risk.

PUB029

Discrepancies between Urinary and Plasma NGAL Concentrations in Patients Admitted to the Medical Intensive Care Pierre Delanaye,[1] Bernard Lambermont,[1] Philippe Morimont,[1] Jean-Marie H. Krzesinski,[1] Nicolas Maillard,[2] Guillaume Claisse,[2] Christopher R. Mariat,[2] Etienne Cavalier.[1] *[1]Univ of Liège; [2]Univ Jean Monet, Saint-Etienne.*

Background: Both plasma and urinary NGAL concentrations are presented as useful tests to detect acute kidney injury (AKI) in intensive care units (ICU). However, little is known about the concordance between these two biomarkers at the individual level.

Methods: Urinary and plasma NGAL were measured in ICU patients within the first 24h after admission. The same method was used to quantify NGAL both in urine and plasma (Bioporto, Gentofte, Denmark). For urinary NGAL, both absolute value and ratio to urinary creatinine were considered. Different cut-offs were used for the diagnosis of AKI in the two milieus: 100, 150, 200 or 300 ng/mL. We focused on the cut-off value of 150 ng/mL. Discrepant results were patients with higher values than a defined threshold (for example 150 ng/mL) in the urine but lower in the plasma, or conversely.

Results: We included 98 patients: mean age of 64±15 y, 59% of men. Median [IQR] plasma concentrations was 218 [118-440] ng/mL. Median urinary concentrations (absolute and ratio) were 57 [23-295] ng/mL and 115 [52-479] ng/g. Considering the absolute urinary NGAL concentrations, we observed a concordance in the AKI diagnosis between urinary and plasma results which ranges from 40 to 76%, according to the cut-offs used. The best concordance was observed for a cut-off of 300 ng/mL and 150 ng/mL for the plasma and the urine, respectively. If the cut-off of 150 ng/mL was considered for both milieus, the global concordance was 64%. In the 62 patients with concordant values, NGAL was higher than 150 ng/mL in 53%. In the discordant values, the plasma concentration was higher than 150 ng/mL in 33 patients. Only 2 patients had urinary concentrations higher than 150 ng/mL although plasma concentrations remained lower. Regarding urinary concentration with the ratio, the diagnosis concordance ranged from 45 to 73%.

Conclusions: At best, our study showed that measurement of NGAL in the urine versus plasma was discordant in 25% of ICU patients. In most discrepants, the urinary NGAL was below the defined cut-off whereas the plasma NGAL was above.

PUB030

Incidence and Outcomes of Acute Kidney Injury in Unselected Admissions to a Large Tertiary-Care Mexican Facility Jonathan Chavez, Paulina Albarran, Guillermo Garcia-Garcia. *Nephrology Div, Hospital Civil de Guadalajara, Guadalajara, Jal, Mexico.*

Background: Acute kidney injury (AKI) is a common and serious problem in hospitalized patients. Frequently, AKI is not detected and these cases are commonly not referred to nephrology, resulting in inadequate care. We evaluated the incidence and outcomes of acute kidney injury in unselected admissions, with and without nephrology referral, in a large tertiary-care Mexican facility.

Methods: We reviewed the records of 402 patients admitted to the hospital in a single day. Patients ≤ 15 years old and those admitted to nephrology or obstetrics services were not included. Patients were followed until their demise or discharge. Outcome measures were the presence or absence of AKI using KDIGO criteria and mortality. Student T test and χ^2 were used when appropriate.

Results: 127 (32%) patients were identified with AKI; they were predominantly medical cases (56% versus 33%, p=0.000) male (65% versus 52%, p= 0.01)), older (median age 67 versus 52 y, p=0.05) and diabetic (43% versus 17%, p=0.000) than those without AKI. 47 (37%) cases were KDIGO I, 42 (33%) KDIGO II, and 38 (30%) KDIGO III. Main AKI causes were sepsis (36%), hypovolemic (30%), and nephrotoxicity (18%). Only 14 (11%) cases were referred to nephrology. Results of patients with and without nephrology care are described in table 1.

	Nephrology referral n (%)	No nephrology referral	p
	14 (11)	113 (89)	
Age (y)	69 (46-94)	49 (22-76)	0.02
Diabetes	9 (64)	44 (39)	0.12
Hypertension	8 (57)	29 (25)	0.03
Deaths	6 (43)	19 (17)	0.05
Deaths by KDIGO stage			
KDIGO I	0	0	
KDIGO II	0	10 (9)	
KDIGO III	6 (43)	9 (8)	0.000
SCr double than baseline at discharge	5 (36)	34 (30)	0.92
Outpatient follow up	8 (57)	1 (0.88)	0.05

Conclusions: AKI occurred frequently in hospitalized patients, affecting 32% of unselected admissions to our hospital; the majority of these cases were not referred to nephrology care and AKI resolved spontaneously, but it was associated to an increased risk of death. Also, a large percentage of these patients had a high serum creatinine at discharge and lacked outpatient follow-up. Nephrology referral and intervention may result in better clinical outcomes.

PUB031

Renin Angiotension System Inhibitor in Treatment of Lupus Nephritis with Thrombotic Microangiopathy Chao Li, Hang Li, Yu-Bing Wen, Hai-Yun Wang, Jie Ma, Ying Wang, Bing-Yan Liu, Rui-Tong Gao, Jian-Ling Tao, Yan Qin, Qun-Sheng Yuan, Ying Su, Yang Yu, Ming-Xi Li, Xue-Mei Li, Xuewang Lee. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: To investigate whether RAS inhibitor can improve the renal function in treatment of lupus nephritis (LN) with thromboticmicroangiopathy (TMA)confirmed by renal pathology.

Methods: 15 LN patients with TMA proven by renal biopsy, from January 2000 to December 2013 in PUMCH, were enrolled. The changes of SCr and BP before and after using RAS inhibitor were analyzed retrospectively.

Results: (1)Male/female ratio is 1:14. All of the patients had renal dysfunction, and median peak value of creatinine was 396μmol/L (160-643μmol/L). 5 cases (33.3%) required acute dialysis during hospitalization. Hypertension occurred in 15 patients, while 6 cases (40.0%) were diagnosed malignant hypertension. (2) Anemia and thrombocytopenia occurred in 15 and 14 cases, respectively. 3 cases (20.0%) and 5 cases (33.3%) were diagnosed MAHA definitely and probably, respectively. (3) Renal biopsy showed class II in 1 case, III in 4, IV-(G) in 2, IV(S) in 5 and IV+V in 3 cases. Active lesions were predominant in glomeruli, as well as renal vasculopathy. (4) All the patients received immunosuppressive therapy, of whom 9 cases were given steroid pulse therapy, 13 case received cyclophosphamide, and the rest 2 cases also receive mycophenloate. Only 5 patients' creatinines (55.6%) decreased after steroid pulse therapy. In 13 patients (86.7%), hypertension ameliorated and SCr decreased within one week after implementing RAS inhibitors, which falled medianly 15.8% and 17.0%, repectively. (5) 11 Patients were followed from 8 to 135 months (median 32 months), although 4 patient were lost to follow up. 5 cases on dialysis during hospitalization didn't require renal replacement therapy, while renal function of other cases improved further.

Conclusions: Patients diagnosing LN with TMA who develop AKI and refractory hypertension should be treated with RAS inhibitors. Improved renal survival and successful discontinuation of dialysis are possible benefits when ACE inhibitors are used to treat LN with TMA.

PUB032

How Important Is GFR in Heart Failure Re-Admission? Mohinder Reddy Vindhyal, Brent A. Duran, Hussam H. Farhoud, Ken James Kallail. *Internal Medicine, KUSM - Wichita, KS.*

Background: Heart Failure is the leading cause of morbidity and mortality, as well as hospitalization rates in the U.S. An impetus has been created to identify improved predictors to prevent hospital readmission. The average life span of patients admitted to the hospital for the heart failure is 5.5 years. The aim of this study was to determine if renal function (GFR) has an association with heart failure readmissions. Even though the DOSE trial validates that the kidney function (GFR and creatinine) will be normal two months after placing them on high dose diuretics in heart failure patients, but doesn't mention about readmissions or the renal function status with in the month. Moreover CKD patients were excluded from the study.

Methods: A retrospective cohort study was performed utilizing data from three community hospitals in the United States. A total of 132 patients with heart failure were evaluated over one year comparing *glomerular filtration rate (GFR)* at admission and discharge and 30-day readmission status.

Results: There is a significant difference by readmission status in the change in GFR from admission to discharge. The GFR of patients readmitted in 30 days had an average decrease in GFR by 2.46 mL/min/1.73 m^2 whereas patients not readmitted in 30 days had an average increase in GFR by 1.92 mL/min/1.73 m^2. In the 28 readmitted patients, 13 (46%) had a decrease in GFR, 6 (21%) had an increase, and 9 had no change (32%). In the 99 patients not readmitted, 33 (33%) had a decrease in GFR, 48 (48%) had an increase, and 18 (18%) had no change.

Conclusions: A decline in renal function over hospitalization in patients with heart failure is associated with an increase in readmission for heart failure. Providers should be cognizant of the need to optimize renal function as well as cardiac function during hospitalization.

PUB033

Efficacy and Morbidity of Urinary Derivation (UD) to Treat Obstructive Uropathy (OU) Related Acute Kidney Injury (AKI) in Cancer Patients Renato Antunes Caires,[1] Veronica T. Costa e Silva,[1] Regis Franca Bezerra,[3] Elerson Costalonga,[1] James Hung,[1] Luis Yu,[1] Emmanuel A. Burdmann,[1] William C. Nahas,[2] Mauricio Dener Cordeiro,[2] Rafael Ferreira Coelho.[2] *[1]Nephrology Div, Sao Paulo State Cancer Institute - Sao Paulo Univ Medical School, Sao Paulo, Brazil; [2]Urology Div, Sao Paulo State Cancer Institute - Sao Paulo Univ Medical School, Sao Paulo, Brazil; [3]Radiology Div, Sao Paulo State Cancer Institute - Sao Paulo Univ Medical School, Sao Paulo, Brazil.*

Background: There is scanty data on efficacy and morbidity of UD to treat OU related AKI in cancer pacients (pcts).

Methods: We prospectively analyzed UD procedures in OU related AKI adult cancer pcts in the Sao Paulo State Cancer Institute, from March 2009 to December 2011. AKI was defined as an increase > 50% in the baseline serum creatinine (SCr). Renal function recovery (RFR) was defined as return to baseline SCr. Radiology tests were assessed by a radiologist with expertise in cancer urinary diseases.

Results: A total of 109 AKI pcts were assessed. Pcts' characteristics were mean age 57.5 +/- 15 y and 56% female. Tumor origins were: gynecologic system 34.8%; genitourinary tract 33%; gastrointestinal tract 24.7%. Metastasis was observed in 49.5% of pcts. Baseline SCr was 1.0 (0.82 – 1.33) mg/dL and six months mortality was 53.2 %. OU was diagnosed by computed tomography in 87.2% of pcts, considered bilateral in 86.2% and graded at level 3 or 4 in 70% of them. Percutaneous nephrostomy (NT) was performed in 81.7% of pcts. At UD, blood tests were: SCr 4.48 (2.91 – 7.13) mg/dL; urea 108 (71 – 150) mg/dL; K 4.5 (5 – 3.9) mEq/L; Hb 8.3 (7.5 – 9.35) g/dL; platelet 326,000 (203 – 403)/mm^3 and INR 1.1 (1.0 – 1.29). Hemodialysis was necessary in 30 (27.7%) pcts. Hematuria requiring blood transfusion was observed in 9.3% pcts in the immediate post UD period. At 30 days, SCr was 1.4 (1.0 – 1.97) mg/dL, RFR was observed in 68% of pcts and only four pcts remained dialysis dependent. During follow-up, NT repositioning was necessary in 12.3% of pcts and pyelonephritis was observed in 23.9% pcts.

Conclusions: UD was an efficient treatment for OU related AKI in cancer pcts, with high rate of RFR and acceptable morbidity.

PUB034

Acute Kidney Injury among Very Elderly Patients Hospitalized in a Single Center: Epidemiology and Outcomes from a Retrospective Cohort Ederson Vidal Moura, Hugo Pinheiro, Cintia Germana Mergulhão da Costa, Gisele Vajgel Fernandes, Luis H.B.C. Sette, Geraldo José de Amorim. *Nefrologia, Hospital das Clínicas - Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Background: Acute Kidney Injury (AKI) is commom condition among in-hospital patients, but only a few studies evaluated the epidemiological profile and outcomes in very elderly patients (VEP).

Methods: We analized medical records of nephrology referrals (NR) from January 2011 to December 2013 in order to identify very elderly patients (older than 75 years) who developed AKI during in-hospital stay. AKI was classified at the first day of NR based on Scr AKIN criteria and CKD was defined based on prior baseline Scr >1.3 mg/dL.

Results: Among 778 medical records analyzed, 80 of them were VEP with AKI and acute on-CKD (A-CKD), with mean age 82y. AKI was found in 55 VEP (68.75%) and

A-CKD was found in 25 patients (31.25%). There was female predominance in AKI group (52.7%) and male predominance in A-CKD group (76%). Ischemic etiology was the main renal injury factor (42% of all cases) and dialysis requirement was higher in AKI group (41.8%) compared with A-CKD group (36%), but without significance (P=0.80). Mean Charlson Commorbitity Index was 6,41 (95%CI: 5.75 - 7.06) in AKI patients and 5,44 (95%CI: 4.52 - 6.36) in A-CKD group.Sepsis was found in 45% of AKI group and 32% of A-CKD patients, and pneumonia was the major cause in 32% and 50% of groups patients, respectively. Overall mortality rate was 41% and unadjusted analysis showed higher mortality in AKI group (36.4%) when compared to A-CKD group (16%), P=0.033. There was no difference in mortality among patients with dialysis requirement compared to non-dialytic patients both in AKI and A-CKD groups: P=0.73 and P=0.53, respectively. At the time of the NR, AKIN 3 was the most common stage of renal injury found in AKI group (30.9%), and AKIN 1 was more prevalent in A-CKD patients (40%) than AKI patients (25.4%), P=0.014.

Conclusions: Very elderly patients have a high incidence of AKI and high mortality rate. When compared to A-CKD patients, the AKI group have more prevalence of sepsis, worse renal dysfunction at time of nephrologist referral and higher mortality rate.

PUB035

Acute Kidney Injury in United Arab Emirates, Incidence, Etiology, and Outcome Bassam O. Bernieh, Yousef Boobes, Mohamed Raafat Al Hakim, Qutaiba Hussain Daoud, Mohamed E.O. Ahmed, Ahmed Ahmed Ahmed, Hanan Eljack, Imran Khan, Ahmed Chaaban, Walaa Dabbas, Osama S.R. Ouda, Amany Hillis. *Nephrology, Tawam Hospital, Al Ain, Abu Dhabi, United Arab Emirates.*

Background: Acute kidney injury (AKI) is a public health burden increasing, morbidity, mortality, Health care costs, and associated with increased risk for the development of CKD and ESRD. The incidence of AKI is not well known in United Arab Emirates (UAE). In the current study, we are reporting the incidence, etiology and the outcome of AKI in our tertiary care institution.

Methods: retrieving from the hospital HIS, all adult patients with the ICD-9 code of AKI, and ARF, for six months period from 01/01/2013 till 30/06/2013. Inclusion criteria: Patients with ICD-9 code of AKI / ARF, and fulfilling the KDIGO definition of AKI. Total number of patients who fulfilled the above criteria was 460. Total number of adult patients admitted in the hospital during the same period was 7352. Number of patients included in the analysis was 388/460 (84%).

Results: total number of patients 388, 221 (57%) were male, mean (SD) age was 63.6 (18) year. 214 (55%) were UAE nationals. Long of stay in the hospital was 14.7 (15.3) days. Incidence of AKI in this cohort was 62.6/ 1000 patient admissions. 21% of the patients were in ICU and 79% in the inpatient wards. Dehydration and sepsis were the etiology of AKI, encountered in 51 and 47% respectively. Hypertension and diabetes were the most common comorbidities, found in 72 and 59% of the patients respectively. Only 53% were referred to nephrology. 73% had KDIGO stage I AKI, 20% stage II, and 7% stage III. 76% had community acquired, and 24% had hospital acquired AKI. 89% were managed conservatively, and 11% required renal replacement therapy. Renal outcome: 45% had full recovery of kidney function, 38% had partial recovery, and 17% did not recover. Patients' outcome: 77% survived, and 23% died. Age> 65, presence of CKD, or malignancy were all significantly associated with bad patients' outcome.

Conclusions: AKI has a high incidence in the UAE community, it carries high morbidity and mortality, affecting mainly old age group. More efforts are required to validate this data at the national level.

PUB036

A Case of Tenofovir Induced Distal RTA Causing AKI Sravan Jasti,[1] Ashwin Narasimhan,[2] Nishitha Cherukumalli.[3] *[1]Nephrology, Albert Einstein, Philadelphia, PA; [2]Medicine, Our Lady of Fatima, Providence, RI; [3]Nephrology, Upenn, Philadelphia, PA.*

Background: 62 year old male with hx of latent syphilis and HIV on Truvada therapy came with generalized weakness. No prior history of autoimmune disease was noted.Admission BP was108/80,Pulse-74, RR-12, T-98 Physical exam showed no crackles, lymphadenopathy, murmurs or organomegaly. Pertinent labs:Hgb-11.7,K-1.6,CO2-13,Cr-4.7,Ca-7.3,Phos-4.1,Alb-1.7,Mg-1.9,CPK-16310,AG-16,Urine Na-98,UrineK-28,UrineCl-124,Urineurea-122,Urine Uric Acid-14,Urine Creatinine-16,Urine Phosphorous<5,UrinaryAG-2.0,UA showed large blood.Baseline creatinine was 0.7 and bicarbonate was 24 prior to HAART therapy.

Methods: With no Glycosuria or elevated fractional excretion of phosphorous and Uric acid,distal RTA was diagnosed.AKI was suspectedfrom underlying Rhabdomyolysis causing ATN .ID was consulted and HAART therapy was discontinued. Pt received 360 meq of KCL on day 1 with a standing order of KCL 40meq every 4 hrs for the next 4 days .Once potassium improved to 3.2 mmol/lit, he was started on Bicitra to correct his acidosis. He was discharged 6 days later with a serum potassium of 3.4 mmol/lit, bicarbonate of 22 mmol/lit. on KCL 40 meq daily with Bicitra 15ml bid. His CPK improved to 10,000 and his creatinine normalized upon discharge.His HAART therapy was put on hold.

Results: Tenofovir disoproxil fumarate is nucleotide reverse transcription inhibitor eliminated via glomerular filteration and active tubular secretion,enters proximal tubule cells via human organic anion transporters 1 and 3 and exits cells via multidrug resistance protein.It causes nephrotoxicitywith increases in creatinine,glycosurea, hypophosphatemia and ATN.Ifosfamide,valproic acid and antiretrovirals such as Tenofovir cause proximal RTA. Distal RTA is generally asymptomatic but may rarely present as hypokalemic paralysis In a study of 271 patients, 10 percent initiated with TDF developed AKI .In a French Study of 222 patients with HIV, 29 had tubulopathy fromTDF.

Conclusions: Although Tenofovir is known to cause proximal RTA this seems to be the first case of Distal RTA .The mechanism of distal RTA is unclear,tenofovir could lead to distal tubular damage with it being a known mitochondrial toxin.

PUB037

Urinary Exosomal miRNA27b in Patients with Acute Decompensated Heart Failure Ping Li,[1] Usman J. Rahmat,[1] Jonathan Street,[2] Ethan Ko,[1] Richard Amdur,[1] Sonya Malekzadeh,[1] Federico E. Mordini,[1] Lakhmir S. Chawla,[1] Peter S.T. Yuen,[2] Carlos E. Palant.[1] *[1]Medical and Research Services, Washington DC VAMC, Washington, D.C.; [2]NIDDK, NIH, Bethesda, MD.*

Background: Previous studies show that development of acute kidney injury (AKI) during inpatient hospitalization for acute decompensated heart failure (ADHF) is associated with increased morbidity/mortality. Urinary biomarkers may become a useful tool to monitor renal function in ADHF patients. Urinary miRNA27b is a marker of AKI in animal models. We hypothesized that increased urinary excretion of miRNA27b might be associated with renal tubular damage in ADHF.

Methods: 21 patients were studied and divided into 3 groups: 8 controls (CON), 5 stable CHF patients, and 9 ADHF hospitalized patients. One urine for each CON and stable CHF patient was analyzed and 3 urine specimens were collected in ADHF patients on consecutive days. Urinary miRNA27b was quantified via multi-step ultracentrifugation and quantitative reverse transcription PCR (Taqman). Urine microRNA27b was normalized with urinary creatinine. Patients with hepatitis B and/or C, HIV infection or urinary infections were excluded. One way ANOVA was used for statistical analysis.

Results: Mean baseline serum creatinines (SC) were: 1.05 ± 0.16, 1.06 ± 0.27 and 1.46 ± 0.52 mg/dL for CON, stable CHF and ADHF patients respectively. Ejection fraction was 24 ± 11% and 22 ± 5.3% for stable CHF and ADHF patients respectively. Urinary miRNA27b were 441 ± 518, 1524 ± 842 zmoles/mg in CON and stable CHF groups respectively. In ADHF patients, microRNA27b levels were 1273 ± 1091, 1352 ± 1471, and 2057 ± 1872 zmoles/mg ($p<0.01$ ADHF day 3 versus CON)and SC levels were 1.46 ± 0.52, 1.53±0.70 and 1.11±0.17 mg/dL on day 1, 2 and 3 following IV diuretics.

Conclusions: miRNA27b is found in the urine of human subjects. In this pilot study, patients with ADHF showed a tendency to excrete higher concentrations of miRNA27b than CON patients. A larger clinical trial seems justified by these preliminary data.

PUB038

Impact of Severe Acute Kidney Injury on Long Term Survival Muhammad Taufiq Dawood, Vivienne Ralph, Christine Sarah Catley, Anthony Chan, Abdelgalil Abdelrahman Ali, Sumith C. Abeygunasekara. *Renal Unit, Mid Essex Hospitals NHS Trust, Chelmsford, Essex, United Kingdom.*

Background: We looked at patient mortality in hospital, at thirty days and at one year after suffering an episode of severe Acute Kidney Injury (AKI), and to determine factors predictive of a poor outcome.

Methods: Data was collected from August to November 2012 of patients who developed AKI stage 3 (RIFLE criteria) during admission to a district general hospital in the UK. The patient demographic data included co-morbidities, drugs and renal function on discharge, as well as the date of death.

Results: A total number of 271 patients with AKI stage 3 (RIFLE criteria) were identified during the 6-month period. There were 48 in hospital deaths. Results showed 95 patients died within thirty days of developing AKI and 144 patients died within one year. Thirty-day all cause mortality was 35%, while twelve month mortality was 53%. The initial analysis of this data has revealed that there is a significant all cause mortality rate associated with these patients who have suffered an AKI.

Conclusions: It is clear from our study that patients who developed severe AKI have very high mortality as inpatients as well as on discharge. Positive predictive factors include advanced age, number of comorbidities and extent of the recovery of renal function prior to discharge. It is becoming increasingly clear that AKI is an important contributor to mortality generally, and that suffering an AKI is a more global process than its name suggests and may reflect a more generalized ischemic state. In the future AKI should not be viewed as simply a reversible process that is forgotten once 'normal' kidney function has returned. Rather it is an indicator of a significant insult to the body, and that it alone may increase mortality.

PUB039

Predictors of Mortality in Patients with Congestive Heart Failure (CHF) Receiving Darbopoeitin (DAR) a Potential Interaction Between DAR and Acute Renal Dysfunction (ARD) Jose I. Iglesias,[1] Savan Ghetiya,[2] Jerrold S. Levine.[3] *[1]Dept Medicine Section of Nephrology, Rowan Univ School of Osteopathic Medicine, Stratford, NJ; [2]Dept of Medicine, Medical Univ of Silesia, Katowice, Poland; [3]Dept of Medicine, Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL.*

Background: Anemia and renal dysfunction commonly coexist in patients with congestive heart failure (CHF) and are known as the cardiorenal anemia syndrome (CRAS). CRAS is associated with adverse clinical outcomes. Although the treatment of CRAS with DAR has been extensively studied, there is a paucity of data regarding the use of DAR in patients admitted with decompensated CHF that is complicated by ARD.

Methods: We retrospectively examined the impact of DAR on 60-day mortality in 465 patients admitted with decompensated CHF of whom 155 developed ARD.

Results: Univariate analysis revealed that DAR use was associated with an increase in mortality (5.5% versus 15%, $p <.0.01$). By forward stepwise regression analysis,

however, DAR was not an independent predictor of mortality. The following variables were independent predictors of mortality: severe ARD (defined as a rise in SCr ≥ 0.5mg/dl)p=0.00001, OR 7.4, 95% 3.8-13 ; lack of renin angiotensin system (RAS) inhibition,p =0.009, OR 0.4, 95% CI 0.2-0.8. and advanced age, p=0.024, OR 1.05, 95% CI 1.007-1.09. When patients were stratified according to DAR use, only severe ARD was associated with mortality in pts receiving DAR. This effect was independent of the effect of anemia. In patients who developed ARD, the following variables were independent predictors of mortality: use of inotropes, p= 0.030, OR 3.49, 95 % CI 1.12-10.82, use of DAR, p= 0.0004, OR 6.29, 95% CI 1.8-21.8 and advanced age, p=0.012, OR 1.08, 95% CI 1.02-1.14.

Conclusions: Our data suggest that although DAR is not independently associated with an increased risk of mortality, the development of ARD in association with DAR usage may confer an increased risk.

Pharmacogenetics of Cisplatin Acute Kidney Injury (AKI)

Melanie S. Joy,[1,2] Lucas Ellison,[1] Madeleine Gomez,[1] Nickie L. Johnston,[1] Cassie B. Jarvis,[1] Brittney Wright,[1] Steven R. Kleeberger,[3] Lauren Aleksunes.[4] *[1]Skaggs School of Pharmacy, Univ of Colorado, Aurora, CO; [2]School of Medicine, Univ of Colorado, Aurora, CO; [3]NIEHS; [4]School of Pharmacy, Rutgers Univ.*

Background: Cisplatin is an inorganic metal-containing chemotherapeutic used to treat solid tumors, with AKI reported in one-third of patients. The current study represents preliminary data from a larger study (n=250) that is testing whether functional single nucleotide polymorphisms (SNPs) in genes relevant to metabolism and transport of cisplatin (*SLC22A2, SLC47A1, ABCC2, GSTA1, GSTP1, GGT1*) and antioxidant response to toxicity (*NFE2L2, KEAP*) associate with differential susceptibility to AKI in cisplatin-treated cancer patients.

Methods: Blood(5mL) was obtained from patients(n=89) who prospectively or retrospectively received cisplatin. Genotyping assessments included candidate SNPs in drug transporter(*SLC22A2, ABCC2, SLC47A1*), metabolism (*GSTA1, GSTP1, GGT1*) and toxicity response (*NFE2L2/KEAP1*) genes. Genotyping was performed using QuantStudio and genotypes were coded [0(wt/wt), 1(wt/var), 2(var/var)]. Glomerular filtration rate(GFR) was calculated from the MDRD equation. Univariate and multivariate analyses were performed using genotyping results and population covariates.

Results: Patient demographics(mean±sd) were age 53±13y, weight 81±21kg, BMI 27±7.4, Caucasian 97%, gender (51%M/49%F), and cisplatin dose (64±23mg/m^2). Univariate assessments demonstrated SNPs in *GSTP1*(rs1695), NFE2L2(rs2706110), and *KEAP1*(rs1048290) predicted GFR with p<0.2. BMI was the only non-genetic univariate covariate that predicted GFR. Two multivariate models predicted GFR(p<0.05). Model 1 included *GSTP1* and *KEAP1*: GFR = 0.0214 + 5.173(*GSTP1*) – 6.397(*KEAP1*); p=0.031. Model 2 included *GSTP1*, *KEAP1*, and *NFE2L2*: GFR = -1.322 + 5.366(*GSTP1*) – 6.638(*KEAP1*) + 4.748(*NFE2L2*); p=0.042. The multivariate models accounted for 12% of the change in GFR demonstrated during treatment with cisplatin.

Conclusions: The current preliminary data demonstrate the role of genetic variants in AKI due to cisplatin treatment. Ongoing studies are further refining the pharmacogenetic analysis and utilizing novel biomarkers as subclinical measures of AKI.

PUB041

Is "NPO" a Risk Factor for AKI in Hospitalized Patients?

Saisindhu Narala, Linda Awdishu, Dinna Cruz, Yu-Ting Christi Kao, Ravindra L. Mehta. *Univ of California, San Diego, San Diego, CA.*

Background: The American Society of Anesthesiologists suggest that healthy patients should be NPO 6 hours from solids and 2 hours from liquids for certain hospital procedures. However, studies suggest that physicians are still recommending "NPO after midnight." Prolonged fasting regimens lead to increased hospital stay and mortality. We hypothesized that fasting orders would be longer than recommended and would be correlated with an increased incidence of AKI.

Methods: UCSD Medical Center admissions between 1/2011-12/2012 were screened using the EPIC database. Patients <18 years, ICU patients, admission <48 hours, transplant and emergent surgical patients, and patients requiring RRT were excluded. 94 patients with at least one order of NPO during their hospitalization were sampled. Demographics, procedure characteristics, exposures, and outcomes were collected. The specific NPO order restrictions, actual duration, and reasons were retrieved. SPSS 20 was used.

Results: The average ordered NPO duration was 15.0 hours and the actual NPO duration was 21.0 hours. A multivariate logistic regression model with risk factors for AKI revealed the following significant variables: multiple NPO orders during a hospitalization (p = 0.033, OR 3.59 [1.11-11.57]), nephrotoxin exposure (p = 0.017, OR 4.11 [1.29-13.1]), and >25% increase in NPO time above ordered (p = 0.076, OR 2.84 [0.74-9.36]). Multivariate regression for outcomes in the AKI population revealed the following: longer length of stay (p=0.003) and need for RRT (p=0.043).

AKI Stage	**n = 20 (21.3%)**		
Stage 1	n = 17 (85.0%)		
Stage 2	n = 2 (10.0%)		
Stage 3	n = 1 (5.0%)		
Demographic Characteristics	**No AKI (n = 74)**	**AKI (n = 20)**	**p-value**
Age > 60	41 (55.4%)	9 (45.0%)	0.456
Male gender	39 (52.7%)	12 (60.0%)	0.620
BMI > 30 (Morbidly obese)	22 (29.7%)	5 (25%)	0.786
Diabetes	19 (25.7%)	7 (35.0%)	0.411
CHF	8 (10.8%)	5 (25.0%)	0.141
HTN	6 (8.1%)	0 (0%)	0.336
CKD	11 (14.9%)	3 (15.0%)	1.00
Emergency Room Admission	16 (21.6%)	6 (30.0%)	0.552
Multiple NPO Orders	34 (45.9%)	15 (75.0%)	0.025
Contrast Exposure	26 (35.1%)	11 (55.0%)	0.127
Nephrotoxic Medication Exposure	29 (39.2%)	15 (75.0%)	0.006
Surgical Patients	35 (47.3%)	8 (40.0%)	0.620
Total Time NPO (hours)	39.0 (20.8-56.8)	45.0 (28.0-69.8)	0.468
> 25% Increase in NPO Time	38 (51.4%)	15 (75%)	0.076
Outcome Data	**No AKI (n = 74)**	**AKI (n = 20)**	**p-value**
Length of Hospital Stay (days)	5.5 (4.0-10.0)	11.0 (6.3-15.0)	0.003
Need for Renal Replacement Therapy	0 (0%)	2 (10.0%)	0.043
Transfer to Skilled Nursing Facility	11 (14.9%)	3 (15.0%)	0.208
Hospitalization Within 6 Months	33 (44.6%)	3 (15.0%)	0.019

Conclusions: Patients were ordered to be NPO longer than recommended by the guidelines: 15 instead of 6 hours for food. Multiple NPO orders during a hospitalization, increase in the actual duration of NPO over ordered, and nephrotoxin exposure were significantly associated with AKI. AKI was significantly associated with worse outcomes.

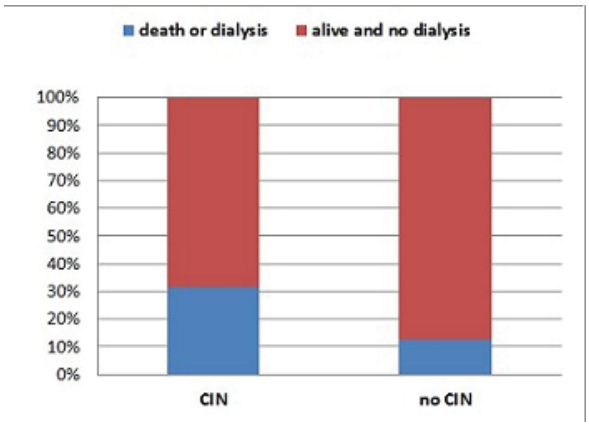
Contrast-Induced Nephropathy – Predictive Biomarkers and Long-Term Effects

Alina Baer,[1] Ralf Schindler,[1] Nadine Koch,[1] Patrick T. Murray,[2] Thomas Otto Joos,[3] Stephen R. Sultana,[4] Natalie M. Otto.[1] *[1]Charite Berlin, Germany; [2]Univ College Dublin, Ireland; [3]Univ of Tuebingen, Germany; [4]Novartis Companion Diagnostics.*

Background: Contrast-induced nephropathy(CIN) is reversible in most cases and rarely leads to dialysis therapy. Most studies concerning CIN prevention concentrate on the acute short-term situation; data on long-term consequences of CIN are scarce.

Methods: We analyzed the long-term effects of CIN in patients with a baseline-eGFR below 60 ml/min who were followed 1 year after contrast exposure. We measured 12 biomarkers after angiography and related them to long-term GFR progression as well as to mortality. 154 patients were followed 1 year after angiography.

Results: Overall, the study comprised 161 patients of which 22 suffered CIN. One year after angiography, mortality could be obtained for 154, the need for dialysis for 130 and renal function could be identified in 40 patients(16 with CIN and 24 non CIN). The mean increase of serum creatinine after one year was 0,77±1,52 mg/dl in the CIN group and 0,02±0,26 mg/dl in the non CIN group(p=0,0047). 3 patients in the CIN(18%) and no patients in the non CIN group developed end stage renal disease. One-year mortality was 18% in the CIN group and 8% in the non CIN group. Figure 1 shows the combined endpoint death or dialysis, being significant different(p=0.034) between CIN and non-CIN patients:



The ROC-Analysis of 12 biomarkers revealed the highest AUC value for combined clinical endpoint death or dialysis for cystatin C(0.85); IL-18(0.77); NGAL(0.77), serum creatinine(0.77) and RBP4(0.75).

Conclusions: Patients with CIN are at higher risk for worsening renal function or mortality 1 year after contrast exposure. Biomarkers measured at the time of CIN have a prognostic value for death or dialysis. Analyzing biomarkers at the time of CIN may prove to be a useful tool for risk stratification.

PUB043

The Incidence, Risk Factors and Clinical Outcomes of Acute Kidney Injury Associated with Scrub Typhus Kyungo Hwang, Eun Ju Lee, Hyun Seop Cho, Hyun-Jung Kim, Se-Ho Chang, Dong Jun Park. *Div of Nephrology, Dept of Internal Medicine, Gyeongsang National Univ Hospital, Jinju, Gyeongsangnam-do, Korea.*

Background: Renal involvement of scrub typhus is clinically various from simple urinary abnormalities to acute kidney injury (AKI) leading to death. Predictors to scrub typhus associated AKI were not well known. This study was done to evaluate incidence, predictors, and prognosis of scrub typhus associated AKI according to RIFLE (risk, injury, failure, loss, end-stage kidney disease) criteria.

Methods: We retrospectively evaluated medical records of patients diagnosed as scrub typhus from January 2001 to November 2013 in Gyeongsang National University Hospital.

Results: Male to female ratio was 48:52 and the mean age was 57.9±18.9 years old. Total 510 patients were diagnosed as scrub typhus during above time and AKI incidence was 35.9% in our study. Patients of risk, injury, and failure were 132 (73.4%), 37 (19.8%), and 14 patients (6.8%), respectively. In comparison with patients in non-AKI group, the patients in AKI group were older (73.9 versus 63.4, p<0.001) and had more co-morbidity such as hypertension, diabetes mellitus (DM), and chronic kidney disease (CKD). AKI frequently occurs in patients with HT taking ARB or ACEi (p=0.002) and diabetes which were higher HbA1c values (p=0.033). Hematuria and proteinuria were more frequent in AKI group. There was no positive relationship between severity of proteinuria and occurrence of AKI. More ICU care and death was present in AKI group. Renal function of most AKI patients recovered without sequelae except for one patient who had underlying DM CKD. Multivariate analysis showed that age, presence of CKD, and serum albumin values were independent risk factors for predicting AKI in patients with scrub typhus (p=0.015, p=0.049, p<0.001).

Conclusions: AKI according to RIFLE criteria in patients with scrub typhus is frequent and may lead to death although AKI in scrub typhus is usually mild and renal recovery occurs in most patients. Physician should suspect scrub typhus and start treatment early if patients with acute febrile disease accompanied with AKI were admitted.

PUB044

Dengue Viral Infection: Culprit of Acute Kidney Injury Yusra Habib Khan,[1] Azmi Sarriff,[1] Amer Hayat Khan,[1,2] Azreen Syazril Adnan,[2] Fauziah Jummaat,[3] Nurul Jannah Ambak,[2] Azhar Amir Hamzah.[2] *[1]Dept of Clinical Pharmacy, Univ Sains Malaysia, Penang, Malaysia; [2]Chronic Kidney Disease Resource Center, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia; [3]Dept of Obstetrics and Gynecology, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia.*

Background: Dengue fever is a viral infection that is of potential public health concern. One of the most severe and poorly understood complications of dengue fever is acute kidney injury (AKI).

Methods: We retrospectively reviewed medical records, laboratory findings and comorbidities of dengue infected patients for the last five years i.e. 2008 until 2013 at a tertiary care hospital in Kelantan, Malaysia. Patient records with incomplete demographics and renal function data were excluded.

Results: From January2008 to April 2013, total 93 dengue infected patients (male: 49, female: 44, ratio; 1:1.1) with mean age of 27.37± 14.18 were enrolled in current study. Majority of the enrolled patients had Classical dengue fever while only 1 patient suffered Dengue hemorrhagic fever (DHF). No mortality was observed in our study. AKI was observed in 7 (7.5%) of enrolled patients resulting in elevation of following as compared to those patients without AKI: mean rank of bilirubin (61.41 versus 23.43; p: 0.028). There was no statistically significant difference in platelet count (46.19 versus 63.10; p: 0.194), serum calcium (37.38 versus 52.17; p: 0.170) and serum phosphate (56.38 versus 46.67; p: 0.336) levels between AKI and non-AKI cohort. Furthermore, other laboratory findings revealed proteinuria 3(32%), hematuria 6(65%), hyponatremia 5 (53%) and hypokalemia 5(53%).

Conclusions: Thecurrent findings suggest dengue infection is significantly associated with development of AKI. If untreated it may lead to several life threatening complications. A cautious diagnosis and timely management should be the first and foremost step for management of such patients.

PUB045

Incidence and Characteristics of Acute Kidney Injury in Leptospirosis; a Retrospective 5 Year Study Tauqeer Hussain Mallhi,[1] Amer Hayat Khan,[1,2] Azmi Sarriff,[1] Azreen Syazril Adnan,[2] Fauziah Jummaat,[3] Yusra Habib Khan,[1] Muhammad Salman,[1,2] Nurul Jannah Ambak.[2] *[1]Dept of Clinical Pharmacy, Univ Sains Malaysia, Penang, Malaysia; [2]Chronic Kidney Disease Resource Center, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia; [3]Dept of Obstetrics and Gynecology, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia.*

Background: Leptospirosis is most widespread zoonotic disease endemic in warm and humid climate.The incidence of leptospirosis in Malaysia is 13%. Renal involvement is most dreaded complication of leptospirosis and is most common cause of death. Incidence of leptospirosis induced acute kidney injury (AKI) is 40-60% having mortality rate of around 22%.

Methods: A 5 years (2004-2008) retrospective database for patients presenting with leptospirosis was initiated at tertiary care hospital, Kelantan, Malaysia. Patients with concurrent infections, incomplete demographics and renal function tests were excluded from study.

Results: A total of 45 (Male: 40, Female: 5, ratio 8:1) leptospirosis patients with mean age of 38.6 ± 14.31 years were enrolled in this study. According to AKIN classification, overall incidence of AKI was 46.6%. Incidence was higher (61.1 %) in risk groups as compared to non-risk groups (38.9%). AKIN-1 was seen in 6 (16.7%) patients while 7 (19.4%) and 8 (22.2%) patients had AKIN-2 and AKIN-3 respectively. Hypokalemia and hyponatremia was observed in 33.3% and 58.3% of patients. Statistical significant (p<0.001) difference in renal profile and hospital stay was observed in patients with AKI and without AKI at admission e.g. Serum creatinine (Mean rank: 25.17 versus 9.17), blood urea (Mean rank: 25.21 versus 9.10) and hospital stay (Mean rank: 23.52 versus 11.47) respectively. Predictors of AKI in our study were old age and association with risk groups while risk factor of severe form of AKI was age > 40 years. We observed no mortality in our study group.

Conclusions: AKI is common and fatal complication of leptospirosis. Early diagnosis, evaluation of risk factors and prompt treatment can reduce further renal deterioration and hospital stay.

PUB046

Predictors of Acute Kidney Injury in Patients Undergoing Lower Extremity Amputation Nina A. Patel,[1] James Fry,[2] Rajiv K. Dhamija.[1,2] *[1]Nephrology, Ranchos Los Amigos National Rehabilitation Center, Downey, CA; [2]Western Univ of Health Sciences, Pomona, CA.*

Background: Proteinuria is established as an important prognostic factor for the development of acute kidney injury (AKI) in patients undergoing cardiac procedures. In this study, we aim to establish a direct relationship between pre-operative proteinuria and development of AKI postoperatively in patients undergoing lower extremity amputations (LEA).

Methods: We performed a five year single center retrospective analysis from 2009-2013 on all patients undergoing LEA. Data on the patients' demographic characteristics, medical history and laboratory test results were retrieved from medical records. A rise in serum creatinine of 0.3mg/dL or greater, per the Acute Kidney Injury Network (AKIN) guidelines, was used to determine AKI.

Results: A total of 478 LEA surgeries were reviewed out of which 260 were excluded (toe-only amputations, incomplete data, or advanced CKD); 218 surgeries were included. An increased incidence of AKI was found to be associated with moderate preoperative proteinuria using the independent sample T test [p<.009]. Those with CKD III were at an increased risk for AKI [p<.000]. However, when both were correlated using directional measures Somers'd test, those with CKD III and severe proteinuria were at an increased risk for AKI [p<0.029]. The overall incidence rate of AKI was 9.6%.

Conclusions: Individually, both CKD III and moderate proteinuria are independent risk factors for AKI post LEA. When correlated, patients with CKD III and severe proteinuria are at an even higher risk for AKI post LEA in a predominantly Hispanic patient population.This is the first study with a majority Hispanic population that shows proteinuria is a predictor of AKI in patients undergoing LEA. The study population was at high risk for AKI, with 91.7% diabetic, 44.5% with CKD, 69.3% hypertensive, and 77.9% with proteinuria. Existing literature recognizes microalbuminuria, CKD, and post-operative AKI with adverse outcomes in overall morbidity and mortality. To fully understand the extent of risks of AKI development in LEA, a randomized controlled trial needs to be conducted.

PUB047

Are Ace Inhibitors and Angiotensin Receptor Blockers Really Safe in the Elderly? Vivienne Ralph, Muhammad Taufiq Dawood, Christine Sarah Catley, Anthony Chan, Abdelgalil Abdelrahman Ali, Sumith C. Abeygunasekara. *Renal Unit, Broomfield Hospital Mid Essex Hospital Trust, Chelmsford, Essex, United Kingdom.*

Background: AKI accounts for 13-18% of hospital admissions in the UK. A 2009 report published by the National Confidential Enquiry into Patient Outcome and Death highlighted the importance of managing AKI effectively. Despite being diagnosed with AKI, 54% of patients do not have nephrotoxic medications stopped. We identified risk factors for developing Acute Kidney Injury(AKI) in an inpatient cohort, with the objective that awareness of these may prevent AKI.

Methods: Data was retrospectively collected from two cohorts of patients admitted to a District General Hospital in the UK between August and November 2012. The first

group developed severe AKI (RIFLE criteria stage three) during admission, and the second did not. Potential risk factors compared between these groups included age, creatinine, and medications.

Results: The patients who developed severe AKI were prescribed more nephrotoxic medications than the group that did not develop AKI. The largest difference between the two groups was in the prescription of ACE inhibitors and ARBs, which were almost twice as likely to be prescribed in the AKI group.

Parameter	AKI Patients	Control group
Age	75.85 ±12	67.99 ± 20.7
Serum Creatinine	443.8 ± 240.28	84 ± 29.2
ACEI/ARB risk score	0.44 ± 0.4	0.29 ± 0.46
Diuretics score	0.41 ± 0.33	0.33 ± 0.29
NSAID score	0.04 ± 0.19	0.02 ± 0.15
Metformin	0.11 ± 0.3	0.04 ± 0.2
Medications risk score	1.0 ± 0.9	0.6 ± 0.8
Over all risk score	1.58 ± 1.1	1.08 ± 1.06
Death	0.27 ± 0.44	0.10 ± 0.30

The AKI cohort of patients were found to be of a higher mean age in comparison to the control cohort, and have a higher mortality rate.

Conclusions: Diuretics, ACEI and ARBs were commonly prescribed in the patients who developed AKI. The AKI cohort were of higher mean age compared to the control and which in part may contribute to the increased number of nephrotoxic drugs on admission. The risk factors for developing AKI during hospital admission were identified as age above 65 years and taking nephrotoxic medications. It is imperative that physicians have a higher index of suspicion for AKI in patients who meet these criteria.

The Risk Factors Study of Contrast-Induced Nephropathy in Patients Undergoing Cardiac Surgery of PTCA+PCI

Lin Wei,[1] Wenbo Zhao.[2] *[1]Dept of Neuropathy, Guangdong Province Traditional Chinese Medical Hospital, Guangzhou, Guangdong, China; [2]Dept of Nephrology, the Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: To Confirm the risk factors and estimate the incidence of CIN in patients having PTCA+PCI; To decrease the risks and prevent AKI.

Methods: 60 Patients were enrolled underwent coronary intervention (PTCA+PCI), Serum creatinine Scr was measured at any time a week before the angiography and 48 hours Post Procedure; The definition of CIN is the increase of the serum creatinine of 0.5mg/dl or 25% of the baseline at 48 hours after the use of contrast media. eGFR calculated by CKD-EPI formula. Incidence of CIN undergoing coronary intervention was investigated and multivariate predictors used logistic regression.

Results: 64 cases generated CIN; 6 cases needed to blood purification treatment, and 2 cases to death. Multi-factors logistic regression analysis showed independent risk factors including renal insufficiency, diabetes mellitus LVEF<50%, hsCRP>1, female. The maximum likelihood values were 38.41, 26.95; 20.66, 10.39, 12.11.

Conclusions: The incidence rate of CIN in patients of PTCA+PCI was 17.8%; The Renal dysfunction was the most important risk factors. The patients with renal dysfunction has significantly higher the incidence of CIN; The incidence of CIN in intravenous fluid hydration and non-hydrated patients were no significant difference.

PUB049

A Rare and Emerging Cause of Acute Kidney Injury in a Young Patient

Dilini C. Reyhart,[1] Gordon W. James.[2] *[1]Internal Medicine - Pediatrics Residency, UICOMP, Peoria, IL; [2]Nephrology, Renal Care Associates, Peoria, IL.*

Background: Acute tubular necrosis is the most common cause of intrinsic kidney disease causing acute kidney injury (AKI). It is known to be caused by a multitude of insults with an ischemic event or exposure to nephrotoxic agents being the most common causes. We are reporting a case of AKI secondary to synthetic cannabinoid.

Methods: Our patient was a 20 year old male who presented in Status Epilepticus. He was tachycardia, had dilated pupils and coarse breath sounds at presentation. Neurological exam was limited due to sedation. Patient had 'K2' in his possession. He had no personal or family history of renal disease. Initial labs showed an elevated WBC count of 20,000, Creatinine (Cr) of 1.6, BUN of 10, bicarbonate of 6, anion gap of 42 and lactic acid of 30. UA showed 3+proteinuria, 4+hematuria and 1-5 hyaline casts. Urine protein-Cr ratio was 3.3. CT head was normal. Serum and urine testing for common ingestions were negative. He required propofol drip and versed for seizure control which was weaned off after 24 hours. Workup was done to assess for glomerulonephritis (GN). His C3, C4, ANCA, Anti GBM and ASOT titer were all normal. History revealed no NSAIDS, ACEI, ARB intake to

suggest such medications contributing to AKI. Etiology for AKI was most likely secondary to 'K2' use. AKI was managed with bicarbonate containing fluids. His Cr peaked to 6.7 after which showed improvement and came to baseline by day 20. He never required dialysis.

Conclusions: Synthetic cannabinoids are analogs of naturally occurring chemicals found in marijuana. They are marketed under many different names, including "Spice", "K2", "Spice Gold" etc. Standard rapid urine immunoassays are unable to detect them, thus allowing synthetic cannabinoid users to escape easy detection. In our patient there was no reported history of any other nephrotoxic medication and workup for GN was negative. Prerenal causes were less likely since there was no period of hypotension. Synthetic cannabinoid has the potential to cause AKI, per a limited number of recently reported cases. Therefore it is important to consider synthetic marijuana as a potential cause for AKI in patients with unexplained AKI.

PUB050

Assessment of Kidney Function in Patients Treated with Mild Therapeutic Hypothermia After Cardiac Arrest. A Pilot Study Silvia De Rosa,[1,2] Stefano Marcante,[1] Massimo de Cal,[1] Stefania Aresu,[1] Chiara Pasqualin,[1] Enrico Tonini,[1] Massimo Antonelli,[2] Claudio Ronco.[1] *[1]Nephrology and Dialysis, International Renal Research Institute (IRRIV), San Bortolo Hospital, Vicenza, VI, Italy; [2]Intensive Care and Anaesthesiology, Univ Cattolica del Sacro Cuore, Rome, RM, Italy.*

Background: In animal models and in humans studies, it has been shown that induced hypothermia decreased glomerular filtration rate and renal plasma flow.Currently available trials indicate that therapeutic hypothermia (TH) does not prevent AKI including dialysis requirement but is associated with lower mortality. Unfortunately, the currently trials were not designed to examine the effect of TH on a primary kidney endpoints.The aim of this study was to assess the effect of mild hypothermia on kidney function during cooling and rewarming temperatures.

Methods: We performed a prospective observational study in 19 post-cardiac arrest patients. Inclusion criteria were patients with CA (VF without pulse, asystolia, PEA intra and extra hospital) and Myocardial Infarction. The decision to initiate TH (33–34 °C) was made by the treating physician. Temperature, hemodynamic parameters, serum creatinine, vasoactive medication use, urine output, and intravenous fluid were registered from admission to 24 h after rewarming.

Results: Nineteen patients (84% males; Mean age 66±11) were treated with TH. From admission to 24 h after rewarming, there is no significative difference in serum creatinine and urine output (p<.05;p=NS). Furthermore, there is not a significative modification of hemodynamics parameters, of intravenous fluid requirement (p<.05;p=NS) but also of modified inotrope score and vasoactive inotrope score over 48 hours (p <.05;p=NS).

Conclusions: These findings suggest that renal function was preserved with a normal urine output without a decrease in systolic blood pressure, and a further increase in vasoactive and inotrope medication use in patients treated with mild therapeutic hypothermia. Future studies with bigger study populations will be required to confirm these findings and to further investigate these conclusions.

PUB051

Nephrology Research in a Combat Zone Ian J. Stewart,[1] Jonathan Sosnov,[1] Edward D. Siew,[2] T. Alp Ikizler,[2] Kristen R. Glass,[1] Benjamin D. Morrow,[1] Wayne A. Latack,[3] Kristin K.P. Saenz,[1] Kevin Chung.[4] *[1]San Antonio Military Medical Center; [2]Vanderbilt Univ Medical Center; [3]Kessler Medical Center; [4]U. S. Army Institute of Surgical Research.*

Background: Research is difficult under the best of circumstances. Here we describe the process of translational research in an austere location, the intensive care unit (ICU) at Bagram Airfield (BAF), Afghanistan. Our hypothesis for the study was that urinary biomarkers (NGAL, IL-18, L-FABP, Cystatin C and KIM-1) would predict subsequent acute kidney injury (AKI) in this population.

Methods: We conducted a prospective study examining urinary biomarkers (UB) of acute kidney injury in U.S. service members admitted within 48 hours of traumatic injury, had a Foley catheter placed and required ICU level care. Ten ml of urine at admission and then every morning until evacuation were collected. Samples (10 samples per patient per time point) were stored at BAF in a study dedicated -80ºC freezer until shipped to the U.S. Samples were split into 5 shipments (each with at least one complete set of specimens) with temperature data loggers.

Results: Of 126 patients admitted to the ICU at BAF from Oct 2012 to Dec 2013, 89 were included in the cohort resulting in 166 time points and 1660 samples. Enrollment spanned 3 deployment cycles and involved 6 investigators. Of the 5 shipments, 4 arrived in the U.S. intact. Samples shipped through differing combinations of 7 countries and 3 U.S. states. The one shipment that did not make it intact took 8 days to arrive and the peak temperature was 3.1ºC. The four successful shipments took from 2.5 to 7.6 days to arrive and the peak temperatures were -72.5 to -40ºC.

Conclusions: Nephrology research is feasible in a forward deployed combat environment. Biologic specimens can be kept at low enough temperatures in both the austere environment and in transit back to the U.S. for analysis. We present mitigation strategies for dealing with follow up data across multiple States and suggestions for future research in austere conditions. Furthermore, the association of urinary biomarkers with subsequent AKI will also be reviewed.

PUB052

Successful Treatment of Atipical Hemolytic Uremic Syndrome with Eculizumab: Long Term Remission and Improvement of Renal Function Jorge Alexandre Fares,[1] Carlos Eiji Koga,[1] Andre F.G. Larrubia.[2] *[1]Nephrology, Rede D´Ór - Hospital Sao Luiz Morumbi, Sao Paulo, Brazil; [2]Hematology, Rede D´Ór - Hospital Sao Luiz Morumbi, Sao Paulo, Brazil.*

Background: AAS, 28 yrs-old, female, was admitted to hospital in 02-13-2013, with intense weakness, and muscles pains. Labs at admission showed Coombs negative Hemolytic Anemia, plaquetopenia, ARI and proteinuria. A sample for analysis of ADAMTS13 was drawn, and Plasma Exchange was immediately started.

Methods: ECZ was available for infusion 104 days after diagnosis of aHUS. After the first infusion of ECZ, no PE were required(total:25 sessions).

Results: Labs at admission: Hb:10 g-dl; Plaq: <5.000mm3; Schistocytes + in peripheral blood; LDH:2,700U-l; Indirect Bilirrubin :2,7; D-Dimer : >10,000; C:2.7m-dl; ADAMTS13 (02-13-2013)- Activity Assay >100 %. Daily PE Started on day01. Outcome:kidney function deteriorated and HD sessions were required:BUN:100 mg-dl C:8.0 mg-dl. Discharge on day24 to be submitted to intermitent outpatient PE. Labs at discharge: C:3,5 mg-dl; BUN:59 mg-dl; Plat:113.000 mm3; LDH:789 U-l. Readmission on day38: Hemolytic Anemia relapse: Hb:4.0g-dl; LDH:>2,00U-l; Hapto: undetectable;Worsening of ARI, pt. returned to hemodialysis and PE**.** Discharge on day78 with no hemolysis or plaquetpenia. Labs at discharge: C:2.6 mg-dl. Outpatient PE - twice/week. Last PE session, and first dose ECZ induction on day110. No signs of Hemolysis at the first dose of Eculizumab:Hb:12.4; plat:240.000. D-dimer: 1.200.C:2,2; creatinine clearence 24 h: 39 ml/min. Proteinuria 24 h: 0,9g.Outcome after 4 biweekly doses of Eculizumab : 105 days after the first dose(day215):Hb:12,3; Plat:294.000mm3; Hapto: 140; LDH: 380U-l; Reticulocytes:1,46%, D-dimer:250; Creatinine:1.71mg-dl; BUN:25mg-dl. Creatinine clearence 24h: 49ml-min(10 ml-min improvement) Proteinuria 24h: 0,38g; Hematúria<10.000. Labs in jan-2014. (creatinine;1,7mg-dl); Prot. 24h: <0,300 mg, Hematuria:< 10.000. Current creatinine;1.4 mg-dl; Creatinine clearence 24h: 51 ml-min.

Conclusions: Despite Eculizumab's first infusion was done months after the diagnosis of aHUS, renal function improved, proteinuria became negative, and no relapse occurred.

PUB053

Evaluation of the RIFLE Outcome Criteria Loss and End-Stage in Pediatric Continuous Renal Replacement Therapy Patients Alyssa A. Riley,[1] Mary Neil Watson,[2] Sarah J. Swartz,[1] Poyyapakkam Srivaths,[1] Ayse Akcan Arikan.[1] *[1]Pediatrics, Baylor College of Medicine, Houston, TX; [2]Financial Services, Texas Children's Hospital.*

Background: The original standardized definition of acute kidney injury (AKI) proposed by the Acute Dialysis Quality Initiative, the RIFLE criteria, included two outcome strata: Loss –defined as complete Loss of kidney function for >4 weeks and End-stage kidney disease-defined as complete loss of kidney function >3 months (12 weeks). This definition has never been applied to critically ill pediatric patients with AKI. We aimed to determine short term renal outcomes in pediatric patients who required continuous renal replacement therapy (CRRT) for management of AKI and its sequelae.

Methods: Utilizing our institutional database, we identified 105 patients who received CRRT between 2011-2013. Patients were excluded if they had preexisting chronic kidney disease (n=11), were treated for hyperammonemia (n=8) or ingestion (n=2).

Results: The 84 patient cohort was 46% male with a mean age of 8±7 years and mean weight of 33.4±29.8 kg. Patients were treated with CRRT for a mean duration of 12.6±13.2 days. Additional patient descriptors included hospital length of stay 45±40 days, intensive care unit length of stay 23±20 days; 96% of patients were ventilated with mean length of ventilation 20±16days. Hospital mortality was 63% (n=53). Two patients had recovery of kidney function allowing discontinuation of CRRT, but later died during hospitalization. Of the 31 patients surviving to hospital discharge, 23 patients required less than 28 days total renal replacement therapy (RRT), including CRRT, hemodialysis, and peritoneal dialysis, 5 patients (16%) received 4-12 weeks total RRT (RIFLE-L), 3 patients (9.6%) received more than 12 weeks RRT (RIFLE-E). Two of the RIFLE=E patients had subsequent recovery of kidney function and one patient was declared end-stage renal disease.

Conclusions: Our data suggest that critically ill pediatric patients who meet RIFLE-E criteria for AKI may still demonstrate delayed recovery sufficient to discontinue RRT, thus the RIFLE criteria may warrant redefinition to account for a possible prolonged recovery in pediatric patients.

PUB054

Prevalence and Risk Factors for Aute Diarrhea Positive HUS in Children Judith Sebestyen, Uri S. Alon. *Div of Nephrology, The Children's Mercy Hospital, Kansas City, MO.*

Background: Hemolytic uremic syndrome (HUS) is the most common cause of acute renal failure in childhood. Due to the fact that our hospital is surrounded by rural areas, which it serves as an exclusive referral hospital, we see a higher number of children with diarrhea positive HUS. The primary goals of the study were to identify the demographic characteristics of the patients and to identify risk factors for complicated acute versus favorable course. The secondary aim was to determine the risk factors for development of chronic kidney injury.

Methods: 120 pediatric patients (< 22 years old) who were admitted to our hospital between February 1995 and January 2011 were identified via ICD-9-CM code. Complete information was available in 58 patients who were categorized by age, gender, white blood cell count (WBC), hemoglobin (HGB), thrombocyte number (PLT), antibacterial

treatment prior to admission, urine output (UO) and serum creatinine level as well if the patient required dialysis or not. Follow-up record was reviewed for diagnosis of chronic kidney disease.

Results: Thirty one patients (53.4%) required dialysis. The mean age was 3.76 year (9 month-14 year) with no difference between those needing dialysis or not. Female (57.4%) were more likely to require dialysis ($p = 0.041$), as well who were anuric (UO < 0.5 ml/kg/h) at admission ($p < 0.001$). A trend was noted in those with prior antibiotic therapy ($p = 0.054$). Age of less than 2 years, leukocytosis (WBC> 20,000), low PLT count (<20 000) or extreme anemia on admission (HGB< 6.0) were not risk factors for acute dialysis. The mean serum creatinine at admission was significantly higher among patients who required dialysis (3.074 versus 2.47 95 %CI 2.1-3.4, $p < 0.005$). Risk factors for development of CKD, diagnosed in 5 patients were use of antibiotic therapy ($p < 0.005$) and being anuric at admission ($p < 0.005$).

Conclusions: Being female, anuric and receiving antibiotic therapy prior to development of HUS were risk factors for initiation of acute dialysis, and the latter two factors were associated with development of CKD. Further studies are indicated to learn if patients identified to be at high risk may benefit from closer monitoring and early intervention.

Deciding to Get a Flu Shot: Don't Make a Rash Decision

Sunny Mickey Kar,[1] Anuradha Bhavsar,[3] Jafar Mahmood,[2] Pran M. Kar.[2] *[1]Lake Erie College of Osteopathic Medicine; [2]Dr Phillips Hospital; [3]Avalon Univ School of Medicine.*

Background: Rhabdomyolysis can be associated with infections, drugs, hypoxia, and metablic derangements. It can cause acute renal impairment secondary to myoglobinuria. Rhabdomyolysis triggered by an influenza vaccination is rare. Typically, cases of rhabdomyolysis involve multiple risk factors, including the concomitant use of high risk drugs such as statins, fibrates or cyclosporine. A pilot study of 98 patients on statin therapy who received the influenza vaccine did not report any adverse reactions. This may be due to small study size in conjunction with variations in vaccine the formulation. Rhabdomyolysis triggered by an influenza vaccination is an important complication to be aware of, as early recognition can lead to better outcomes in patients.

Methods: A 76 year old male with a history of Chronic Kidney Disease and hyperlipidemia managed on atorvastatin, presented to the emergency room for a new, widely distributed, weeping rash.

He received influenza vaccination three days prior to rash onset. Initial laboratory investigations revealed a creatinine of 4.4 mg/dl, up from his baseline of 2.0 mg/dl. Further, his creatinine kinase levels were found to be elevated at 2610 IU/L. He was admitted to the intensive care unit for renal replacement therapy, and was empirically started Solu-Medrol and diphenhydramine for presumed rhabdomyolysis secondary to Stevens-Johnson Syndrome. The diagnosis was later confirmed by skin biopsy, which showed epidermal sloughing, necrotic keratinocytes and vacuolar interface dermatitis.

PUB056

Rhabdomyolysis Induced Acute Renal Failure Secondary to Severe Hashimoto Hypothyroidism: An Unusual Association

S. Amir Afsharimani. *Medicine, St. Francis Hospital, Evanston, IL.*

Background: Hashimoto's thyroiditis is the most frequent cause of hypothyroidism. The most common neuromuscular manifestations include myalgia, fatigue, proximal muscle weakness and hypoactive tendon reflexes. However, infrequent severe cases of rhabdomyolysis with markedly elevated levels of creatine phosphokinase (CPK) and renal disease have been reported. Association between severe hypothyroidism and acute kidney injury (AKI) is rare.

Methods: We report a case of rhabdomyolysis, acute kidney injury, and myopathy as the only manifestations of severe hypothyroidism secondary to Hashimoto's thyroiditis.

Results: A 32 year old male was admitted to the hospital with bilateral upper and lower extremities progressive pain and swelling. Symptoms started three days prior to admission and became worse the night before admission. Pain was worse with movement. He denied any vigorous activity, trauma, previous medications, and fever. Neurological examination revealed decreased muscle strength symmetrically on lower limb (3 + / 5 +) and upper limbs (4 + / 5 +), and diminished tendon reflexes (1 + / 4 +) symmetrically. Laboratory evaluation revealed the following serum levels: CPK, 2256 IU/L (38-174), creatinine 2.6 mg/dl (0.5-1.20), free thyroxine (FT4) <0.20 ng/dl (0.93-1.70), thyroid stimulating hormone 259.70 uIU/ml (0.400- 5.40), and thyroid peroxidase antibody 452 IU/ml (<35). After ruling out adrenal insufficiency by cosyntropin stimulation test, treatment was started with 125 ug oral levothyroxine. The symptoms gradually improved. The patient was discharged from the hospital five days later, showing only mild muscle pain. CPK levels reduced significantly, and creatinine normalized.

Conclusions: Asymptomatic mild to moderate elevation of creatine kinase frequently develops in hypothyroidism. However,marked creatine kinase elevation with rhabdomyolysis have been reported only in a very small number of cases with undiagnosed hypothyroidism.Although hypothyroidism rarely presents with AKI and rhabdomyolysis, it should be suspected in patients presenting with impaired renal function and high creatine kinase level in the absence of other causes of rhabdomyolysis.

PUB057

Pseudo Renal Injury Associated with Isopropyl Alcohol

Rawan Tayseer Al Odat,[1] Laith Farah Al-Rabadi.[2] *[1]Internal Medicine, Al-Khalidi Hospital, Amman, Jordan; [2]Nephrology, Boston Univ Medical Center, Boston, MA.*

Background: Isopropyl alcohol is a disinfectant and cleaning agent that can potentially suppress CNS when ingested accidentally or in suicide attempts. Isopropyl alcohol (IPA) intoxication is mostly encountered in alcoholics as ethanol substitute. Acute renal injury due to IPA has only been infrequently reported.

Methods: Case report.

Results: Herein, we present a case of 32 year old alcoholic patient who was admitted for alcohol detoxification. He developed doubling of his creatinine level to 1.5 mg/dl in the setting of taking Cal Stat, a rubbing alcohol containing isopropyl alcohol used in medical facilities. Patient was drinking it from containers available on hospital walls to help with his withdrawal symptoms. Osmolar gap was elevated with no evidence of metabolic acidosis. Urine ketone test was positive. Completely normal BUN raised doubts about the validity of the elevation in creatinine. When Creatinine level was obtained from an arterial sample a normal value of 0.7 mg/dl was found. IPA level was elevated. The decrease in osmolar gap and urine ketones level correlate with the decrease in IPA concentration and can serve as surrogate for actual blood levels.

Conclusions: Isopropyl is metabolized through alcohol dehydrogenase to acetone that can't be oxidized to carboxylic acids. Hence, academia does not usually occur and if present, should prompt clinician to look for other coingested substances. Acetone can cause false elevation of serum creatinine by interfering with the colorimetric assay for creatinine. Most analyzers use the Jaffe-alkaline-picrate reaction. Some substances including acetone can react with picric acid and cause spurious elevation in the creatinine level. Measuring creatinine level by enzymatic assay in blood gas analyzer will accurately estimate serum creatinine and avoid the interference of acetone. We emphasize the importance of being aware of the false elevation of creatinine in the setting of IPA intoxication to assist in diagnosis and management and to avoid incorrect diagnosis of acute renal injury.

PUB058

Neutrophil Gelatinase-Associated Lipocalcin (NGAL) and Stress-Induced Hyperglycemia in Critically Ill Children

Roberto Gordillo. *Pediatrics, Univ of Illinois College of Medicine at Peoria, Peoria, IL.*

Background: Hyperglycemia is common in critical ill patients and it has been associated with increased mortality and morbidity in adults and children. However, it is still not clear if stress-induced hyperglycemia correlates with acute kidney injury (AKI). NGAL has been used for early clinical recognition of patients at risk for AKI.

Methods: We conducted a prospective cohort study of 27 critical ill subjects admitted to the pediatric intensive care unit (PICU). No infants and subjects with known kidney disease were included. We determined the intensity of acute kidney injury using the pediatric RIFLE criteria. Two groups were compared, subjects with AKI on admission and subjects without AKI on admission. Urine and serum NGAL were measured on admission.

Results: 27 critically pediatric subjects were included. 8 of those patients had AKI according to the pediatric RIFLE criteria. A positive correlation between peak glycemia during admission and serum NGAL was found, $p = 0.03$. Urine NGAL was not associated with higher glycemia, $p=0.9$. Demographics are shown in table.

	AKI (n=8)	No-AKI (n=19)	P
Age (years)	9.6±7	8.2± 5.5	0.6
Caucasian (%)	50	63	0.6
Length of hospital stay (days)	61.7 ±SEM 41	27.6±SEM 7.5	0.3
Urine NGAL (ng/ml)	358±SEM 324	18.42±SEM 8	0.2

Conclusions: We found a positive correlation between serum NGAL on admission and peak glycemia during PICU admission. Although we found higher levels of NGAL in urine in subjects with AKI, it was not statistically significant. Serum glucose and NGAL are useful tools in treating critically ill pediatric subjects.

PUB059

Modified High-Density Lipoprotein May Contribute to Systemic Inflammation in Patients with Chronic Kidney Disease by Interacting with Polymorphonuclear Leukocytes

Gerald Cohen, Jana Raupachova, Chantal Maureen Kopecky, Marcus Saemann. *Dept of Internal Medicine III, Medical Univ of Vienna, Vienna, Austria.*

Background: Disturbed functions of polymorphonuclear leukocytes (PMNLs), cells of the first-line non-specific immune defense, contribute to cardiovascular disease in patients with chronic kidney disease (CKD). Decreasing renal function is associated with gradual changes in the protein composition of high-density lipoprotein (HDL), such as enrichment of serum amyloid A (SAA), resulting in loss of its anti-inflammatory properties. We tested the effect of HDL from hemodialysis patients (HD-HDL), CKD stage 3 and 4 patients (CKD3- and CKD4-HDL) and healthy subjects (HS-HDL) on different PMNL features.

Methods: HDL was isolated by a one-step density gradient centrifugation. PMNLs were isolated from heparinized blood using discontinuous density gradient centrifugation. Spontaneous apoptosis was assessed by evaluating morphological features of PMNLs with fluorescence microscopy and by measuring their DNA content. The surface expression of CD11b on PMNLs was quantified by flow cytometry.

Results: HD-HDL, CKD3- and CKD4-HDL significantly reduced spontaneous apoptosis of PMNLs from healthy controls, an effect typical for pro-inflammatory mediators. Apoptosis of PMNLs from HD patients was reduced by HD-HDL to the same extent as of PMNLs from HS. SAA alone and HS-HDL spiked with SAA significantly attenuated PMNL apoptosis suggesting that SAA contributes to the observed effect of uremic HDL. Experiments with signal transduction inhibitors suggest that HD-HDL exerts its anti-apoptotic effect by activating pathways involving phospho-inositide 3-kinase and extracellular-signal regulated kinase. The integrin CD11b is involved in the pathogenesis of vascular damage and increased atherosclerotic risk. In contrast to HDL from CKD and HD patients, HS-HDL showed anti-inflammatory properties by significantly reducing expression of CD11b on activated PMNLs.

Conclusions: We conclude that modified HDL may contribute to systemic inflammation in CKD patients by interacting with PMNLs.

Eryptosis and Oxidative Stress Induced By Indoxyl Sulfate and *p*-Cresyl Sulfate Are Attenuated by N-Acetyl Cysteine

Andrea Novais Moreno-Amaral,[1] Natalia Borges Bonan,[1] Gabriela Ferreira Dias,[1] Viktoriya Kuntsevich,[2] Wesley M. Souza,[3] Andréa Marques Stinghen,[4] Lia S. Nakao,[4] Fellype C. Barreto,[1] Peter Kotanko,[5] Roberto Pecoits-Filho.[1] *[1]School of Medicine PPGCS, PUCPR, Brazil; [2]Mount Sinai Beth Israel New York; [3]Dept Clinical Analysis UFPR, Brazil; [4]Basic Pathology Dept UFPR, Brazil; [5]Renal Research Institute New York.*

Background: Uremic toxins play a critical role in chronic kidney disease(CKD)-related anemia inducing eryptosis thorough mechanisms not fully understood. Renal anemia is involved in the pathogenesis of increased oxidative stress in patients, due its association with the overproduction of reactive oxygen species (ROS) and reduction of antioxidant defenses. *N*-acetyl-L-cysteine (NAC) is a cysteine donor with antioxidant properties. The present study explored the potential of indoxyl sulfate (IS) and *p*-cresyl sulfate (*p*CS) in promoting eryptosis and ROS production and the effect of NAC treatment.

Methods: Erythrocytes obtained from healthy donors were incubated for 24h with NAC before 24h incubation with different concentration of IS or *p*CS. Eryptosis was evaluated by positivity of cells expressing phosphatidylserine (PS) by Annexin-V-PE. Intracellular ROS generation was evaluated by DCFH-DA oxidation using flow cytometer.

Results: IS induced eryptosis in a dose-dependent manner, with its highest concentration (236μg/L) resulting in about 35±11% of annexin-V-PE positive erythrocytes. *p*CS (2.6mg/L, higher concentration) induced eryptosis by 25±9.5%. In the presence of NAC, uremic toxins lost their pro-eryptotic activity. We also observed that *p*CS and IS were capable of promoting ROS generation, though in different intensity (20±5.6% at *p*CS 2.6 μg/ml; and 56±19.7% at IS 236mg/L). NAC pre-incubation inhibited the ROS generation by uremic toxins.

Conclusions: Thus, taken together our results suggest that besides the high exposure of PS on erythrocytes surface induced by uremic toxins, these toxins promote increased ROS generation, effects that were attenuated by NAC. These findings indicate the potential role of uremic toxins on eryptosis and parallel an increased ROS generation that may partially explain the systemic vascular effects of anemia in CKD.

PUB061

Overendocytosis of Gold Nanoparticles Increases Autophagy and Apoptosis in Hypoxic Human Renal Proximal Tubular Cells

Fengan Ding, Ping Sheng Chen. *Pathology, School of Medicine, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Gold nanoparticles (GNPs) can potentially be used in biomedical products ranging from therapeutics to diagnostics, and their use will result inincreased human exposure. Many studies have demonstrated that GNPs can be deposited in the kidneys, particularlyin renal tubular epithelial cells. Chronic hypoxia is inevitable in chronic kidney diseases (CKD), and it results in renal tubular epithelial cells that are susceptible to different types of injuries. However, the understanding of the interactions between GNPsand hypoxic renal tubular epithelial cells is still rudimentary.

Methods: Wesynthesized and characterized GNPs by various biophysicalmethods, including transmission electron microscopy (TEM), dynamic light scattering, and UV-vis spectrophotometry. Then we explored the cell viability, autophagy and apoptosis, and reactive oxygen species production both in oxic and hypoxic conditions.

Results: It was found that 5-nm GNPsresulted in cytotoxic effects only in hypoxic human renal proximal tubular cells (HK-2) treated for 24 hwith 5-nm GNPs at a concentration of 50 nMusing theCell Counting Kit-8 (CCK-8) assay. To further understand the cytotoxic mechanism of the smaller GNPs,the cells were exposed to 5-nm GNPs (50 nM) for 24 hunderoxic and hypoxic conditions. The TEM revealed that GNPs were either localized in vesicles or free in the lysosomes in the HK-2 cells, and the cellular uptake of the GNPs was significantly higher under hypoxic than normoxic conditions. In normoxic HK-2 cells, GNP (5 nm) treatment at a concentration of 50 nM could cause autophagy and cell survival; however, in hypoxic conditions, GNP exposure at the same concentration led to the production of reactive oxygen species (ROS), and an increase in apoptosis and autophagic cell death.

Conclusions: Our results provide an important basis for understanding the risks associated with GNP use and provideguidance for the potential GNP-related therapies in CKD patients.

PUB062

Docosahexaenoic Acid Attenuates Palmitate-Induced Unfolded Protein Response-Related Changes in Protein Degradation in Muscle Cells

Russ Price,[1,2] Myra Woodworth-Hobbs.[1,3] *[1]Medicine/Nephrology, Emory Univ, Atlanta, GA; [2]Atlanta VAMC, Atlanta, GA; [3]NHS Program, Emory Univ, Atlanta, GA.*

Background: Hyperlipidemia and skeletal muscle atrophy are frequent consequences of chronic kidney disease and diabetes. Accumulation of saturated fatty acids in skeletal muscle causes dysregulation of protein metabolism. In cultured myotubes, the saturated fatty acid palmitate (PA) stimulates protein degradation and decreases cell size, while co-treatment with the omega-3 polyunsaturated fatty acid docosahexaenoic acid (DHA) prevents the response. PA also induces endoplasmic reticulum (ER) stress and activates the unfolded protein response (UPR) in myotubes, resulting in decreased protein synthesis. ER stress can also activate caspase proteases in some cell types. This study investigated how PA and DHA affect the UPR and components of protein metabolism including caspases and protein synthesis in muscle cells.

Methods: C2C12 myotubes were treated with 500 μM PA and/or 100 μM DHA for 24 h. Proteins and mRNAs associated with ER stress, caspase activation and protein translation were evaluated by immunoblot analysis and qPCR, respectively. Results are were analyzed by ANOVA and post-hoc tests. Results are reported as mean percent of untreated control ± SEM.

Results: PA induced activation of PKR-like endoplasmic reticulum kinase (PERK), as indicated by a 984±321% ($P<0.05$) increase in phospho-PERK:total PERK ratio. PA also increased the phosphorylation (i.e. inactivation) of eukaryotic initiation factor 2α (eIF2α) by 223±52% ($P<0.05$) and the level of Nrf2 protein by 223±52% ($P<0.05$). Co-treatment with DHA attenuated the effects of PA on PERK ratio and restored Nrf2 protein to the control level; DHA did not reduce PA-induced eIF2α phosphorylation. PA also induced CHOP mRNA by 744 ± 45% ($P<0.05$) and the appearance of activated caspase-3 peptide whereas DHA reversed these responses.

Conclusions: DHA attenuates many of the effects of PA on the UPR and caspase 3 but does not appear to counter responses related to global protein synthesis. Changes in CHOP and caspase 3 indicate that DHA restores myotube diameter primarily by inhibiting PA-induced proteolyic responses.

PUB063

Distinct Cytokine mRNA Expression Pattern in Immunoglobulin G4-Related Kidney Disease Associated with Renal Cell Carcinoma Tetsuhiko Yasuno. *Internal Medicine, Fukuoka Univ, Fukuoka, Japan.*

Background: We treated a 61-years-old man with IgG4-related kidney disease (IgG4-RKD). He had been diagnosed as renal cell carcinoma (RCC) and received left kidney segmental resection at 59 years old. He had allergic diseases and an allergic reaction in past history, and have diagnosed as autoimmune pancreatitis (AIP). According to his clinical course it was clarified that the value of serum amylase and the number of peripheral eosinophils were increased after the development of RCC. We constructed a hypothesis that RCC might induce the development of AIP and IgG4-RKD, and examined extracted RCC tissue. Typical findings of IgG4-RKD attached with RCC were recognized.

Methods: The evaluation of mRNA expression levels of cytokines in the tissues of this case and other ten ordinary RCC cases was performed.

Results: All cases showed sufficient values of IL-10 and great values of TGFβ. Although prominent differences were not observed in Th1, Th17, and Treg cytokines in all cases, concerned with Th2 cytokines only this case showed increased productions of IL-4 and IL-5, and which were not detected in ordinary RCC cases.

Conclusions: Although a mechanism for development of IgG4RKD has not been clarified, Th2 and Treg cells are thought to be predominantly involved in the pathogenesis. It was suggested that immune response against RCC might trigger for the development of IgG4-RKD.

Mesangial Tissue Transglutaminase Activity in Patients with IgA Nephropathy: Implications for the Pathogenesis Kazuo Takahashi,[1] Tomohiro Mizuno,[2] Takanori Onouchi,[1] Shin'ichi Akiyama,[4] Stacy D. Hall,[3] Hideki Tatsukawa,[5] Mamoru Kusaka,[1] Yutaka Tsutsumi,[1] Tadashi Nagamatsu,[2] Shoichi Maruyama,[4] Hiroshi Kitamura,[6] Jan Novak,[3] Kiyotaka Hitomi,[5] Yukio Yuzawa.[1] *[1]Fujita Health Univ School of Medicine, Toyoake, Japan; [2]Meijo Univ, Nagoya, Japan; [3]Univ of Alabama at Birmingham, Birmingham, AL; [4]Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [5]Nagoya Univ Graduate School of Pharmaceutical Sciences, Nagoya, Japan; [6]Chiba-East Hospital, Chiba, Japan.*

Background: Tissue transglutaminase (TG2) is essential for mesangial activation by IgA1-containing complexes in a mouse model resembling IgA nephropathy (IgAN). Although TG2 plays an important role in a mouse model of IgAN, its pathological significance for human IgAN is unknown. TG2 is a ubiquitously expressed enzyme and transforms into catalytically active TG2 through extensive conformational changes. Thus, it is crucial to detect catalytically active TG2 to assess the role of TG2 in IgAN.

Methods: We detected TG2 activity and its distribution in renal tissue using FITC-labeled highly reactive substrate peptides and fluorescence microscopy. Renal biopsy specimens were obtained from 50 patients with biopsy-proven IgAN and from 42 disease controls (patients with biopsy-proven kidney diseases without predominant IgA deposition).

Results: TG2 activity was detected in the glomerular vascular pole, but not in the mesangial area in most samples from disease controls. In contrast, 28 of 50 patients with IgAN (56%) exhibited mesangial TG2 activity. Furthermore, IgAN patients with mesangial TG2 activity had higher level of proteinuria (2.3 *versus*. 0.9 g/day, *P*= 0.02) and higher mesangial score (0.54 *versus*. 0.39, *P*= 0.08) defined by Oxford classification than those without TG2 activity in the mesangium.

Conclusions: These results suggest that mesangial TG2 activity may be related to mesangial proliferation in patients with IgAN. Detailed studies of mesangial TG2 expression and activity will provide new information relevant to the pathogenesis of IgAN.

Henoch-Schönlein Purpura: Assessment of IgG-IgA1 Immune Complexes in Patients with and without Nephritis Ling Yun Lai,[1] Jing Qian,[1] Ping Cheng,[1] Chuanming Hao,[1] Stacy D. Hall,[2] Bruce A. Julian,[2] Jan Novak.[2] *[1]Div of Nephrology, Fudan Univ, Huashan Hospital, Shanghai, China; [2]Dept of Microbiology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Henoch-Schönlein purpura (HSP) is a vasculitis associated with skin deposits of IgA1-containing immune complexes (IC). Joints and/or gastrointestinal tract may be affected; 40-60% HSP patients develop nephritis (HSPN) 4-6 weeks after onset of purpura. Renal pathology is similar to that of IgA nephropathy, with IgA-containing IC deposits. Circulating IgG-IgA IC likely contribute to the pathogenesis of both diseases.

Methods: Serum was collected from 45 adults (21 females; age range 17-70 yr). 35 patients had HSP and 10 patients had minimal-change disease (MCD). 20 HSP patients with abnormal urinalysis had biopsy-proven HSPN; 15 HSP patients had normal urinalysis for 1 year after onset of HSP. Serum IgA and IgA-IC were purified and IgG and IgA-IgG IC were measured.

Results: All HSP(N) patients had purpura; 53% had arthralgia or abdominal pain. Frequency of joint or gastrointestinal tract involvement did not differ between HSPN patients and HSP patients (p=1.0). Total serum IgA, IgG, or C3 did not differ between HSPN and HSP patients (IgA, 3.33±1.74 *versus* 3.19±0.76 g/L, p=0.84; IgG, 9.72±2.91 *versus* 11.01±2.36 g/L, p=0.29; C3 1.10±0.27 *versus* 1.16±0.22 g/L, p=0.64). For HSPN, HSP, and MCD patients, gender ratio and mean age were similar (p=0.22, p=0.34, respectively); mean serum creatinine was 80.4±37.8, 63.4±14.1, and 74.0±15.8 mmol/L, respectively (p=0.47). Amount of IgG co-purified with IgA in HSPN patients was similar to that for HSP and MCD patients [130 (0, 285) μg/ml, 100 (0, 350) μg/ml, and 105 (0, 293) μg/ml, p=0.906]. Levels of IgG-IgA1 IC were 0.35±0.24, 0.26±0.16, and 0.34±0.19 U/mL in HSPN patients compared to HSP and MCD patients (p=0.43). Moreover, median ratio of IgG complexed with IgA to total serum IgG was 0.0138(0, 0.031) *versus* 0.0076 (0, 0.0195) for HSPN patients *versus* HSP patients (p=0.111).

Conclusions: Patients with HSPN, HSP, and MCD had IgG complexed with IgA1, although HSPN patients tended to have a higher percentage of such IgG. Thus, more specific tests are needed to differentiate HSPN from HSP.

PUB066

Detection of Anti-Phospholipase A2 Receptors Antibodies in the Diagnosis of Primary Membranous Glomerulonephritis Using Immunoassay and Indirect Immunofluorescence A. Bernard Collins, Christie M. Swett, Ivy A. Rosales, Rex Neal Smith, Robert B. Colvin. *Dept of Pathology, Massachusetts General Hospital, Boston, MA.*

Background: The detection of autoantibody against the M-Type phospholipase A2 receptors (PLA2R), a transmembrane glycoprotein expressed on the surface of the glomerular podocyte is diagnostic of primary membranous (MGN). Circulating antibody to the PLA2R receptor is present in most patients with primary MGN but rarely in patients with secondary (MGN) or other glomerular diseases. Quantitation of the level of anti-PLA2R provides important clinical markers for management and treatment.

Methods: This study evaluates the sensitivity and specificity using Immunoassay (ELISA) and indirect immunofluorescence (IIF) compared to the results of WB. Circulating antibody to PLA2R was detected by (IIF) on BIOCHIPs (Euroimmun) on either HEK293 tissue culture cells transfected with a recombinant construct of PLA2R and control transfected cells and by ELISA (Euroimmun) using a purified human recombinant PLA2R receptor from transfected HEK293 cells as a substate. Patients with primary MGN on renal biopsy (n=19) and a peribiopsy serum specimen were tested for anti-PLA2R by WB, ELISA, and IIF. Contols included non-primary MGN immune complex GN; secondary MGN (n=2), immune complex GN (n=5), de novo MGN (n=2), lupus Class 5 (n=1), additional controls included autoimmune sera (n=19); Celiac Disease (n=3), Crest syndrome (n=3), SLE + ANA (n=7), negative ANA (n=3), anti-CCP(n=3), ANCA (n=7), anti-GBM (n=2), and normal blood donors (n=20).

Results:

Diagnosis	Pos WB	Neg WB	WB	Pos ELISA	Neg ELISA	ELISA	Pos IIF	Neg IIF	IIF
MGN (n=19)	14	5	73.6% Sensitivity 100% Specificity	14 (Mean= 588.6 RU/ml) (Range 89->1500 RU/ml)* positive= >14RU/ml	5	76.4% Sensitivity 100% Specificity	10	9	52.6% Sensitivity 100% Specificity
Non Primary MGN Immune Complex	0	10		0	10		0	10	
Control Groups (n=56)	0	48		0	48		0	48	

Conclusions: The detection of anti-PLA2R antibody using ELISA and IIF provides a sensitive and specific tool for detection when compared to WB. The additional advantage of ELISA is quantitation a potential useful marker of treatment response.

PUB067

Oncostatin M Represents a Potent Co-Stimulator of Inflammatory Chemokines in Human Proximal Tubular Cells Rita Sarkozi, Ulrike Corazza, Philipp Osterkamp, Markus Pirklbauer, Gert J. Mayer, Herbert Schramek. *Internal Medicine IV, Nephrology and Hypertension, Innsbruck Medical Univ, Innsbruck, Tirol, Austria.*

Background: Increased production of inflammatory chemokines such as MCP-1 and RANTES promotes the accumulation of monocytic cells into injured renal tissue, a common feature observed in diabetic nephropathy. In this context we reported that oncostatin M (OSM) exerts antifibrotic effects in human kidney-2 (HK-2) cells.The present study was performed to investigate OSMs effects on MCP-1 and RANTES mRNA expression in proximal tubular HK-2 cells both in the absence and presence of IL-1β, TNF-α or TGF-β1.

Methods: Cell culture, real-time PCR, RNA silencing.

Results: Administration of 10 ng/ml IL-1β, TNF-α or TGF-β1 led to a rapid, time-dependent induction of MCP-1 mRNA lasting for at least 48 h. OSM (10 ng/ml) stimulated MCP-1 mRNA expression after 30 min and 1 h, which was reduced nearly to basal levels as early as 3 h after incubation. Both, IL-1β and TNF-α led to a slowly building, time-dependent upregulation of RANTES mRNA expression. In contrast, neither TGF-β1 nor OSM significantly affected RANTES mRNA levels for up to 48 h. Treatment of HK-2 cells with IL-1β, TNF-α or TGF-β1 in the presence of OSM for 6 h and 24 h resulted in a

strong additive effect on MCP-1 mRNA expression. Similar additive effects, albeit lower in size, were obtained for RANTES when HK-2 cells were stimulated either with IL-1β or TNF-α in combination with OSM. Furthermore, siRNA-mediated selective silencing of ERK1, ERK2, STAT1 or STAT3 suggests that, in contrast to ERK1/2, both STAT1 and STAT3 are involved in the regulation of basal MCP-1 expression. Most importantly, selective knockdown of these signaling molecules revealed evidence that the additive effect of OSM on IL-1β-induced MCP-1 mRNA expression, at least partially, depends on STAT3 but not on STAT1, ERK1 or ERK2.

Conclusions: OSM enhances the stimulatory effect of IL-1β and TNF-α on mRNA expression of MCP-1 and RANTES in HK-2 cells. OSMs additive effect on IL-1β-induced MCP-1 mRNA expression partially depends on STAT3. The results suggest, that OSM is a co-stimulator of these inflammatory chemokines in human proximal tubular cells.

PUB068

Uric Acid Induces Inflammasomes Formation and Pyroptosis in Human Renal Proximal Tubular Cells Shabirul Haque, Shallu Sharma, Maria Sultana-Syed, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: The inflammasome is a multiprotein oligomer composed of caspasse-1, PYCARD adm NALPH.The inflammasome promotes the maturation of the inflammatory cytokines such as interleukin (IL)-1ß and IL-18. Uric acid (UA) crystals have been demonstrated to promote gouty arthropathy through inflammasome formation. High serum uric acid has also been considered to promote both acute and chronic tubulointerstitial disease. However, the role of uric acid in the induction of tubular cell inflammasome formation has not been studied. We hypothesized that uric acid enhances tubulointerstitial fibrosis through the induction of tubular cell inflmmasome formation and pyroptosis.

Methods: Human renal proximal tubular cells (HRPTCs) were incubated in media containing either buffer or different concentrations of uric acid for 24 and 48 hours and assayed for pyroptosis through staining with H3342 and propidium iodide. To determine the involved mechanism, HRPTCs treated with UA (100 µg/ml) for 48 h were followed by RNA and protein extraction. cDNA as well as protein blots were probed for NLRP3, IL-1 and caspase-1. To establish causal relationship between caspase-1 activation and pyroptosis, HRPTCs were treated with UA in the presence or absence of caspase-1 inhibitor and then evaluated for occurrence of pyroptosis and inflammasome formation.

Results: Uric acid enhanced tubular cell pyroptosis in a dose and time dependent manner. Uric acid promoted transcription of NLPR3 and pro-caspase-1. Uric acid also enhanced protein expression of IL-1 ß and caspase-1. Since caspase-1 inhibitor not only inhibited tubular IL-1 ß expression but also reduced number of tubular cells displaying pyroptosis, it appears that this effect of uric acid is mediated through caspase-1 activation.

Conclusions: Uric acid enhances tubular cell pyroptosis and inflammasome formation through the activation of caspase-1.

Erythropietin Modulates Endothelial Cell From High Glucose Induced Injury Haruka Yasuda,[1] Yasunori Iwata,[2,3] Kengo Furuichi,[3,4] Takashi Wada.[1,3] *[1]Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Japan; [2]Div of Infection Control, Kanazawa Univ, Kanazawa, Japan; [3]Div of Nephrology, Kanazawa Univ, Kanazawa, Japan; [4]Div of Blood Purification, Kanazawa Univ, Kanazawa, Japan.*

Background: Diabetic nephropathy (DN) is a major cause of end stage kidney disease and a strong risk factor for cardiovascular diseases. High glucose induces endothelial injury in vasculature, resulting in tissue injury in diabetic condition. Chronic inflammation has been reported to play an important role for the progression of high glucose induced cell injury. Growing data showed that erythropoietin (EPO) protect the tissues from some kind of injury, such as hypoxia and mechanical stress. However, the contribution of EPO to high glucose induced tissue injury remains to be explored. Therefore, we hypothesized that EPO modulates endothelial cells from high glucose (HG) induced injury via the regulation of inflammatory and anti-inflammatory balance.

Methods: To explore this possibility, we performed genome-wide transcriptome profiling in human umbilical vein endothelial cells (HUVEC), which were stimulated by high glucose (HG) with/without EPO treatment and detected the expression of inflammation associated genes.

Results: Hieralchial clustering analysis showed the different pattern of mRNA expression in HG stimulated HUVEC with/without EPO. While inflammatory cytokines/chemokines mRNA expression were increased by the HG stimulation in HUVEC, Th2 related cytokine receptors and intracellular signaling molecules showed the reduced mRNA expression levels. EPO treatment reduced inflammatory cytokines/chemokines mRNA expression and increased Th2 related cytokine mRNA expression levels. Real-time PCR analysis confirmed the increased expression of inflammatory related genes, those were decreased in HG stimulated HUVEC with EPO treatment. Moreover, EPO stimulation increased mRNA expression of EPO receptor and b-common receptor.

Conclusions: Taken together, EPO signaling modulates high glucose induced cell injury by the regulation of immune balance.

The Function of Macrophage in Intestinal Tract with Bacterial Translocation in Chronic Renal Failure Model Rats Hongli Jiang,[1] Meng Wang,[2] Hua Liu.[3] *[1]Hemodialysis Center, First Affiliated Hospital of Medical College of Xi'an Jiaotong Univ, Xi'an, Shaanxi, China; [2]Hemodialysis Center, First Affiliated Hospital of Medical College of Xi'an Jiaotong Univ, Xi'an, Shaanxi, China; [3]Hemodialysis Center, First Affiliated Hospital of Medical College of Xi'an Jiaotong Univ, Xi'an, Shaanxi, China.*

Background: Our rencent studies have confirmed that intestinal bacterial translocation is an important reason for micro-inflammatory state exsiting in the patients and rat models with chronic renal failure, which is closely associated with the high mortality rate and a variety of complications. Furthermore, previous studies had shown that the function and status of intestinal macrophages were closely related to the intestinal bacterial teanslocation in many diseases. Therefore, the present study aimed at understanding the function and status of the intestinal macrophage in the rats model with chronic renal failure.

Methods: We used double immunofluorescence staining technique to observe the function and status of intestinal macrophages with specific membrane antigen CD68 and activiated macrophage marker of TLR4, NF-kB and MHC-II between the chronic renal failure group and the sham group.

Results: a. There are more CD68 positive cells in all intestinal segments of the chronic renal failure group than the sham group. b.The fluorescence intensity of TLR4, NF-kB on macrophages of the chronic renal failure group are all stronger than the sham group, especially in ileum. C. Both groups don't express MHC-II on intestinal macrophages.

Conclusions: In all intestinal segments, there are more macrophages infiltrating and activating in the rats model with chronic renal failure, especially in ileum. The activated state of the intestinal macrophages show stronger ability to identify, absorb and engulf pathogens, but no ability to present them. It suggests that the intestinal bacterial translocation appears more in ileum.

The Expression of Tristetraprolin and Its Relationship with Urinary Protein in Diabetic Nephropathy Patients Zhangsuo Liu,[1] Fengxun Liu,[2] Guo Jia.[3] *[1]the first affiated hospital of zhangzhou Univ; [2]the first affiated hospital of zhangzhou Univ; [3]the first affiated hospital of zhangzhou Univ.*

Background: To investgate the relationship of Tristetraprolin (TTP, a RNA-binding protein) and diabetic nephropathy.

Methods: This study included 128 cases, age (60.7±10.9) years old. A total of 54 cases of patients with diabetic nephropathy, based on the amount of protein divided into microalbuminuria, macroalbuminuria group, choose the same period 33 cases of diabetes, 41 cases of healthy people as the control group. Patient's blood and urine samples was used to analyze the expression of TTP by PCR and ELISA kits.

Results: Urine electrophoresis showed that TTP decreased companied with urinary protein increased in every groups. pairwise comparisons showed proteinuria and microalbuminuria group was significantly lower than that in diabetic group and normal control group ($P < 0.05$), while a large number of proteins no significant difference ($P > 0.05$) between the two groups with urinary microalbuminuria group. Blood samples from the same period of the ELISA assay Tristetraprolin, consistent with the results of the urine specimen. Compared to normal control group (284.77±20.61pg/ml) and simple diabetic patients (196.14±17.11pg/ml),Tristetraprolin in microalbuminuria and proteinuria in patients with a large plasma levels were lower: 140.53 ± 19.22bpg/ml and 81.34 ± 16.51 pg / ml, the difference was statistically significant ($P > 0.05$). Tristetraprolin were negatively correlated with urinary protein excretion, the correlation coefficient was -0.572 ($P < 0.05$) and -0.685 ($P < 0.05$).

Conclusions: 1,TTP involved in the inflammatory response in diabetic nephropathy.

Xylene Induced Apoptosis and Change of DNA Methylation in HK-2 Cells Wei-Song Qin, Xianghua Cao, Zhao-Hong Chen, Chun-Xia Zheng, Caihong Zeng, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing Univ School of Medicine, Nanjing, Jiangsu, China.*

Background: Xylene is used as a solvent with wide areas of application. Cortical tubular epithelial cells are a common site of organic solvents induced injury. However, the role and mechanism of xylene induced injuries in proximal tubular cells has not been well documented. We propose to study the role of xylene in inducing the toxicity of HK-2 cells and investigate the change of DNA methylation level of apoptosis associated genes.

Methods: Xylene was dissolved with DMSO and added in the culture medium of HK-2 cells. NGAL, as a marker of renal tubular epithelial cell injury, was detected with ELISA. The apoptosis ratio was analyzed with flowcytometry. Caspase-3 activity was detected using a fluorometric assay kit. Genomic DNA was extracted, bisulfite converted and then hybridized to the HumanMethylation450 Analysis BeadChip. Array methylation results were validated by pyrosequencing.

Results: We found that xylene could induce injury in HK-2 cells in this study. Secretion of NGAL increased while the concentration of xylene and treatment time increased. Xylene could induce the apoptosis of nearly 98% HK-2 cells at the concentration of 2.0mM after 48h. Caspase-3 activity in HK-2 cells was significantly increased after treatment with xylene. Global DNA methylation was analyzed using the Illumina Infinium 450K

microarray platform. Results showed that 243 CpG sites were indicated as differentially methylated, including 109 sites of hypermethylation and 134 sites of hypomethylation. Differential DNA methylation was related to 138 genes involved in cell apoptosis and cell cycle related proteins. Quantitative DNA methylation analysis was performed by pyrosequencing and showed 7% and 4% decrease in methylation of BAX gene and 6.0% decrease in methylation of FAF1 gene.

Conclusions: Xylene could induce the apoptosis in HK-2 cells. The DNA methylation of FAF1 was decreased while the DNA methylation of BAX was increased. The causative effect of these DNA methylation change on the injury of xylene needs to be further explored.

PUB073

***Salvia miltiorrhiza* Bunge Protects Renal Function in Partial Ureteral Unilateral Obstruction in Rats** Maria Fatima De Paula Ramos,[1] Josne Carla Paterno,[1] Vera Lucia Rehder,[2] Clara Versolato Razvickas,[1] Nestor Schor,[1] Vicente De Paulo Castro Teixeira.[1] *[1]Medicine / Nephrology Div, Univ Federal de Sao Paulo/EPM, Sao Paulo, Brazil; [2]Centro Pluridisciplinar de Pesquisas Químicas, Biológicas e Agrícolas (CPQBA), UNICAMP, Paulinia, Sao Paulo, Brazil.*

Background: Aqueous extracts of *Salvia miltiorrhiza*Bunge root (S. miltiorrhiza) is one of the most commonly used traditional Chinese herbs. The aim of this study was to investigate the effects of aqueous extracts of *Salvia miltiorrhiza* Bungein experimental model of partial ureteral unilateral obstruction in rats.

Methods: Male Wistar rats were submitted to partial ureteral unilateral obstruction and right nephrectomy (PUONx), divided in two groups and studied along eight weeks (n = 5 per group). Control (PUONx): PUONx+ control vehicle (saline); *Salvia miltiorrhiza* (PUONx-S): animals received orally *Salvia miltiorrhiza* aqueous extract (100 mg/kg b.w.) daily by gavage. We measured 24h-proteinuria, microalbuminuria and urine NGAL(neutrophil gelatinase associated lipocalin). The statistical significance of the results was evaluated by ANOVA followed by Tukey test. Values were expressed as mean ± SD.

Results: The orally administration of aqueous extracts of *Salvia miltiorrhiza* ameliorated physiological dysfunctions of 24h urinary protein excretion ($p<0.001$): 12.42 ± 8.3 mg/24h versus 35.34 ± 15.2 mg/24h (PUONx-S versus PUONx) and microalbuminuria ($p<0.007$): 0.55 ± 0.26 mg/24h versus 1.47 ± 0.73 mg/24h (PUONx-S versus PUONx). PUONx-S treated group displayed a significantly ($p<0.02$) reduced loss urinary NGAL than control group (53.72± 40.08 versus 168.20 ± 126.66 pg/mL, respectively).

Conclusions: *Salvia miltiorrhiza*, in turn, had a beneficial effect on early renal function evidenced by normalization of proteinuria and decrease in levels of NGAL in the urine. Our results suggest that *Salvia miltiorrhiza* aqueous extracts could be beneficial in the treatment partial ureteral unilateral obstruction.

PUB074

Propargylglycine Increases Kidney Weight Independently of Effects on Kidney Function Nynke R. Oosterhuis,[1] Anne-Roos S. Frenay,[2] Sebastiaan Wesseling,[1] Marianne C. Verhaar,[1] Harry Van Goor,[2] Jaap A. Joles.[1] *[1]Nephrology and Hypertension, UMC Utrecht, Netherlands; [2]Pathology and Biomedical Biology, UMC Groningen, Netherlands.*

Background: Hydrogen sulfide (H_2S) and nitric oxide (NO) share signaling and vasorelaxant properties and H_2S can increase cell number by effects on proliferation and apoptosis. Blocking NO induces hypertension and proteinuria. However, hypertension and proteinuria induced by blocking production of NO are prevented by concomitant blockade of H_2S production with propargylglycine (PAG) [Wesseling et al. 2014]. We hypothesized that blocking H_2S producing enzymes ameliorates hypertension and proteinuria.

Methods: We studied effects of concomitant PAG in healthy rats and two different models of kidney injury: angiotensin II infusion (AngII) and $^5/_6$ nephrectomy (SNX).

Results: In healthy rats PAG administration did not affect systolic blood pressure (SBP) or proteinuria. PAG reduced SBP and proteinuria in AngII rats compared with vehicle (180 ± 12 versus 211 ± 19 mmHg and 66 ± 35 versus 346 ± 92 mg/24h, $p<0.01$), but not in SNX rats: 159 ± 27 versus 150 ± 27 mmHg, and 141 ± 114 versus 86 ±52 mg/24h. Surprisingly, kidney to body weight ratio was increased in all groups by PAG compared with respective vehicle groups (**Figure 1**). Proximal tubule damage was not affected by PAG in healthy and SNX rats and reduced by PAG in AngII rats ($p<0.05$). PAG did not affect tubular lumen area compared with respective vehicle groups.

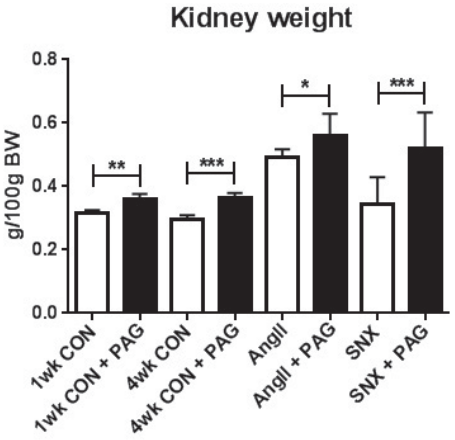

Figure 1. Kidney to body weight ratio was increased in all PAG-treated groups irrespective of effects on blood pressure and proteinuria. *p<0,05 **p<0,01 ***p<0,001.

Conclusions: Blocking H_2S producing enzymes with PAG increased kidney weight independent of effects on SBP and proteinuria. Kidney enlargement was not caused by tubular damage or dilatation, and was possibly due to increased cell number or due to increased intracellular osmoles.

Dysfunction of the Epithelial Cell Transforming Sequence 2 Gene May Cause Tubulointerstitial Injury Leading to Secondary Focal Segmental Glomerulosclerosis in the Mouse Model of Kidney Injury with Aristolochic Acid Administration Tomoki Miyazawa,[1] Akane Izu,[1] Takuji Enya,[1] Hitomi Nishi,[1] Keisuke Sugimoto,[1] Hidehiko Yanagida,[2] Mitsuru Okada,[1] Tsukasa Takemura.[1] *[1]Pediatrics, Kindai Univ Faculty of Medicine, Osakasayama, Osaka, Japan; [2]Pediatrics, Sakai Hospital Kindai Univ Faculty of Medicine, Sakai, Osaka, Japan.*

Background: Secondary focal segmental glomerulosclerosis (FSGS) follows congenital or acquired tubulointerstitial alterations. Failure of adequate regeneration after tubulointerstitial injury or abnormal tubulogenesis can disturb intrarenal blood circulation, causing excessive glomerular filtration. The product of the epithelial cell transforming sequence 2 gene (*ECT2*) is a transforming protein related to Rho-specific exchange factors and cell cycle regulators. We previously reported two patients with tubulointerstitial disorders, followed by FSGS. These patients carry a nonfunctional genotype of *ECT2*. Alistorochic acid (AA) is known as oncogenic material causing Balkan endemic nephropathy (BEN). One of the locations of DNA injured in BEN, which was located on 3q26.1 to 3q26.3, was consistent with *ECT2* mutation which had been showed in our patients.

Methods: We created the mouse model of kidney injury with AA injection and investigated the relationship between *ECT2* dysfunction and kidney injury. We gave intraperitoneal injection of AA 3 mg/kg to C57BL/6N for 6 weeks once in 3 days from the 6 weeks of their age.

Results: Their histological features of kidney at 20 weeks of their age showed cloudy degeneration, vacuolation of uriniferous tubules, tubular epithelial cell detachment and glomerular swelling. They were identical to finding of *ECT2* mutation. Then, gene expression was screened by the comparative genomic hybridization. Down-regulation of *ECT2* was observed in some mice injected AA. Our results supposed that *ECT2* mutation of our patients congenitally occurred structural and/or functional tubulointerstitial disorder and gradually contributed to the progression of secondary FSGS.

Conclusions: *ECT2* dysfunction could be the primary cause of BEN. Congenital mutation of *ECT2* might be associated with the development of FSGS in some of the patients with FSGS.

PUB076

Plasma Inflammatory Profile in CRS5 Patients: What Is the Cause of Multi-Organ Damage? Alessandra Brocca,[1] Grazia Maria Virzì,[1] Stefano Marcante,[2] Silvia Pastori,[1] Chiara Pasqualin,[1] Massimo de Cal,[1] Claudio Ronco.[1] *[1]Nephrology-IRRIV, S Bortolo Hosp; [2]ICU, Vicenza.*

Background: Cardiorenal Syndrome Type 5 (CRS5) is characterized by the combination of cardiac and renal dysfunction due to systemic disorders. CRS5 mechanism is not well-known, although specific cellular and molecular changes are reported. We examined the inflammatory profile in CRS5 patients (pts) and the *in vitro* response of renal tubular cells (RTCs) treated by CRS5 plasma.

Methods: We enrolled 11 pts with CRS5 (68.4±10.8yrs), and 16 healthy controls (CTR)(52.0±7.7yrs). Plasma from different groups were incubated with RTCs for 24h and, subsequently, cell death was evaluated by Annexin-V/Propidium Iodide assay. Plasma levels of IL6, IL1β, IL8, IL10, IFNγ were measured by ELISA and plasma NGAL (pNGAL) was detected by TRIAGE Alere.

Results: A significantly lower viability, a significantly higher apoptosis and necrosis were observed in RTCs incubated with CRS5 plasma compared to CTR (all p<.05). Plasma pro- and anti-inflammatory cytokines were significantly increased in CRS5 pts compared with CTR (p<.05).

parameters	CRS5	CTRL
IL6 (pg/ml)	64.6 (59.3-83.8)	5.9 (3.5-7.3)
IL10 (pg/ml)	19.6 (8.1-54.6)	3.1 (2.0-3.9)
IL8 (ng/ml)	87.1 (78.0-119.5)	20.3 (12.6-47.6)
IL1β (pg/ml)	80.8 (45.9-273.9)	8.3 (4.3-41.1)
IFNγ (pg/ml)	17.9 (16.9-20.8)	2.0 (1.4-3.2)
pNGAL (ng/ml)	249.0 (134.2-615.7)	60 (60-60)
Viability (%)	82.8 (81.2-85.6)	96.6 (94.8-97.5)
Necrosis (%)	4.2 (2.2-11.5)	1.0 (0.7-1.3)
Apoptosis (%)	15.1 (13.8-17.6)	1.5 (1.2-1.9)

There was a significant positive correlation between RTCs necrosis and IL1β and IL6 levels (rho=.82, rho=.77) and a significant negative correlation between IL6 and cell viability (rho=-.73). An interesting negative correlation between IL1β and cell viability was observed both in CRS5 pts (rho=-.91) and in CTR (rho=-.92).

Conclusions: We observed a strong cytokines dysregulation in CRS5 pts. Furthermore our study demonstrated the induction of cellular death in RTCs incubated with CRS5 plasma. In conclusion, we hypothesize a signals congestion involved in CRS5 pathophysiology: anti-inflammatory cytokines were abundantly released but are insufficient to contain a systemic inflammation that cause multi-organ damage.

Sealing the Slits: A Protective Response of Podocytes against High Shear Stress? Wilhelm Kriz,[1] Kevin V. Lemley.[2] *[1]Medical Faculty Mannheim, Univ of Heidelberg; [2]Dept of Pediatrics, Univ of Southern California.*

Podocytes are lost by detachment from the GBM as viable cells. This is a gradual process, which may begin at a single part of a podocyte and progress to include the entire cell as well as adjacent podocytes. The structural details of this process suggest that shear stress may be a crucial factor. Podocytes are highly susceptible to shear stress (Friedrich et al.: AJP Renal 2006). In vivo, the effect of increased shear stress may directly be seen in podocytes that have come to lie within the urinary orifice before finally undergoing detachment as bottle-shaped cells. The crucial site where podocytes are exposed to shear stress is likely the filtration slits. Without considering the slit diaphragm (SD), the shear stress of filtrate flow acting on foot processes (FPs) has been calculated to be 10-fold higher than that acting on podocyte cell bodies (Endlich and Endlich: Seminars Nephrol 2012). We hypothesize that the SD mitigates shear forces on FPs. Depending on the local situation (comprising FP geometry, slit density, and local filtrate flow rate), the shear forces on FPs may become intolerably high, compromising their attachment to the GBM The transmitted forces likely initiate a process of sealing of the slits. The replacement of SD by occluding junctions has been described in many studies, including several-fold increase of tight junctional proteins in PAN nephrosis (Fukasawa et al.: JASN 2009). This is widely considered as the start of podocyte deterioration called “FP effacement” (FPE) but, in our view, it represents a locally protective response against detachment. This FPE reaction may have three outcomes: (i) reversal, in case the rheological situation improves, (ii) progression to the completed stage of FPE leading to a firm attachment to the GBM and (iii) failure, exposing the FPs to high shear stress, starting the process of detachment. Since at other sites of the same podocyte the lateral connection to adjacent podocytes remains intact, podocytes frequently detach in groups.

PUB078

Establishment of a High Throughput Recombinant Protein Synthesis System for Experimental Therapeutics Using Hollow Fiber Kidney and Stable Cell Lines Maria Del Nogal, Hector Donoro Blazquez, Camille E. Mace, Lionel C. Clement, Sumant S. Chugh. *Dept of Medicine Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Cell culture in hollow fiber bioreactors were developed to generate large amounts of recombinant protein. Hollow fiber bioreactors contain artificial porous capillaries with continuously culture medium perfusion that confers a matrix for high density cell culture. Secreted proteins are retained in the extra-capillary space and can be collected for experimental therapeutic use.

Methods: Expression constructs of human Angiopoietin-like 4 (Angplt4) or human Angptl4 mutants were generated in pcDNA3.1V5-His and stable cell lines developed using HEK-293 cells. These stable cell lines were inoculated into the outer dialysate chamber of hollow fiber kidneys housed in 5% CO2 incubators and cell media was recirculated through the hollow fibers using a positive displacement pump. After three weeks of cell growth, fetal bovine serum was removed and substituted with a chemical serum replacement. *N*-acetyl-D-mannosamine was also added to insure adequate sialylation of recombinant protein.

Results: The glucose consumption of the systems was 1 gram per day and 15 ml of extra-capillary space medium containing the recombinant protein were collected every day. Harvested medium were dialyzed overnight in autoclaved PBS and purified over nickel columns. Recombinant protein was quantified using human Angptl4 ELISA, anti V5 ELISA, and Western blot. Each unit produces at least 500 µg of recombinant protein per day. Using a setup of two systems per incubator and 12 functional systems, 6 mg of one or more recombinant protein can be produce per day. Recombinant protein was injected intravenously into animal models to test and confirm in vivo efficacy. In addition, 2D gel electrophoresis and Western blot analysis were conducted to confirm posttranslational changes in the recombinant protein.

Conclusions: Hollow fiber bioreactors are an excellent tool to obtain a large amounts of recombinant protein required to develop and test novel protein based therapeutics for kidney disease.

Human Leptospirosis: A Model of Acute Lipotoxicity Caroline Azevedo Martins,[1] Mauro C. Faria,[1] Mauricio Younes-Ibrahim.[1] *[1]Internal Medicine, Univ do Estado do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Leptospirosis is a worldwide acute infectious zoonosis and presenting a peculiar lipid disorder associated to increase of the nonesterified fatty acids. In vitro previous studies showed that both Leptospira’s endotoxin effect on Na/K-ATPase activity and free fatty acid cytotoxicity are aggravated by lower serum albumin levels, supposedly due to albumin adsorptive properties for hydrophobic molecules.

Methods: Prospective observational cohort study was realized in 28 hospitalized patients with Weil’s syndrome. During their hospitalization, the serum concentration of nonesterified fatty acids (NEFA) levels and albumin were performed sequentially. Of these, 20 patients were cured and 8 died. The oleic acid: albumin molar ratio was used as a biomarker of lipotoxicity.

Results: All patients presented at admission significant increase in oleic acid: albumin molar ratio when compared to control. Patients who survived rescued the oleic albumin molar ratio to normal levels, which did not occur in patients who died.

Conclusions: The rescue of oleic acid albumin molar ratio was correlated with good outcome in severe leptospirosis and can be used as a biomarker of lipotoxicity in acute affections.

PUB080

Histological and Clinical Evaluation of Adult Patients with Henoch-Schöenlein Purpura Nephritis from a Single Hospital in China: Review of 114 Cases Ling Yun Lai,[1] Huixian Li,[1] Chuanming Hao,[1] Bruce A. Julian,[2] Jan Novak,[2] Lea Novak.[2] *[1]Div of Nephnology, Fudan Univ, Huashan Hospital, Shanghai, China; [2]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Henoch-Schönlein purpura nephritis (HSPN) has been less studied in adults than in children. The aim of this study was to evaluate pathological changes and clinical data of adult HSPN patients from a single hospital in China.

Methods: Renal-biopsy slides were collected from 114 adult HSPN patients (63 females; age range 18-78 y) who underwent biopsy from August 2002 to May 2013. Two pathologists graded histological changes. Cellularity of each glomerulus was graded and a mean mesangial score was calculated. Clinical data were collected at time of biopsy. 110 patients with known date of onset of purpura were grouped based on interval from the onset to renal biopsy: Group 1 (G1, <1 mo); Group 2 (G2, 1 – 6 mos), and Group 3 (G3, >6 mos).

Results: All patients had purpura, proteinuria, and microscopic but not macroscopic hematuria. 27% had abdominal pain and 26% had arthralgia. Increased serum IgA level (>3.9 g/L) was detected in 18%. The 3 groups had similar mean 24-h proteinuria, hematuria, mean eGFR, and frequency of ACEI/ARB treatment. The percentages of circulating white blood cells as neutrophils differed (G1 = 71%, G2 = 66%, G3 = 57%, p <0.001). Histology showed mean mesangial score 1.1, presence of segmental sclerosis (18%), global sclerosis (26%), glomerular crescents (56%), glomerular adhesion (26%), tubular atrophy (43%), tubular casts (46%), interstitial fibrosis (39%), and interstitial lymphocytes (51%). Histologic findings of Groups 1-3 did not differ except for median percentage of glomeruli with lymphocytes (G1 = 57%, G2 = 10%, G3 = 21%, p<0.001) and mean percentage of interstitial fibrosis (G1 = 36%, G2 = 31%, G3 = 55%, p = 0.05).

Conclusions: Patients with renal biopsy within 1 mo of onset of purpura more commonly had glomerular lymphocytes. Severity of crescents was not related to the timing of the biopsy. This unique large cohort can serve for comparison with data on adult HSPN patients in other geographic locations.

PUB081

A Recipe for an “All Purpose” Perfusion Fixation of Rodent Kidneys for Morphology and Cytochemistry Sebastian Bachmann, Carsten Dittmayer. *Anatomy, Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Current advances in rodent transgenic technology have increased the need for high resolution morphology and histochemistry protocols including suitable fixation recipes. Adequate preservation of the kidney requires particular care owing to the complexity of its parenchyma. Immersion fixation results in poor morphology and inadequate cell biological analysis. Conventional *in vivo* vascular perfusion protocols may be complicated to perform and may require separate approaches for ultrastructural and histochemical investigation, resulting in large animal group sizes and related conflicts with animal welfare regulations. We aimed to establish a simple fixation protocol which permits global structural evaluation at high quality standards within a single experimental animal.

Methods: Retrograde perfusion of the abdominal aorta was done under anesthesia using flushing buffer and aldehyde fixative. Parameters varied were the perfusion pressure, composition of the carrier and fixative solutions, post-fixation protocols and sample processing techniques including cryopreparation. Paraformaldehyde (PFA) fixatives were

compared to standard glutaraldehyde fixation. Variations in carrier osmolalities were adapted to the conditions required for the individual parenchymal zones with particular focus on podocyte preservation. A focus was set on podocyte structural preservation and cytochemical evaluation.

Results: High-end quality was obtained using perfusion at 180 cm H_2O, modified phosphate buffer as carrier solution, 4% PFA as fixative, followed by various post-fixation treatments adapted for cryo- and paraffin sectioning, conventional EM, freeze substitution or Tokuyasu technique, and immuno-EM. State-of-the-art confocal LM and EM techniques including tomography and STEM led to excellent results.

Conclusions: In sum, a universal fixation protocol with appropriate post-fixation treatments of rat and mouse kidney tissues can be easily adapted for global evaluation techniques within a single experimental animal, allowing for high standard glomerular, tubular and interstitial evaluation techniques.

PUB082

Simple Method Ameliorating Phenotypes of Primary Cultured Podocytes

Eishin Yaoita,[1] Hiroshi Kawachi,[2] Tadashi Yamamoto.[1] *[1]Dept of Structural Pathology, Institute of Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Dept of Cell Biology, Institute of Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: We have previously established primary culture of rat podocytes which have an arborized morphology without cobblestone-like appearance and retain well podocyte-specific markers including podocalyxin and podocin (Kidney Int 2006, 69:2101). The markers, however, are deeply down-regulated with time during culture. After 8 days of primary culture, nephrin decreases to less than one thousandth of that of isolated glomeruli, and claudin-5 drops sharply to an undetectable level even by PCR. After reviewing many substances, we have found that heparin acts directly on cultured podocytes to improve highly their phenotypes in transcript and protein levels (Nephrology 2014, 19:195). Even so, further improvements are necessary, because expression levels of nephrin, podocalyxin and podocin still remained about 1/60, 1/20 and 1/10 of those of isolated glomeruli, respectively.

Methods: We tried a decrease in the concentration of bovine fetal serum (FBS) and culture on porous membrane, because FBS contains many factors activating podocytes and porous membrane provides the culture condition where media access attachment cells from both their apical and basolateral sides.

Results: Each of the decrease in FBS from 5% to 0.5% and culturing on porous membrane increased nephrin expression significantly. When combined with heparin, 0.5% FBS and culture on porous membrane, cultured podocytes extremely increased expression level of nephrin approximately to 1/3 of that of isolated glomeruli. Those of podocin and podocalyxin expressions reached the same level or more than isolated glomeruli. Especially claudin-5 increased to 1/10 of that of isolated glomeruli. It is in stark contrast to the undetectable level in the original culture condition. Morphologically podocytes extended primary processes which intersected adjacent ones.

Conclusions: These findings suggest that the above simple method takes the intracellular environment of cultured cells closer to that of podocytes *in vivo.*

PUB083

Evaluation of Urinary Kidney Injury Biomarkers in the Acute PAN Model: Indication of Both Podocyte and Tubule Injury

Kelly Larson, Lauren Olson, Kathryn Houseman, Deborah Widomski, Bruce Leroy, Andrew J. King, Steve McGaraughty, Zhi Su. *Early Renal Discovery, Abbvie.*

Background: Acute treatment of rats with PAN (puromycin aminonucleoside) is widely used as a model of podocyte injury (acute PAN model). Urinary protein excretion rate (UPER) and electron microscopy (EM) examination of podocytes are major biomarkers/ tools for evaluation of podocyte injury in the acute PAN model. In the current study, we employed a number of novel urinary biomarkers to further evaluate PAN-induced kidney injury in rats.

Methods: The acute PAN model (8-day) was generated by a single subcutaneous injection of PAN (100-150 mg/kg) to male rats (125 -150 grams). In addition to EM, urine sample (24 hrs) was collected at designated time points after PAN injection for analysis of UPER, nephrin, podocalyxin, neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), osteopontin (OPN), 8-hydroxy-deoxyguanosine (8-OH dG), and isoprostanes. Serum creatinine (SCr) and urea nitrogen (BUN) levels were also assessed, and a reference compound mizoribine tested.

Results: Foot process effacement, loss of slit diaphragm, large vacuoles, deposition of electron dense granules was observed in podocytes (EM section of kidney cortex) from PAN-injected rats. PAN produced dose- and time-dependent increases in UPER (peaking at day 8-10 post PAN dosing), as well as urinary nephrin and podocalyxin (indicating podocyte injury). Urinary excretion of NGAL, KIM-1, and OPN was also increased in a time-dependent manner (suggesting acute renal tubular injury). However, SCr and BUN were minimally increased in PAN-injected rats. Urinary 8-OH dG and isoprostanes (markers for oxidative stress) were not increased in PAN-injected rats. The increases of urinary biomarkers for podocytes and renal tubules were significantly suppressed by prophylactic treatment with mizoribine (10 mg/kg).

Conclusions: Urinary excretion of both podocyte and renal tubular injury markers is significantly increased in the acute PAN model. These results indicate that in addition to podocyte injury, renal tubules are also subsequently damaged in the acute PAN model.

PUB084

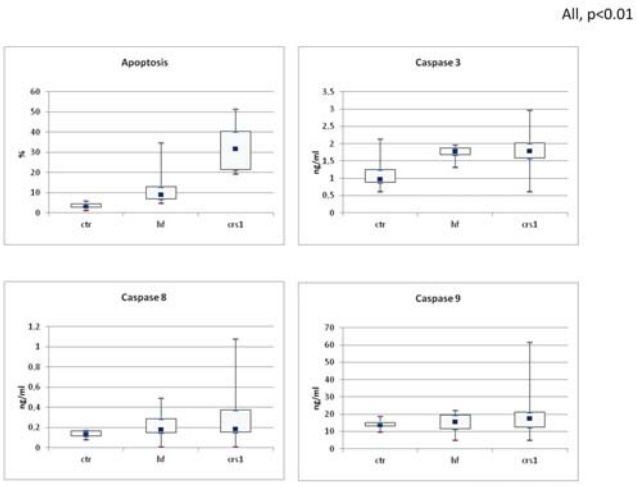
Cardiorenal Syndrome: Activation of Dual Apoptotic Pathways

Grazia Maria Virzì, Alessandra Brocca, Massimo de Cal, Enrico Tonini, Claudio Ronco. *Nephrology-IRRIV, San Bortolo Hospital, Vicenza.*

Background: Cardiorenal syndrome Type 1 (CRS1) is characterized by a rapid worsening of cardiac function leading to acute kidney injury(AKI). CRS1 pathophysiology is complex and an immune-mediated damage, an alterations in the immune response with monocytes apoptosis and cytokine-release have been reported as a potential mechanisms. In this study, we examined the putative role of Renal Tubular Epithelial Cells (RTCs) apoptosis as a pathogenic mechanism in CRS1. In particular, we investigated the Caspase pathways involved in this induced apoptosis.

Methods: We enrolled 29 patients with Heart Failure (HF) (age 73.6±9.5yrs, sCr baseline 0.91mg/dl±.27), 11 patients with CRS1 (74.±13.1yrs, sCr baseline 1.12mg/ dl±.24). Patients who had AKI prior to the episode of HF, or had any other potential causes of AKI, were excluded. Plasma from different groups were incubated with RTCs for 24h. Subsequently, cell apoptosis was evaluated by Flow Cytometer. Renal Tubular cells were assayed for activation of Caspase3, 8 and 9.A *p*-value <.05 was considered statistically significant.

Results: Quantitative analysis of apoptosis by Flow Cytometer showed significantly higher apoptosis rates in CRS1 compare to HF and CTR (p<.01).This increase of apoptosis was confirmed by Caspase3 levels with a strong correlation (rho=.73). Caspase 8 and 9 were significantly higher in CRS1 compare to HF and CTR (p<.01)



Furthermore, Caspase3 levels showed a significantly positive correlation with Caspase8 (rho=.57) and 9(rho=.47).

Conclusions: This study demonstrated the significantly heightened presence of dual apoptotic disequilibrium in CRS1 compared to HF patients and CTR. For the first time we demonstrate evidence for the delineation of 2 distinct apoptotic pathway activations in CRS1. Our findings indicated that apoptosis may have a central role in the mechanism of CRS1 and it could be a potential therapeutic target in this syndrome.

PUB085

Effects of Fumonisin B1 (FB1) on Cell Cycle in Mouse Kidney and Liver

Sae Jin Lee,[1] Su-Youn Lee,[1] Seikwan Oh,[2] Ki-Hwan Han.[1] *[1]Dept of Anatomy, Ewha Womans Univ, Seoul, Korea; [2]Dept of Molecular Medicine, Ewha Womans Univ, Seoul, Korea.*

Background: Fumonisin B1 (FB1), a mycotoxin produced by Fusarium verticillioides, inhibits the enzyme ceramide synthase. Animal experiments have indicated that FB1 induces both cell death and cell proliferation. The purpose of this study was to examine the expression of cyclin-dependent kinases (CDKs) and CDK inhibitors in FB1-treated kidney and liver.

Methods: C57BL/6 mice were divided into 3 groups and received FB1 (0, 5, and 20mg/kg bw/day, i.p) for 5 days. Kidney and liver tissues were processed for immunohistochemistry and immunoblot analysis.

Results: A 5 mg/kg dose of FB1 did not affect serum AST, BUN, and creatinine levels. However, a 20 mg/kg dose of FB1 significantly increased serum AST and caused extensive liver necrosis. A 20 mg/kg dose resulted in histological changes (e.g. vacuole formation) in the kidney, but BUN and creatinine levels did not rise. Both 5mg/kg and 20mg/kg dose significantly induced proliferation. Hepatic PCNA content was increased 4.69- (5 mg/kg) to 4.86-fold (20 mg/kg) and renal PCNA was increased 15.9- (5 mg/kg) to 16.4-fold (20 mg/kg), respectively. Hepatic and renal expression of CDK2, CDK4, and CDK6 was significantly increased in both 5mg/kg and 20mg/kg dose. Also, expression of CDK associated cyclins (D1 and D3) was increased. Confocal microscopy showed that CDK2 was co-localized with PCNA in the nucleus of many hepatocytes and renal tubular cells in FB1-treated mice. In contrast, hepatic and renal expression of P18Ink4c and P27Kip1 was significantly decreased in FB1-treated mice. Interestingly, localization of

P27Kip1 shifted from the nucleus to the cytoplasm in the liver. In the kidney, the decrease in P27Kip1 expression was more marked in the proximal tubules than the distal tubules.

Conclusions: We conclude that expression and cellular localization of CDKs and CDK inhibitors may play an important role in FB1-induced cell proliferation in the kidney and liver. This work was supported by the National Research Foundation of Korea (NRF-2013R1A1A2058028).

PUB086

Comparison of Pharmacological Properties of Antioxidant Drugs, Probucol and Resveratrol, in Adenine-Diet Model Rats of Chronic Kidney Disease (CKD) Yuko Matsushita,[1] Hirofumi Jono,[1,2] Hideyuki Saito.[1,2] *[1]Dept of Clinical Pharmaceutical Sciences, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan; [2]Dept of Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.*

Background: Oxidative stress is considered to be a key pathogenic event in the kidney of CKD patients. Oxidative stress develops from free radical production evoked by mitochondrial dysfunction and/or accumulation of a uremic toxin indoxyl sulfate (IS). Pharmacotherapies using antioxidants such as alpha-tocopherol and N-acetylcysteine were reported to suppress oxidative stress in CKD patients, but the pharmacological events have been suggested to be diverse.

Methods: In this study, two antioxidants, probucol (lipid-lowering drug) and resveratrol (phytochemical polyphenol with a potent inhibitory effect on hepatic sulfotransferase (SULT)-mediated IS production), were examined for their pharmacological properties in adenine-diet model rats of CKD. Five week-old male rats were given free access adenine-containing diet (0.3% w/w) with or without probucol (1% w/w) or resveratrol (0.05% w/w), and serum creatinine (sCr), BUN, total cholesterol and IS were periodically determined.

Results: sCr and BUN were elevated from 1 week of adenine intake and continued to increase until 8 weeks, and simultaneous intake of probucol had no preventive effect on renal function. Serum cholesterol level increased from 2 weeks of adenine intake, but this increase was significantly suppressed by probucol intake. Probucol failed to reduce the serum cholesterol level when renal dysfunction was aggravated. IS accumulated gradually in serum of CKD rats, but was not attenuated by probucol intake. Simultaneous intake of diet containing resveratrol significantly ameliorated sCr and BUN of CKD rats from 2 weeks of adenine intake. Resveratrol intake caused a significant reduction of serum IS accumulation.

Conclusions: In conclusions, probucol has a cholesterol-lowering effect, but is ineffective in preventing progression of adenine CKD. Resveratrol suppresses serum IS accumulation by inhibiting hepatic SULT activity, thereby reducing IS-inducible oxidative stress in the kidney with nephropreventive action in adenine CKD rats.

Circulating Mitochondrial DAMPs Are Not Effective Inducers of Proteinuria and Kidney Injury in Rodents Jing He, Hong Xia, Liang Yaojun, Xiao Wang, Chun-Xia Zheng, Zhihong Liu, Shaolin Shi. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing Univ School of Medicine, Nanjing, China.*

Background: Mitochondria in eukaryotic cells are derived from bacteria in evolution. Like bacteria, mitochondria contain DNA with unmethylated CpG motifs and formyl peptides, both of which have recently been shown to act as damage associated molecular patterns (DAMPs) and induce immune response and cell injury. Based on the facts that the levels of mitochondrial DAMPs (mtDAMPs) are elevated in the circulation of patients of trauma or burn injury who also have proteinuria, that mtDAMPs can activate immune cells which could in turn secrete glomerular permeability factors, that renal intrinsic cells express a variety of DAMP receptors, and that mtDAMPs can increase endothelial cell permeability *in vitro*, we speculate that mtDAMPs may be novel circulating factors capable of inducing proteinuria and kidney injury.

Methods: We tested the hypothesis by directly injecting mtDAMPs samples, i.e., mitochondrial DNA (mtDNA) or mitochondrial debris soluble components (MTD), into rodents via tail vein, and examining urinary protein and kidney histology.

Results: Injection of mtDNA into mice for 20 μg/ml in circulation, which was much higher than clinical range, did not cause any detectable proteinuria or renal lesions, but the injection resulting in 40 μg/ml mtDNA in circulation could cause transient increase of urinary albumin. Injection of MTD to mice for 60 μg/ml MTD protein in circulation (above clinical range) did not result in proteinuria but subtle lung lesions. In rats, the injection resulting in 450 μg/ml MTD protein in circulation, which was much higher than clinical range, caused mild and transient proteinuria, as well as lung lesions that suggested systemic inflammation.

Conclusions: Clinical levels of mtDAMPs in circulation do not cause proteinuria and even the extremely high, hence clinically irrelevant, levels of mtDAMPs could cause only slight and transient increase of urinary protein in rodents, suggesting that circulating mtDAMPs are not effective inducers of proteinuria and kidney injury in patients with trauma, burn injury, or even kidney disease.

The Expression of Numb in Normal Kidney Tang Li,[1] Jing Nie.[2] *[1]VIP Medical Center, The Third Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guangdong, China; [2]Div of Nephrology, NanFang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China.*

Background: Numb gene is widely expressed in mammalian tissue and organs. Numb not only plays an important role in the development and various diseases of mammalian, but also in the pathogenesis of human carcinoma. We have previously reported that Numb protects renal proximal tubular cells from puromycin aminonucleoside-induced apoptosis through inhibiting Notch signaling pathway. Up to now, there is little report about the function of Numb in renal disease. Therefore, in order to provide the basis for further research, we conduct this study to investigate the expression of Numb in normal kidney.

Methods: Kidneys of normal male Sprague-Dawley rats were collected. Different markers were used to tag the different kinds of intrinsic renal cells, respectively. The expression of Numb protein in normal kidney was detected by double-immunofluorescence and confocal laser scanning microscopy.

Results: Double-immunofluorescence staining showed that Numb labeling was generally exhibited in normal rat kidney. In the glomerulus, the capillary endothelial cell exhibited intense Numb labeling. However, Numb labeling showed no co-localization with markers of the mesangial cell and podocyte. All the segments of renal tubule we detected exhibited Numb labeling, but the distribution and intensity of the labeling were different in various segments. In the epithelium of proximal tubule, intense Numb labeling mainly located in the apical and basolateral membrane. The thin descending limb of Henle exhibited weak Numb labeling. The epithelium of the thick ascending limb of Henle and distal tubule showed dispersive Numb labeling in cytoplasm. The collecting tubule exhibited prominent Numb labeling at the lateral cell-cell contacts.

Conclusions: Numb protein is generally expressed in normal kidney. In the glomerulus, Numb protein is expressed in the capillary endothelial cell. In the renal tubule, the distribution and intensity of Numb protein are different in various segments.

PUB089

Sensing DNA in the Cytoplasm? AIM for the PYHIN Family in Systemic Lupus Erythematosus Allyson Catherine Egan,[1] Michael D. Jones.[2] *[1]Dept of Medicine, Hammersmith Hospital, Imperial College London, United Kingdom; [2]Genomics Laboratory, MRC clinical Sciences Centre, Imperial College London, United Kingdom.*

Background: Aim2 is a novel cytoplasmic DNA sensor, which instigates the caspase pathway and formation of the inflammasome leading to cell death via IL1β and IL18. The protein is a member of the interferon response PYHIN family. Microarray data reported overexpression of family member Ifi202 in lupus prone mouse model BXSB and New Zealand subcongenic B6.Nba2.

Methods: C1 genomic DNA fragments were sequenced by the Wellcome Trust Sanger Institute using Illumina Next Generation Sequencing technology. Fragments were aligned to the mouse reference genome using the Integrated Genome Viewer 2.2.5. Promoter, intronic and exonic sequences were scanned for single nucleotide polymporphisms. Ensemble/ncbi databases, blast searches and clustral sequence comparisons were employed to investigate homology within the region. Real time PCR of Aim2 was compared in autoimmune prone strain BXSB to B10.Yaa control.

Results: This polymorphic region contains multiple SNPs in exonic, intronic and promoter regions in genes Ifi202, Ifi203, Ifi205, Mnda and Aim2. A lysine to glutamine switch occurs in Ifi202, Ifi203 and Ifi205. The start codon in Ifi203 contains a switch from methionine to threonine. Ifi205 has altered charge due to glutamic acid replacement by glycine. In Mnda, glycine is switched to arginine along with a leucine switch to proline, which may cause alteration in protein structure. Exon 1 (E1) appears to be homologous in certain family members. Full length E1 appears in Mnda. Truncated versions occur in Ifi202 and Ifi204. Ifi205 demonstrates 81-83% homology with the other family members. AIM2 E1 shares only 17% homology with Mnda E1. In real-time PCR expression of the autoimmune strains BXSB and subcongenic B10.Yaa.Bxs3 is down regulated in comparison to the control strain B10.Yaa.

Conclusions: Bioinformatic analyses identified homology between the gene family members at E1, with the exception of Aim2. Expression of AIM2 in the lupus prone model BXSB and subcongenic B10.Yaa.Bxs3 in comparison to control B10.Yaa is reduced. Extensive polymorphic changes occurs in the region, which may alter protein structure.

Remote Usability Testing of a Mobile Phone-Based Medication Inquiry System (MIS) in Chronic Kidney Disease (CKD) Clarissa Jonas Diamantidis, Marni Zuckerman, Jennifer S. Ginsberg, Lisa Lucas, Jeffrey C. Fink. *Medicine, Univ of Maryland School of Medicine, Baltimore, MD.*

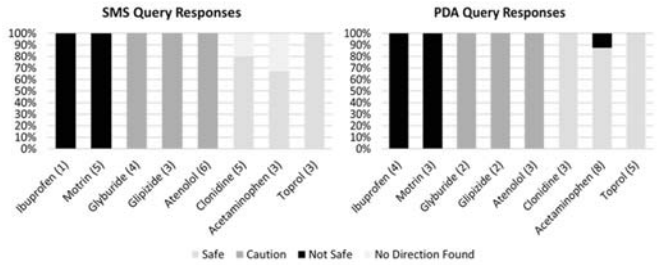
Background: Mobile phones are ubiquitous, and tailored mobile health (mHealth) applications may offer opportunities for innovative safeguards against medication errors observed in CKD. Patients' ability to use such applications requires preliminary study for the tailored designed of effective mHealth applications.

Methods: Participants with CKD enrolled in the Safe Kidney Care (SKC) cohort (ClinicalTrials.gov NCT01407367) were invited to participate in remote usability testing of a mobile phone-based medication inquiry system (MIS) that provides precautionary information on the safety of selected medications in CKD. Participants were randomized to 1 of 2 mobile platforms: 1.) SMS text, or 2.) Personal Digital Assistant (PDA; e.g. iPod

Touch) and were asked to bring the device home for remote testing. Participants were then mailed 3 dummy pill bottles with prescription labels and were asked to input each medication into the MIS and record the responses. Participants completed a user satisfaction survey at study's end.

Results: 20 participants were randomly assigned the SMS (n=10) or PDA (n=10) platform. Participants were predominantly black (80% versus 70%, respectively), with diabetes (60% versus 80%), with > high school diploma (80% versus 60%), and had used the Internet previously (90% versus 60%). 30% of SMS users and 40% of PDA users were > 65 years old. All participants owned a cell phone, but only 30% of SMS users and 10% of PDA users owned a smartphone. Of 60 medication queries inputted into the MIS, there were only 3 reported errors, 2 of which were in the SMS group.

Figure 1. MIS query results by phone platform



Median satisfaction survey score was 7 (strongly agree) for both groups.

Conclusions: Mobile phone search applications have the potential to provide guidance on the proper use of medications and improve patient safety in the CKD population.

Pore Size Control and Evaluation in Skin Layer of Polysulfone Hollow Fiber for Hemodialysis Changjun Mu, Tiancheng Xu. *Research and Development Dept, WEGO Blood Purification Products Co., Ltd, Weihai, Shandong, China.*

Background: A pore size in skin layer of polysulfone hollow fibers is one of essential factors to dominate functions of dialyzers. By controlling the pore size of polysulfone hollow fibers, dialyzers can be prepared to fit different treatments such as hemodialysis, hemofiltration and hemodiafiltration. Generically, the polysulfone hollow fibers with a homogeneous pore size distribution in the skin layer are preferred to improve the therapeutic performance.

Methods: In this paper, we introduced a series of spinning conditions such like solution composition, coagulation temperature, bore fluid composition, drying temperature and speed of spinning fluid for the pore size control, and as a method to evaluate the pore size in skin layer, a gel permeation chromatography (GPC) was proposed by us. Additionally, as a performance indicator, ultrafiltration coefficients (K_{UF}: mL/hr/mmHg) of the hollow fibers were also derived with a bovine blood at a transmembrane pressure of 50mmHg.

Results: It was found that the pore size in skin layer and the K_{UF} of the hollow fibers increased with a dimethylacetamide concentration in the bore fluid and a narrow pore size distribution could be obtained by changing a speed of spinning fluid.

PUB092

Optimizing Kidney-Targeted Gene Delivery for Polycystic Kidney Disease Sara J. Holditch,[1,2] Vicente E. Torres,[3] Yasuhiro Ikedo.[2] *[1]Mayo Graduate School, Mayo Clinic, Rochester, MN; [2]Molecular Medicine, Mayo Clinic, Rochester, MN; [3]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Polycystic kidney disease (PKD) is an inheritable renal cystic disease, for which there are limited therapeutic options. Adeno-associated virus (AAV)-based vectors are characterized by their efficient transduction of non-dividing cells, proven ability to persist for long term gene expression and low toxicity. Recent successful clinical trials using AAV vectors have paved the way for gene therapy applications for numerous genetic and chronic disorders. However, previous studies have demonstrated variable and suboptimal success in transducing the kidney by AAV vectors.

Methods: Here, we present two studies comparing the transduction efficiency of AAV vectors serotyped 2, 8, and 9, administered at 5.0E+11 gc/kg expressing luciferase. To increase transcriptional kidney-targeted gene delivery, we compared a 2kb- promoter of Acyl-coenzyme A synthetase (ACSM2) against the constitutively expressed viral promoter, CMV.

Results: A) A single injection directly into the renal artery (RAI), delivered 5.0E+11 vector genomes per animal. Upon RAI, we assessed the transduction of AAV2 versus AAV9 vectors through expression of luciferase using the Xenogen non-invasive live imager at 7, 14 and 21 days post injection. We found that administration of an AAV2 vector with a CMV internal promoter efficiently transduced kidney. AAV2-CMV-Luc vector luciferase expression, compared to AAV vectors with ACSM2 promoter or AAV9 capsid, had stronger, and higher renal specificity. B) A single injection directly into the renal pelvis, delivered 5.0E+11 vector genomes per animal. Luciferase expression was monitored as described above. Data is currently being analyzed and will be included in the final presentation.

Conclusions: Although these studies require further optimization, such as a more robust study population, alternate serotypes and routes of administration, and a more thorough interrogation of potential kidney specific promoters, our results demonstrate the unrealized potential for AAV vectors in the treatment of chronic or genetic renal diseases, such as polycystic kidney disease.

PUB093

A Novel Renal Doppler Based Marker to Quantitate Acute Stress Madan Bahadur,[1] Jawahar Jain,[2] Shreyans Gandhi.[3] *[1]Dept of Nephrology, Jaslok Hospital and Research Centre, Mumbai, Maharashtra, India; [2]TTT - Think Tank Team, Samsung Research America, San Jose, CA; [3]Dept of Electrical Engeneering, IIT, Mumbai, Maharashtra, India.*

Background: A medically consequential manifestation of stress is stimulation of renal sympathetic nerve activity. While it has been shown that stress causes an increase in the renal resistive index (RRI), this measure has limited reliability. We present a novel frequency domain method for analyzing renal blood flow (RBF) that appears to have substantially higher signal-to-noise ratio than RRI.

Methods: A pilot study was conducted on 8 healthy volunteers. A baseline renal Doppler was recorded. The participant was then given a analytical test to solve in a limited time. Stress was enhanced by linking it to honorarium award and adding peer pressure. However the questions were so set that it was near impossible to solve them in given time. A renal Doppler was recorded while his unsuccessful performance was being assessed by the examiner. The second part of the stress induction was the anticipation of pin prick however none of the participants were pricked. He was told several times to be ready for the prick generating stress and doppler recorded. A scaled feedback of perceived stress was taken.

Results: The Doppler RBF graphs were digitized and subjected to Fourier transform. This corresponds to the power strength of each signal corresponding to each frequency component.It was seen that the signals corresponding to the baseline and stress phases vary a lot in the low frequency region around 1 Hz. While baseline and stress response could be distinctly identified by their respective RIs, this difference was magnified several-fold in the frequency domain.

Conclusions: RI values do not use the full information available from the doppler waveforms compared to frequency domain analysis. Unlike RI's this method is resilient to noise. Only the low frequencies where maximum change is seen, matters, as a result the high frequency noise does not affect the analysis. This novel analysis of the Doppler RBF spectrum picks up acute stress in a more sensitive and specific manner and may be used as an objective method to document stress.

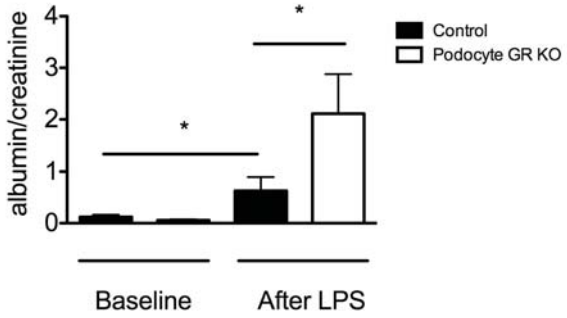
PUB094

Loss of the Podocyte Glucocorticoid Receptor Worsens Proteinuria after Low Dose LPS Julie Goodwin. *Pediatrics, Yale Univ School of Medicine, New Haven, CT.*

Background: Nephrotic syndrome is common in both children and adults and glucocorticoids are a mainstay of treatment in the majority of cases. Despite widespread use of this class of agents the molecular mechanisms by which glucocorticoids induce remission of proteinuria remain unclear. It is known that the glucocorticoid receptor is expressed in podocytes.

Methods: We have created a mouse model with a tissue-specific knockout of the glucocorticoid receptor in podocytes. Proteinuria was induced in control and knockout mice by injection of low-dose LPS. Serum and urine electrolytes, serum creatinine and serum albumin were measured before and twenty four hours after treatment.

Results: At baseline there was no difference in serum creatinine, serum albumin or urine albumin/creatinine ratio between the 2 groups. After LPS treatment control animals showed a modest increase in urine albumin/creatinine ratio (0.12 ± 0.04 before versus 0.63 ± 0.27 after, n=4/group, $p<0.05$). However, podoctye GR KO mice showed a much greater increase in proteinuria following LPS treatment (0.06 ± 0.02 before versus 2.11 ± 0.77 after, n=4/group, $p<0.05$).



Conclusions: These results suggest that:

(1) the podocyte glucocorticoid receptor is important in limiting proteinuria in this model

(2) this receptor may play a role in the development of proteinuria in other states, including nephrotic syndrome.

PUB095

Calcineurin Binding Protein-1 Is Associated with Podocyte Injury Yueqiang Wen,[1] Hui Peng,[2] Wenbo Zhao.[3] *[1]Dept of Internal Medicine, Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Internal Medicine, Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [3]Dept of Internal Medicine, Div of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Calcineurin binding protein-1 (cabin1) is a non-competitive inhibitor of calcineurin (CaN), it's N terminus is responsible for interaction with p53, cabin1 renders p53 transcriptionally inactive. Cabin1 plays a critical role in regulating apoptosis in synoviocyte and cancer cell, yet the exact localization and function in kidney is not reported up to now.

Methods: Mouse podocytes were cultivated at 33° to propagate in the presence of 10-20U/ml mouse recombinant γ interferon, then cells were transferred to an incubator at 37° without interferon to allow differentiation for 10-14 days. Differentiation podocyes were divided into three experimental groups: (1) normal control; (2) 10^{-6}M AngiotensionII (AngII); (3) 10^{-6}M AngII plus 10nM tacrolimus. Cells were harvested at 12h, 24h and 48h for protein extraction and immunofluorescence staining(IF).

Results: IF showed well-defined actin stress fibers and strong staining in cytoplasm yet weak staining in nucleus of cabin1 in normal podocytes. AngII induced disruption of F-actin and strong staining in nucleus of cabin1, while tacrolimus stabilized actin filaments and cabin1. Cabin1 protein content significantly increased at 48h which lowered by tacrolimus.

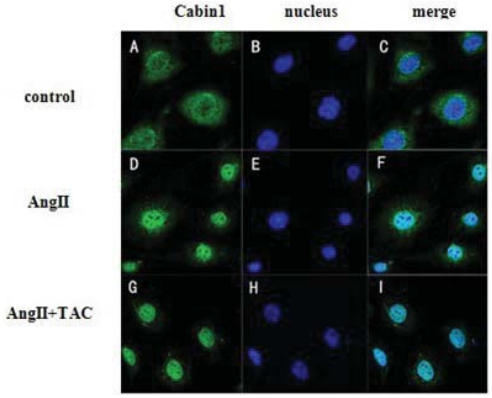

Figure 1: Immunofluorescence staining (fluorescence microscope x 400) showed strong staining in cytoplasm yet weak staining in nucleus of cabin1 in normal podocytes (A and D). AngiotensionII induced strong staining in nucleus of cabin1(D and F), while tacrolimus stabilized cabin1 (G and I).

Conclusions: The expression of cabin1 is increased during podocyte injury, and returned to normal while podocyte recovered. Cabin1 maybe a new target for antiproteinuic drugs.

PUB096

Hypoxia Stimulates the Expression of Tissue Factor and Suppresses Tissue Factor Pathway Inhibitor in Human Podocytes in Culture Ikuyo Narita,[1] Michiko Shimada,[1] Norio Nakamura,[1] Reiichi Murakami,[1] Takeshi Fujita,[1] Moin Saleem,[2] Hideaki Yamabe,[1] Ken Okumura.[1] *[1]Nephrology, Hirosaki Univ, Hirosaki, Japan; [2]Renal Unit, Bristol Univ, Bristol, United Kingdom.*

Background: The role of podocytes in the crescent formation has been suggested. Besides, the coagulation pathways are implicated due to the fibrin deposition. Tissue Factor (TF) is the initiator of extrinsic coagulation pathway and is also related to proliferation and inflammation. We have previously shown the expressions of TF and tissue factor pathway inhibitor (TFPI) in the podocytes, however, their regulations are not well known.

Methods: Conditionally immortalized podocytes were grown at 33°C and then converted to differentiated cells by incubating at 37°C. The differentiated cells were treated in normoxic or hypoxic conditions. The effect of cobalt chloride which mimics hypoxia was also tested for the verification. Total RNA was harvested and mRNA expressions of TF and TFPI were analyzed by quantitative RT-PCR. Additionally, the effect of hypoxia-inducible factor-1α (HIF-1α) small interfering RNA (siRNA) was tested to assess the role of HIF-1α which regulates the numerous changes in hypoxia. The expression of TF was confirmed by immunofluolescent staining, and TFPI in the supernatant was tested by enzyme linked immunosorbent assay (ELISA).

Results: Hypoxia increased the mRNA expression of TF (6h: 2.29 ± 0.05 fold, $p<0.001$, 24h: 5.6 ± 2.4 fold, $p<0.05$) and suppressed TFPI (6h: 0.54 ± 0.04 fold, $p<0.05$, 24h: 0.24 ± 0.06 fold, $p<0.001$) compared with normoxia. Incubation with cobalt chloride 150 μM for 6 - 24h resulted in the similar results. Interestingly, HIF-1α siRNA did not suppress the expression of TF. TF was stained in the cytosol of podocytes and TFPI was detectable in the culture supernatant by ELISA, although the changes by hypoxia were not significant up to 24 h.

Conclusions: Hypoxia increased the expression of TF and reduced TFPI. These changes were both towards pro-thrombotic condition. Increased expression of TF by hypoxia was not suppressed by HIF-1α suggesting other regulating factors in the podocytes. These data suggest that podocytes may contribute to the pro-coagulant changes lead to fibrin deposition.

Mitochondrial Reactive Oxygen Species Mediated Vancomycin-Induced Apoptosis in LLC-PK1 Cells Takahisa Yano,[1] Yuya Sakamoto,[2] Yuki Hanada,[2] Aki Takeshita,[2] Nobuaki Egashira,[1,2] Satohiro Masuda.[1,2] *[1]Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; [2]Clinical Pharmacology and Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Vancomycin chloride (VCM), a glycopeptide antibiotic, is widely used for the therapy of infections caused by methicillin-resistant *Staphylococcus aureus* (MRSA). However, nephrotoxicity is a major concern during VCM therapy. In this study, we investigated the cellular mechanisms underlying VCM-induced renal tubular cell injury using the porcine proximal tubular cell line LLC-PK1 cells.

Methods: LLC-PK1 cells were seeded at density of 1.0×10^4 cells/cm^2 onto plastic plates and used for experiments on the following day, on which they reached 70-80 % confluence. After treatment with VCM (1-5 mM) for 3-24 h, cells were washed with phosphate-buffered saline. Apoptosis was assessed by flow cytometry using the TUNEL staining. Production of intracellular reactive oxygen species (ROS) was measured by using a cell-permeative ROS indicator, carboxy-H_2DCFDA and a specific mitochondrial superoxide indicator, MitoSOX red. Changes in mitochondrial membrane potential were assessed by the JC-1 staining. Mitochondrial cytochrome c was determined by Western blot analysis.

Results: Exposure of LLC-PK1 cells to VCM caused a concentration- and time-dependent increase in the numbers of TUNEL-positive cells, which were reversed by caspase-3-specific inhibitor zDEVD-fmk and a caspase-9 inhibitor zLEHD-fmk. VCM also induced an increase in DCF fluorescent intensity and MitoSOX fluorescent intensity. Vitamin E and mitoTEMPO prevented VCM-induced cell apoptosis and mitochondrial membrane depolarization, while vitamin C or n-acetyl cysteine (NAC) did not show significant protection against VCM-induced cell death.

Conclusions: VCM caused the mitochondrial-mediated ROS generation leading to a concentration- and time-dependent cell apoptosis in LLC-PK1 cells. Moreover, a lipophilic antioxidant vitamin E and a mitochondria-targeted antioxidant mitoTEMPO significantly prevented the VCM-induced mitochondrial dysfunction and apoptosis in LLC-PK1 cells.

PUB098

Hyperglycemia Induces Early Disassembling of Slit-Diaphragm in Podocytes in an Oxidative Stress-Dependent Way Pablo Bautista-Garcia,[1] Brenda Luna,[2] Marisol Martinez,[2] Rafael Rodriguez-Munoz,[1] Maria del Carmen Namorado,[1] Alejandro Perez-Lopez,[1] Jose L. Reyes.[1] *[1]Physiology, Biophysics and Neuroscience, Cinvestav, Mexico City, Mexico; [2]Pharmacology, Cinvestav, Mexico City, Mexico.*

Background: Diabetic nephropathy (DN) is a severe complications of diabetes mellitus (DM). This pathology produces dysfunction of slit-diaphragm leading to the end-stage renal disease. The increase production of advanced glycation end products (AGEs) and the activation of their specific receptors for advanced glycation ends products (RAGEs), stimulate NADPH oxidase, a source of reactive oxygen species (ROS). It has been previously shown that ROS is involved in renal damage during the late phase of diabetes mellitus (DM). Thereby, our aim was to evaluate whether hyperglycemia disassembles the slit-diaphragm proteins during the early phases of DM.

Methods: Diabetes mellitus was induced in rats by a single tail vein injection of streptozotocin (STZ 60 mg/kg Body Weight). Control were injected with equal volume of citrate buffer. Urine was collected for proteinuria determination. Kidney form each group were excised for immunofluorescence to evaluate nephrin and ZO-1 and glomerular isolation from each group were performed to evaluate the expression of RAGEs, nfr-2, NOS-2, nitrotyrosine, nephrin and PCK-β2 by western blot.

Results: By immunofluorescence, we observed that nephrin and ZO-1 are delocalized or absent in glomeruli of diabetic rats. WB demonstrated that initial stages of hyperglycemia increased NOS-2, nitrosylated proteins, PCK-β2 and the activation of transcriptional factors induced by oxidative stress, such as nfr-2. These changes are related to a significant increase of proteinuria at the third week.

Conclusions: Our results suggest that hyperglycemia increase the prooxidant enviroment in glomeruli during the early phases of diabetes. The induction of this deleterious phenomena might provoke delocation of slit-diaphragm proteins through activation of PKC-β2, these changes leading to development of proteinuria an important predictor of evolution of chronic renal disease.

PUB099

Bisphenol A Induces Inflammatory Response and Cytokine Release in Renal Mesangial Cells Shing-Hwa Liu,[1] Bo-Lin Chen,[1] Yuan-Siao Chen,[2] Chih-Kang Chiang,[3] Cheng-Tien Wu.[1] *[1]Graduate Institute of Toxicology, National Taiwan Univ, College of Medicine, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [3]Dept of Integrated Diagnostics and Therapeutics, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Bisphenol A (BPA) is a common ingredient of plastic products, which wildly exists in daily life. In addition to its estrogen-like disrupter effect, reproductive toxicity and renal toxicity have also been implicated. BPA exposure has been demonstrated to be associated with low-grade albuminuria in adults. Here, we investigated the effect and possible mechanism of BPA on glomerular mesangial cells.

Methods: Mouse mesangial cell (MMC) were applied to test the effects of BPA. Cell viability was tested by using MTS assay. PI-Annexin V staining, caspase-3 and PARP cleavages was applied to evaluate the induction of apoptosis. ELISA, Western blotting and kinase assay were applied for evaluating the potential signal pathways.

Results: In this study, MMC was treated with 0~100 μM BPA. The cell phenotyping was not changed during BPA treatment. Cell viability was not affected by 25 and 50 μM BPA after 24 h treatment, but cell viability was decreased to 90% under treatment with 100 μM BPA. BPA 100 μM did not increase the cell apoptosis by PI-Annexin V staining. It also did not change the caspase-3 and PARP cleavages. These data indicated that BPA seems only to decrease the cell growth rate, but does not cause cell death in MMC. After BPA treatment, COX-2 protein expression and PGE2 secretion and nuclear factor κ-B (NFκB)-p65 phosphorylation in MMC were increased in a dose dependent manner. The interleukin-1β levels were also increased in MMC culture medium after BPA treatment. BPA could also activate the AMP-activated protein kinase (AMPK), which is involved in the energy balance and plays an inflammation and oxidative stress regulator, in a dose dependent manner.

Conclusions: Taken together, these results indicate that BPA at non-cytotoxic concentrations is capable of increasing the expression/secretion of COX-2/PGE2 and cytokines in MMC, and imply that BPA may cause inflammatory response in renal glomeruli and influence the renal function.

PUB100

Inhibition of Glycogen Synthase Kinase-3β Ameliorates Angsiotensin II-Induced Podocyte Apoptosis through Modulating Inflammation Zhangsuo Liu,[1] Qian Zhang,[2] Guo Jia.[3] *[1]The First Affiliated Hospital of Zhengzhou Univ; [2]The First Affiliated Hospital of Zhengzhou Univ; [3]The First Affiliated Hospital of Zhengzhou Univ.*

Background: Emerging evidence indicates that diabetic nephropathy is an inflammatory disease. Angsiotensin II is a key factor in glomerulosclerosis as well as in podocyte injury. We aimed to investigate whether angsiotensin II(Ang II) induces inflammation in podocytes and whether glycogen synthase kinase-3β is involved.

Methods: Podocytes were exposed to Ang II(10^{-8}mol/L-10^{-5}mol/L) for 48 hours.In another set of experiments,GSK-3β was inhibited by LiCl or scilenced by GSK-3β siRNA before Ang II exposure.Podocyte apoptosis was assessed by flow cytometry.GSK-3β and caspase3 activity was assessed by an activity assay kit. GSK-3β expression was detected by western blot. IL-1β,TNF-α in the supermatant was assessed by ELISA.

Results: Podocyte apoptosis,IL-1β,TNF-α secretion and GSK-3β activity was increased after Ang II stimulation in a dose-dependent manner($P<0.05$).GSK-3β inhibition by LiCl or siRNA suppressed IL-1β,TNF-α secretion,caspase3 activation as well as podocyte apoptosis caused by Ang II($P<0.05$).

Conclusions: Our experiments reveal that GSK-3β is involved in AngII-induced podocyte apoptosis through modulating inflammation and AngII-induced effects could be alleviated by GSK-3β inhibition.

PUB101

The Effects of Endothelial Microparticles on the Neointimal Hyperplasia Formation and Vascular Smooth Muscle Cells Proliferation Jung-Hwa Ryu, Shina Lee, Hee Sung Ko, Dong-Ryeol Ryu, Duk-Hee Kang, Kyu Bok Choi, Seung-Jung Kim. *Dept of Nephrology, Ewha Womans Univ, School of Medicine, Seoul, Republic of Korea.*

Background: Vascular access stenosis occurs frequently and predominantly as a result of neointimal hyperplasia (NH) formation due to migration and proliferation of VSMCs at the venous anastomosis site. However, effective preventions or treatments for NH formation in this setting are lacking. Increased endothelial microparticles (EMPs) in uremic condition are closely associated with vascular dysfunction and atherosclerosis. The aim of this study is to investigate the effects of EMPs on proliferation of VSMCs and NH formation.

Methods: Human umbilical vein endothelial cells (HUVECs) were cultured and stimulated by indoxyl sulfate (IS; 250μg/mL). The pellet obtained via ultracentrifugation of the culture media at 100,000 Xg was resuspended and analyzed by flow cytometry. The absolute count of EMPs was defined by Trucount tube. Human aortic smooth muscle cells (VSMCs) were treated by collected EMPs. Western blot analysis for TGF-β sub-signaling; Akt, ERK, p38, and Smad3 and BrdU cell proliferation assay were performed. Ex vivo experiments were also performed on porcine internal jugular veins (n=5) with vehicles, EMPs (2.0×10^6), and TGF-β (5ng/mL) for 12 days, respectively. The tissues were stained by H&E, Masson's trichrome and immunostained by α-smooth muscle actin (α-SMA).

Results: The EMPs were well produced by IS and the quantity of them was similar to the amount generated by positive control, TNF-α (10ng/mL). IS-induced EMPs stimulated the TGF-β sub-signalings and the proliferation of cultured VSMCs in a dose-dependent manner. In *ex vivo* culture, NH was significantly developed in EMPs-treated veins compared to controls, which was similar with the patterns developed by stimulation of TGF-β (5ng/mL). Luminal narrowing was noted in EMP and TGF-β treatment group and the intima/media ratio was significantly increase in EMPs-treated vessel.

Conclusions: IS-induced EMPs directly stimulate the proliferation of VSMCs and significant NH formation in porcine vein. Further investigation is needed to demonstrate the fine mechanism and active role of EMPs on vascular access stenosis.

PUB102

Association of Intracellular Localization of Slit–Diaphragm Proteins with Size Selectivity in Idiopathic Nephrotic Syndrome Kiyonobu Ishizuka,[1] Yutaka Harita,[2] Haruko Tsurumi,[2] Noriko Sugawara,[1] Hiroko Chikamoto,[1] Yuko Akioka,[1] Motoshi Hattori.[1] *[1]Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Dept of Pediatrics, Graduate School of Medicine, Univ of Tokyo, Tokyo, Japan.*

Background: While slit diaphragm (SD) proteins are critical components of glomerular filtration, detailed expression and localization of SD proteins in idiopathic nephrotic syndrome (INS), and its association with glomerular size selectivity, remains unclear.

Methods: Using a confocal microscopy, we analyzed intracellular localization of Nephrin, Podocin, Neph1 and ZO–1 in podocytes in renal specimens from patients with INS (MCNS: 9, FSGS: 12). Five samples from posttransplant recurrence of FSGS were also analyzed. All the patients had proteinuria at renal biopsy.

Results: Expression levels of Nephrin, Podocin, Neph1, and ZO–1 in podocytes of INS patients did not alter compared to those of controls. 15 samples (71.4%) showed alteration of intracellular localization of either Nephrin (4 samples), Podocin (4 samples) or both (7 samples). In these specimens, Nephrin or Podocin altered their localization from slit–diaphragm to cytoplasm. In all the samples from posttransplant recurrent FSGS, both Nephrin and Podocin were translocated to cytoplasm in as early as 1 hour after transplantation and part of them was localized to Golgi apparatus. Alteration of cytoplasmic localization of Neph1 was not observed. Neither the change of localization of Nephrin nor that of Podocin could distinguish histopathological diagnosis. However, there was significant difference in selectivity index (the clearance ratio of lgG/ transferrin) between cases with Nephrin alteration and ones without ($p=0.024$), and in the amount of urinary protein between cases with Podocin alteration and ones without ($p=0.012$).

Conclusions: Changes of intracellular localization, but not of expression level, of SD proteins were observed in INS. In the pathological situations, localization of Nephrin and Podocin were independently regulated, and proper localization of Nephrin at SD, but not of Podocin, provides size selectivity of glomerular filtration.

PUB103

Optimization of Urine Collection for the Isolation of Extracellular Vesicles Harry B. Holthofer,[1] Wenxiao Zeng,[1,2] Luca Musante,[1] Xinyu Liu,[1] Dorota Ewa Tataruch,[1] Giulio Calzaferri.[1] *[1]Centre for BioAnalytical Sciences (CBAS), Dublin City Univ; [2]Blood Purification Center, The Fifth Affiliated Hospital of Sun Yat-sen Univ.*

Background: Urinary extracellular vesicles (UEVs) represent a fascinating new source of biomarkers. However, several shortcomings limit their practical use like protocols for rapid vesicle enrichment or data normalisation. Furthermore, urine collection itself lacks optimized standards. Here we streamline the urine collection protocol and provide new information of the major interfering protein, Tamm-Horsfall Protein (THP).

Methods: Urine was collected from normal subjects using the void 1st and 2nd morning urine in consecutive 50ml tubes. Additionally, the 3rd 4th and 5th urine was collected after intake of a litre of water. All subjects also provided a 24 hour collection. The samples were first centrifuged at 2,000g and UEVs isolated by hydrostatic dialysis (HD). Fractions were analyzed by electrophoresis and Western blots (WB) to detect a specific exosome marker, Tumor Susceptibility Gene 101(TSG101). Images of Coomassie gels and WB were acquired by Odyssey® scanner and relative quantification performed by Odyssey software.

Results: HD proved to be superior to conventional differential centrifugation method without qualitative changes in the resulting UEV protein pattern. A higher amount of TSG101 was recovered in the 1st morning urine with minimal interference of THP. TSG101 decreased progressively in the successive samples with reciprocal THP increase, particularly after overload of water. THP in precipitated form was successfully spun down at 2,000g in the 1st and 2nd and 3rd morning urine samples while no THP was recovered in the same low speed pellet of 4th and 5th collection after hydration. Thus, hydration and prolonged time in bladder appears to trigger THP polymerization.

Conclusions: We showed that the major variability in the UEV and THP recovery depends on time and modality of collection. Caveats with the first morning urine samples have a practical impact on the design of urine collection for discovery research and diagnostics alike, especially if the whole void urine volume is collected so as to avoid the "mid-stream" catch.

PUB104

Hormetic Effects of the Nrf2 Inducer, Bardoxolone Methyl (BARD) Analogs, on Chronic Kidney Disease (CKD) Progression
Nosratola D. Vaziri, Shuman Liu, Seyed Farzaneh, Sohrab Nazertehrani, Mahyar Khazaeli. *Div of Nephrology and Hypertension, Univ of California, Irvine, CA.*

Background: Oxidative stress and inflammation which play a major role in progression of CKD are, in part, due to impaired activity of Nrf2, the master regulator of endogenous phase 2 detoxifying and antioxidant molecules. Natural Nrf2 activators have been shown to ameliorate kidney disease in experimental animals. However, treatment with potent synthetic Nrf2 inducers, BARD analogs RTA 405 (50 and 100 mg/kg) and dh404 (5-20 mg/kg/day), has been shown to intensify inflammation and CKD progression in diabetic obese Zucker rats (Zoja et al, 2013). Moreover due to adverse outcomes, clinical trial of BARD in patients with diabetic nephropathy was recently halted (De Zeeuw et al, 2013). In contrast treatment with low dose dh404 (2 mg/kg/day) was recently shown to retard CKD progression in 5/6 nephrectomized rats (Aminzadeh et al, 2013). Notably, natural Nrf2 inducers which serve as insecticides to protect the plants against insects are known to have hormetic properties with beneficial effects at nanomolar and toxic effects at higher concentrations. This study was designed to determine if the reported divergent effects of BARD analogs are dose related.

Methods: SD rats were subjected to 5/6 nephrectomy (CKD) or sham operation and randomized to receive either10 or 2mg/kg/day of dh404 or vehicle for 12 weeks.

Results: The vehicle-treated CKD group exhibited glomerulosclerosis, interstitial fibrosis and inflammation, upregulation of NAD(P)H oxidase, activation of NFkB, reduced Nrf2 activity, and down-regulation of catalase, heme oxygenase-1, and glutamate-cysteine ligase. Administration of low dose dh404 restored Nrf2 activity and expression of its target genes, attenuated oxidative stress, inflammation, glomerulosclerosis, and interstitial fibrosis. In contrast at high dosage dh404 caused massive weight loss, intense proteinuria, and exacerbation of kidney lesions and dysfunction.

Conclusions: The data illustrate the dose-dependent dimorphic impact of BARD which is consistent with the known hormetic properties of the natural Nrf2 inducers.

PUB105

Impaired Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2) Activity Involves in Aristolochic Acid-Induced Renal Tubular Epithelial Cell Injury
Juan Wu,[1,2] Xinhui Liu,[1,2] Juan Wang,[1,2] Xueqing Yu,[1,2] Xiao Yang.[1,2] *[1]Nephrology, The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Key Laboratory of Nephrology, Ministry of Health, Guangzhou, Guangdong, China.*

Background: Recently we have demonstrated in vivo that bardoxolone methyl (BARD), the most potent known activator of the nuclear factor erythroid 2-related factor 2 (Nrf2) signaling pathway, could prevent aristolochic acid (AA)-induced acute kidney injury. In this vitro study, we investigated the role of Nrf2 and related signaling pathway in AAI injury to renal tubular epithelial cells (NRK52E cells).

Methods: NRK-52E cells were incubated with different concentrations of AAI for several time points. The role of Nrf2 was determined in NRK-52E cells through Nrf2 knockdown by its specific siRNA. Cell viability and reactive oxygen species (ROS) were evaluated by MTT and Flow Cytometer assay, respectively. Cell apoptosis was examined by western blotting of cleaved caspase-3 and Flow Cytometer assay. Expression of Nrf2 and its downstream protein hemeoxygenase-1(HO-1), and NAD(P)H quinoneoxidoreductase-1(NQO-1) was analyzed by western blotting and immunofluorescence.

Results: AAI reduced cell viability and increased apoptosis in a concentration- (0, 5, 10, 25, 50 uM) and time- (0, 4, 8, 12, 24 hrs) dependent manner. ROS production was detected as early as 5 min, and early apoptosis as indicated by cleaved caspase-3 reached highest level at 8 hrs after AAI exposure. After AAI (25 uM) treatment for 24 hrs, Nrf2 protein located in cytoplasm of NRK-52E cells was significantly down-regulated and failed to translocate to the nuclear, which indicated impaired Nrf2 activation. This was consistent with our previous finding in vivo. Moreover, knockdown of Nrf2 led to a significant reduction of HO-1 and NQO1 protein expression, and enhanced ROS production and cell apoptosis induced by AAI.

Conclusions: These results indicate that AAI-induced renal tubular epithelial cell injury was associated with impaired Nrf2 activation and expression of its downstream target genes. Activation of Nrf2 signaling pathway may be a potential treatment target for AA nephropathy.

PUB106

Screening of Microarray Profile of Kidney Human From Diabetes And/ Or Renal Cell Carcinoma for a New Biomarker
Samy L. Habib,[1,2] Adam Kosti,[2] Hung-I. Harry Chen,[3] Yidong Chen.[3] *[1]Geriatric Research, Education, and, Clinical Center, South Texas Veterans Healthcare System, San Antonio, TX; [2]Cellular and Structural Biology, Univ of Texas Health Science Center, San Antonio, TX; [3]Greehey Children's Cancer Research Institute, Univ of Texas Health Science Center, San Antonio, TX.*

Background: Recent study from our laboratory showed that patients with diabetes are at a higher risk of developing kidney cancer. In the current study, we have screened the microarray profile of kidney tissue collected from patients with diabetes, RCC or RCC+diabetes for a new biomarker.

Methods: DNA copy number profiling was performed using the Agilent Human CGH microarrays. Microarray data from healthy control (group1), diabetes (group 3), RCC(group 4) and RRC+diabetes (group 2) were further processed using Nexus Copy Number 7.5 (BioDiscovery) with FASST2 segmentation method for copy number analysis. The copy number gain and loss log2 ratio thresholds are 0.4 and -0.5, respectively. The aberrant regions that occurred in at least one sample in each group were selected.

Results: We found that 901 genes gain of copy number and 171 genes loss of copy number in group 2, 669 genes gain of copy number and 307 genes loss of copy number in group 3, 457 gene gain of copy number and 38 loss of copy number in group 4, after removing gain/loss genes obtained from healthy control group (group 1). Cell survival genes including such as AKTs showed gain of copy number in group 2 while AKTs gain in group 3. In cell apoptosis genes including BCL2, PARP and caspases, we found gain of copy number in group 2 while gain in certain PARPs in group 3. In tumor suppressor genes, we found loss of copy number of VHL gene in group 2 and 4. We also found gain in copy number of DNA damage genes including SETD9 and ATR in both group 2 and 3.

Conclusions: These data showed a potential DNA alteration specifically in pathways that important in the early stages of tumor initiation. Our data shed a light on certain candidate target genes that can be beneficial as a biomarker for diagnosis RCC within diabetic patients.

Intra-Renal Artery Infusion of Fenoldopam Prevents Acute Renal Failure in CKD Patients Post Contrast Media Exposure
Jack E. Rubin, Dipak J. Ranparia, J. Joseph Hewett. *Los Angeles PAD Center, Inglewood, CA.*

Background: Chronic kidney disease (CKD) patients run a substantial risk for contrast media induced nephrotoxicity with further worsening of their kidney function. To avoid this, intra-renal artery fenoldopam (F) was administered 41 times to 34 distinct patients with peripheral artery disease (PAD) prior to their angiography.

Methods: The patients' estimated glomerular filtration rates (EGFR) were calculated using the Korckoff Gault formula and their creatinine (C) levels were obtained before their angiograms (A) and within 2 days after the A's were performed. Standard interventional methods were used to place a selective infusion system catheter delivering F to both renal arteries catheter and/or placing a Cobra catheter catheter in one renal artery. Low osmolar contrast media was injected to confirm its location in the renal artery and was used for the A's. A F drip was started through the catheter at 0.2mcg/kg/min injected into the renal circulation was continued for 5 minutes and was then increased to 0.4 mcg/kg/min and continued for another 55 minutes. Blood pressure records were closely monitored during the angiogram. Their pre and post A C levels were analyzed using a paired two tailed t-test.

Results: No patient was admitted to a hospital for ARF post A. Their mean EGFR was 42.7 ml/min +/- 12.2 and their mean age was 73.3 years +/- 11.Their C levels are seen in the table below.

Patinet selection	Mean Pre Angiogram Creatinine mg/dl	Mean Post Angiogram Creatinine mg/dl	P value
All F procedures (41)	1.65 +/- .5	1.64 +/- .5	P=.47
Only One Renal Artery with Fenoldopam infusion (34)	1.62+/- .4	1.59 +/-.4	P=.23
Both renal arteries with Fenoldopam infusion (7)	1.84 +/-.9	1.82 +/-.9	P=.04

Conclusions: There were no cases of ARF in our study population nor were there any significant changes in C levels in pre and post A blood in our study patients with CKD who were exposed to contrast media. F infused into the one, or two renal arteries, avoided AFR following contrast media exposure in a elderly population with advanced CKD. This technique allows necessary angiographic studies to proceed in an elderly population of CKD patients with PAD without the fear of developing ARF.

PUB108

Serum Anti-Müllerian Hormone in Young Hemodialysed Women with Chronic Kidney Disease and after Kidney Transplantation
Marcin Adamczak,[1] Ewelina Sikora-Grabka,[1] Magdalena Szotowska,[1] Piotr Kuczera,[1] Andrzej Wiecek,[1] Pawel Madej.[2] *[1]Dept of Nephrology, Endocrinology and Metabolic Diseases, Medical Univ of Silesia, Medical School in Katowice, Katowice, Poland; [2]Dept of Gynecological Endocrinology, Medical Univ of Silesia, Medical School in Katowice, Katowice, Poland.*

Background: In women with chronic kidney disease (CKD) infertility is observed. Anti - Müllerian hormone (AMH) is produced by the ovarian follicles and is a paracrine factor inhibiting the excessive recruitment of primordial follicles. Until now serum AMH concentration in women with CKD and after kidney transplantation has not been determined. The aim of the study was to evaluate the serum AMH concentration in young females with CKD treated with hemodialysis (HDP) and in young female patients in early period after a successful kidney transplantation (KTP).

Methods: In 46 female HDP, 14 female KTP and 46 healthy women (HW) aged 18-40 years old serum AMH concentration in HDP and HW was assessed once, and in KTP 4 times: immediately before surgery, in the 14th and 30th day and 6 months after the transplantation. The results are presented as means and 95% CI.

Results: Serum AMH concentration in female HDP (4.16ng/ml; 3.18-5.15ng/ml) and in HW (4.43ng/ml; 3.49 - 5.36ng/ml) did not significantly differ (p = 0.594). Mean AMH serum concentration in female HDP without dysmenorrhea (n=21) was significantly (p=0.018) lower than in HW with regular menstrual cycles (n=40); 2.42ng/ml (1.58-3.26ng/ml) and

4.07ng/ml (3.23-4.90ng/ml),respectively. A significant (p=0.007) decrease of serum AMH concentration from 4.28 ng/ml (2.29-6.26 ng/ml) at baseline to 2.42 ng/ml (1.44 - 3.4 ng/ml) (p=0.048) at 30 days after surgery and to 1.89ng/ml (1.31-2.47ng/ml) (p=0.013) at 6 months after transplantation were found.

Conclusions: 1. The subgroup analysis of regularly menstruating women showed significantly lower AMH serum concentration in HDP than in HW suggesting the reduction of ovarian reserve in the HDP. 2. Successful kidney transplantation leads to further decrease of serum AMH concentration.

PUB109

Evaluation of Endothelium Function, Left Ventricular Structure and Function in Patients with Chronic Kidney Disease Piotr Bartnicki, Beata Franczyk-Skora, Mariusz Kowalczyk, Jacek Rysz. *Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Lodz, Poland.*

Background: CKD is strongly connected with high risk of cardiovascular complications which is appearing already in early CKD stages and is the highest in patients treated with dialyses. The aim of this study was to evaluate endothelium function, left ventricular structure and function in patients with CKD stage IV and V.

Methods: Three study groups included: 30 patients in stage IV, 30 patients in stage V under hemodialysis treatment and 15 patients without CKD - control group. Blood concentrations of ADMA and NOS were assessed with ELISA system. Echocardiographic parameters were evaluated: intraventricular septum systolic diameter (IVSs) and diastolic diameter (IVSd), left ventricular mass (LVM), left ventricular end-systolic diameter (LVESd) and end-diastolic diameter (LVEDd), left atrium diameter (LA), aorta diameter (Ao), ejection fraction (EF), presence of left ventricular hyperthrophy (LVH) and disorders of left ventricular relaxation (LVR).

Results:

CKD	Stage IV (n=30)	Stage V (n=30)	Control group (n=15)
eGFR (ml/min)	22,5 ± 10,7*	10,3 ± 5,9*•	79,6 ± 12,3
ADMA (μmol/l)	0,63 ± 0,38*	0,77 ± 0,43*	0,36 ± 0,12
NOS (pg/ml)	3380 ± 999*	3833 ± 1005*	10000 ± 1950
IVSd (mm)	13 ± 1,3*	15 ± 2,8*•	10 ± 1,6
IVSs (mm)	16 ± 2,3*	17 ± 3,5*•	12 ± 1,4
LVM (g)	287,8 ± 70,1*	358,1 ± 86*	206 ± 42,2
Ao (mm)	32,7 ± 3,7*	31,8 ± 3,6*	26 ± 2,9
LVESd (mm)	41 ± 6,2*	38,9 ± 6,2*	36 ± 5,9
LVEDd (mm)	48,5 ± 6,7*	50,1 ± 5,6*	40 ± 7,4
LA (mm)	41,9 ± 2,7*	42,3 ± 3,2*	31 ± 2,2
EF (%)	50 ± 12*	45 ± 10* •	60 ± 9
LVH (% of evaluated)	100*	100*	20
LVR (% of evaluated)	96,7*	78,6*•	27

* p <0,05 to control group, •p<0,05 to stage IV

Conclusions: Our results confirm vascular endothelium dysfunction and disadvantageous morphological and functional changes of left ventricle in patients with CKD in comparison to control group. Disorders are greater in the stage V but largely without statistical significance compared with the stage IV of CKD.

PUB110

Differences in Nutritional Parameters, Body Composition and Muscle Strength between Diabetics and Non-Diabetic Patients with Advanced Chronic Kidney Disease (CKD) Guillermina Barril, Angel Nogueira Perez, Carmen Sanchez-Gonzalez, Almudena Nuñez Sanchez, Jose-Antonio Sanchez-Tomero. *Nephrology, Hospital U. de la Princesa, Madrid, Spain.*

Background: Assess nutritional parameters, body composition and muscle strength in 253 patients comparing ACKD results in the group of diabetics versus non-diabetics.

Methods: We evaluated 253 patients with ACKD xage±4 y, 60.5 % men They are divided into two groups according to the ethiology: G1-Diabetes Mellitus (DM) 33.7% and G2 other etiologies66.3% Anthropometric data were assessed, body composition by bioimpedance vector (BIVA),biochemical data: albumin, prealbumin, CRP, total lymphocytes, cholesterol and trasferrin.Muscle strength was asses by dynamometry.

Results: The results and differences between G1 and G2 are in the below.

Diabetes	Mean	St Deviation	p
% TSFold Yes No	123,46 115,99	60,35 53,38	0,1
CRP Yes No	0,58 1,12	0,79 3,09	0,05
MDRD Yes No	18,93 20,25	7,28 10,14	0.02
Phase A. Yes No	4,10 4,60	1,17 1,33	0.04
Na/K Yes No	1,53 1,36	0,54 0,51	0,02
BCM% Yes No	38,02 40,87	10,81 10,12	0,05
ECW% Yes No	56,67 53,50	8,96 9,31	0,01
ICW Yes No	43,31 46,19	8,96 9,48	0.03

G1 patients had significantly lower phase angle, but Na / k interchangeable lower, % BCM, increased ECW and lower ICW. Albumin and prealbumin were lower in G1 without statistical significance We found no significant difference between groups in SGA, OGA or MIS. The MDRD was lower in the group G1 versus G2 $p < 0.13$ nevertheless albumin and prealbumin were similar When comparing muscle strength by dynamometry xg1 found that was significantly lower than G2 mainly on the right side in men but not in women. Analyzing the groups according to sex major statistical significances between G1 and G2 shown in men.

Conclusions: 1-The group of patients with Diabetes Mellitus and CKD body composition traits have more ECW than nondiabetic group that is not justified by the reduction in glomerular filtration 2 -Evidence of decreased muscle strength in the diabetic group that correlates with lower BCMI in BIVA.

PUB111

Subendocardial Viability Ratio and Nt-Pro-BNP in Patients with Chronic Kidney Disease Robert Ekart,[1] Benjamin Dvorsak,[2] Masa Knehtl,[2] Sebastjan Bevc,[2] Nina Hojs,[2] Martin Hren,[1] Eva Jakopin,[2] Tina Stropnik Galuf,[1] Radovan Hojs.[2] *[1]Dept of Dialysis, Univ Medical Centre Maribor, Clinic for Internal Medicine, Maribor, Slovenia; [2]Dept of Nephrology, Univ Medical Centre Maribor, Clinic for Internal Medicine, Maribor, Slovenia.*

Background: The subendocardial viability ratio (SEVR) represents a noninvasive measure of myocardial perfusion related to LV function. The aim of our study was to investigate the relationship between SEVR,NT-pro-BNP and other cardiovascular (CV) risk factors in chronic kidney disease (CKD) patients.

Methods: We performed a cross-sectional study in a cohort of 86 nondialysis CKD patients. SEVR was assessed by radial applanation tonometry (SphygmoCor). NT-pro-BNP and CV risk factors were measured. In all subjects 24-h ABPM was performed using a non-invasive ABPM monitor (Schiller). The patients were asymptomatic regarding heart failure and were divided into two groups according to the median value of SEVR:lower SEVR group (SEVR<151%,n=44), higher SEVR group (SEVR>151%,n=42).

Results: Mean age of patients was 60,3±13 years, 65% were men, 44% were smokers, 24% had diabetes. Other descriptive data for all patients are presented in Table 1. Using t test, we found significant difference between both groups in NT-pro-BNP (P<0.05),but not in ABPM and other CV risk factors.

Variable	All patients (n=86)	Lower SEVR group: SEVR<151% (n=44)	Higher SEVR group:SEVR>151% (n=42)	P-value
Age(years)	60.3±13	61.9±13.6	58.7±12.1	0.26
Cystatin C(mg/L)	2.1±0.9	2,3±0.9	2±0.9	0.11
Cholesterol(mmol/L)	5±1.3	4.9±1.3	5.2±1.4	0.29
Triglycerides(mmol/L)	2.4±3.2	2.5±4.3	2.2±1.2	0.71
hs-CRP(mg/L)	6.1±11.5	5.8±9.2	6.3±13.6	0.86
NT-pro-BNP(pmol/L)	121.5±177.2	158.2±200.2	83.1±141.8	**0.048**
BMI(kg/m^2)	28.5±5.3	28.1±5.4	28.9±5.1	0.5
24-h systolic ABPM(mmHg)	135.4±17.6	138.6±17.3	132.1±17.6	0.08
24-h diastolic ABPM(mmHg)	76.1±9.3	74.8±9.3	77.6±9.2	0.17

Conclusions: Results of our study show that higher values of NT-pro-BNP are associated with lower SEVR, and both can be recognised as early markers of LV dysfunction in asymptomatic non-dialysis CKD patients.

PUB112

Clinical Significance of Troponin T in Chronic Kidney Disease Patients Presenting with Acute Coronary Syndrome Nimisha Venugopal,[1] Bhavna Pandya.[2] *[1]Medical School, Univ of Liverpool, Liverpool, Merseyside, United Kingdom; [2]Dept of Nephrology, Univ Hospital of Aintree, Liverpool, Merseyside, United Kingdom.*

Background: Chronic Kidney Disease patients have chronically elevated Troponin T values regardless of a cardiac event. This is a diagnostic difficulty should these patients present with acute chest pain, as clinicians are unsure how to interpret raised Troponin T values. This study aims to find a more appropriate cut-off diagnostic value of Troponin T in CKD patients.

Methods: This retrospective study collected baseline data from 1053 patients for analysis. Troponin T values and corresponding outcomes were collected between January 2011 to December 2012. A cut-off point was devised using a Receiver Operating Characteristic (ROC) curve. A Kaplan-Meier curve was calculated to evaluate survival and outcome predictors were analysed using the Cox Regression analysis.

Results: The ROC curve showed that a cut-off point of 58.5 ng/L had highest sensitivity (79.4%) and specificity (79.7%). Kaplan-Meier survival curves showed that there is a statistically significant decrease in survival in patients with Troponin T values above 41.5ng/L. Cox Regression analysis showed that Troponin T values and a history of ischaemic heart disease were the only outcome predictors that had a significant contribution towards a cardiac event.

Conclusions: This study shows that Troponin T values above 58.5ng/L is a predictor for a cardiac event in moderate- severe CKD patients. Thus, these patients should be monitored carefully and treatment should be started in order to avoid progression of the cardiac event.

PUB113

Relationship between Heart Rate Variability and the Progression of Chronic Kidney Disease Shuhei Watanabe,[1] Keiji Kono,[2] Kentaro Nakai,[2] Shunsuke Goto,[2] Hideki Fujii,[2] Shinichi Nishi.[2] *[1]Div of Nephrology, Akashi Medical Center, Akashi, Japan; [2]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.*

Background: Heart rate variability (HRV) is known to be a measure of autonomic tone. Recently, it is reported that low HRV is an independent risk factor for cardiovascular events and mortality in general population. However, the relationship between HRV and the progression of CKD remains unclear. We aimed to examine the association between HRV and clinical characteristics in patients with CKD.

Methods: We included 67 patients with CKD stage 2-5 who admitted to Akashi medical center for CKD educational program from April 2012 to March 2014. All the patients underwent 24 hour ambulatory blood pressure monitoring to evaluate blood pressure and heart rate. For the assessment of HRV, we used heart rate standard deviation (HR-SD) and coefficient of variance (HR-CV), and performed cosinor analysis (HR-midline estimating statistics of rhythm (HR-Mesor) and HR-Amplitude). Laboratory tests were carried out by standardized clinical laboratory methods.

Results: HR-SD and HR-CV were decreased as declining glomerular filtration rate (GFR) and increasing proteinuria. The presence of diabetes mellitus (DM) reduced HR-SD and HR-CV. Furthermore, HR-Mesor had significant positive correlation with proteinuria. HR-Amplitide had significant negative correlation with GFR and proteinuria.

Conclusions: Our results demonstrated that HRV reduced along with the progression of CKD.

PUB114

Skin Advanced Glycation End Products (AGEs) Accumulation and Body Composition by Bioelectrical Impedance (BIA) in Chronic Kidney Disease (CKD) Stage 1-5.Role of Skin Autofluorescence (SAF) Secundino Cigarran,[1] Juan Latorre,[1] Ana Isabel Fernandez-Alonso,[1] Montserrat Pousa,[1] Walter Luis López Alarcón,[1] Guillermina Barril,[3] Jesus Calvino,[2] Saray Lopez-Prieto,[1] Miguel A. Garcia-Gonzalez.[4] *[1]Nephrology, Eoxi Lugo-Cervo-Monforte, Burela, Lugo, Spain; [2]Nephrology, Eoxi Lugo-Cervo-Monforte, Lugo, Spain; [3]Nephrology, Hospital Univ de la Princesa, Madrid, Spain; [4]Nephrology, Health Research Institute of Santiago de Compostela (IDIS)., Santiago de Compostela, La Coruña, Spain.*

Background: AGEs are involved in CKD progression.Major sources of systemic AGES are endogenous, generated in the body, and exogenous AGEs, in foods, particularly proteins of animal origin.Both are eliminated by kidney.In CKD, AGEs are retained and may influence the body composition.Aim is to assess the relationship between AGEs level and body composition by bioimpedance.

Methods: 259 caucasian pts CKD stage 1-5 were included (mean age 72 yo),61.4% men,37.1% diabetes status.Comorbidity (Charlson Index age-adjusted),Body composition assessment was performed by BIA analyzer (EFG. Biomednet. Akern. Fl.Italy) whole,tetrapolar,in supine in non dominant arm and spectroscopy bioimpedance (BCM,FMC,Bad Homburg,GER).AGEs were evaluated with SAF (arbitray units) (AGE Reader,DiagnOptic s,Groningen,The Neetherlands)by mean of three readings. Data were processed with software package SPSS 20.0 (Chicago,ILL,U.S.A.).Spearman´s rank correlation test was used to estimate the relationships between variables.A p value <0.05 was considered significant.

Results: AGEs level has a significant relationship with parameters BIA derived.

VARIABLE	R Spearman	P
AGE	.336	<0.001
GENDER male	-.268	<0.001
COMORBID INDEX (Charlson)	.337	<0.001
Na-K exchange	.334	<0.001
Hydration Index (OH) L	.302	<0.001
TBW (%)	.342	<0.001
ECW(%)	.174	0.008
ICW (%)	-.167	<0.001
Lean Body Mass (%)	.229	<0.001
Fat Mass (%)	-.252	<0.001
Phase Angle (º)	-.172	0.009
GFR-EPI	-.411	<0.001

Conclusions: AGEs levles have relation with body composition. Lifestyle changes (exercise),Diet counselling (avoid salt and additives) and physical activty(increasing lean body mass) may reduce AGEs accumulation,specially in older males .SAF is a useful tool to monitorize outcome. Prospective studies are required.

Comparison of Subclinical Cardiovascular Damage in Patients with Chronic Kidney Disease Stage G3a and G3b Pawel Strozecki,[1] Agnieszka Pluta,[2] Mariusz Flisinski,[1] Zbigniew Serafin,[3] Jacek Manitius.[1] *[1]Dept of Nephrology, Hypertension and Internal Medicine, Nicolaus Copernicus Univ, Bydgoszcz, Poland; [2]Institute of Public Nursing, Nicolaus Copernicus Univ, Bydgoszcz, Poland; [3]Dept of Radiology and Diagnostic Imaging, Nicolaus Copernicus Univ, Bydgoszcz, Poland.*

Background: KDIGO 2012 Clinical Practice Guideline divided chronic kidney disease stage 3 into G3a and G3b, based on data supporting different outcomes. Left ventricular hypertrophy (LVH), aortic pulse wave velocity (PWV) and carotid intima-media thickness (IMT) are well defined markers of subclinical cardiovascular (CV) damage and predictors of CV events. Left ventricular mass index (LVMI) and PWV increase with progression of CKD. The aim of the study was to compare subclinical CV damage between patients in CKD stage G3a and G3b.

Methods: The study population consisted of 58 CKD patients stage 3, aged 57 ± 12. In all participants echocardiography with LVMI calculation was performed. LVMI ≥ 110 g/m2 in females and ≥ 125 g/m2 in males was considered as LVH. Aortic PWV and common carotid artery IMT were measured; PWV>10 m/s and IMT>0,9 mm were assumed as increased. Systolic (SBP) and diastolic (DBP) blood pressures were measured. Glomerular filtration rate (eGFR) was estimated using CKD-EPI formula.

Results: Mean eGFR in study population was 45±8 ml/min/1,73m2. There were 11 (19%) diabetic patients. LVH, elevated PWV, and elevated IMT was found in: 24(41%), 30(52%), and 10(17%) patients, respectively. Patients with eGFR 45-59 ml/min/1,73m2 and eGFR 30-44 ml/min/1,73m2 were compared. Results are shown in the table below.

	CKD G3a (n=29)	CKD G3b (n=29)	P
Age (years)	57±11	59±12	NS
Male gender (%)	20(69%)	17(59%)	NS
Patients with diabetes	4(14%)	7(24%)	NS
eGFR (ml/min/1,73m^2)	52±4	38±5	<0,001
SBP (mmHg)	136±16	136±26	NS
DBP (mmHg)	81±10	79±10	NS
LVMI (g/m2)	113±26	113±32	NS
PWV (m/s)	10,9±3,1	10,4±2,3	NS
IMT (mm)	0,72±0,17	0,77±0,22	NS

Conclusions: The study did not show differences between G3a and G3b CKD patients in markers of subclinical CV damage. Satisfactory blood pressure control in CKD patients may prevent subclinical CV damage.

PUB116

Non-Transplant Renal Patients on Cyclophosphamide Should Have Cytomegalovirus Surveillance Fenella J. Beynon, Ravindra Rajakariar. *Nephrology, Barts Health NHS Trust, London, United Kingdom.*

Background: Cytomegalovirus (CMV) is a cause of significant morbidity and mortality in the immunocompromised. No guidelines currently exist for CMV surveillance in non-transplant immunosuppressed patients. This service evaluation sought to determine current practice for CMV screening, prophylaxis, and outcomes at a UK tertiary renal unit.

Methods: Electronic records of non-transplant renal patients biopsied from Jan 2010 – Dec 2013 were retrospectively reviewed. Patients were included if they had renal disease (newly diagnosed or relapsed), requiring cyclophosphamide (CYC) treatment. Data was

collected on demographics, diagnoses, other immunosuppression, and CMV DNA testing, treatment and complications. Significant DNAemia was considered to be >3000, based on local guidelines for transplant recipients.

Results: 70 patients were included (40 women, 30 men). Mean age 48 (17-82). Ethnicity: South Asian 31% Afro-Caribbean 27% Caucasian 24% Other 16%. Diagnoses: Lupus nephritis 43% ANCA associated vasculitis 33% Minimal Change 4% Membranous 4% FSGS 4% Other 10%. Of 70 patients started on CYC, 52(74%) were ever tested for CMV DNA. There was variability in timing and frequency of testing: mean no. tests 4 (1-21), mean months to first test 2 (0-11). DNAemia was found in 20, 10 of whom had DNA >3000 (19% of those tested). 4/20 (20%) were only tested once, 8/20 (40%) were positive on their first test. Mean no. months to first DNAemia was 2 (0-6). 7 patients were treated for presumed CMV disease (2 CMV syndrome, 2 colitis, 2 pneumonitis, 1 hepatitis). 6/7 required hospital admission, 1 patient died. 4 were treated for asymptomatic DNAemia. 12 were prescribed valganciclovir prophylaxis on starting CYC, none of whom had significant (>3000) DNAaemia.

Conclusions: The current approach to CMV testing, prophylaxis and treatment is variable. Further prospective research is needed to evaluate the risks and benefits of prophylaxis and treatment of asymptomatic CMV DNAemia. Whilst the true prevalence cannot be determined from this evaluation, a significant number of patients developed CMV DNAemia and disease. We therefore recommend regular surveillance and increased awareness of CMV in non-transplant patients receiving cyclophosphamide.

PUB117

Anemia Management in Chronic Kidney Disease Not on Dialysis (CKD ND). Results from a French Survey M. Touam, F. Chantrel, David Attaf, Jm Hurot, B. Vendrely, A. Testa. *[1]Nephrology, Necker, Paris, France; [2]Nephrology, Centre Hospitalier de Mulhouse, France; [3]Dialysis MA, Fresenius, France; [4]Dialyse, Nephrocare Tassin Charcot, France; [5]Hopital Prive Saint-Martin, Pessac, France; [6]Echo Nantes, Nantes, France.*

Background: Anemia management evolves because of new Erythropoiesis-Stimulating Agents (ESAs) and IV irons, Clinical Trials (TREAT), and guidelines (KDIGO, 2012). Data related to CKD ND are poor. We aim to evaluate medical practices in CKD ND at the time of 2012 KDIGO's guidelines release.

Methods: Survey (PrEPOFer) evaluating medical practices via online questionnaire for nephrologists (NP). It covers **Diagnostic/Treatment/Monitoring** of anemia in CKD ND. Practices are compared with current guidelines.

Results: 428 NP responded to the survey. 35 % delegate management to other physicians or nurses. **Concerning Diagnostic :** 84 and 6 % use Hb+F+CST or HRC/CHr respectively. **Concerning Treatment :** 22, 57 and 37% of patients have an ESA, Iron or ESA+iron, respectively. Biological criteria for ESA/iron initiation : 36, 33 and 25% of NP initiate ESA/iron if Hb <10, <10,5 or <11 g/dl respectively. 74, 12% of NP initiate Iron if CST <20 or < 25% respectively. 57 and 23% of NP start iron if F <100 or < 200 mg/l respectively. 58 and 11% of NP target Hb = [10-12], |9-11] g/dl respectively. 23, 46 or 12% of NP target F < 500, [500-800] or > 800 mg/l respectively. 9, 10 and 61 % of NP target a CST <30, <40 or <50%. 71% of patients have an oral iron as first line. IV iron is given to 12 % of patients, either sucrose (52%), or carboxymaltose (32%) or Dextran (18% of NP). 69, 15 and 7% of NP give an IV iron dose < 300, [300-500] and [500-1000] mg, respectively. IV iron is given at home or in center (data not shown). IV iron is given weekly, monthly, bimonthly or quarterly. If F. is > target most of NP reduce frequency or dose of iron. If Hb > target most of NP reduce frequency or dose of ESA. Definition of ESA resistance is not consensual.

Conclusions: Impact of recent trials and guidelines is significant: lower Hb target, lower frequency or dose of ESA If Hb > target. First line Iron treatment is oral, upper limit of F. not consensual unlike lower limit of F. and CTS. This survey is a representative picture of practices at time of anemia KDIGO 2012's release.

PUB118

The Association of Carbamylated Albumin and Mortality in Non-Dialyzed Patients with Chronic Kidney Disease Anders H. Berg,[1] John Danziger,[1] David J. Friedman,[1] Sahir Kalim,[2] Julia Beth Wenger,[2] Ravi I. Thadhani,[2] S. Ananth Karumanchi.[1] *[1]Beth Israel Deaconess Medical Center; [2]Massachusetts General Hospital.*

Background: Carbamylation is a protein modification by urea that is promoted by chronically elevated urea and amino acid deficiencies. Serum carbamylated albumin (C-Alb) levels have been associated with mortality in ESRD patients on hemodialysis. This study tested whether C-Alb levels are associated with mortality in non-dialyzed patients with chronic kidney disease (CKD), and compared the risk of high C-Alb to that of conventional markers of uremia.

Methods: 119 patients with stages 2 – 5 CKD were enrolled. C-Alb was measured in baseline serum samples using LC-MS/MS. Serum was also analyzed for BUN, creatinine, cystatin C, and calculated MDRD, CKD-EPI, and Cystatin C-based estimated glomerular filtration rates. 3.6 years of survival data was collected. The association between mortality and standardized kidney biomarker values was estimated using Cox proportional hazard ratios (HR).

Results: 10 of 97 included subjects died during the study, 22 were lost to follow-up. The median C-Alb value of subjects who died was twice as high as in survivors (7.7 versus 15.5, p<0.001). Univariate Cox proportional hazards analysis demonstrated a significant association between mortality and C-Alb values (HR 3.54, 95%CI 2.19 – 5.73, p<0.001). There were also statistically significant risks associated with serum creatinine, blood urea nitrogen, cystatin C, $eGFR_{MDRD}$, $eGFR_{CKD-EPI}$, and $eGFR_{Cystatin}$. However, when multivariable HR analysis adjusted for age, C-Alb, BUN, cystatin C, eGFR, gender, race, phosphorous, glucose, calcium, and parathyroid hormone levels, C-Alb was the only variable that remained associated with mortality (HR 3.30, 95%CI 1.19 – 9.16, p=0.02).

Conclusions: New uremic biomarkers that are associated with mortality should be tested for their ability to predict which CKD patients will benefit from early initiation of renal replacement therapy. In this study of non-dialysis-dependent CKD patients, we found that elevated C-Alb was strongly associated with risk of future death, and this association appeared more robust compared to other conventional kidney biomarkers.

PUB119

Ivabradine Use in CKD and ESRD Patients: A Single Centre Experience Sanjana Gupta,[1] Magdi Yaqoob,[1] Andrew Wragg,[2] Kieran Mccafferty.[1] *[1]Dept of Nephrology, Barts Health NHS Trust, London, United Kingdom; [2]Dept of Cardiology, Barts Health NHS Trust, London, United Kingdom.*

Background: Ivabradine (IVD) is a novel class of drug which specifically inhibits the sinoatrial node through inhibition of the i_f current, leading to a reduction in heart rate and cardiac work. It is indicated for treatment of patients with stable angina or heart failure (New York Heart Association Class II-IV), who are in sinus rhythm, with a heart rate of >75BPM and in whom beta-blockers are contraindicated or not tolerated. Cardiovascular disease is the most common cause of death in patients with advanced CKD/ESRD with up to 1/3 of incident dialysis patients having echocardiographic evidence of heart failure. This is associated with poor long-term outcomes. IVD is safe and effective in patients with mild to moderate CKD however very little data exists on the safety of IVD in severe renal failure, dialysis and transplantation. We sought to examine the prescribing and tolerability of IVD in a tertiary renal unit.

Methods: We performed a retrospective analysis of IVD use in our unit over the last 10 years. We identified patients who had been prescribed IVD and collected their clinical and demographic data.

Results: We identified 56 patients who had received IVD in our unit.

Age	69 (57-76)
Male n (%)	39 (70)
Ethnicity (White/Black/Asian) %	30/7/63
Aetiology of CKD (Diabetes/BP/Ischaemic nephropathy/other) %	45/9/21/25
Modality (CKDI-III/CKDIV-V/HD/PD/Tx)%	29/29/18/13/13
Indication for IVD (ischaemia/heart failure/other) %	61/30/9
Dose of IVD (mg)	10 (5-10)
Duration of IVD Treatment (months)	49 (22-84)
Mean arterial Pressure (pre IVD) mmHg	87 (63-97)
Change in MAP Post IVD mmHg	-3 (-15-10)
Heart rate (on IVD)	74 (65-82)
Side effects (hypotension/dizziness/dyspnoea/headache) %	18/2/2/2

45% of the cohort remain on IVD, of those that are no longer on it the most common reason for this is patient death (44%). Hypotension was seen in 19% of patients, however only 4% had to stop IVD due to this.

Conclusions: IVD appears safe and well tolerated in this cohort, however there is a small risk of hypotension. Future prospective clinical trials in the use of IVD with respect to tolerability and cardiovascular outcomes in ESRD are warranted.

PUB120

Transferrin Saturation Is More Useful Than Ferritin as a Marker for Iron Deficiency in Chronic Kidney Disease Hye Jin Lim,[1] Young-Hwan Hwang,[2] Su-Ah Sung,[2] Hayne C. Park,[3] Kook-Hwan Oh,[3] Dong-Wan Chae,[3] Kyu Hun Choi,[4] Kyu-Beck Lee,[5] Yong-Soo Kim,[6] Soo Wan Kim,[7] Joongyub Lee,[8] Curie Ahn.[3] *[1]Dept of Internal Medicine, Gachon Univ, Gil Hospital, Incheon, Korea; [2]Dept of Internal Medicine, Eulji General Hospital, Seoul, Korea; [3]Dept of Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [4]Dept of Internal Medicine, Yonsei Univ, Severance Hospital, Seoul, Korea; [5]Dept of Internal Medicine, Kangbuk Samsung Medical Center, Seoul, Korea; [6]Dept of Internal Medicine, Catholic Univ, Seoul St. Mary Hospital, Seoul, Korea; [7]Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [8]Medical Research Collaborating Center, Seoul National Univ Hospital, Seoul, Korea.*

Background: Iron deficiency is known to be prevalent in chronic kidney disease (CKD) patients and should be corrected along with the use of erythropoiesis stimulating agents in the management of anemia. Transferrin saturation (TSAT) and ferritin are widely used as markers for iron deficiency, however, ferritin may reflect inflammatory state at the same time.

Methods: We examined the prevalence and risk factors of anemia in CKD stage 1-5 (non-dialysis) patients, using the baseline data obtained from a prospective cohort study (KNOW-CKD). Anemia was defined as hemoglobin (Hb) <13 in male and <12 g/dL in female. Iron deficiency was defined when transferrin saturation (TSAT) was <20% or ferritin level < 100 ng/ml.

Results: Anemia was identified in 45% of 1,416 subjects at baseline. Iron deficiency by current criteria was found in 30-50% of male and 50-70% in female CKD patients. Hb

level decreased significantly once TSAT lowered to < 20%. In contrast, high ferritin level (>500 ng/ml) instead of low ferritin (<100 ng/ml), was associated with low Hb. TSAT was independently associated with anemia (OR 3.9 with TSAT 10-19% compared to 30-50%; OR 3.0 with TSAT < 10%, both P<0.01), when adjusted for gender, age, diabetes, serum albumin and logCRP. There were no significant correlation between serum ferritin and C-reactive protein (CRP) or serum albumin.

Conclusions: Low TSAT (<20%) was associated with anemia of CKD, whereas low serum ferritin level was not correlated to Hb level.

PUB121

The Relation between Pulmonary Hypertension, Peripheral Vascular Calcification, and Major Cardiovascular Events in End Stage Renal Disease Patients Undergoing Dialysis

Sun Chul Kim, Hyojeong Chang, Myung-Gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Korea Univ Anam Hospital.*

Background: Pulmonary hypertension (PHT) is a recently recognized complication of chronic kidney disease and end-stage renal disease (ESRD). In this study we investigated the association between pulmonary hypertension, peripheral vascular calcifications (VCs), and major cardiovascular events.

Methods: In this retrospective study, we included 172 ESRD patients undergoing dialysis (HD=84, PD=88) who had enrolled previous cross-sectional study in March 2009. PHT was defined as an estimated pulmonary artery systolic pressure of more than 35mmHg using echocardiography. Simple vascular calcification score (SVCS) was measured using plain radiographic films of both hand and the pelvis.

Results: The prevalence of PHT was significantly higher in HD patients (57.1% versus 25.0%, p<0.001). ESRD patients with PHT had significantly higher prevalence of severe vascular calcifications (SVCS≥3), and mitral valve disease. They were older, and had higher left ventricular (LV) mass index. In multivariate analysis, the presence of severe VCs (OR, 2.42, p=0.02) and mitral valve disease (OR, 7.11, p<0.001), undergoing hemodialysis (OR, 3.72, p<0.001), and higher LV mass index (OR, 1.01, p=0.04) were independent risk factors for PHT. The patients with PHT had a significantly shorter event-free survival of major cardiovascular events (Log Rank test, p<0.01). In a multivariable Cox regression model, high parathyroid hormone group (HR 4.73, p=0.046), lower hemoglobin levels (HR 0.131, p=0.021), and the presence of severe VCs (HR 4.45, p=0.007) and PHT (HR 3.80, p=0.020) were significant predictors for major cardiovascular events.

Conclusions: The prevalence of PHT was higher in HD patients and is associated with higher major cardiovascular events. The presence of severe vascular calcifications is thought to be independent risk factor for predicting PHT in ESRD patients. Therefore, in ESRD patients with PHT, careful attention should be paid to the presence of vascular calcifications and the occurrence of major cardiovascular events.

PUB122

Risk Factors for Discontinuation of Cinacalcet

Diane Reams,[1] Paul Dluzniewski,[2] Thy P. Do,[2] Brian D. Bradbury,[2] A. V. Kshirsagar,[1] M. Alan Brookhart.[1] *[1]UNC, Chapel Hill, NC; [2]Amgen Inc., Thousand Oaks, CA.*

Background: Predictors of cinacalcet discontinuation and levels of parathyroid hormone (PTH) and calcium (Ca) prior to discontinuation have not been previously reported. We examined predictors of cinacalcet discontinuation and biochemical levels prior to discontinuation in a large population of patients receiving chronic hemodialysis (HD).

Methods: Using data from the United States Renal Data System merged with clinical data from a large dialysis provider, we identified new users of cinacalcet from 2007 through 2010 using Part D prescription claims. Patients received in-center HD and were 18 years or older with continuous Medicare coverage during the study period. New users were identified as patients with at least one 30-day cinacalcet prescription fill and no cinacalcet use 6 months prior to the initial prescription. Covariates, including cardiovascular and renal risk factors, laboratory values, and medications, were assessed in 30-day intervals following cinacalcet initiation. Movement between quintiles of laboratory distributions was examined to determine changes in biochemical levels prior to discontinuation. We calculated hazard ratios (HR) and 95% confidence intervals (CI) for the risk of cinacalcet discontinuation.

Results: We identified 17,791 eligible cinacalcet initiators who contributed 101,147 30-day follow-up intervals. Over half of all patients discontinued cinacalcet by month 4. Proximal PTH levels <150pg/mL were associated with discontinuation: HR = 1.23 (95% CI: 1.11-1.36), whereas low Ca (<7.5 mg/dL) was only weakly associated, HR = 1.10 (95% CI 0.92-1.32). Entering the Medicare Part D gap period increased discontinuation risk: HR = 1.19 (95% CI: 1.00-1.42), and low-income subsidy status decreased the risk of discontinuation: HR = 0.77 (95% CI 0.69-0.86). Increasing PTH and Ca levels: HR = 1.15 (95% CI: 1.08-1.23) and HR = 1.23 (95% CI: 1.15, 1.31), respectively, may be early markers of discontinuation.

Conclusions: Early discontinuation following cinacalcet initiation is common, and occurs frequently for clinical or economic reasons. It also appears that an unanticipated increase in biochemical levels may be an early marker of patient discontinuation.

PUB123

Low Plasma Level of Cathelicidin Is Associated with Decreased eGFR

Ha Yeon Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: Infectious complications are a frequent cause of hospitalization in patients with chronic kidney disease, and the second leading cause of mortality after cardiovascular disease. Infectious mortality rates increased with lower kidney function. This study assessed plasma cathelicidin, 25-OH vitamin D, and natural killer (NK) cell which play an important role in innate immunity.

Methods: The study cohort included175 patients who have a variety of estimated glomerular filtration rate (eGFR) at the Chonnam National University Hospital. Plasma catehlicidin levelwas measured by ELISA and absolute count of NK cell was determined by flow cytometry. NK cell was identified phenotypically as CD3-CD56+.

Results: The study population was divided into 3 groups according to the eGFR:Group I, eGFR ≥ 60 mL/min/1.73 m^2, n=33 (18.9%); group II, 15 ≤ eGFR < 60 mL/min/1.73 m^2, n=47 (26.8%); group III, eGFR < 15 mL/min/1.73 m^2, n=95 (54.3%), respectively. Plasma cathelicidin level was decreased with lower eGFR (189.3 ± 18.21 ng/ml in group I, 182.6 ± 17.69 ng/ml in group II, and 179.7 ± 17.76 ng/ml in group III, P=0.032, respectively). On the other hand, percentages and absolute numbers of NK cells were significantly higher in the peripheral blood of patients wtih lower eGFR(1897.7 ± 1584.05 in group I, 2110.8 ± 2168.37 in group II, and 2833.8 ± 2149.65 in group III, P=0.034, respectively). A 25-OH Vitamin D was not distinguish in these groups, but after an exclusion of pateints with hemodialysis, 25-OH vitamin D level showed decreasing tendency with lower eGFR (16.4 ± 6.22 ng/ml in group I, 12.4 ± 4.74 ng/ml in group II, and 11.2 ± 4.96 ng/ml in group III, P=0.166, respectively).

Conclusions: The plasma cathelicidin level was significantly decreased with lower eGFR while an absolute count of NK cell was increased with lower eGFR, which might be associated with dysfunction of NK cell. After an exclusion of patients with hemodialysis, 25-OH vitamin D concentiration showed decreasing tendency with lower eGFR. Further research is needed to determined NK cytotoxicity and understand the mechanisms of decreased innate immunity affecting infectious mortality in chronic kidney disease.

Predicting Coronary Artery Disease in Chronic Kidney Disease Patients Referred for Kidney Transplant Using a Novel Risk Score

Raven A. Voora,[1] Randal K. Detwiler,[1] A. V. Kshirsagar,[1] Alan L. Hinderliter.[2] *[1]UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC; [2]Div of Cardiology, Univ of North Carolina, Chapel Hill, NC.*

Background: Evaluation for CAD is an important aspect of the pre-operative assessment of transplant candidates. Currently, there is no well-established risk calculator to assess the likelihood of CAD in CKD patients. We examined traditional and non-traditional risk factors in CKD patients referred to the University of North Carolina Transplant Clinic to create a simple risk score to predict CAD in kidney transplant candidates.

Methods: The risk score was derived from a cohort of CKD patients referred for cardiac evaluation prior to possible kidney transplant. The average age of our cohort (n = 1028) was 56 ± 11 years; 56% were male and 60% were African-American. 779 (76%) patients had Stage-5D CKD and 205 (20%) had CAD.

Results: In a multivariate logistic regression analysis, the following variables were significant (p<0.05) independent predictors of CAD: smoking history [OR 2.0 (CI 1.5-2.8)], presence of peripheral arterial disease (PAD) or cerebrovascular disease (CVD) [OR 1.8 (CI 1.3-2.6)]; white race [OR 2.2 (CI 1.6-3.0)], diabetes [OR 2.0 (CI 1.5-2.9)], and end-stage-renal-disease (ESRD) status [OR 1.9 (CI 1.3-2.8)]. Variables that were not significant independent predictors of CAD included: gender, BMI, duration of diabetes, systolic and diastolic blood pressure, lipid levels, C-reactive protein, and homocysteine. Since the independent contributions of smoking history, PAD or CVD, white race, diabetes, and ESRD to the risk of CAD were roughly equivalent, we assigned one point to each of these risk factors and defined the risk score (ranging from 0 to 5) as the sum. In our derivation cohort, the prevalence of CAD was 0% when the risk score was 0; 9% with a score of 1; 17% with a score of 2; 25% with a score of 3; 43% with a score of 4; and 69% with a score of 5.

Conclusions: Using our cohort of patients, we derived a simple risk score for CAD prediction in CKD patients. If validated in other populations, this score may prove useful in guiding the evaluation of patients referred for kidney transplantation.

PUB125

N-Terminal Pro-B-Type Natriuretic Peptide and Proadrenomedullin Reflect Volume Status in Hemodialysis and Peritoneal Dialysis Patients

Sihyung Park,[1] Kyubok Jin,[1] Bongsoo Park,[1] Jeong Nyeo Lee,[2] Yang Wook Kim.[1] *[1]Dept of Internal Medicine, Inje Univ Haeundae Paik Hospital, Busan, Republic of Korea; [2]Dept of laboratory Medicine, Inje Univ Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: Although control of normal hydration state is a key parameter for cardiovascular mortality in dialysis patients, the question for biomarkers of volume excess continues. Body composition monitor (BCM; Fresenius Medical Care, Bad Homburg, Germany) has been proven as a non-invasive, quantitative method for measuring body fluid status. In addition, N-terminal pro-B-type natriuretic peptide (NT-proBNP), myeloperoxidase (MPO), copeptin and proadrenomedullin are associated with cardiac dysfunction and systemic blood volume. Present study investigated the relationship between body fluid status and volume markers in dialysis patients.

Methods: Cohorts of pre-dialysis (pre-D), hemodialysis (HD) and peritoneal dialysis (PD) patients and age-and gender-matched healthy individuals were recruited in the study (N=80). In all patients BCM and echocardiography were performed. HD patients were measured at the midweek session before dialysis and PD patients were measured with a full abdomen. Also NT-proBNP, MPO, cepeptin and proadrenomedullin were measured. Clinical overhydration was defined as an overhydration-to-exracellular water ratio of > 15%.

Results: No difference was found the groups in terms of total body water, extracellular water and intracellular water. Clinical overhydration was more prevalent in HD and PD patients compared to control and pre-D patients significantly. This was associated with significantly ($p<0.001$) higher NT-proBNP and proadrenomedullin levels in HD and PD patients than in the control and pre-D groups. However, no significant difference was found in levels of MPO and copeptin in the study groups. In multivariate models, clinical overhydration was directly related to NT-proBNP and proadrenomedullin concentrations in the study population ($r=0.454$ [$p<0.001$] and $r=0.505$ [$p<0.001$]).

Conclusions: NT-proBNP and proadrenomedullin levels increase in association with systemic blood volume in HD and PD patients with cardiovascular disease, however, MPO and copeptin are not volume markers.

PUB126

Renal Insufficiency Evolution in Patients with Relapsed Multiple Myeloma: Preliminary Results of a Large Observational Study Enrique Morales,[1] Antoni García,[2] Fernando Escalante,[3] Soledad Duran,[4] Mercedes Gironella,[5] Tomas J. Gonzalez,[6] Manuel Perez,[7] Ignacio Espanol,[8] Elena Cabezudo,[9] Javier De la Rubia.[10] *[1]H 12 Octubre; [2]H U Arnau de Vilanova; [3]H Leon; [4]H U Ciudad de Jaen; [5]H Vall d´Hebron; [6]H U de Burgos; [7]C H U de Santiago; [8]H Santa Lucía; [9]H Althaia; [10]H la Fe.*

Background: Patients(pts) with RRMM have commonly(20-40%) impaired renal(IR) function, associated with a shorter survival. In RRMMpts, renal response to anti-myeloma drugs according to MDRD, CKD-EPIformulas has not been described prospectively. Aims: Describe renal response in RRMM pts with IR function(CrCl<50ml/min), myeloma response rate(IMWG-criteria), overall survival, safety, and health resource use. We show a descriptive analysis of the first 100pts.

Methods: Spanish observational, prospective, multicenter ongoing study:300RRMM pts with moderate(50-30ml/min)(n=225)/severe (<30ml/min)(n=75)IR function. Planned follow up: 36 months after end of therapy.

Results: 50 out of the first 100pts presented moderate IR function and 50 severe. At study entry 50%, 34% and 16% of pts were in 1st, 2nd and ≥3rdrelapse, respectively. At relapse, 64%pts had anemia, 37%bone lesions, 19%hypercalcemia, and 11%extramedullary plasmacytomas. Anti myeloma therapies were based on lenalidomide, 37%; or bortezomib 39%.

Conclusions: In a high percentage, RRMMpts with IR are elderly with concomitant diseases(IR-associated) that affect diagnosis and further evolution. It is essential to apply glomerular filtration formulas to properly assess renal function in these pts. As in non-IR pts, most frequent anti MM therapies are based on lenalidomide or bortezomib. Further analysis will be available when more pts were included.

PUB127

Simple Renal Cysts Were Associated with Renal Dysfunction and Hypertension Jian Hui Yang, Qiang He, Yiwen Li. *Nephrology, Zhejiang Provincial People's Hospital, Hangzhou, Zhejiang, China.*

Background: The relationship between simple renal cysts are not well understood. Present study was to investigate the impact of simple renal cysts on renal function and blood pressure.

Methods: 99Tcm-DTPA renal dynamic imaging were performed in sixty-eight patients with spiral computed tomography proven single simple renal cysts. Forty healthy people were used as normal control. Their single renal glomerular filtration rate, fractional blood flow, time to peak secretion, time to half excretion, location of cysts, diameter of cysts were recorded. All the clinical features,especially blood pressure and serum creatinine, were monitored before and after ultrasound-guided ethanol sclerotherapy.

Results: Sixty-five patients' renal cysts located inside kidney area. Their diameters of cysts ranged from 4.6cm to 16cm. Their fractional blood flow (FRB) and single glomerular filtration rate (sGFR) in the intact kidney of patients were not significantly different from those in normal controls(47±9 versus 45±8ml/min, 55±6 versus 53±5%), but significantly higher than those of affected kidney(38±8ml/min, 35±7%). The time to peak secretion and time to half excretion were obviously pre-longed in affected kidney compared with intact kidneys(3.4±0.7 versus 4.6±0.6min; 10.1±7.1 versus 15.3±8.2min). FRB and sGFR were negatively relative to the diameter of renal cysts. After ethanol sclerotherapy, their serum creatinine level and diastolic blood pressure decreased obviously(from 95±11 to 88±10 μmol, from 84±12 to 80±11 mmHg). However, there were three patients whose simple renal cysts located outside the kidney areas. Their FRB and sGFR did not differ between affected and intact kidneys.

Conclusions: Simple renal cysts might affect renal function and blood pressure, they should be treated in time.

PUB128

Sleep Disorder and mRNA Expression Profile of Sleep Related Gene on Peripheral Blood Cells in CKD Patients Shinji Kitajima, Yasuyuki Shinozaki, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

Background: Although uremic substances would be candidates involved in sleep disorder, detailed mechanisms remain unclear so far. In this study, we evaluated polysomnography analysis and mRNA expression profile on peripheral blood cells (PBC) in CKD/HD patients.

Methods: Polysomnographic analysis was performed in 9 patients with CKD and 6 healthy subjects. Sleep and awakening related genes were evaluated by RNA microarray in 19 patients, including CKD/HD patients and control subjects.

Results: Polysomnographic analysis revealed that the magnitude of REM/non-REM phase in total sleep time was different between CKD patients and healthy control. In mRNA microarray evaluation, hierarchial clustering analysis showed the different pattern of sleep related gene expression in the patients with HD. The mRNA expression levels of GABA receptor, noradrenaline receptor, dopamine receptor and histamine receptor showed an inverse correlation with renal function. Moreover, orexin and its receptor mRNA expression also showed an inverse correlation with renal function.

Conclusions: These data raise the possibility that sleep related gene expression on PBC in CKD/HD patients may be associated with sleep disorder.

PUB129

Concomitant Intravenous Iron Use Drives Change in Iron Indices Across Geographical Regions in a Sucroferric Oxyhydroxide Study Stuart M. Sprague,[1] Adrian Covic,[2] Jürgen Floege,[3] Markus Ketteler,[4] Bruce S. Spinowitz,[5] Jaco Botha,[6] Anjay Rastogi.[7] *[1]NorthShore Univ Health System; [2]'Gr. T. Popa' Univ of Medicine and Pharmacy, Romania; [3]RWTH Univ Hospital Aachen, Germany; [4]Coburg Clinic and KfH-Dialysis Center, Germany; [5]New York Hospital Queens; [6]Vifor Pharma, Switzerland; [7]Univ of California.*

Background: A randomized Phase 3 study assessed sucroferric oxyhydroxide (SFO; VELPHORO®/PA21), an iron-based phosphate binder, versus sevelamer carbonate (SEV) in dialysis patients. This *post hoc* analysis compared iron indices in patients with or without concomitant intravenous (i.v.) iron across regions: EU, U.S.A. and other countries.

Methods: 1,059 patients were randomized to SFO (1.0–3.0 g/day) or SEV (2.4–14.4 g/day) for 12 weeks' dose titration plus 12 weeks' maintenance. Eligible patients enrolled in a 28-week extension study.

Results: 549 patients completed the extension study. A higher proportion of U.S.A. patients received i.v. iron: SFO (93.2%) and SEV (92.5%) versus EU (69.4%; 77.8%) and other countries (37.8%; 45.1%). Changes in mean iron indices by region are shown in the Table.

Table: Iron indices by i.v. iron use.

	SFO n=322		SEV n=227	
	i.v. iron n=237	No i.v. iron n=85	i.v. iron n=183	No i.v. iron n=44
Δ Ferritin, ng/mL

USA	240.5*# ± 362.7	−52.9 ± 450.5	81.7 ± 455.3	−166.0 ± 477.6
Other countries	158.2* ± 326.2	40.0 ± 362.1	73.8 ± 268.0	31.4 ± 160.9
Δ TSAT, %				
EU	3.7 ± 18.7	7.9 ± 17.0	2.4 ± 15.8	0.7 ± 6.8
USA	5.3* ± 21.5	−6.6 ± 15.7	1.4 ± 17.0	−4.9 ± 8.0
Other countries	6.0*# ± 14.4	3.3 ± 13.6	−0.4 ± 11.6	3.3 ± 13.1
Δ Hb, g/L				
EU	3.3*# ± 10.6	−1.4 ± 12.4	−2.1 ± 11.2	−6.1 ± 6.9
USA	−3.3* ± 12.6	−3.9 ± 17.3	−3.0* ± 10.9	0.6 ± 10.2
Other countries	4.8* ± 18.4	7.7* ± 19.2	1.2 ± 13.6	6.0 ± 17.4

Data are mean changes (baseline to endpoint [last post-baseline non-missing value]) ± standard deviation.
*P<0.05 baseline to endpoint change; #P<0.05 SFO vs SEV in i.v. iron groups.
TSAT, transferrin saturation; Hb, hemoglobin.

Conclusions: Changes in iron indices across regions in both study arms were mainly attributable to concomitant i.v. iron use. Differences between treatment groups may be due to minimal iron uptake from SFO, although no signs of iron accumulation or overload were observed.

Funding: Pharmaceutical Company Support - Vifor Pharma

PUB130

Active Involvement of Erythrocyte Asymmetric Dimethylarginine in Renal Anemia Miyuki Yokoro,[1] Seiji Ueda,[1] Daisuke Saigusa,[2] Nana Obara,[1] Yosuke Nakayama,[1] Ryotaro Ando,[1] Takaaki Abe,[3] Seiya Okuda.[1] *[1]Div of Nephrology, Dept of Medicine, Kurume Univ School of Medicine, Kurume, Kurume City, Fukuoka, Japan; [2]Dept of Integrative Genomics, Tohoku Medical Megabank Organization, Tohoku Univ, Sendai City, Miyagi, Japan; [3]Dept of Clinical Biology and Hormonal Regulation, Tohoku Univ, Sendai City, Miyagi, Japan.*

Background: Asymmetric dimethylarginine (ADMA) have been reported to be accumulated and play important role in vascular injury in chronic kidney disease (CKD) patients. Recently, we have reported that rat erythrocyte could be one of modulator of plasma ADMA levels. In addition, L-arginine was reported to be an essential factor for erythrocyte maturation. However, erythrocyte ADMA metabolic system and its involvements in renal anemia in CKD patients are still unknown.

Methods: We collected blood samples of 16 healthy subjects and 25 non-dialysis CKD patients. The expression of DDAH, ADMA-degrading enzyme, and PRMT, ADMA-producing enzyme, were determined by western blotting. ADMA concentrations were measured by LC-MS/MS.

Results: We found that DDAH and PRMT were expressed in human erythrocytes. Compared to healthy control, DDAH expressions in erythrocytes were significantly decreased and ADMA levels were markedly higher in CKD patients. Ex vivo analysis revealed that cultured erythrocyte can immediately take in ADMA, which was completely abolished by L-lysine, a competitive inhibitor of cationic amino acid transporter, suggesting that erythrocyte may regulate circulating ADMA through cationic amino acid transporter. In addition, erythrocyte ADMA levels were found to be negatively correlated to RBC count ($r = -0.467$, $p < 0.05$), and tended to be positively correlated to serum ferritin level ($r = 0.392$, $p = 0.087$) and plasma hepcidin level ($r = 0.463$, $p < 0.05$).

Conclusions: Although further evidence is needed, the present study suggests that erythrocyte could be a modulator of ADMA in CKD patients and erythrocyte ADMA accumulation may have a role in the development of renal anemia.

PUB131

Anti-Müllerian Hormone Levels and Sperm Quality Are Decreased in Men with Terminal Renal Failure Anders G. Christensson, Laila Bruun, Dag Eckersten. *Dept of Nephrology, Clinical Sciences, Malmö, Sweden.*

Background: Male reproductive function is impaired in end-stage renal disease (ESRD). Disturbances in the hypothalamic-pituitary-gonadal axis is one of the major causes. Earlier studies have shown elevated levels of prolactin, luteinizing hormone (LH) and follicle-stimulating hormone (FSH).It has also been demonstrated decreased levels of testosterone. Anti-müllerian hormone (AMH), produced by the Sertoli cells in the testes inhibits the production of androgens, and is a marker for Sertoli cells and testicular function. AMH in healthy men is correlated with non-obstructive azoospermia. It has not been studied in men with ESRD. This study is aimed at studying AMH and inhibin B in men with ESRD.

Methods: Twenty male patients on hemodialysis, median age 40 (26-48) years, were analysed for follicle-stimulating hormone, luteinizing hormone, prolactin, sex hormone-binding globulin, testosterone, estradiol, anti-müllerian hormone and inhibin B levels. Furthermore, semen quality parameters were analyzed in 7 of these patients. We used 144 proven fertile men, median age 32 (19-44) years, as a control group to find differences by using multiple linear regression.

Results: Males with end-stage renal disease demonstrated higher mean values for prolactin, 742 versus normals 210 mIE/L (95%CI 60.3, 729), luteinizing hormone, 8.87 versus normals 4.5 IE/L (95%CI 2.75, 6.14), and estradiol 89.7 versus normals 79.0 pmol/L (95%CI -1.31, -0.15). Mean value for anti-müllerian hormone was lower, 19.5 versus normals 47.3 pmol/L (95%CI -37.6, -11.6). There were no differences regarding follicle-stimulating hormone, sex hormone-binding globulin, inhibin B and testosterone. The seminal analyses revealed low sperm count and decreased motility.

Conclusions: We conclude that the most important difference was found for anti-müllerian hormone, a marker of Sertoli cell function in the testes, that was decreased by close to 60% compared to controls. Combined with an increase in luteinizing hormone, these findings may indicate a dysfunction of Sertoli cells and an effect on Leydig cells contributing to a potential mechanism of reproductive dysfunction in men with end-stage renal disease.

PUB132

Low Activities of Daily Living Related to Be Unstable on Hemodynamicsduring Dialysis Therapy Atsushi Ueda,[1] Aki Hirayama,[2] Kei Nagai,[3] Chie Saito,[3] Kunihiro Yamagata.[3] *[1]Nephrology, Hitachi General Hospital, Hitachi, Japan; [2]Integrated Medicine, Tsukuba Univ of Technology, Tsukuba, Japan; [3]Nephrology, Univ of Tsukuba, Tsukuba, Japan.*

Background: In hemodialysis (HD) patients, hemodynamics is unstable during dialysis therapy. Improvements of activities of daily living (ADL) may affect beneficial effects on hemodynamics during the HD therapy. We investigated the change of blood pressure during HD session and laboratory data divided into ADL levels.

Methods: We employed retrospectively 47 HD patients treated regularly. They were divided into three groups. 1)Wheelchair group (n=9); in need ofawheelchairwhen moving, 2) DM group; diabetes mellitus and a free standing ADL (n=16), 3) NDM; non-diabetes and a free standing ADL (n=22).a) Systolic blood pressure at the start of dialysis, b) lowest systolic blood pressure during dialysis, c) systolic blood pressure difference between a) -b) were measured on recent dialysis session. Daily urinary volume and laboratory data were measured between at the time of initial dialysis therapy and after one year respectively.

Results: There were significant differences in NDM group (22.5±14.6 mmHg) and the wheelchair group (69.6±35.3) on the systolic blood pressure difference c). However, there were no significant differences on ultrafiltration volume. The urine volume in the wheelchair group was dramatically decreased one year after the initiation of dialysis. Serum albumin in the wheelchair group was significantly decreased at initial dialysis period, however the difference had disappeared after one year. As for serum creatinine, there was no difference among the three groups in the introduction of dialysis therapy, however that in the wheelchair group was significantly decreased (8.2 ± 2.4 mg/dL) compared to that of the NDM groups (11.5 ± 2.9) one year after the initiation.

Conclusions: The wheelchair group with reduced ADL decreased markedly in systolic blood pressure during the dialysis session. Despite of this group showed an improvement of serum albumin level after one year of dialysis, serum creatinine was reduced. This suggests that a decrease in motor function leads to a decrease in muscle mass, which leads to blood pressure regulation declined during dialysis.

PUB133

Iron Status and Inflammation in Early Stages of Chronic Kidney Disease Jolanta Malyszko, Ewelina Lukaszyk. *2nd Dept Nephrology, Medical Univ, Bialystok, Poland.*

Background: One of the potential mechanisms of anaemia in chronic kidney disease is functional iron deficiency, where iron availability for erythropoiesis is reduced despite normal iron resources in the body. Iron status is regulated by number of factors including inflammation, hepcidin production, dietary intake etc. Due to subclinical inflammation accompanying chronic kidney disease there is a need to look for pathomechanisms responsible for developing this kind of anaemia, which may contribute to improve the effectiveness and rationalization of aneamia treatment in this population. The aim of the study was to assess iron status in patients in early stages of chronic kidney disease, prevalence of anaemia in this population, iron correlation with inflammation parameters and others potential iron concentration regulators.

Methods: The study group consisted of 80 patients with the diagnosis of early stage chronic kidney disease in 46% of cases. We assessed plasma and serum levels of following parameters: creatinine, urea, haemoglobin, iron concentration, transferrin saturation (TSAT), ferritin, high sensitive C-reactive protein (CRP), fibrinogen, hepcidin, hemojuvelin, GDF-15, interleukin-6, sTfR and performed statistical analysis.

Results: In over 42% of cases in patients in early stages of chronic renal disease iron concentration was below normal values. In the half of this cases iron deficiency was classified as functional. Iron deficiency (absolute and functional) was more often associated with increased fibrinogen concentration (p=0,02) and CRP concentration (p=0,001). We also revealed that concentration of GDF-15 (p=0,029) and sTfR (p=0,001) is higher in patients with functional iron deficiency. However, there was no statistically significant difference in the level of hepcidin, hemojuvelin and interleukin-6 level in groups with and without iron deficiency.

Conclusions: Iron deficiency may parallel deterioration in kidney function. Moreover, functional iron deficiency is associated with inflammation, which is reflected by elevated CRP and fibrinogen hence it requires the evaluation for inflammation before treatment.

PUB134

Stenosis Diameter Predicts Outcome after Intervention for Renal Artery Stenosis Neeraj Kohli, Wladyslaw M. Gedroyc, Neill D. Duncan, Damien Ashby. *West London Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

Background: Renovascular disease is increasingly recognised as a cause of renal impairment but the role of endovascular intervention in this setting is unclear. Recent multi-centre trials have established that revascularisation does not improve renal prognosis in the average patient, but many clinicians believe that there is a subgroup of patients who benefit.

Methods: In this retrospective single-centre cohort study we included all patients who had renal angioplasty during a 2 year period for whom 12 month follow-up data were available. Patient outcomes were defined according to change in creatinine in the 3 years post intervention, with ordinal outcome scores assigned: 1= improved by 20umol/l; 2= no change; 3= declined by 20-100umol/l; 4= declined by more than 100umol/l, died or started dialysis during follow-up.

Results: Sixty-two patients (aged 51-85, 74% male) underwent angioplasty which was bilateral or to a single functioning kidney in 33% of cases. Outcome scores 1 to 4 were seen in 12.9, 43.5, 24.2 and 19.4% of patients. Absolute stenosis diameter increased across outcome group (mean 1.2, 2.2, 2.4 and 2.4mm) with stenosis diameter significantly correlated with outcome group (R=0.324, p=0.010). Percentage stenosis diameter was not related to outcome. Outcome score 1 was seen in 24% of patients with diameter less than 2mm, and only 5% of patients with diameter over 2mm (p=0.067).

Conclusions: Heterogeneity of outcome can be expected after intervention for renal artery stenosis. Patients benefitting from the procedure have tighter absolute stenosis diameter.

PUB135

Appetite, Body Mass Index and Energy Intake in Predialysis Patients Anita Saxena,[1] Amit Gupta,[1] Anil Bhalla,[2] Georgi Abraham.[3] *[1]Nephrology, SGPGIMS, Lucknow, Uttar Pradesh, India; [2]Nephrology, Sir Ganga Ram Hospital, New Delhi, UT, India; [3]Nephrology, Madras Medical Mission, Chenai, Tamil Nadu, India.*

Background: Dietary intake and nutritional status of CKD patients on first visit to a nephrology center was assessed to evaluate when malnutrition sets in.

Methods: Three days dietary recall of 141 patients in CKD stage 3 and 4 (GFR <60ml/min1.73 m^2) was taken.

Results: Serum albumin was 2.87± 2.10 and 3.56±0.58; total serum protein and proteinuria was 2+ in males and females respectively. Out of 140 patients, 74 (52.8%) had normal BMI, 21 (15%) were underweight, 8 (5.71%) were severely underweight and 38 (27.1%) overweight. Weight (p 0.000), appetite (0.004), dietary intake, fluid intake (0.001), energy (0.004) carbohydrate (0.003), potassium (0.019), phosphorus (0.036) and iron (0.011) between four BMI groups was significantly different. Energy intake based on BMI was 19.4 ±7.92/18.6±13.5 in normals, in underweight 14.5±11.0 and 12.46±10.6, in severely underweight 16.2±14.9 and 18.4±6.5 and in overweight 19.4±8.8 and 18.9±6.0 kcal/kg/d in males andfemales. In normals protein intake was 0.73 ±0.31 and 0.65±0.35; in underweight 0.55±0.63 and 0.42.±0.56 and, in severely underweight 0.57±.53 and 0.87±.31, overweight 0.62±.21 and 0.67±.18. Appetite significantly correlated (p 0.000) with weight, BMI, dietary energy protein, fat, serum albumin and creatinine. BMI was significantly correlated (0.000) with dietary energy, protein and carbohydrate, creatinine and serum total protein and proteinuria. Based on appetite energy and protein intake in male patients with normal appetite was 29.9±4.6 and 1.0±.38, with average 20.7±3,9 and 0.79±.2; poor 18.8±6.4 and 0.69±0.24 and anorexic in 0.39±0.36 and 9.9±6.1 respectively. In females energy and protein intake in patients with normal appetite was 31.3 ±8.2 and .97±.16, in average 26.3 ±8.6 and .94±.49, in poor 17.6±4.9 and 0.69 ±0.17 and in anorexic12.2±5 and 0.64±0.45.

Conclusions: Inadequate dietary intake, body mass index (BMI) and low serum albumin and protein are markers of malnutrition in predialysis population. Appetite, BMI and albuminuria are associated with low energy intake and have synergistic effect on low serum and protein levels in CKD stage 3 and 4 patients.

PUB136

HA Clinical Study of the Efficacy of YiShenXieZhuo Decoction in Patients with Chronic Kidney Disease and Hyperuricemia Lin Wang,[1] Pan Gan,[2] Shenfu You,[1] Xianwen Zhang,[1] Yueyi Deng,[1] Niansong Wang,[3] Min Yin,[4] Lanping Du,[1] Yiping Chen.[1] *[1]Longhua Hospital, Shanghai, China; [2]Shanghai Univ of TCM, China; [3]Sixth People's Hospital, Shanghai Jiao Tong Univ, China; [4]Xuhui District Central Hospital, China.*

Background: Hyperuricemia (HUA) is associated with the development and progression of chronic kidney disease (CKD). YiShenXieZhuo Decoction (YS) is a Chinese herbal medicine prescription used to treat chronic kidney failure accompanied by HUA in Long Hua Hospital for decades. To evaluate the efficacy of YS, we conducted retrospective cohort and prospective cohort studies.

Methods: In the retrospective study, 66 patients were treated with YS only and 49 patients were treated with YS plus allopurinol. Serum creatinine (SCr), estimated glomerular filtration rate (eGFR), uric acid (UA), and blood urea nitrogen (BUN) levels were measured and compared in these two groups 1-year. 2-years and 3-years after treatment. The decrease in eGFR-slope was subjected to hazard function analysis. In the prospective cohort study, fifty patients were treated with YS (treatment group, N = 27) or allopurinol (control group, N = 25) for 12 weeks. The SCr, eGFR, UA and BUN of the two groups were measured and compared.

Results: In the retrospective cohort study, both treatment groups showed significantly decreased SCr levels and increased eGFR levels at all points evaluated, compared to baseline. There was no difference in the UA levels of the two groups at one year. eGFR-slope of both groups increased significantly after 1 year of treatment and slightly more in the following 2 years. However, the hazard ratios of eGFR-slope decrease of the two groups were not statistically different. In the prospective cohort study, patients in the treatment group had a significantly lower SCr and UA levels and improved eGFR, compared to the control group. The UA levels of the control group decreased significantly, but the SCr and eGFR levels did not improve.

Conclusions: YS significantly improved the renal function of CKD patients with HUA. The effect of YS was not mediated by its UA lowering properties. Allopurinol lowered serum UA levels but did not improve renal function.

PUB137

The Need for a Dedicated Nephro-Oncological Evaluation of Nephrectomized Cancer Patients Receiving or Not Active Oncological Treatment Laura Cosmai,[1] Camillo Porta,[2] Marina Foramitti,[1] Wanda Liguigli,[3] Fabio Malberti.[1] *[1]Nephrology, Istituti Ospitalieri, Cremona, Italy; [2]Medical Oncology, IRCC San Matteo Hospital Foundation, Pavia, Italy; [3]Medical Oncology, Istituti Ospitalieri, Cremona, Italy.*

Background: nephrectomized cancer pts have an increased risk of developing chronic kidney disease (CKD); such a risk is higher in those under active Oncological treatment (aTx) due to its possible renal toxicity. Our limited knowledge of these complications and the data suggesting that the survival of kidney donors is greater than that of non-donors, has led us to follow, in a dedicated outpatient Onco-Nephrology Ambulatory, nephrectomized cancer pts with normal kidney function but with concomitant risk factors and nephrectomized cancer pts with CKD; furthermore, pts were either under aTx or just followed-up.

Methods: To date, 127 pts have been referred to us; 51 had stage I-III CKD, 32 stage IV CKD (17 being under aTx) and 23 stage V CKD (13 being on aTx). Pts were evaluated every 3 months for 1 year after nephrectomy if renal function was normal or in case of stage I-III CKD, and then every 6 months (for both followed-up and treated pts); pts with stage IV and V CKD were seen every 30-60 days.

Results: In stage I-III CKD pts no cases of CKD progression were recorded, but 1 case of reversible AKI was observed, together with 2 cases of proteinuria from aTx (which was stopped). Of stage IV CKD pts, 1 developed acute kidney injury (AKI) after heart failure induced by cancer therapy (which was stopped), while 2 others had a worsening of their CKD with the need for aTx dose adjustment. Finally, among stage IV CKD pts, 2 started dialysis treatment, but continued aTx, and 2 more had a reversible episode of AKI due to dehydration.

Conclusions: The role of the Nephrologist in the management of nephrectomized cancer pts, either under aTx or not, is key, potentially leading to relevant benefits: reduced progression of pre-existing CKD, reduced risk of developing de novo CKD, continuation of life-prolonging aTx even in pts with severe CKD or receiving dialysis. Further development of Onco-Nephrology (including dedicated ambulatories) is warranted.

PUB138

Allopurinol Dosing in Stage 4-5 Chronic Kidney Disease Betzaida Rodriguez,[1] Lindsey Norris,[1] Bela Alex Kosztaczky,[2] Zsolt Lengvarszky,[3] Mohit Agarwal,[1] Tibor Fulop.[1] *[1]Dept of Medicine, Univ of Mississippi, Jackson, MS; [2]Dept of Medicine, Danville VAMC, Danville, IL; [3]Dept of Mathematics, Louisiana State Univ, Shreveport, LA.*

Background: Current dosing guidelines recommend major dose reduction of allopurinol in advanced (stage 4-5) Chronic Kidney Disease (CKD). To achieve target uric acid levels, clinician may have to use larger than customary doses in the context of race, obesity and certain dietary habits of the current era.

Methods: We retrospectively reviewed our CKD clinic patients over the last 3 years, where information on both uric acid level and allopurinol dosing were simultaneously available. We collected data on multiple clinical and laboratory parameters for 83 consecutive CKD clinic patients with stage 4-5 CKD (race-adjusted MDRD estimated Glomerular Filtration Rate (eGFR) < 30 mL/min/1.73m^2; 22.9% receiving renal replacement therapy), representing a local urban cohort from the Southeast U.S. Data were analyzed with SPSS v19 and expressed with means (SD) and percent (%).

Results: Mean age of the cohort was 60.6 (12.1) years, weight 93.1 (22) kg with and BMI 33.7 (8.6) kg/m2; 57.8% was female, 77.1% African-American, 49.4% had diabetes and 53% had the diagnosis of gout. Aspirin was used in 51.8% of participants. Mean race-adjusted MDRD eGFR was 21.7 (6.5) mL/min/1.73m^2 [date purged for dialysis patients]. Overall metabolic control was acceptable: potassium 4.2 (0.5) mEq/L; HCO3 24.2 (3.6) mEq/L, phosphorus 4.3 (1.4) mg/dL, hemoglobin 10.8 (1.8) g/dL, albumin of 4.1 (1.2) g/dL; white blood cell count 7.3 (2.3) x1000/mm^3. Mean allopurinol dose was 164 (83) mg/day [median: 100; 25-75%: 100-200 mg/day]; serum uric acid 7.6 (2.5) mg/dL in the entire cohort. Uric acid did not correlate with allopurinol dose, weight, BMI, race or MDRD eGFR in this cohort of patients.

Conclusions: Conventional dosing recommendations for allopurinol dosing in advanced CKD are unlikely to suffice to reach target serum uric acid goals. In our cohort, larger-than-usual allopurinol doses were well tolerated without hematologic side effects.

PUB139

Association of PreS1-Ag, HBeAg, HBV-DNA in the Serum of Patients with Hepatitis B and Chronic Kidney Disease Chenggang Shi, Xun Liu, Cailian Cheng, Qiong-Li Yin, Mei Li, Weizhao Mo. *Dept of Nephrology, the Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: To investigate the relationship between the HBV antigens and hepatitis B and chronic kidney disease (CKD).

Methods: Baseline data, biochemical data and serum virological indicators were analyzed retrospectively between hepatitis B with CKD group and without chronic kidney disease group.

Results: 178 patients were enrolled as the CKD group, and 156 patients as the control group (without CKD). Age, liver functional indicators, renal functional indicators, incidence of liver cirrhosis and serum albumin had significant differences. The percentage of high HBV-DNA copy (>1×10^{5}IU/ml)(P=0.001), the positive rates of HBeAg(P<0.001) had significant differences between the two groups. The positive rates of PreS1 were high both two group(69.1% in experimental group, 65.4% in control group, P=0.54), but not significant differences between the two groups.

Conclusions: The percentage of high HBV-DNA copy (>1×10^{5}IU/ml)and the positive rates of HBeAg is higher of the patients with hepatitis B and kidney injury, and high positive rates of PreS1 of patients with hepatic lesion or kidney injury. The percentage of high HBV-DNA copy(>1×10^{5}IU/ml)and the positive rates of HBeAg tend to the occurrence of chronic kidney disease.

PUB140

Predialysis Patients Intramuscular Hepatitis B Vaccination Response Andre F. Charest, Nimesh Patel, Bharat Nathoo. *Medicine/Div Nephrology, Mackenzie Health Hospital, Richmond Hill, ON, Canada.*

Background: Seroconversion rate to Hepatitis B virus (HBV) vaccination remains low in dialysis patients.It is unclear if HBV vaccination in earlier stages of chronic kidney disease would affect response rate. We conducted a retrospective study to determine which clinical factors predict seroconversion, and effects of booster dose on antibody (Ab) titres.

Methods: Patients were screened for previous HBV vaccination and infection. Patients (n = 153) received a 4-dose Intramuscular (IM) vaccination at 0, 1, 2, and 6 months with 40 mcg recombinant Engerix-B IM and a subset received a single IM booster when Ab levels were <100 IU/L. Ab titres were measured a month after and *responders* were grouped—**low** (10-99 IU/L), **good** (100-999 IU/L), **excellent** (>1000 IU/L).

Results: Clinical factors and eGFR values were compared between *responders* (>10 IU/L) and *nonresponders* (<10 IU/L). Seroconversion occurred in 75%. *Nonresponders* were significantly older (76.8±8.8 versus 68.2 ± 12.8 y;p<0.001) and had greater eGFR (19.7 ±5.6 versus 17.3±5.5 ml/min/1.73m^2;p=0.03) at vaccination. After controlling for age (OR: 0.92 (95CI: 0.88-0.97)) in a multivariate logistical regression, only eGFR at vaccination significantly contributed to seroconversion (OR: 0.92 (95CI: 0.86-0.99)). A subset(n=37) had repeat Ab titres with over 60% of patients still immune after 60 months. Baseline factors did not significantly predict loss of immunity. Ninety percent of patients(**n=19**) receiving a booster dose achieved greater peak Ab titres. Of those with initial **low** titres, 62.5% (5/8) improved to **good** response levels, while 63.6% (7/11) with good initial titres improved to excellent response levels and 36.4% (4/11) remaining at good titres.

Conclusions: We found that older age decreases seroconversion rate.However, higher eGFR did not associate with better outcomes when adjusting for age. All but two patients that received a booster dose achieved greater Ab titres. As higher antibody titres correlate with longer duration of immunity, it is expected that patients with excellent response levels to a booster dose would likely be immune at dialysis initiation. More studies are required with larger cohort.

PUB141

Effect of Tolvaptan on Patients with Chronic Kidney Disease due to Diabetic Nephropathy with Heart Failure Eiichi Sato,[1] Tsukasa Nakamura,[2] Mayuko Amaha,[2] Yoshihiko Ueda.[1] *[1]Dept of Pathology, Dokkyo Medical Univ, Koshigaya Hospital, Koshigaya, Saitama Prefecture, Japan; [2]Div of Nephrology, Dept of Internal Medicine, Shinmatsudo Central General Hospital, Matsudo, Chiba Prefecture, Japan.*

Background: The efficacy of tolvaptan for treating heart failure has already been shown. Adequate data relating to the effect of tolvaptan on the correlation of water balance in renal disease are not available. A retrospective study was conducted on the efficacy and adverse reactions of tolvaptan for treating nephrotic syndrome.

Methods: The subjects of this study were 26 patients with chronic kidney failure of diabetic nephropathy with heart failure who were administered tolvaptan and seen between December 2011 and October 2013. The endpoints were urinary outputs, physical findings, and blood analyses. The expression of aquaporin-2 in the collecting duct which is related to the action of tolvaptan was investigated by immunohistochemistry using the kidney tissues obtained for the diagnosis.

Results: Responders were seen in 19 of the patients. In the histopathological investigation there was severe glomerulosclerosis in patients with diabetic nephropathy, but the responders were noticeable in showing mild tubulointerstitial damage. Non-responders exhibited profound tubulointerstitial damage. The expression of aquaporin-2 was conducted in 8 patients, of which 7 were responders and tested positive for aquaporin-2. The remaining one case was a non-responder and showed noexpression of aquaporin-2.

Conclusions: Tolvaptan is considered effective for some cases of nephrotic syndrome. There are no clear parameters for predicting an effect, but the present study showed that aquaporin-2 was expressed in the epithelial cells of collecting duct of tolvaptan responders.

PUB142

N-Terminal Pro-Brain Natriuretic Peptide and Troponin T Are Linked to Cardiac Dysfunction in Pre-Dialytic and Dialytic Stages of Chronic Kidney Disease Belda Dursun,[1] Hilmi Dogu,[1] Dogu Kilic,[2] Halil Tanriverdi,[2] Rota Simin.[3] *[1]Nephrology, Pamukkale Univ Medical School, Denizli, Turkey; [2]Cardiology, Pamukkale Univ Medical School, Denizli, Turkey; [3]Biochemistry, Pamukkale Univ Medical School, Denizli, Turkey.*

Background: Left ventricular systolic dysfunction, left ventricular hypertrophy and left atrial/ventricular dilatation are determinants of cardiovascular events. Aim to assess the relationship between echocardiographically determined cardiac dysfunction and N-terminal pro-brain natriuretic peptide (NT-proBNP) as well as cardiac troponin T as cardiac-derived biomarkers in pre-dialytic and dialytic chronic kidney disease (CKD) patients.

Methods: 50 nondiabetic patients stage 3-5 CKD, 49 hemodialysis patients and 50 controls were enrolled. Serum NT-pro BNP was measured by ELISA assay. Cardiac troponin T was measured by immunoassay. Left ventricular ejection fraction, left ventricular mass index (LVMI) and volume diameters, left atrial (LA) diameter were echocardiographically measured.

Results: NT-proBNP (pg/ml) was higher in dialysis (1069±763, p=0.000) and predialysis (632±748) patients than controls (379±722, p=0,000). Troponin T (ng/ml) was higher in dialysis (0.024±0.045, p=0.000) and predialysis patients (0.005±0.019, p=0.002) than controls (0). LA volume index (ml/m^2) was higher in dialysis (23.7±7.9, p=0.000) and predialysis patients (21±8.3, p=0,016) than controls (17.4±5.5). LV volume index w(ml/m^2) was higher in dialysis (72.3±16) and predialysis patients (67±13.5; p=0.000) than controls (60.5±14.4, p=0.028). LVMI (g/m^2) was higher in dialysis (132.4±43, p=0.000) and predialysis patients (111.9±42.3, p= 0.003) than controls (87.5±33.4). In predialysis patients, NT-proBNP levels showed positive correlations with LV volume index, while Troponin T levels showed positive correlations with LVMI, LV volume index. In dialysis patients, NT-proBNP levels showed negative correlations with LA volume index, whereas Troponin T levels showed positive correlations with LA diameter, LVMI.

Conclusions: Increased levels of NT-proBNP, and Troponin T levels in both predialytic and dialytic stages of CKD are related to cardiac dysfunction, and these biomarkers may have prognostic value in these patients.

PUB143

Relationship Between Levels of Urinary Full-Length Megalin and Histological Findings in Patients with IgA Nephropathy Takuto Seki,[1,2] Katsuhiko Asanuma,[2,1] Rin Asao,[1] Kanae Nonaka,[1,2] Fumiko Kodama,[1] Yu Sasaki,[1] Miyuki Takagi,[1] Hiroyuki Kurosawa,[3] Yoshiaki Hirayama,[3] Satoshi Horikoshi,[1] Akihiko Saito,[4] Yasuhiko Tomino.[1] *[1]Div of Nephrology, Juntendo Univ Faculty of Medicine, Japan; [2]TMK Project, Medical Innovation Center, Kyoto Univ Graduates School of Medicine, Japan; [3]Reagents Development Dept, Denka Seiken Co. Ltd, Japan; [4]Dept of Applied Molecular Medicine, Niigata Univ Graduate School of Medicine and Dental Sciences, Japan.*

Background: Megalin is highly expressed at the apical membranes of proximal tubular cells. Urinary full-length megalin (C-megalin) assay is linked to the severity of type2 diabetic nephropathy. It is still unknown whether urinary C-megalin is associated with histological findings in IgA nephropathy (IgAN) patients. In this study, we examined the relationship between urinary levels of C-megalin and histological findings in IgAN.

Methods: Urine samples voided in the morning on the day of renal biopsy were obtained from 73 adult patients with IgAN (29 men and 44 women). All renal biopsy specimens were analyzed histologically. Pathologic variables of IgAN were analyzed by the Oxford classification of IgAN and Shigematsu classification. Levels of urinary C-megalin were measured by sandwich ELISA.

Results: Histological analysis based on the Oxford classification revealed that the levels of urinary C-megalin were correlated with tubular atrophy and interstitial fibrosis in IgAN patients without reduced eGFR, but not in all patients. There was a significant correlation between levels of urinary C-megalin and severity of chronic extracapillary abnormalities according to Shigematsu in all patients group and patients without reduced eGFR group.

Conclusions: It appears that the levels of urinary C-megalin are associated with histological abnormalities in adults IgAN patients.

PUB144

Audit of Influenza and Pneumococcal Vaccination in Haemodialysis Patients Qurat Tak, Ajay Prabhakar Dhaygude. *Nephrology, Royal Preston Hospital, Preston, United Kingdom.*

Background: Haemodialysis (HD) is associated with significantly increased mortality, cardio-vascular aetiology being the leading cause. According to U.S. and UK data infection is the second leading cause of death in the dialysis population[1,2]. Respiratory infections including pneumonia is the commonest source and is potentially preventable with vaccinations. The National Health Service offers free Influenza and Pneumococcal Vaccination to patients with chronic kidney disease and patients are actively encouraged and primary care physicians are educated about this. Influenza vaccine is offered every winter

and the Pneumococcal Vaccine should be administered once every five years. In this study we assessed the compliance of our HD patients with the Influenza and Pneumococcal Vaccine.

Methods: We contacted primary care physicians of all HD patients to ascertain vaccination uptake of all prevalent HD patients.

Results: In total there were 115 HD patients. Information was available for 95 patients. Results are presented in Table. Pneumococcal vaccine in last 5 years Pneumococcal vaccine >5 years ago Pneumococcal vaccine declined by pts Influenza vaccine given this season Influenza vaccine given>12 months ago Vaccine declined 15/95 (16%) 15/95 (16%) 6/95 (6.0%) 55/95 (58%) 5/95 (5%) 6/95 (6.0%).

Conclusions: These results suggests

· Pneumococcal vaccine uptake remains poor in HD patients

· Influenza vaccine uptake is better but there is room for further improvement.

Discussion: Improving patients and primary care physicians education is crucial to reduce morbidity and mortality in HD patients of these preventable diseases.

Serum sFas Levels Identify Chronic Kidney Disease Patients at High Risk for Red Blood Cell Transfusion

Miguel A. Goes,[1,2] Maria Eugenia F. Canziani.[1]
[1]Nephrology Div, Univ Federal de São Paulo, Sao Paulo, Brazil; [2]Emergencial Div, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.

Background: Soluble Fas (sFas) levels are increased and associated with anemia in chronic kidney disease (CKD) patients. **Objective:** To evaluate the prognostic value of serum sFas levels for red blood cells (RBC) transfusion in CKD patients.

Methods: A prospective observational cohort study was conducted over 10-year period. A total of 52 CKD patients (32 male) were followed up until year 10 or death. Hemoglobin concentration (Hb), iron status, glomerular filtration rate (GFR), serum levels of sFas and IL-6 were performed at baseline. We observed the necessity of RBC transfusion from baseline. We perform comparisons between the RBC transfusion (group1) and non-RBC transfusion. Binary logistic regression and ROC curve in the group 1 to evaluate the prognostic value.

Results: Seven patients (3F:4M; 52 ±12 years) required RBC transfusion and 45 patients non-RBC transfusion (57±12 years; p=0,34). At baseline we observed that group1 had lower Hb concentration at baseline (11.1±1.5, 12.8±2.2 g/dl; p=0.04) and GFR (25±10, 34±10 ml/min; p=0.04). We observed higher sFas levels (4885±1261, 2847±938;p<0.001) and transferrin saturation(28±11, 22±4%; p=0.02) in group1. We did not observe any difference in serum ferritin and IL-6 levels between the two groups. Serum sFas was an independent predictor of the need for RBC transfusion in binary logistic regression (95%CI=1.003, 1.000-1.005; p=0.03). ROC curve analysis ascertained that the threshold value of sFas with the highest sensibilty/specificity was 3888, with 85.7% and 89%, respectively (AUC 0.937; p<0.001).

Conclusions: These results suggest that initial serum sFas levels could be helpful in identifying CKD patients at high risk of RBC transfusion.

PUB146

Clinical Outcomes of IgA Nephropathy Patients with Different Proportions Crescents

Wang Zhang,[1,2] Qiongqiong Yang,[1,2] Wei Chen,[1,2] Xueqing Yu.[1,2]
[1]Dept of Nephrology, The First Affiliated Hospital, Sun Yet-sen Univ, Guangzhou, Guangdong, China; [2]Key Laboratory of Nephrology, Ministry of Health, Ministry of Health, Ministry of Health, China.

Background: Several clinical characteristics and pathologic parameters have been established to be predictors of renal progression in patients with IgA nephropathy (IgAN), but the prognostic significance of extracapillary proliferation in IgAN is still controversial. We aimed to investigate the effect of different proportions of crescents on the outcome of IgAN patients.

Methods: A retrospective cohort enrolled 565 primary IgAN patients presenting crescents on renal biopsy, and registered in IgAN database of The First Affiliated Hospital of Sun Yet-sen University (http://igan.medidata.cn) from January, 2000 to December, 2011. The endpoint was defined as a composite of (1) doubling of baseline serum creatinine, (2) ESRD (maintenance hemodialysis/ maintenance peritoneal dialysis/renal transplantation), or (3) death.

Results: After a median follow-up time of 44 months (range 12 to 154 months), 84 patients (14.9%) developed the adverse outcomes. The 5-year, 10-year survival rates of IgAN patients with crescents was 83.2%, 53.3% respectively. Crescent proportion (increase by 5%: HR =1.12, 95%CI 1.00-1.24, P=0.048), impaired renal function at baseline (eGFR<60 ml/min per 1.73 m^2: HR=5.27, 95%CI 2.22-12.53, P<0.001), hypertension (HR=2.15, 95%CI 1.13-4.09, P=0.019), proteinuria (HR=1.46, 95%CI 1.18-1.81, P= 0.001), endocapillary hypercellularity (HR=2.22, 95%CI 1.09-4.51, P=0.028), and segmental sclerosis (increase by every 5%: HR =1.25, 95%CI 1.11-1.40, P<0.001) were revealed to be independent predictors of adverse outcomes in multivariate Cox proportional hazard model.

Conclusions: Every 5% increment in crescent proportion carried additional 12% risk of progression in IgAN, which confirmed the unfavorable predictive value of crescent for IgAN patients.

PUB147

Mortality and Causes of Death in Patients with the Syndrome of Rapid Onset End Stage Renal Disease versus "Classic" ESRD in a Mayo Clinic Northwestern Wisconsin Hemodialysis Unit

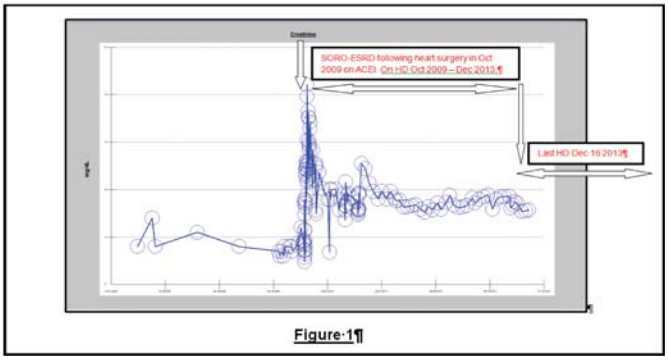
Macaulay A. Onuigbo,[1,2] Ibraheem Abbas,[2] William J. Maierhofer,[2] Suhail B. Shuja,[2] Nneoma Agbasi.[3]
[1]Medicine, Mayo Clinic College of Medicine, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Psychiatry Nursing, North East London NHS Foundation Trust, London, United Kingdom.

Background: We first described the syndrome of rapid onset end stage renal disease (SORO-ESRD) in 2010. This is acute precipitate yet irreversible ESRD after AKI versus "classic" ESRD where CKD-ESRD progression was progressive and predictable. SORO-ESRD accounts for ~30% of incident U.S. adult ESRD but its impact on ESRD mortality is unknown.

Methods: A retrospective three-year interval analysis of mortality in patients with SORO-ESRD versus "classic" ESRD.

Results: Twenty-two of 31 (71%) SORO-ESRD patients versus 42 of 60 (70%) "classic" ESRD had died. Other findings are shown in table including common causes of death.

Characteristic Examined	SORO-ESRD	"Classic" ESRD
Total (n)	31	60
Number dead (%)	22 (71%)	42 (70%)
Number alive (%)	9 (29%0	18 (30%)
Number remaining on RRT (%)	5 (16%)	12 (20%)
Number that came off RRT (%)	3 (10%)	2 (3%)
Number with new kidney transplant (%)	1 (3%)	4 (7%)
Death from failure to thrive (%)	3 (10%)	7 (12%)
Death from sudden death/cardiac arrythmia (%)	3 (10%)	6 (10%)
Death from septic shock (%)	3 (10%)	5 (8%)
Death from pneumonia (%)	1 (3%)	3 (5%)
Death from respiratory failure (%)	-	3 (5%)
Death from COPD (%)	1 (3%)	2 (3%)



Figure·1¶

Conclusions: We demonstrated no mortality difference between SORO-ESRD and "classic" ESRD after another three years follow up. More patients came off HD in SORO-ESRD versus "classic" ESRD, p=0.16, NS. More "classic" ESRD patients were transplanted, p=0.44, NS. The causes of death were similar with sudden cardiac death due to arrhythmias and septic shock being the leading causes. Larger studies are warranted.

PUB148

Serum Phosphorous and Anemia in Patients with Stage 4-5 CKD

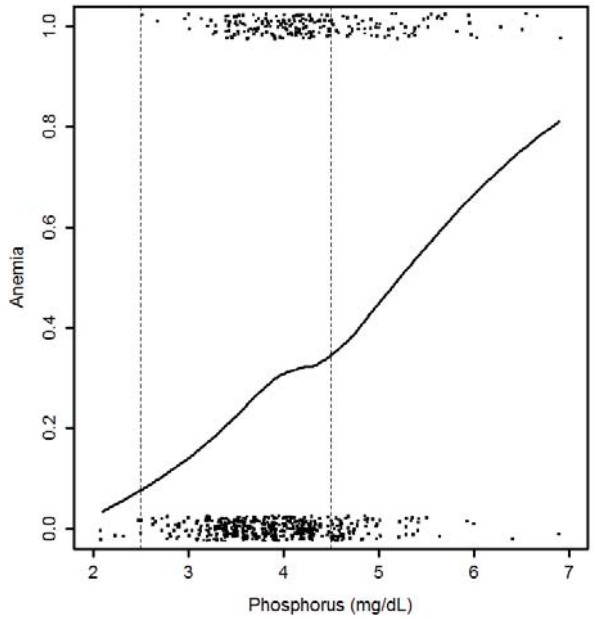
David T. Gilbertson, Allan J. Collins. *Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.*

Background: Hyperphosphatemia and anemia are common and associated with adverse outcomes in maintenance dialysis patients. Among patients with CKD not on dialysis, erythropoiesis diminishes as CKD stage increases, and serum phosphorus typically increases. We aimed to examine hemoglobin and serum phosphorus levels in later-stage CKD patients aged 20-64, and to examine serum ferritin levels in a subset of these patients.

Methods: We used MarketScan data to identify patients with CKD stages 4-5, Oct 2009-Sep 2010, using ICD-9 codes and calculating eGFR for those with lab data available. A further subset had both phosphorus and hemoglobin measurements available. Anemia was defined in these patients as hemoglobin < 11 g/dL, and the phosphorus normal range as 2.5-4.5 mg/dL. A final subset included patients whose serum ferritin values were also available.

Results: We identified 661 CKD stage 4-5 patients with phosphorus and hemoglobin levels available for analysis, and 246 with serum ferritin values also available. Mean age was 55 years; 20% of patients had phosphorus levels above the upper limit of normal (4.5 mg/dL), and 30% had hemoglobin levels < 11 g/dL. The figure, displaying phosphorus levels (x-axis) and the probability of anemia (y-axis), shows a monotonically increasing

relationship between phosphorus and the likelihood of anemia (c-statistic = 0.65); 45% of patients with hyperphosphatemia were anemic. For patients with available ferritin levels, average values for those below and above the phosphorus upper limit of normal were 247 and 196 ng/mL, respectively.



Conclusions: In patients with later stage CKD the linear relationship between serum phosphorus and the likelihood of anemia is apparent across the range of phosphorus levels, even within the normal range. Serum ferritin is inversely associated with serum phosphorus.

PUB149

Prevalence of Hypertension, Proteinuria, and Nocturia in the Rural Middle Belt of Ghana Jerica Johnson,[1] Easmon Otupiri,[2] Adjase Emmanuel Teye,[3] Andrea M. Nelson,[1] Martin C. Gregory.[1] *[1]Internal Medicine, Univ of Utah, Salt Lake City, UT; [2]KNUST, Kumasi, Ghana; [3]College of Health and Well-Being, Kintampo, Ghana.*

Background: There are few studies on the prevalence of chronic kidney disease (CKD) in rural Ghana even though this is an increasingly recognized health problem in sub-Saharan Africa. However, there is limited access to laboratories where serum creatinine can be measured to make a definitive diagnosis of CKD. This favors the use of less expensive screening measures, such as evaluation of hypertension (HTN), proteinuria, and nocturia. The primary aim of this cross-sectional study was to determine the prevalence of HTN, proteinuria, and nocturia in rural Ashanti and Brong-Ahafo areas in Ghana.

Methods: Community health nurses administered surveys to collect demographic information and relevant health information in 695 participants. Blood pressure measurements and dipstick urinalyses were collected for all participants. Outcome measures were defined by: HTN (SBP≥140 or DBP≥90 for ages 18 years and older, ≥95th percentile by age and gender for ages 17 and younger); proteinuria (≥2+); and nocturia (≥2 awakenings per night).

Results: Overall prevalence of HTN was 25%. Prevalence of HTN was 9.2% in ages 7-18, 12.4% in ages 19-39, and 40% in ages 40-60. The overall prevalence of proteinuria was 6.8%. Prevalence of proteinuria was 8.7% in ages 7-18, 6.4% in ages 19-39, and 6.2% in ages 40-60. However, there was no difference in age between those with and those without proteinuria (p=0.38). Systolic blood pressure was significantly higher in those with proteinuria (p=0.013). The overall prevalence of nocturia was 63%. Prevalence of nocturia was 46% in ages 7-18, 66% in ages 19-39, and 76% in ages 40-60. There was no association between proteinuria and nocturia (p=0.65).

Conclusions: Our study showed higher than anticipated rates of HTN, proteinuria, and nocturia. The high prevalence of these outcome measures as well as the youth of those affected justifies further study of renal disease in rural Ghana. Screening for HTN, proteinuria, and nocturia may be used in the community for early detection of renal disease.

PUB150

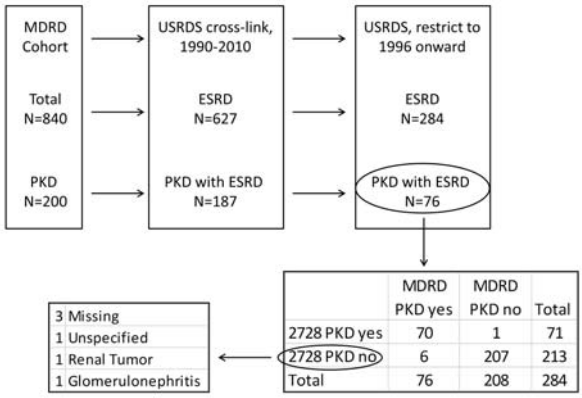
Does the USRDS National Registry Accurately Reflect the Burden of PKD as a Cause of ESRD? Meyeon Park,[1] Barbara A. Grimes,[1] Elaine Ku,[1] Kirsten L. Johansen,[1] Mark J. Sarnak,[2] Chi-Yuan Hsu.[1] *[1]UCSF; [2]Tufts.*

Background: Polycystic kidney disease (PKD) is an important cause of ESRD. Whether or not the U.S. Renal Data System (USRDS) national registry accurately captures the burden of PKD as a cause of ESRD, based on Medical Evidence Report (2728 form), is unknown. Prior studies have shown that the 2728 form may be inaccurate for diagnosing glomerulonephritis and insensitive for capturing comorbid conditions.

Methods: The Modification of Diet in Renal Disease (MDRD) study is an NIH-sponsored clinical trial that enrolled ~25% of participants with PKD as the underlying cause of CKD. We cross-linked the MDRD dataset with USRDS (data complete through December 2010). We analyzed data of patients who developed ESRD from January 1, 1996 onward, as the current 2728 form was implemented in 1995. We assessed the test characteristics of a diagnosis of "Polycystic kidneys, adult type (dominant)" on the 2728 form relative to the gold-standard diagnosis of PKD from MDRD. We used "glomerulonephritis" (GN) as a comparison group.

Results: Out of 840 individuals in MDRD, 627 developed ESRD by the end of 2010 (Fig). Of the 76 with PKD and ESRD, 70 had "Polycystic kidneys, adult type (dominant)" listed as etiology of ESRD on the 2728 form (sensitivity 92.1%, PPV 98.6%). The 6 patients who had PKD based on MDRD that was not captured by 2728 form had primarily missing diagnoses (Fig). Compared to a diagnosis of GN, sensitivity, specificity, positive (PPV) and negative (NPV) predictive values, and kappa were all higher for PKD (Table).

Figure. Derivation of study population.



2728 Form Diagnosis	Sensitivity	Specificity	PPV	NPV	Kappa
"Polycystic kidneys, adult type (dominant)"	92.1%	99.5%	98.6%	97.2%	0.94 (0.89-0.98)
"Glomerulonephritis"	31.4%	91.4%	61.4%	75.4%	0.27 (0.15-0.38)

Conclusions: Although there may be an under-estimation of about 5-10%, the USRDS national registry captures the burden of ESRD due to PKD relatively well.

Funding: NIDDK Support

PUB151

Bioelectrical Impedance as Non Invasive Screening Tool for Preventing Radionuclear Contrast Nephropathy in Chronic Kidney Disease Anita Saxena,[1] Amit Gupta,[1] Georgi Abraham,[2] Anil Bhalla.[3] *[1]Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India; [2]Nephrology, Madras Medical Mission, Chenai, Uttar Pradesh, Iraq; [3]Nephrology, Sir Ganga Ram Hospital, New Delhi, Union Territory, India.*

Background: Radio contrast nephropathy (RCN) is 5-10% in diabetic kidney disease compared to 3% in chronic kidney disease. To evaluate use of bioelectrical impedance (BIA) as a screening tool for kidney disease in general population using creatinine clearance (Crcl) and glomerular filtration rate (GFR).

Methods: Cross-sectional screening study conducted on 52 subjects from general population for presence of CKD. Maltron BIOSCAN derived GFR was caliberated with ^{99m}Tc-DTPA derived GFR (95.0ml/min p 0.001%), a comparative study done on voluntary kidney donors. There was no significant difference between GFR derived from two methods. Hume *et al 's* equations were used to check BIA accuracy in estimating total body water (TBW). There was no significant difference between two methods (33.7 ± 6.6 L and 34.8 ±6.18 L 0.189, p 0.001%).

Results: Mean serum creatinine for males was 0.94 ± 0.14 and for females was 0.91± 0.84 mg% and BIA derived Crcl was 97.3 ± 28.98 and 107.6 ± 34.0 ml/min. Based on BIA derived GFR (male 74.1±25.9 female 65.17±21.14 ml/min), subjects were classified into CKD stages. 15.5% were in CKD stage 1, 44.2% in stage 2, 34.6% in stage 3, 1.9% in stage 4 and 1.9% in stage 5. Microalbuminuria was present in 7.0 %. 36% had normal blood pressure, 15.5% were in prehypertension stage, 30.7% were in stage 1 hypertension, 11.5% were in stage 2 hypertension and 3.8% were in crisis hypertension.

Conclusions: All subjects screened had CKD but they were not symptomatic. CKD has a latent period during which the disease is present but is asymptomatic. Screening for CKD identifies people with renal injury so that early intervention can prevent morbidity and delay progression to end stage renal disease. GFR is index of kidney function. BIA can estimate GFR without use of radionuclear agents. If BIA instrument is validated against radionuclear method, it is a handy and inexpensive tool for measuring GFR and screening CKD in general population and preventing RCN.

PUB152

Comorbidity and Outcomes in Chronic Kidney Disease Simon D.S. Fraser,[1] Maarten W. Taal,[2] Paul J. Roderick.[1] *[1]Academic Unit of Primary Care and Population Sciences, Southampton Univ, United Kingdom; [2]Div of Medical Sciences and Graduate Entry Medicine, Nottingham Univ, United Kingdom.*

Background: CKD is often considered in isolation but commonly occurs in conjunction with other chronic conditions. Little information exists on the prognostic implication of multiple comorbidities in CKD. We aimed to investigate the association of degree of comorbidity with several key outcomes in a large cohort of people with CKD.

Methods: A retrospective cohort of people with eGFR <60ml/min/1.73m^2 on 2 occasions was identified from a routine data repository. Comorbidities included hypertension, diabetes, ischemic heart disease, heart failure, peripheral vascular disease, cerebrovascular disease, hypothyroidism, liver disease, and chronic anti-inflammatory use (reflecting musculoskeletal conditions).Descriptive statistics, Poisson and Cox regression models were used to compare those with CKD+2 or more comorbidities with those with CKD only or CKD+1 and their emergency room (ER) attendance, emergency hospital admission, new renal replacement therapy (RRT), acute kidney injury (AKI) and mortality.

Results: 24,021 people with CKD were identified. Mean follow up 5.3 years. Mean age was 77±11 years and baseline eGFR 47±12ml/min/1.73m^2. Prevalence of isolated CKD,CKD+1,CKD+2 and CKD+3 comorbidities were 13%, 36%, 30% and 21% respectively. During follow up 37% of those with CKD+3 died compared to 27% of those with CKD+2 and 22% of those with CKD only or CKD+1 (p<0.001).CKD+2 or more comorbidities independently predicted ER attendance, hospital admission, new RRT and mortality

Outcome	Univariate		Multivariable*	
	RR	p	RR	p
Attend ER	1.20 (1.16-1.24)	<0.001	1.13 (1.09-1.17)	<0.001
Emergency admission	1.37 (1.24-1.52)	<0.001	1.27 (1.15-1.41)	<0.001
RRT	1.69 (1.33-2.15)	<0.001	2.06 (1.60-2.67)	<0.001
AKI	1.44 (1.11-1.88)	0.01	1.29 (0.99-1.70)	0.06
Mortality	1.53 (1.45-1.60)	<0.001	1.27 (1.20-1.33)	<0.001

*adjusting for age, sex, deprivation index, baseline eGFR

Conclusions: Isolated CKD was rare in this elderly population. Greater comorbidity was associated with several adverse outcomes. Further research should focus on managing disease burden and reducing risk across multiple comorbidities in people with CKD.

PUB153

Inflammatory Marker MRP8/14 Is Correlated with Body Mass Index and Modulates Disease Progression in Japanese Patients with CKD Tatsuki Matsumoto,[1] Yoshinori Taniguchi,[1] Kazu Hamada,[1] Yoshiko Shimamura,[1] Kosuke Inoue,[1] Koji Ogata,[1] Taro Horino,[1] Kenji Yuasa,[2] Shinpei Fujimoto,[1] Yoshio Terada.[1] *[1]Kochi Univ, Nankoku, Japan; [2]Kochi-Takasu Hospital, Kochi, Japan.*

Background: Inflammatory marker, Myeloid-Related Protein 8/14 complex (MRP8/14), is an endogenic ligand of toll-like receptor (TLR)-4. Although it has been reported that MRP8/14 related to arteriosclerosis and coronary lesion in type 2 diabetes, there are few reports about the relationship between MRP8/14 and chronic kidney disease (CKD). We studied the association between MRP8/14 levels and several parameters in CKD.

Methods: A total of 432 patients (mean age 60±17) with CKD were enrolledand a longitudinal follow-up study for 12 months was performed. Serum samples were collected, and MRP8/14 levels were measured by using ELISA kit. Serum creatinine (Cr), urine protein/Cr ratio, and the other parameters were also measured. This study was approved by Kochi Medical School review board. All patients provided written informed consent.

Results: MRP8/14 levels were positively associated with serum Cr (p=0.007, r=0.135), BUN (p<0.001, r=0.175), UA (p=0.011, r=0.127) levels, urinary protein/Cr ratio (p<0.001, r=0.212) and especially Body Mass Index (BMI) (p<0.001, r=0.189), and were inversely associated with eGFR p=0.006, r=-0.137). Moreover, MRP8/14 levels in CKD patients with diabetes and hypertension were significantly increased (p<0.05), compared to patients without diabetes and hypertension. Stepwise multiple regression analysis showed that MRP8/14 levels correlated well with BMI. During the study period of 12 months observation, MRP8/14 levels showed significantly inverse correlation to the decline rate of eGFR for 12 months in sub-group with BMI >25% (p<0.05), although not in all patients.

Conclusions: Serum MRP8/14 positively correlated with BMI in Japanese patients with CKD, and especially in BMI >25% group, is critical for disease progression in CKD.

PUB154

IgA Nephropathy with Nephrotic Syndrome in Children Yuko Shima,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Masashi Sato,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Hiroshi Kaito,[2] Kandai Nozu,[2] Ryojiro Tanaka,[3] Kazumoto Iijima,[2] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayana Medical Univ., Wakayama, Japan; [2]Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Hyogo, Japan; [3]Pediatric Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Hyogo, Japan.*

Background: Nephrotic syndrome (NS) is rare in IgA Nephropathy (IgAN) in children. Clinical characteristics and long term outcomes of IgAN with NS have not been fully clarified yet.

Methods: We analyzed retrospectively consecutive 427 children. There were 31 IgAN children (7.3%) with NS (NS-IgAN) at onset. We compared clinical and pathological findings between 31 patients with NS-IgAN and the remained 396 patients to clarify the characteristics of NS-IgAN in children.

Results: Onset modes of 31 children with NS-IgAN were annual school screening (9), gross hematuria (5), acute nephritic syndrome (AN, 1), NS alone (10), and AN and NS (6). Logistic analyses showed that male (OR: 3.1, P=.006), gross hematuria (OR: 3.2. P=.004), duration from onset to renal biopsy (1.5 versus 8.4M, P=.001), mesangial hypercellularity score (1.3 versus 0.6, P<.0001), ratios of endocapillary hypercellularity (27.3 versus 3.9%, P<.0001), tubular atrophy/interstitial fibrosis (5.2 versus 3.1, P=.01) nd crescents (12.7 versus 4.3%, P=.0001) were significantly related to NS. Twenty-three children of NS-IgAN (74%) were treated with PSL or combination therapy including PSL and immunosuppressant. Mean observation period was 6.2±3.2 yrs. Complete remission (CR) occurred in 22 (71%) patients. All patients with CR maintained remission during the observation period. Three cases (9.7%) reached chronic renal failure (eGFR<60) at the latest observation. All 3 cases were treated with PSL or combination therapy. They demonstrated heavy proteinuria after their 2-year initial treatments. The Kaplan-Meier analysis showed that the cases with NS-IgAN demonstrated significantly lower renal survival curve than the rest (P=.04). Cox analysis showed that NS was a significant factor for renal failure with adjusting by PD (HR: 5.6 [95%CI 1.2-18.9], P=.03).

Conclusions: Patients with NS-IgAN who were refractory to treatments showed poor renal survival. On the other hand, once they achieved CR, they had favorable outcome.

PUB155

The Incidental Relationship of Microalbuminuria with the Degree of NAFLD in Non-Diabetic Korean Men Dong-Young Lee,[1] Beom Kim,[1] Kyoung Hyoub Moon,[1] Sung Keun Park,[2,3] Sangyoon Lee.[4] *[1]Internal Medicine, Veterans Health Service Medical Center, Seoul, Korea; [2]Total Healthcare Center, Kangbuk Samsung Hospital, Sungkyunkwan Univ, Seoul, Korea; [3]Depts of Preventive Medicine, School of Medicine, Kyung Hee Univ, Seoul, Korea; [4]Dept of Occupational and Environmental Medicine, Haeundae Paik Hospital, Inje Univ, Busan, Korea.*

Background: Epidemiological researches have demonstrated that risk of microalbuminuria was significantly associated with nonalcoholic fatty liver disease (NAFLD) in diabetic population. However, there is only limited information about this association in non-diabetic population. Thus, this study was conducted to investigate the incidental relationship of microalbuminuria with the degree of NAFLD in non-diabetic Korean men.

Methods: A prospective cohort study was conducted on 2,855 non-diabetic Korean men without microalbuminuria in 2005. They were categorized into 3 groups by the degree of NAFLD (normal, mild, moderate-to-severe), and followed-up from 2005 to 2010. The incidences of microalbuminuria were evaluated, and Cox proportional hazard model was used to measure the hazard ratios (HRs) for the development of microalbuminuria according to the degree of NAFLD.

Results: Total 123 cases of microalbuminuria (4.3%) developed during 5 year follow-up. Participants with microalbuminuria were older with higher BMIs, BP measurements, lipid profiles, and insulin resistance than those without microalbuminuria. In the unadjusted model, HR for microalbuminuria was 1.69 in mild NAFLD and 4.98 in moderate to severe NAFLD group (P<0.001). These associations were attenuated but remained statistically significant after adjusting for epidemiologic and chemistry characteristics (mild NAFLD: 1.03, moderate to severe NAFLD 2.61, P= 0.002).

. Hazard ratios for microalbuminuria in each NAFLD category

	HR (95% Confidence Interval)	
	Unadjusted	Model 1
NAFLD		
Normal	1.00 (reference)	
Mild	1.69 (1.15 - 2.47)	1.03 (0.66 - 1.61)
Moderate to severe	4.98 (2.57 - 9.68)	2.61 (1.20 - 5.71)
Age		1.03 (1.01 -1.05)
BMI		1.03 (0.96 - 1.12)
HOMA-IR		1.56 (1.33 -1.82)

Conclusions: The degree of NAFLD is independently associated with the development of microalbuminuria in healthy Korean men.

PUB156

Incidence of Biopsy-Defined Glomerulonephritis in Northern Iraq
Michael D. Hughson,[1] Alaa A. Ali,[1] Safa E. Almukhtar.[2] *[1]Shorsh General Hospital, Sulaimaniyah, Iraq; [2]Hawler Univ College of Medicine, Erbil, Iraq.*

Background: The incidence of specific types of glomerular diseases can be analyzed by renal biopsies obtained from a population of known size and age distribution. Ratios relative to membranous glomerulonephritis (MGN) have been used to evaluate whether IgA nephropathy (IGAN), focal segmental glomerulosclerosis (FSGS), and lupus nephritis (LN) vary among different ethnic and racial groups or change over time. In the Middle-East, there is little data on the frequency of specific types of renal disease except their relative proportions in biopsy series. This study estimates the incidence of subtypes of glomerulonephritis (GN) in a Middle-East region with active nephrology services and a well characterized population.

Methods: In 2012-2013, all renal biopsies performed in the Kurdish region of Northern Iraq were studied by light and immunofluorescence microscopy. Of 744 native renal biopsies, 561 were satisfactory for a specific diagnosis. The 2011 update of the World Health Organization (WHO) 2002 regional census was used to determine the biopsy rate and WHO world standardized age and gender adjusted annual incidence rates per 100,000 population for MN, FSGS, IGAN, LN, and all GN (without minimal change disease).

Results: Biopsies of native kidneys were performed on 369 females and 370 males. The annual biopsy rate was 7.59/100,000. For specific diagnoses, the number of cases (2 years), the male to female ratio, and the age and gender adjusted annual incidence rates were as follows: MGN (n=69, 1:1.2, 1.01), FSGS (n=121, 1.2:1, 1.49), IGAN (n=26, 1.9:1, 0.31), LN (n=51, 1:5.3, 0.50) and all GN (n=349, 1:1, 4.47).

Conclusions: With biopsy rates that are somewhat, but not exceedingly low, compared to the U.S., the incidence of MN and LN is similar to that seen in European Americans (EA) but without the marked male predominance for MN. FSGS well exceeds any other type of glomerulonephritis at an incidence and proportion of biopsies seen in EA populations after the 1990s. The rate of IGAN is very low, findings previously reported in nearby Arab countries, but distinctly different from most populations of European ancestry. This may reflect regional biopsy practices or a low epidemiologic risk for IGAN.

PUB157

Visceral Adiposity Index, Hypertriglyceridemic Waist Phenotype, and Risk of Chronic Kidney Disease
Yongqiang Li, Hequn Zou. *Dept of Nephronology, Institute of Nephronology and Urology, The Third Affiliated Hospital of Southern Medical Univ, Guangzhou, GuangDong, China.*

Background: To explore the relationships between visceral adiposity index(VAI), hypertriglyceridemic waist phenotype (HW phenotype) and chronic kidney disease(CKD).

Methods: A cross-sectional study was conducted in Zhuhai city from June to October 2012. Participants aged 18 years and older (n=2142) were recruited. The relationship between VAI, HW phenotype and CKD were determined. Logistic regression was used to evaluate the associations between VAI, HW phenotype and CKD.

Results: After adjustment for age, VAI was significantly associated with CKD (OR 2.16, 95% CI 1.23 to 3.74, P=0.006, comparing the highest to the lowest quartile) in female subgroup. But this association was not seen in male(OR1.72, 95% CI 0.95 to 3.13, P=0.08). Further adjusted for potential confounders, the association was still significant in female subgroup(OR 1.91, 95% CI 1.06 to 3.41, P=0.03, comparing the highest to the lowest quartile). The association was abolished when adding diabetes and hypertension to the model(OR 1.68, 95% CI 0.91 to 3.10, P=0.096). The age-adjusted OR (95% CI, P) of CKD associated with HW phenotype was 2.21 (1.29 to 3.76, 0.004) and 2.54 (1.53 to 4.22, <0.001) for men and women, respectively. Further adjusted for potential confounders, the associations were still significant in female subgroup and male subgroup. The OR were 2.24 (95% CI 1.28 to 3.92, P =0.005) and 2.30 (95% CI 1.28 to 4.12, P =0.005), respectively. When further adjusted for diabetes and hypertension, the association of HW phenotype and CKD was significant (OR 1.91, 95% CI 1.05 to 3.59, P=0.035) in female subgroup. But the association between HW phenotype and CKD was abolished when diabetes and hypertension were added to the model in male subgroup(OR 1.53, 95% CI 0.82 to 2.84, P=0.66).

Conclusions: Our results suggested that both VAI and the HW phenotype were significantly associated with CKD in female. HW phenotype was significantly associated with CKD in male. But VAI was not associated with CKD in male. Compared with VAI, the HW phenotype might be a better predictor of CKD in Chinese men and women.

PUB158

In a Cohort of Older Patients with Confusion, Admission Renal Function Predicts Poor Discharge Outcomes
Kathryn Daniel,[1] Belinda A. Vicioso.[2] *[1]Nursing, UT Arlington, Arlington, TX; [2]Div of Geriatric Medicine, Dept Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Delirium is often misdiagnosed as an acute confusional state in hospitalized patients. Delirium affects up to 10-20% of all hospitalized adults and is associated with adverse outcomes including decreased functional status, fall risk, prolonged hospital stay, and increased use of physical and chemical restraints. Chronic kidney disease has been suspected, but not yet linked, to risk of confusion. The purpose of this study was to explore the relationship between estimated glomerular filtration rates (eGFR) among older patients with confusion, to two outcomes: 1) length of stay (LOS) and 2) discharge destination.

Methods: We examined all clinical records of inpatients at a large tertiary teaching hospital in the southwestern U.S., who had any diagnosis reflecting confusion during calendar year 2011. Demographic information, serum creatinine, LOS, and discharge destination were collected. Data were analyzed using ANOVA to explore the relationship of eGFR and LOS and Spearman's rank correlation coefficient to describe the relationship between eGFR and discharge destination.

Results: We identified 1292 cases out of 37,850 admissions; 670 in patients age 65 or older. Mean age was 79, +8.9, range 65-110 years. Mean creatinine was 1.63 (+ 1.65) and ranged from 0.4-20 mg/dL. Mean eGFR was 52 (+ 24.5) ml/min/1.73 m2 and ranged from 2-112. Mean LOS was 10.6 days, +8.9, range 1-76 days. The sample was 71% Caucasian, 22% black, and 4% Hispanic. LOS was significantly related to eGFR (F=1.52, df=47, p<.017). Lower eGFR was associated with worse discharge destination (extended care or death) (r=.119, p<.002).

Conclusions: Older hospitalized patients with any diagnosis of confusion who had lower eGFR were more likely to have longer LOS, not be discharged home, or die during hospitalization.

PUB159

Effect of Serum Phosphorus Level on Progression of Kidney Disease: A Systematic Review and Meta-Analysis
Xinfang Xie,[1] Jing Jing Da,[1,2] Myles S. Wolf,[3] Sinee Disthabanchong,[4] Jinwei Wang,[1] Jicheng Lv,[1] Luxia Zhang,[1] Hai Yan Wang.[1] *[1]Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China; [2]Renal Div, Dept of Medicine, Guizhou Provincial People's Hospital, Guiyang, Guizhou, China; [3]Div of Nephrology and Hypertension, Dept of Medicine and Div of Biostatistics, Dept of Epidemiology and Public Health, Univ of Miami Miller School of Medicine, Miami, FL; [4]Div of Nephrology, Dept of Medicine, Faculty of Medicine Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.*

Background: Recent studies indicated that phosphorus might have an independent pathogenic role in the progression of chronic kidney disease (CKD), but some of those studies were underpowered and yielded inconsistent results.

Methods: Studies assessing the risk ratio of serum phosphorus on kidney failure and mortality for patients with non-dialysis dependent chronic kidney disease published between January 1950 and March 2013 were included following systematic searching of the MEDLINE, EMBASE databases and the Cochrane Library.

Results: Twelve cohorts with 25,546 patients, 1,442 (8.8%) of patients developed kidney failure and 3,089 (13.6%) patients died. Overall, every 1 mg/dl increase of serum phosphorus was independently associated with an increased risk of kidney failure (relative risk, 1.36 [95% confidence interval [CI], 1.22-1.51]) and mortality (relative risk, 1.20 [95% CI, 1.08-1.33]). The risk of kidney failure increased gradually with blood level of phosphorus, starting from 3.87 mg/dl.

Conclusions: This is a first meta-analysis reveals an independent association between serum levels of phosphorus and kidney failure and mortality among non-dialysis-dependent CKD patients, and suggests that large-scale, randomized controlled trials should target disordered phosphorus homeostasis in CKD.

Post-Operative Complications for Patients Treated by Hemodialysis Undergoing Orthopedic Procedures
Amanda Jo DeMauro,[3] David Bennett,[3] Ting-Jung Pan,[1] Mayu Sasaki,[2] Stephen Lyman,[1] Steven K. Magid,[2] Jeffrey I. Silberzweig.[3] *[1]Healthcare Research Institute, Hospital for Special Surgery, New York, NY; [2]Quality Research Center, Hospital for Special Surgery, New York, NY; [3]Medicine, Div of Nephrology and Hypertension, New York-Presbyterian Hospital/Weill Cornell Medical College, New York, NY.*

Background: The in-hospital course for patients with chronic kidney disease (CKD) treated by hemodialysis (HD) undergoing orthopedic procedures documents morbidity up to 100% and mortality up to 28.5%; our patients experience superior outcomes.

Methods: We identified 60 patients between 2004-2008 and reviewed electronic records for age, sex, HD vintage, cause of CKD, comorbidities, and complications. Comparisons were performed using Chi-square test or t-test.

Results: Patients undergoing hip (39) or knee (21) surgery experienced 15 post-operative complications; the most common were tachycardia (6.7%) and altered mental status (6.7%). HD vintage averaged 5.9 +/- 8.5 years. Causes of CKD included hypertension (23.3%), collagen vascular disease (18.3%), and diabetes mellitus (15.0%). Common comorbidities were hypertension (75.0%), anemia (31.7%), valvular disease (20.0%), depression (11.7%), CHF (10.0%), and pulmonary circulation disorders (10.0%). Many had multiple comorbidities (23.3% had Charlson comorbidity index of 2, 36.7% 3, 16.7% 4+). Complication rates did not vary with Charlson comorbidity index. Patients experiencing complications had lower pre-operative hemoglobin (mean 11.1 g/dL versus 12.5 g/dL, p=0.013); patients requiring blood transfusions were more likely to suffer complications (80.0% versus 37.8%, p=0.007). Patients with complications had longer hospital courses (mean 12.1 days versus 7.8 days, p=0.044). There were no in-hospital deaths.

Conclusions: Our results do not corroborate the high morbidity and mortality rates reported for similar populations even among patients with the highest comorbidity scores. We found statistically significant relationships between lower pre-operative hemoglobin values, need for blood transfusion, and complication rates. More study is warranted to guide the management of peri-operative anemia to improve outcomes.

PUB161

Chronic Hemodialysis in Far Rockaway, New York Heino R. Anto, Yan Dorneich, Volodymyr Chornyy, Tatyana Tolchinsky. *Dept of Medicine, Saint John's Episcopal Hospital, New York, NY.*

Background: The U.S. Census Bureau reports that Far Rockaway has a population of about 60,000 people, of which 1/3 are below poverty level. In addition, approximately 25 % of the adult population, mainly 45-64 years old, are said to be without health insurance.We examined how these factors impacted on the trends of new chronic hemodialysis patients, generated through the only hospital in Far Rockaway,St. John's Episcopal Hospital (SJEH), from 2011-2013. We also examined the average lenght of stay (ALOS) between insured and non-insured patients.

Methods: 122 hospital admissions from 2011-2013 which coded for acute or chronic renal failure were reviewed.

Results: From 2011 thru 2013, fifty-eight patients started maintenance hemodialysis with a mean age of 63.4 years. Approximately 9 % had no health care coverage, while 91 % had medicaid, medicare, both medicare and medicaid, or " other " health insurance.The ALOS for non-insured was 27 days, and 18.8 days for insured patients.

Conclusions: Since most of the non-insured in the Far Rockaway area are said to be in the 45-64 years age group, we were surprised that 91 % new hemodialysis patients generated at SJEH, with a mean age of 63.4 years, had health care coverage.In addition, since 25 % of the Far Rockaway adult population is reported to be non-insured, we expected to find more non-insured in our study. This low figure for non-insured could stem from patient fear of having to pay for their own medical expenses, thereby avoiding medical attention. Furthermore, some non-insured may have left the Far Rockaway peninsula and sought medical care elsewhere. ALOS was not affected by severity of illness; since severity was similar in both insured and non-insured cases. The longer ALOS for the non-insured was likely impacted by an inability to place such patients into a for profit dialysis center because of facility reimbursement issues.

PUB162

Tenofovir Exposure Is Associated with Biomarkers of Proximal Tubular Injury in HIV-Infected Men Vasantha Jotwani,[1] Rebecca Scherzer,[1] Michelle M. Estrella,[2] Lisa P. Jacobson,[2] Michael Shlipak.[1] *[1]UCSF; [2]Johns Hopkins.*

Background: Tenofovir disoproxil fumarate (TDF) is widely prescribed for treatment of HIV infection, but has been associated with proximal tubular damage. The proximal tubular injury markers, urine interleukin-18 (IL-18) and kidney injury molecule-1 (KIM-1), may detect tubular damage among HIV-infected individuals exposed to TDF who have normal kidney function.

Methods: This cross-sectional study of 884 HIV-infected men from the Multicenter AIDS Cohort Study evaluated associations of cumulative TDF exposure with urine IL-18, KIM-1, and albumin-creatinine ratio (ACR). We used the LASSO procedure to determine which of multiple antiretroviral (ARV) agents were associated with each biomarker. Multivariable robust regression analysis was then used to model associations of the selected ARVs while controlling for traditional and HIV-related factors.

Results: Duration of TDF use was independently associated with 3-4% higher levels of IL-18 and KIM-1 per year of exposure in adjusted analyses (**Figure 1**). No other individual ARV was associated with higher levels of both IL-18 and KIM-1. TDF exposure was associated with 3.8% higher ACR per year of exposure, but the association was attenuated and no longer statistically significant after adjustment for LASSO-selected ARVs.

Figure 1: Association of cumulative duration of TDF use with biomarker levels

Model	IL-18 % Estimate[1] (95%CI)	KIM-1 % Estimate[1] (95%CI)	ACR % Estimate[1] (95%CI)
Multivariable-adjusted[2]	3.9 (1.4, 6.4)	3.0 (0.66, 5.4)	3.8 (0.56, 7.2)
Multivariable-adjusted +other ARVs[3]	3.3 (0.75, 5.8)	3.4 (1.1, 5.7)	1.4 (-2.0, 5.0)

[1]Outcomes were log-transformed for analyses and back-transformed to produce estimated % differences in biomarker levels attributable to each year of TDF exposure
[2]Adjusted for demographics, traditional kidney risk factors, and HIV-related risk factors
[3]Other LASSO-selected ARVs include zidovudine, efavirenz, lopinavir, nevirapine, and ritonavir

Conclusions: Cumulative TDF exposure is associated with proximal tubular injury markers with weaker effects on albuminuria. Specific urine markers may be required for early detection of TDF-associated nephrotoxicity.

PUB163

Retinopathy Is a Better Predictor for Renal Outcomes Than Echocardiographic Parameters in Patients with Chronic Kidney Disease Hyeon Seok Hwang,[1] Se Young Kim,[1] Yoon-Kyung Chang,[1] Chul Woo Yang,[2] Suk Young Kim,[1] Hye Eun Yoon.[2] *[1]Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Daejeon, Korea; [2]Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Retinopathy and cardiac abnormalities are prevalent in chronic kidney disease (CKD) patients. Echocardiographic parameters are known to be associated with progression of CKD. However, the clinical impact of retinopathy on renal outcomes is less clear in CKD patients.

Methods: Four hundred and two patients with nondialysis-dependent CKD stage 3-5 were included, who were evaluated with presence of retinopathy and echocardiography. We investigated whether retinopathy was predictive for CKD progression and whether retinopathy is more predictive for renal outcome than echocardiographic parameters.

Results: Retinopathy was observed in 181 CKD patients (45.0%). The rate of estimated glomerular filtration rate (eGFR) decline was significantly faster in patients with retinopathy compared with those without retinopathy (-6.6 ± 10.0 ml/min/1.73m^2/year versus -3.5 ± 9.6 ml/min/1.73m^2/year; P = 0.001). Patients with retinopathy showed a lower dialysis-free survival rate than those without retinopathy (P = 0.02). The echocardiographic parameters about systolic and diastolic dysfunction did not differ between patients with and without retinopathy. The presence of retinopathy, lower ejection fraction and higher left ventricular mass index was associated with rate of eGFR decline. In a multivariate analysis, retinopathy was an independent predictor for renal function decline (β = -2.23, P = 0.047), but ejection fraction and left ventricular mass index did not show significant associations with rate of eGFR decline.

Conclusions: Retinopathy is independently associated with renal outcomes in patients with CKD, and the examination of retinopathy is more useful than echocardiopraphic parameters to identify high-risk patients for CKD progression.

PUB164

Clinical Features and Renal Outcomes of Elderly Chronic Kidney Disease Patients – A Cohort Study From a Single Chinese Center Yu Wang, Hui Zhao, Luxia Zhang, Fang Wang, Xiaomei Li, Liqiang Meng. *Nephrology, Renal Div, Dept of Med., Peking Univ First Hospital, Beijing, China.*

Background: Despite the high prevalence of chronic kidney disease (CKD) among the elderly, few studies have described clinical features and renal progression of elderly CKD patients under routine follow-up. In this study, the data from CKD clinic of Peking University 1st Hospital was analyzed to determine the clinical features and renal outcomes of the CKD in the elderly.

Methods: Patients aged 65 or older with baseline CKD stage G1-G4 transferred to our CKD clinic from June 2006 to February 2014 and followed up for more than 3 months were retrospectively studied. Estimated glomerular filtration rate (eGFR) was measured by MDRD formula modified for Chinese. Progression of renal disease was defined as the decline in eGFR categories accompanied by a 25% or greater drop in eGFR from baseline, and/or a doubling of serum creatinine and/or initiation of renal replacement therapy.

Results: A total of 172 patients (85 men, mean age 73.8 years) were enrolled. Compared to those young- and middle-aged CKD patients recruited in the CKD clinic, the elderly patients were more likely to have early presence of anemia and hypophosphatemia. Forty-nine elderly patients (28.4%) had progression of their renal function during an average study period (22.5 months). Compared with the non-progressive patients, those progressed had a lower baseline eGFR (30.1 versus 42.0ml/min/1.73m^2, p<0.001), and a higher percentage of A3 category of proteinuria (63.3% *versus* 35.8%, p=0.004). A higher systolic blood pressure (142.3±11.8 *versus* 135.1±12.6mmHg, p=0.001) and phosphate level (4.06±0.65 *versus* 3.50±0.44mg/dl, p<0.001) on treatment were also observed. Multivariate Cox regression showed that baseline eGFR (HR 0.962, 95% CI: 0.930~0.995), proteinuria (HR 1.630, 95% CI: 1.041~2.552) and systolic blood pressure on treatment (HR 1.437, 95% CI: 1.076~1.919) were independent risk factors for progression of CKD, while using RASI was a protective factor (HR 0.424, 95% CI: 0.198~0.905).

Conclusions: Blood pressure control, especially systolic blood pressure and RASI usage are important to prevent renal progression among elderly CKD patients.

Funding: Government Support - Non-U.S.

PUB165

The Association between Blood Pressure and Change of Renal Function in a Community-Based Population: A Longitudinal Survey of a Nationwide Cohort in Japan Atsushi Hirayama,[1] Hiroko Sato,[1] Keita Kamei,[1] Kazunobu Ichikawa,[1] Tsuneo Konta,[1] Shouichi Fujimoto,[2] Toshiki Moriyama,[2] Kunitoshi Iseki,[2] Kunihiro Yamagata,[2] Kazuhiko Tsuruya,[2] Kenjiro Kimura,[2] Ichiei Narita,[2] Masahide Kondo,[2] Koichi Asahi,[2] Tsuyoshi Watanabe.[2] *[1]Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan; [2]Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkup, Fukushima, Japan.*

Background: High blood pressure is a risk for adverse renal outcomes in chronic kidney disease. This study investigated the effect of blood pressure on renal function in a community-based population.

Methods: We used a nationwide database of 141,514 subjects (aged 29-74, male 39%), participated in an annual health check, "The Specific Health Check and Guidance in Japan" between 2008-2010, and examined the relationship between blood pressure level at baseline and 2-year change of estimated GFR obtained by the Japanese equation.

Results: The analysis of variance (ANOVA) showed the change of eGFR was inversely correlated with systolic blood pressure (SBP), diastolic blood pressure (DBP) and pulse pressure levels (P <0.001). However, in multiple linear regression analysis with the adjustment for possible confounders, the eGFR change was inversely correlated with SBP only, not DBP and pulse pressure, and the regression coefficient of per 10 mmHg increase in SBP was –0.17 (95% confidence interval [-0.13, -0.22], P <0.001). There was a significant interaction between SBP and several parameters including age, gender, alcohol consumption and the presence of diabetes and proteinuria. In subgroups analyses the decline of eGFR (regression coefficient of per 10 mmHg increase in SBP) was especially faster in the subjects with proteinuria (-0.59), diabetes (-0.41), history of heart disease (-0.38), and elderly (-0.25).

Conclusions: This study showed that an increase in SBP is independently associated with faster eGFR decline in the Japanese community-based population and the effect of SBP on renal function might be different depending on the characters of subjects.

PUB166

The Different Kinetics of Dickkopf-1 and Sclerostin in Japanese Patients with Chronic Kidney Disease Kazu Hamada, Yoshinori Taniguchi, Yoshiko Shimamura, Tatsuki Matsumoto, Koji Ogata, Kosuke Inoue, Taro Horino, Yoshio Terada. *Endocrinology, Metabolism and Nephrology, Kochi Univ, Nankoku, Japan.*

Background: The serum proteins Dickkopf-1 (Dkk-1) and Sclerostin are soluble inhibitors of canonical Wnt signaling. The Wnt signaling pathway may play a pivotal role in bone and vascular disturbances seen in chronic kidney disease (CKD). However, the clinical significance of Dkk-1 and Sclerostin in CKD is unclear. We studied the association between DKK-1 and Sclerostin levels and several parameters in CKD.

Methods: A total of 404 patients with CKD were enrolledand serum samples were collected, and Dkk-1 and Sclerostin levels were measured by using ELISA kit. Serum creatinine (Cr), urine protein/Cr ratio, and the other parameters including soluble prorenin receptor (s(P)RR) were also measured. This study was approved by Kochi Medical School review board. All patients provided written informed consent.

Results: Dkk-1 levels were inversely associated with serum Cr (p<0.05), BUN (p<0.05), UA (p<0.05), PTH (p<0.05) levels, and were positively associated with eGFR (p<0.05). Notably, Dkk-1 levels were significantly decreased in CKD stage 3-5 compared with stage 1-2 (p<0.05). In contrast, Sclerostin levels were positively associated with serum Cr (p<0.05), BUN (p<0.05), UA (p<0.05), PTH (p<0.05) levels, and were inversely associated with eGFR (p<0.05). Sclerostin levels were positively associated with stage of CKD (p<0.05). Sclerostin levels were positively associated with s(P)RR levels (p<0.05), known as an adaptor between Wnt receptors and the vacuolar H+-adenosine triphosphatase complex, but Dkk-1 not associated. Stepwise multiple regression analysis showed that Sclerostin levels correlated well with eGFR, but Dkk-1 not.

Conclusions: Same two soluble inhibitors of canonical Wnt signaling, Dkk-1 and sclerostin, show different kinetics in the stage of Japanese patients with CKD.

PUB167

The Utility of Diagnostic Testing Employed in the Initial Evaluation of Chronic Kidney Disease Mallika L. Mendu, Sushrut S. Waikar. *Div of Renal Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: A range of laboratory and imaging tests are available to nephrologists evaluating patients with chronic kidney disease (CKD), but their diagnostic yield is unknown. We sought to identify the most commonly ordered tests for CKD and assess their utility in a retrospective cohort study of 1019 patients.

Methods: We conducted a detailed chart review of patients referred for initial evaluation of CKD to renal clinics affiliated with two academic medical centers. Patients were excluded if they were referred for a second opinion, had an existing diagnosed etiology of CKD, or were referred for another kidney related condition.

Results: Renal ultrasound was the most commonly ordered test (70.5%) other than routine chemistries. 24% of renal ultrasounds showed abnormal findings (most commonly cortical thinning and echogenic kidneys), and 6.4% led to a specific diagnosis (most often due to renal artery stenosis or newly diagnosed atrophic kidney). Serum protein electrophoresis (SPEP) was obtained in 69.1% and led to a diagnosis of paraprotein-related kidney disease in 1.9%. ANA was obtained in 29.5% of patients, abnormal (> 1:40 titer) in 62%, but led to a new diagnosis of lupus nephritis in only 1.3%. ANCA and Anti-GBM were ordered in 12.6% and 3.8%, respectively; no patients were diagnosed with ANCA vasculitis or anti-GBM nephritis.

Conclusions: The diagnostic yield of many commonly ordered tests in the evaluation of CKD is low, and further study is needed to develop an evidence-based approach to diagnostic testing.

PUB168

Outcomes and Perspectives on the Opt-Out Recruitment Strategy in the SNORE Study Muna T. Canales,[1,2,3] Nicole Kay,[1] Areef Ishani,[4] I. David Weiner,[1,2,3] Richard Berry,[1,3] Rebecca Beyth.[1,3] *[1]Malcom-Randall VAMC; [2]Div of Nephrology; [3]Dept of Medicine, Gainesville, FL; [4]VAMC, Minneapolis, MN.*

Background: The opt-out recruitment strategy involves contact of patients by letter with follow-up phone call for non-response. This strategy is highly effective and ideal for scientifically sound and generalizable studies but has been criticized as cold-calling. To date, participant and potential participant views on this method of contact are unknown.

Methods: With IRB approval, we identified veterans age 18-89 in the NF/SGVHS (2/12/12-present) with eGFR 15-44 for enrollment in the SNORE Study, a prospective study of sleep apnea and kidney disease. Target enrollment=250 over 2y. After contacting every PCP in the NF/SGVHS for permission to contact their patients, we invited eligible veterans to participate via letter with follow-up call 3-5 days later if the patient had not responded. Letters referenced their PCP and provided a 1-800 number and email for ease of communication. Beginning 7/22/13, we asked participants and potential recruits their views of this method of by asking Q1) "How comfortable were you with our method of reaching you?" Participants were also asked Q2) "If we called you first, were you comfortable with us calling you?" Comfort was rated on a Likert scale with 10=most and 0=least comfortable.

Results: Of 161 PCPs, 143 gave approval, 2 refused, 12 wanted to be contacted for each patient, 4 did not respond. As of 5/20/14, 1,676 letters have been mailed; of these, 419 veterans called in; we contacted the remaining 1257. Of the 1676, 193 scheduled study visits, 306 were interested but not now, 326 could not be reached by phone, 851 were not interested. Of those who scheduled a study visit, 71% completed enrollment, 2% are pending study visit, 7% will reschedule, 20% cancelled. 148 potential recruits were asked Q1;146 responded with mean 9.1±2.0. 84 participants were asked and responded to Q1, mean 9.8±0.8. For Q2, 80/84 participants responded and rated their comfort with our calling them 9.6±1.4.

Conclusions: The opt-out recruitment strategy met IRB standards and has provided adequate enrollment for our study.Participants and potential recruits appear to be comfortable with this method of contact.

PUB169

CKD Education Classes Do Not Have an Impact on Outcomes of Dialysis Modality, Transplant or No Treatment Vikash Kumar Sinha,[2] Lumi Stutz,[1] Ying Zhou,[1] George C. Kim.[1] *[1]Div of Nephrology and Hypertension, Northshore Univ Healthsystems, Evanston, Illinois; [2]Div of Nephrology and Hypertension, Univ of Chicago, Chicago, IL.*

Background: At our institution, nurse practitioners (NP) administer chronic kidney disease (CKD) clinic that provides ESA treatment, hypertension management, bone mineral disorder management and addresses all aspects of CKD education and treatment. Medicare provides for education in Stage 4 CKD for a variety of reasons. To meet this need, we follow topic oriented lessons provided by the National Kidney Foundation by the NP's which includes education on peritoneal dialysis (PD), hemodialysis (HD), transplant and no treatment option. We attempted to determine if these classes versus standard physician and NP care have any impact on these choices.

Methods: We examined the outcomes of patients who were provided services in our chronic kidney clinics run by NPs (Clinic group) versus a Class group who took educational classes in 2012 and 2013. We examined demographics, clinical characteristics and outcomes after a minimum of 6 months follow-up. In the Class group, 47 of 78 pts reached an outcome and in the Clinic group, 54 of 170 pts reached an outcome. Outcomes were HD, PD, transplant and death without dialysis or transplant (DDT). We conducted a chi-square and t-test analysis on demographic and clinical variables. Multinomial logistic regression was used to compare among outcomes between Class and Clinic groups with adjustment of patient age.

Results: There was a difference in age between Class versus Clinic groups. There was no difference in choice of dialysis modality. When including age in the model, there was a higher likelihood that patients in the Clinic group would die versus go onto PD or transplant versus those patients who were in the Class group.

Group	OR	P value
HD vs PD	1.029 (0.995-1.063)	0.091
DDT vs PD	1.135 (1.053-1.221)	<0.001
DDT vs HD	1.013 (0.988-1.038)	0.318
DDT vs Transplant	1.206 (1.094-1.329)	<0.001

Conclusions: Dedicated education does not appear to have any impact on dialysis modality. Despite additional education on a no treatment option in the Class group, there was no increased incidence.

PUB170

Chronic Kidney Disease, Inflammation, and Risk of Mortality in Rheumatoid Arthritis Masako Kochi,[1] Kentaro Kohagura,[1] Kunitoshi Iseki,[2] Yusuke Ohya.[1] *[1]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus School of Medicine, Japan; [2]Dialysis Unit, Univ Hospital of the Ryukyus, Japan.*

Background: Rheumatoid arthritis (RA) increases the risk of mortality. The effects of chronic kidney disease (CKD) and inflammation on mortality are unknown. Thus, the aim of this study was to investigate the impact of CKD and C-reactive protein (CRP) levels on mortality in RA.

Methods: We included in our analyses 502 RA outpatients in this study. Of these patients, we selected 412 patients who could be followed more than 6 months and whose clinical data was available. We retrospectively investigated whether the presence of lower eGFR (estimated glomerular filtration rate of < 45 mL/min/1.73 m^2) and elevated CRP levels were independently associated with increased risk of mortality, and we also examined the interaction between lower eGFR and CRP for this risk.

Results: Mean age was 61 years, and 20 patients had lower eGFR. Over a median follow-up of 8 years, 40% (8/20) of those with lower eGFR and 6% (23/392) of those without lower eGFR died (p<0.0001). Either lower eGFR or CRP ≥ 0.5mg/dl were significantly associated with increased risk of mortality. Moreover, lower eGFR was further associated with increased risk of mortality when it was accompanied with elevated CRP ≥ 0.5mg/dl (adjusted hazard ratio, 15.6; 95% confidence interval, 4.4–59.1; p < 0.0001).

Conclusions: CKD had an inflammation-augmented association with increased mortality risk in RA. The impact of therapy for CKD and inflammation on mortality outcomes warrants further investigation.

PUB171

Prevalence and Misdiagnosis Analysis of Hospitalized Patients with Renal Failure Chen Yu, Wu Yitai. *Dept of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.*

Background: To realize the prevalence of renal failure in our hospitalized patients; analysis of their morbidity and etiology constitutes; diagnosis and misdiagnosis distribution in each department in order to improve the doctor's knowledge level of renal failure in related department.

Methods: We collected the blood biochemistry results of all hospitalized patients in one year period, screened the clinical data of the patients whose serum creatinine exceeded the upper limit, and performed a restropective analysis.

Results: A total of 1402 patients had renal failure, which accounted for 3.4% of all hospitalized patients at the same term. 63.4% of them were male (n=889), 36.6% of them were female (n=513). The department distribution of renal failure patients was analyzed; 42.2% in nephrology department (n=592), 25.7% in other medicine department (n=360), 32.1% in surgery department (n=450). 26.8% of patients had acute renal failure (n=376) and 3.2% had chronic renal failure (n=1026). Misdiagnosis rates were 36.7% in medicine system and 71.2% in surgery system. The nephrology department consultation rates were 33.4% in medicine system and 20.8% in surgery system.

Conclusions: Renal failure was distributed universally in non-nephrology medical departments. The misdiagnosis rate of renal failure was very high in non-nephrology department, especially in surgery department.

PUB172

Association of Serum Adiponectin, and Leptin Levels with Chronic Kidney Disease in Asian Adults Charumathi Sabanayagam,[1,2] Boon Wee Teo,[3] Qi Chun Toh,[3] E. Shyong Tai,[3] Sunil Sethi,[4] Tien Yin Wong.[1,2] *[1]Singapore Eye Research Institute, Singapore; [2]Office of Clinical Sciences, Duke-NUS Graduate Medical School, Singapore; [3]Medicine, National Univ of Singapore, Singapore; [4]Pathology, National Univ of Singapore, Singapore.*

Background: Adiponectin and leptin, two of the key cytokines secreted by adipocytes have been shown to be associated with cardiovascular disease. However, the association of these adipocytokines with chronic kidney disease (CKD) is not clear. We examined the association of serum adiponectin and leptin levels with CKD in a population-based sample of Asian adults.

Methods: We conducted a case-control study (463 CKD cases and 936 matched controls) involving Chinese and Indian adults aged 40-80 years who participated in the Singapore Epidemiology of Eye Diseases Study (2007-2011). Controls were matched to cases on age, sex and ethnicity. CKD was defined as an estimated glomerular filtration rate <60 mL/min/1.73m^2 from serum creatinine. Serum adiponectin and leptin levels were measured using commercially available ELISA. Odds ratio of CKD associated with elevated adiponectin and leptin levels were estimated using unconditional logistic regression models adjusted for education, smoking, body mass index (BMI), diabetes, blood pressure, total and HDL cholesterol.

Results: Compared to controls, CKD cases had higher levels of adiponectin (mean [SD] = 9.2 [4.2] versus 10.4 [7.4], p=0.001) and leptin (9.6 [11.5] versus16.9 [20.1] ng/mL; p<0.0001). In multivariable models, compared to those in the lowest quartile, the OR (95% confidence interval) of CKD among those in the highest quartile were: 1.94 (1.32-2.85) for adiponectin and 6.31 (3.75-10.60) for leptin. Similar positive association was also observed when adiponectin and leptin were analyzed as continuous variables. This positive association between serum adiponectin, leptin and CKD was consistently present in subgroups of gender, ethnicity, diabetes, hypertension and overweight status (all P-interaction >0.1).

Conclusions: Higher levels of serum adiponectin and leptin were positively associated with CKD independent of traditional risk factors in this Asian population.

Drug Prescription in CKD Patients of Moderate Severity: Results from the German Chronic Kidney Disease (GCKD) Study Silvia Huebner,[1] Stephanie Titze,[1] Matthias Schmid,[4] Thomas Dienemann,[1,3] Anna Kottgen,[2] Kai-Uwe Eckardt.[1] *[1]Dept of Nephrology and Hypertension, Univ Erlangen-Nuernberg, Germany; [2]Div of Nephrology, Univ Medical Center Freiburg, Germany; [3]Biostatistics and Epidemiology, Perelman School of Medicine, Pennsylvania; [4]Medical Biometry, Informatics and Epidemiology, Univ of Bonn, Germany.*

Background: CKD Patients suffer from a high burden of co-morbidities, including hypertension, bone and mineral disease and diabetes, many of which are amenable to drug therapy. Polypharmacotherapy can result in a cumbersome daily pill intake, hamper compliance, and result in complex pharmacological interactions with adverse side effects. However, data on daily drug burden in pre-ESRD patients are scarce. We examined medications and prescription patterns in the GCKD Study.

Methods: At the time of enrollment into the GCKD Study patients had to be 18 to 74 years and have an eGFR of 30-60 ml/min x 1,73m^2 or an eGFR ≥ 60 in the presence of overt proteinuria. Thorough phenotyping was performed according to standardized protocols. Medication intake was assessed by patient-reporting during structured interviews and validated with medical records. Active substances were classified using ATC codes.

Results: The baseline examination was completed by 5217 patients (mean age 60 years, 40% female, 35% with diabetes, 20% with CVD history). Less than 1% of patients did not take any medication at all and the maximum number of medications was 30. Median daily intake amounted to 7.6 substances. The most commonly administered drug classes at baseline were beta blockers (55%), ACE inhibitors (52%), HMG CoA reductase inhibitors (48%) and loop diuretics (39%). The prevalence of hypertension was 95%. Despite almost ubiquitious treatment only 48% met blood pressure targets of 140/90 mmHg.

Conclusions: Patients with moderately severe stages of CKD have a high burden of daily medication raising questions about drug adherence, side effects and interactions. Despite a large number of prescriptions, treatment targets are not consistently met. Management strategies in CKD need to take into account medication burden and treatment priorities.

PUB174

Simultaneous Evaluation of Serum Albumin and Body Mass Index Predicts Chronic Kidney Disease Progression: A Prospective Cohort Study Hiroaki Kikuchi,[1] Eiichiro Kanda,[2] Soichiro Iimori,[1] Teiichi Tamura,[3] Sei Sasaki,[1] Eisei Sohara,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Tokyo Kyosai Hospital, Tokyo, Japan; [3]Yokosuka Kyosai Hospital, Kanagawa, Japan.*

Background: The relationship between nutritional status and renal function has been shown in several studies. Although serum albumin is a widely used biomarker of nutritional status, its validity to evaluate nutritional status is controversial especially in chronic kidney disease (CKD) patients with body fluid imbalance and proteinuria. We evaluated a hypothesis that low albumin level and low body mass index (BMI) were associated with CKD progression in this prospective cohort study.

Methods: 710 patients (CKD stage 2-5) were included in this study, who newly visited our facilities. They were categorized into 4 groups according to their albumin levels and BMI: group 1, low albumin level (<4 g/dL) and low BMI (<23.4); group 2, high albumin level (≥4 g/dL) and low BMI; group 3, low albumin level and high BMI (≥23.4); group4, high albumin level and high BMI. The primary outcome was 15% decline in estimated glomerular filtration rate (eGFR) within 1 year. The secondary outcome was the annual GFR decline, ΔeGFR (mL/min/1.73m^2/year).

Results: The average age and eGFR (SD) were 67.3 (13.4) years and 34.3 (17.4) ml/min/1.73 m^2, respectively. Logistic regression analysis adjusted for baseline characteristics (reference, group 4) showed that group 1 was associated with a high risk of CKD progression; adjusted odds ratio (aOR) 2.055 [95% confidence interval (CI) (1.119, 3.776)]; group2, aOR 1.64 (95% CI 0.907, 2.944); group3, aOR 1.58 (95% CI 0.853, 2.920). A multivariable regression analysis adjusted for baseline characteristics showed that significant difference in ΔeGFR was observed between group 1 and group 4 (β=-2.76, p=0.003).

Conclusions: This study suggested that CKD patients with low albumin level and BMI have a high risk of CKD progression, and that simultaneous evaluation of albumin level and BMI may be helpful for the assessment of nutritional status and prediction of CKD progression.

PUB175

Association of Metabolic Syndrome with Chronic Kidney Disease According to Menopausal Status in a Chinese Population Yongqiang Li, Hequn Zou. *Dept of Nephronology, Institute of Nephronology and Urology, The Third Affiliated Hospital of Southern Medical Univ, GuangZhou, China.*

Background: To explore the relationship between metabolic syndrome (MS) and chronic kidney disease (CKD) according to menopausal status.

Methods: A cross-sectional study was conducted in 1346 community-based women participants from June to October 2012 in Zhuhai city. The prevalence of MS (as defined by the International Diabetes Federation) and CKD (defined as an estimated glomerular filtration rate of <60 mL/min per 1.73 m^2 and/or albuminuria) was determined in premenopausal women and postmenopausal women, respectively. The association between MS and CKD was analyzed using SPSS software(version 19.0).

Results: MS was significantly associated with CKD in the unadjusted analyses as well as after adjustment for potential confounders in premenopausal women. The unadjusted odd ratio(OR) and adjusted OR for MS were 3.10 (95% CI 1.32 to 7.28, P=0.009) and 4.09 (95% CI 1.63 to 10.32, P P=0.003). When adjusted for diabetes and hypertension, there was no association between MS and CKD in premenopausal women (OR 3.25, 95% CI 0.96 to 11.02, P=0.058). MS was associated with CKD (P<0.001) in the unadjusted analyses in postmenopausal women. Further adjustment for potential confounders, MS was still significantly associated with CKD. The OR for MS was 2.60 (95% CI 1.69 to 3.99, P<0.001). When adjusted for diabetes and hypertension, the association of MS and CKD was still significant (OR 1.80, 95% CI 1.09 to 2.98, P=0.022). After adjusting for potential confounders, higher blood pressure, higher serum triglyceride level and higher fast glucose were signicently associated with CKD in postmenopausal women. The OR for elevated blood pressure, elevated serum triglyceride levels and elevated fasting glucose were 2.28 (95% CI 1.22 to 4.26, P=0.01), 1.71 (95% CI 1.03 to 2.86, P=0.039) and 2.25 (95% CI 1.36 to 3.73, P=0.002), respectively.

Conclusions: These findings suggest that MS is associated with CKD in premenopausal women and the association was dependent of diabetes or hypertension. This study also suggest that MS is associated with CKD in postmenopausal women and this association was independent of diabetes or hypertension.

PUB176

Severity of Anemia as a Predictor of Hospital Length of Stay and Readmission in Patients with Chronic Kidney Disease

Katherine Garlo,[1] Lee Lucas,[2] Deanna Williams,[2] Rocket Wong,[2] Stuart Abramson,[1] Mark G. Parker.[1] *[1]Div of Nephrology and Transplantation, Maine Medical Center; [2]Center for Outcomes Research Evaluation, Maine Medical Center, Portland, ME.*

Background: Anemia is highly prevalent in patients with CKD. Descriptive studies suggest that anemia is an independent risk factor for increased hospital length of stay and readmission rate. We report the prevalence of severe anemia in hospitalized patients with CKD stage 3-5 and examine its relationship to hospital length of stay and readmission rate.

Methods: This was a retrospective cohort study of patients admitted to Maine Medical Center over 13 months with eGFR < 60mL/min/1.73 m^2 and not on dialysis. Patients with kidney transplant, acute kidney injury, GI bleeding, cancer, pregnancy, and surgery were excluded. The cohort was split into severe (hemoglobin </= 9 g/dl) versus non-severe anemia. The groups were compared for differences in continuous variables using ttests and categorical variables using chisquare tests or Fisher's exact tests. A p value of 0.05 was significant and two tailed tests were used.

Results: A total of 1,141 patients were included. Of these, 156 (13.7%) had severe anemia (mean 8.1 gm/dl, SD 0.8). Severe anemia was associated with increased hospital length of stay as compared to control; mean 6.4 (SD 6.0) days versus mean 4.5 (SD 4.0) days (P < 0.001) and not associated with increased readmission rate; mean 11.5% versus 10.2% (P = 0.7).

Characteristic	Hb< /= 9.0 gm/dl (n = 156)	Hb > 9.0 gm/dl (n = 985)	P Value
Hemoglobin (gm/dl) mean (SD)	8.1 (0.8)	11.8 (1.6)	<0.001
Age, years (SD)	72.9 (14.3)	76.7 (13.2)	0.001
Female, n (%)	91 (58.3)	566 (57.5)	0.91
Non-Caucasian, n (%)	8 (5.1)	25 (2.6)	0.12
Diabetes, n (%)	82 (52.6)	636 (64.6)	0.005
Heart Failure, n (%)	59 (37.8)	376 (38.2)	1.0
eGFR, mean (SD)	32.6 (16.7)	43.9 (13.3)	<0.001
30 day readmission rate, n (%)	18 (11.5)	100 (10.2)	0.70
Hospital length of stay in days, mean (SD)	6.4 (6.0)	4.5 (4.0)	<0.001

Conclusions: Severely anemic patients with CKD are at risk for increased hospital length of stay. Improved transfusion strategies, iron replacement, and erythropoieitin stimulating agent use, has the potential to improve hospital outcomes.

PUB177

Impact of Type of Referral and Dialysis Start on Clinical Outcomes and Final Renal Replacement Therapy in a Multicenter Integrated Care Setting

Belen Marron Ochoa,[1] Marietta Torok,[2] Delia Timofte,[3] Janusz Ostrowski,[4] Jose C. Divino-Filho.[1] *[1]Home Therapies Medical Office, Diaverum, Munich, Germany; [2]Diaverum, Budapest, Hungary; [3]Diaverum, Bucharest, Romania; [4]Diaverum, Wloclawek, Poland.*

Background: Early referral, choice of RRT modality and planned start may increase patient survival, however international reports show disparities between desirable patterns and practice. **Objectives:** To analyze the effects of Integrated Care and education on dialysis start (planned versus non-planned) and RRT modality choice.

Methods: Retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD Diaverum clinics in Poland, Hungary and Romania during 2012. Scheduled initiation of dialysis with a permanent vascular or peritoneal access was considered as planned start.

Results: Population: 30% DM, mean age 64 y., 84% with previous medical care of renal disease, 49 % late referral, 58 % unplanned start, 92% on HD as modality. Half of those with unplanned start had previous Nephrology follow-up. Patients (n=332) with GFR <30 ml/min were followed up mainly by "general nephrologists" (68%) and 29% in structured predialysis units Modality information (80% of all patients) and general renal education (87%) were more frequent (p<0.001) in planned start. Half of patients were involved in therapy choice whereas informed and dialysis start consents were signed by 57% and 77%. The median time from information to dialysis start was 2 months. Unplanned start (p≤0.05) correlated with nephropathy of uncertain origin, worse clinical status, shorter time from information to RRT start and less PD use. Patient non-compliance (36%) and unexpected GFR loss (19%) contributed to unplanned start. "Optimal care" defined as combination of Nephrology follow-up (> 3 months), modality information and planned start occurred in 22% of the patients.

Conclusions: Despite the high rate of late referral, information and education were widely provided. Unplanned start was frequent and may underlie the low frequency of PD choice. Measures such as implementation of structured predialysis units may facilitate better and timely referral and improve well-being and planning of RRT start as well as increased PD use.

PUB178

Evaluation of Type of Dialysis Access for Incident Patients in HD/PD Integrated Care Clinics in Poland, Romania and Hungary

Belen Marron Ochoa,[1] Delia Timofte,[2] Janusz Ostrowski,[3] Marietta Torok,[4] Jose C. Divino-Filho.[1] *[1]Home Therapies Medical Office, Diaverum, Munich, Germany; [2]Diaverum, Bucharest, Romania; [3]Diaverum, Wloclawek, Poland; [4]Diaverum, Budapest, Hungary.*

Background: HD catheters are associated with higher morbi-mortality and cost. **Objectives:** To analyze the dialysis access at initiation of dialysis and its relationship with the predialysis referral and care.

Methods: Retrospective analysis of 547 patients starting dialysis in 23 HD/PD clinics in 2012. Early referral patients were known for ≥ 3 months in Nephrology prior to dialysis initiation. Scheduled initiation of dialysis with a permanent access was considered planned.

Results: Population: 30% diabetes, mean age 64 years, 84% with previous medical care of renal disease, 49% late referral, 80% received information about dialysis modalities, 58% unplanned start, HD: 92% as first dialysis and 89% as first chronic dialysis. No permanent access at dialysis start (p≤0.05) correlated with shorter time from information to dialysis start, higher sCr and lower at request of dialysis access, lower number of pre-dialysis visits, worse clinical status, 49% permanent HD catheter use (p<0.001) and as first chronic HD access (34%), and less PD. PD was used mainly for early referred and planned start patients.

1st Initial Dialysis Accesses Subgroups n (% vs.row)	Patients (n=547)	Permanent HD catheter (n=267)	Temporal HD catheter (n=47)	A-V Fistula (n=188)	Peritoneal catheter (n=45)	p
Early referral (ER) + Planned (P)	168 (30)	3 (2)	0 (0)	130 (78)	35 (21)	<0,001
ER + Unplanned (NP)	113 (20)	99 (87)	10 (9)	1 (1)	3 (3)	
Late referral (LR) + P	63 (12)	2 (3)	0 (0)	56 (89)	5 (8)	
LR + NP	203 (38)	163 (80)	37 (18)	1 (0,4)	2 (1)	

Conclusions: Regardless type of referral, A-V fistula was largely use for HD planned patients. By contrast, a large proportion of unplanned patients persisted with permanent HD catheters as first chronic vascular access. Adequate planning may decrease HD catheters prevalence whilst PD could be used as a therapy for urgent start patients.

PUB179

The Clinical Examination of Prognostic Factor in Nephrosclerosis

Kumiko Momoki, Hiroshi Kataoka, Takahito Moriyama, Kosaku Nitta. *Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: In recent years, nephrosclerosis is an important chronic kidney disease (CKD), as arteriosclerosis and population aging increase. Although hypertension is major prognosis factor, various factors such as obesity, metabolic syndrome, diabetes mellitus, and hyper uricemia can be also implicated to CKD progress. We examined prognostic factors in biopsy-proven nephrosclerosis.

Methods: We retrospectively examined 53 patients who were diagnosed with nephrosclerosis by kidney biopsy in Tokyo Woman's Medical University Hospital since May to June 2013. The clinical parameters assessed at the time of the renal biopsy were age, gender, mean arterial blood pressure (MAP), body mass index (BMI), proteinuria (grams per day), eGFR uric acid, triglyceride and total cholesterol. Subjects with the duration of follow-up less than 1 year were excluded. Prognostic variables for renal survival were examined by using the simple and multivariate Cox proportional hazards method. The renal endpoint of the present study was defined as a 50% eGFR decline or end stage kidney disease (ESKD). We also investigated the correlations between uric acid and baseline clinical data using regression analysis.

Results: In simple Cox analysis, proteinuria (Hazard ratio=2.61, p=0.0002), uric acid (Hazard ratio=1.65, p=0.007) and BMI (Hazard ratio=1.15, p=0.04) were significantly related to e-GFR decline or ESKD. A multiple regression analysis by the Cox method showed that uric acid was significantly associated with e-GFR decline or ESKD (Hazard ratio=2.72, p=0.04). Uric acid was positively correlated with proteinuria (R=0.37, p=0.007) and male (R=0.36, p=0.009) and negatively correlated with e-GFR (R=-0.28, p=0.04) in a simple regression analysis.

Conclusions: The results of this study suggest that uric acid can be clinical prognostic predictor, which has correlations with proteinuria, male and e-GFR, in patients with nephrosclerosis.

PUB180

HDL Quality and CKD Progression in Patients with Heart Failure with Preserved Ejection Fraction (HFPEF) Chantal Maureen Kopecky,[1] Marlies Antlanger,[1] Marcus Saemann,[1] Diana Bonderman.[2] *[1]Dept of Internal Medicine III, Clinical Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria; [2]Dept of Internal Medicine II, Clinical Div of Cardiology, Medical Univ of Vienna, Vienna, Austria.*

Background: Heart failure with preserved ejection fraction (HFPEF) is a complex disease with several contributing factors including systemic inflammation. Advanced disease stages are characterized by post-capillary pulmonary hypertension and chronic kidney disease (CKD), which in turn may propagate disease progression. CKD and HFPEF may share common pathophysiological pathways both indicative and causally involved in these diseases. The protein composition of high-density lipoprotein (HDL) has been demonstrated to be severely altered in high cardiovascular risk diseases including CKD. Therefore, we assessed HDL quality by analysis of two critical HDL proteins, serum amyloid A (SAA) associated with systemic inflammation and surfactant protein B (SP-B) involved in pulmonary congestion, to represent indicative clinical and diagnostic HFPEF features.

Methods: We developed a simple, laboratory assay to measure HDL-bound SAA and SP-B levels directly from serum. HFPEF patient samples were subjected to this assay at the time of clinical diagnosis. SAA and SP-B levels were correlated with functional and clinical parameters in the cohort, grouped by occurrence of cardiac events during the follow-up period of up to 3 years.

Results: HFPEF patients had profoundly increased levels of HDL-bound SAA and SP-B compared to controls. SAA(HDL) was found to correlate with kidney function and inflammation., whereas SP-B(HDL) was inversely associated with distinct pulmonary functions. Importantly, these correlations were independent of HDL-cholesterol levels and only found in patients who experienced cardiac events after inclusion.

Conclusions: Substantial enrichment of SAA and SP-B on HDL reflect distinct pathophysiological changes in HFPEF, providing potential novel biomarkers of diagnostic value. Moreover, SAA(HDL) emerges as predictor of CKD progression in this patient group, advancing our understanding of potential causal processes in HFPEF.

PUB181

Lessons Learned from Pyridorin Pilot Study to Design the Pivotal Clinical Trial Jamie P. Dwyer,[1] Kausik Umanath,[2] Bob Peterson,[3] J. Wesley Fox,[3] Julia Lewis,[1] Mohammed Sika.[1] *[1]Nephrology, Vanderbilt, Nashville, TN; [2]Nephrology, Henry Ford Hospital, Detroit, MI; [3]NephroGenex, Inc., Durham, NC.*

Background: Pyridorin™ blocks pathways in the progression of diabetic nephropathy. The Pyridorin pilot was designed to test entry criteria and outcomes. Subjects had SCr 1.3 to 3.5 mg/dL, ≥1200 PCR with a surrogate outcome of 52 wk ΔSCr. Subjects had to be on a max tolerated dose of ACE/ARB for 3 mos; stable other antihypertensives for 2 mos; stable diuretic dose for 2 wks, and a BP ≤160/90 mmHg; or enter a Pharmaco-Stabilization Phase (PSP). This pilot failed to detect an effect on ΔSCr in intent-to-treat analysis.

Methods: We queried the locked trial database.

Results: The pre-specified subgroup analyses revealed that subjects not requiring PSP and those with entry SCr <2.0mg/dL had a treatment effect associated with Pyridorin. Subjects who entered the PSP required more changes in antihypertensive medications after randomization and experienced a larger ΔSCr over 52 wks. Initiation/increase in ACE/ARB can have acute effects on GFR. Time required for these to stabilize is unknown. Our data would suggest that it is longer than 3 mos. Subjects in our pivotal trial must be on ACE/ARB for 6 mos. PSP subjects entering the pilot with BP>140/90 mmHg had no treatment effect, whereas those entering with BP ≤140/90 did. Subjects requiring frequent adjustments of antihypertensives, including diuretics, could experience changes in their SCr not related to the progression of CKD. In our pivotal trial, subjects must have a BP≤150/90 and on stable doses of antihypertensives for 26 weeks, or ≤140/90 and on stable antihypertensives for 13 wks. ΔSCr over 52-wks averages the creatinine of all subjects, many of whom have small increases or decreases of SCr related to acute events other than the progression of CKD. In our pivotal trial, our primary outcome is a time to event analysis of baseline SCr to at least a 50% increase in SCr or ESRD. This substantial change in SCr is protected from noise, is clinically relevant, and has been endorsed recently by the FDA-NKF Endpoints Conference.

Conclusions: The Pyridorin pilot provided critical information to guide the design of the pivotal trial.

PUB182

Epidemiology of Chronic Kidney Disease in an Adult Malaysian Population Muhammad Salman,[1,2] Amer Hayat Khan,[1,2] Syed Azhar Sulaieman,[2] Azreen Syazril Adnan,[1] Fauziah Jummaat,[3] Nurul Jannah Ambak,[1] Tauqeer Hussain Mallhi.[2] *[1]Chronic Kidney Disease Resource Center, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia; [2]Dept of Clinical Pharmacy, Univ Sains Malaysia, Penang, Malaysia; [3]Dept of Obstetrics and Gynecology, Univ Sains Malaysia, Kubang Kerian, Kelantan, Malaysia.*

Background: Information concerning etiologies of chronic kidney disease (CKD) - an escalating public health problem worldwide- is scarce in Malaysia, which is prerequisite to reduce the disease burden.

Methods: A retrospective analysis of medical record data of adults (≥18 years old), hospitalized due to CKD at Hospital Universiti Sains Malaysia (HUSM), Kelantan, Malaysia between January 2009 and December 2013 was made. Data regarding socio-demographics, etiology, and stage of CKD were recorded using a standard data collection tool.

Results: A total of 851 eligible patients were recruited with male to female ratio being 1.75: 1 (541:310) and mean age of 61.18 ± 13.37 years. CKD stage 5 was accounted in 39.1% of the cases whereas stage 4, 3b, 3a, 2 and 1 cases were28.2%, 21.9%, 8.7%, 1.8% and 0.4%, respectively. The leading etiologies of CKD identified in our study population were diabetic nephropathy (DN) (44.9%), hypertension (HPT) (24.2%), obstructive uropathy (OBS) (9.2%) and glomerulonephritis (GN) (6.7%). Unknown etiology constituted 9.5% of our patients. The difference in the incidence of CKD due to DN, HPT and GN between patients ≤ 50 years old and > 50 years old was statistically significant ($P = 0.008$, $P < 0.001$ and $P < 0.001$, respectively).

Conclusions: Diabetic nephropathy is the leading cause of CKD –accounting for approximately 50% of CKD- followed by hypertension in Northeast Peninsular Malaysia.

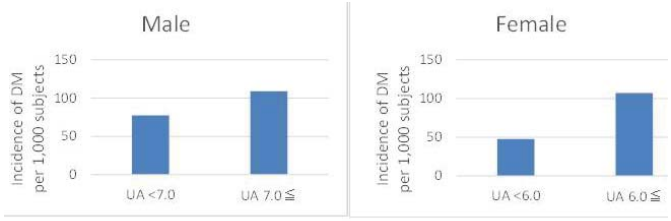
PUB183

Uric Acid as a Risk Factor of Developing Diabetes Mellitus in a Large Community Based Screening Participant Shoji Tsuneyoshi,[1] Kunitoshi Iseki.[2] *[1]Total Renal Care And Team Medicine, Univ Hospital of the Ryukyus, Nishihara, Okinawa, Japan; [2]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara, Okinawa, Japan.*

Background: Hyperuricemia is common among hypertension and diabetes mellitus (DM). However, the epidemiological studies on the effect of serum uric acid on the incidence of DM are still controversial.

Methods: We examined the subjects who participated twice at 1993 and 2003 screening by the Okinawa General Health Maintenance Association (currently Okinawa Health Promotion Foundation) in Okinawa, Japan. All of them have data both serum uric acid (UA) and fasting blood sugar (FBS) (n=12,458). Hyperuricemia wan defined by UA≥7.0mg/dL in male, and ≥6.0md/dL in female. DM was diagnosed as FBS≥126mg/dL. Adjusted odds ratio (OR) and 95% confidence interval (CI) were calculated using age, sex, serum creatinine, obesity, hypertension, and hypertriglyceridemia, by logistic analysis.

Results: Among the subjects in 1993 survey, 453 (3.6%) was diagnosed as DM, and 12,005 (96.4%) was non DM subjects. DM developed 560 (6.0%) subjects in non hyperuricemic (n=9,329), and 290 (10.8%) subjects in hyperuricemic (n=2,676) (OR 1.26, 95% CI 1.07-1.48). In male, DM developed 298 (7.8%) subjects in non hyperuricemic (n=3,844), and 199 (10.9%) subjects in hyperuricemic (n=1,828) (OR 1.18, 95% CI 0.96-1.44). In female, DM developed 262 (4.8%) subjects in non hyperuricemic (n=5,485), and 91 (10.7%) subjects in hyperuricemic (n=848) (OR 1.44, 95% CI 1.09-1.88).



UA (mg/dL)	<7.0	7.0≦	UA (mg/dL)	<6.0	6.0≦
number	3,844	1828	number	5485	848
new DM	298	199	new DM	262	91

Conclusions: Result supports the notion of the role of hyperuricemia on the development of DM. DM is a leading cause of end-stage renal disease (ESRD). Therefore, early detection of hyperuricemia would be a useful strategy on the prevention of ESRD. Further studies are needed to investigate the effect of treatment of hyperuricemia.

PUB184

The Canadian Assessing Inflammatory Markers to Predict Events in Nephrology Study: The CAN-AIM Study Design, Rationale, and Baseline Dataset Description Tabo G. Sikaneta,[1,4] Fernando Camacho,[2] Anita Kit Seung Ng,[1] Ishwarlal Jialal,[3] George G. Wu,[1] Bharat Nathoo,[1] Paul Y. Tam.[1,4] *[1]Institute of Kidney Lifescience Technologies, Scarborough, ON, Canada; [2]Damos Incorporated, Toronto, ON, Canada; [3]Dept of Pathology and Laboratory Medicine, UC Davis Medical Center, Sacramento, CA; [4]Internal Medicine, The Scarborough Hospital, Scarborough, ON, Canada.*

Background: The increased risks of end stage kidney disease (ESRD), cardiovascular (CV) morbidity, and death in patients with chronic kidney disease (CKD) can only partly be predicted. We plan to assess the temporal relationship between serum FGF-23, high-sensitivity C-reactive protein, and these outcomes.

Methods: Planned prospective observational cohort of 2500 patients followed in three CKD clinics in Ontario for 36 months or until ESRD or death ensues. Recorded data include 6-monthly clinic evaluations with estimates of proteinuria and glomerular filtration (eGFR) rates, and medication and co-morbidity updates, yearly electrocardiograph tracings, and trans-thoracic echocardiograms at study entry and completion. Blood samples are being stored for additional inflammatory markers and for genetic analysis of undetermined

and potentially confounding genetic variables. The primary outcome is need for renal replacement therapy, with secondary outcomes being a composite of CV events and CV mortality, and all-cause mortality.

Results: Of 2530 screened and consenting patients, 2256 completed visit one, with 2164 having provided consent for DNA testing. Mean age was 69.2 (+/-12.3) years, with 66% being male, 49% Asian, 41% White, and 8% Black. A history of diabetes mellitus was documented in 48%, hypertension in 93%, and ischemic heart disease in 24%. Mean enrollment C-reactive protein was 3.58 (+/-6.87) mg/L, FGF-23 170.5 (+/-324) RU/mL, urine albumin:creatinine 50 (+/-102.9) mg/mmol, and eGFR 41.4 (+/-13.3) ml/min/1.73m^2. Enrolment blood pressures were 132.7(+/-18.9)/73.7(+/-10.4) mmHg, and body mass index 28.1 (+/-5.6).

Conclusions: The study is expected to close on December 31st 2016.

Funding: Pharmaceutical Company Support - Janssen

PUB185

The Prognostic Impact of Renin-Angiotensin Aldosterone System Blockades on Survival in Cancer Patients with Chronic Kidney Disease

Ae Jin Kim,[1] Hye Jin Lim,[1] Han Ro,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung,[1] Yun Jung Oh,[2] Ji Yong Jung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: Angiotensin converting enzyme inhibitors (ACEi) and angiotensin II receptor blockers (ARB) are commonly prescribed to the huge number of chronic kidney disease (CKD) patients. However, recent report about the harmful effect of ACEi/ARB had raised concerns about their safety in cancer patients. Therefore, we determined the association between the antihypertensive medications and mortality in cancer patients and compared the effect on patients with and without CKD.

Methods: We retrospectively reviewed the cases of 28,047 cancer patients with one or more serum creatinine measurements from January 1, 2000 to December 31, 2013. Cox proportional-hazards regression were used to compare the overall survival of the ACEi, ARB, calcium channel blockers (CCB), beta blockers (BB), or diuretics users and non-users in patients with and without CKD.

Results: In all cancer patients, ACEi shows beneficial effect on overall survival (HR 0.82, 95% CI: 0.71-0.95, p= 0.007). While CCB and diuretics are associated with an increased mortality, ARB and BB have no significant effect on survival. In the subgroup analysis, ACEi still shows a benefit on overall survival (HR 0.77, 95% CI: 0.62-0.97, p= 0.022) only in the CKD patients. While diuretics are associated with significant risk for mortality in both CKD (HR 1.62, 95% CI: 1.40-1.87, p< 0.001) and non-CKD (HR 1.82, 95% CI: 1.62-2.05, p< 0.001) patients, ARB, CCB and BB have no significant effect on survival in both CKD and non-CKD patients.

Conclusions: The use of ACEi may be associated with improved survival in cancer patients, especially with CKD. Our results provide some reassurance that there is no need to hesitate to prescribe these medications in cancer patients diagnosed with CKD.

PUB186

Management and Prognosis of Polycystic Kidney Disease: Results of the Italian ALaMMU Study

Marco Galliani. *On Behalf of ALaMMU Working Group, UOC Nephrology, Pertini Hospital, Rome, Italy.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease and relentlessly progress to end stage renal failure. A specific treatment is not yet available. Moreover, it is a disease with protean clinical features, especially in the predialytic stage, and little is known about the management still highly different among the nephrologists.

Methods: The aim of the present survey is to describe the different approaches and study its clinical course, also in relation to the genetic variants, in order to identify the factors that contribute to its progression. We studied 437 patients from 28 nephrologic centers of ALaMMU Working Group of central Italy, with a median age of 35aa (F/M = 57.6%/42.4%).

Results: The heritability was 34% paternal and 40% maternal, while it was unknown in the remaining 26%. The mode of presentation was familiar in 54% of cases, occasional in 28% and 18% linked to the onset of symptoms. The main clinical symptoms were represented by hypertension in 60% of cases, urinary tract infection in 28%, nephrolithiasis in 22% and microscopic hematuria in 16%. Renal function at onset is described in the table.

Presentation modality	%	GFRml/min	GFR<60ml/min(%)
Familial	54	98	30
Occasional	28	65	49
Symptoms	18	90	21

The distribution of ACE inhibitors and/or ARBs in hypertension therapy was: ACE:50%, ARB:33%, ACE+ARB:17%. The evaluation of renal size was performed with MRI in 10% of cases and by CT in 2%.

Conclusions: This study will give a contribution to the knowledge of the ADPKD phenotypic aspects, about the clinical course and will throw light on the approach at the disease management. The next phase of the study, beyond the increase in the number of cases, will also include the genetic analysis of patients, and will allow to make genotype/phenotype correlations that will be the foundation for future therapeutic approaches.

PUB187

Cardiovascular Risk Factors in the German Chronic Kidney Disease (GCKD) Study

Martin Busch,[1] Katharina Paul,[1] Matthias Schmid,[3] Stephanie Titze,[2] Silvia Huebner,[2] Karl F. Hilgers,[2] Anna Kottgen,[4] Ulla T. Schultheiss,[4] Seema Baid-Agrawal,[5] Johan M. Lorenzen,[6] Georg Schlieper,[7] Claudia Sommerer,[8] Vera Krane,[9] Robert Hilge,[10] Jan T. Kielstein,[6] Florian Kronenberg,[11] Christoph Wanner,[9] Kai-Uwe Eckardt,[2] Gunter B. Wolf.[1] *[1]Int.Med.III, Univ. Hosp., Jena, Germany; [2]Med.Klin.4, Univ., Erlangen, Germany; [3]Med.Inform., Univ., Bonn, Germany; [4]Med.Clin.IV, Univ.Hosp., Freiburg, Germany; [5]Nephrol., Charite, Berlin, Germany; [6]Int.Med., Med.Hochsch., Hannover, Germany; [7]Med. Klin.II, Univ.Clinic, Aachen, Germany; [8]Int.Med., Univ.Hosp., Heidelberg, Germany; [9]Nephrol., Univ.Clinic, Würzburg, Germany; [10]Med.Pol., Univ.Clinic, München, Germany; [11]Gen.Epid., Med.Univ., Innsbruck, Germany.*

Background: CVD is the leading cause of mortality in patients with diabetes mellitus (DM) and chronic kidney disease (CKD). It is not clear whether DM just amplifies the risk or rather modifies the characteristics of CKD patients leading to differences in risk.

Methods: 5217 patients aged 18 to 74 years having an eGFR between 30-60 (mL/min/1.73 m^2) or overt proteinuria were enrolled across 169 renal outpatient centres in Germany.

Results: Baseline data of patients with and without DM are shown.

	Patients with DM n=1842 (35%)	**Patients without DM** n=3375 (65%)	***P-Value***
Age (years)	65 ± 8	58 ± 13	<0.001
Male gender	1228 (67)	1904 (56)	<0.001
Systolic/ Diastolic blood pressure	142 ± 22/ 76 ± 12	138 ± 20/ 81 ± 12	<0.001
BMI (kg/m^2)	32 ± 6	28 ± 5	<0.001
eGFR (mL/min/1.73 m^2)	45 ± 16	48 ± 17	0.07
CRP (mg/L)	3.0 (1.4-6.4)	2.0 (0.9-4.4)	<0.001
Hemoglobin (g/dL)	13.5 (12.3-14.5)	13.7 (12.6-14.7)	<0.001
HbA1c (%)	7.0 (6.8-7.9)	5.8 (5.6-6.0)	<0.001
UACR (mg/g)	47 (9-371)	54 (9-397)	0.45
Current smokers	269 (15)	559 (17)	0.006
LDL-C (mg/dL)	101 (78-129)	121 (96-149)	<0.001
HDL-C (mg/dL)	44 (36-55)	51 (41-64)	<0.001
Triglycerides (mg/dL)	191 (131-268)	159 (112-224)	<0.001
Use of statins (%)	1217 (66)	1444 (43)	<0.001
History of CVD	866 (47)	814 (24)	<0.001

Conclusions: The treatment quality of DM was satisfactory under nephrological care. The higher prevalence of CVD in patients with DM is likely to be related – in addition to DM – to an increased impact of established CVD risk factors, but excluding hypercholesterinemia and albuminuria.

PUB188

Identifying Opportunities to Increase Angiotensin Inhibitor Use in Chronic Kidney Disease Shanza Mujeeb, Sairah Sharif, Candace D. Grant, Pooja Kumari, Milind K. Bhagat, Shayan Shirazian, Joseph Mattana. *Medicine, Winthrop Univ Hospital, Mineola, NY.*

Background: Angiotensin inhibitors (AIs) have a substantial impact on slowing and preventing progression of chronic kidney disease (CKD) to end stage renal disease (ESRD) yet they are often underutilized. It is plausible that in many instances the reasons for nonuse may not necessary preclude using an AI. The objective of this study was to determine reasons for nonuse of AIs in CKD patients in whom it is indicated and to identify potential opportunities to maximize their use.

Methods: The electronic health records of 862 consecutive adult patients with CKD stage 3 and 4 seen in the nephrology faculty practice at our institution were reviewed. Estimated GFR (eGFR) and urine albumin creatinine ratio (ACR) were recorded and CKD stage determined. We considered an indication for an AI to be present for patients with diabetes and ACR >30 mcg/mg and for patients without diabetes and with ACR >300mcg/mg. Medication lists were reviewed for AI use. For patients not on an AI, an exhaustive review of the record was carried out to ascertain the reason.

Results: Of 557 patients with stage 3 and 4 CKD who met the study criteria, 28% (n=155) were found not to be on an AI. The category with the most patients (n=79, 51%) was the "No Reason" category, meaning that there was no explanation provided in the medical record. The next three categories were history of AKI (n=21, 13%), hyperkalemia (n=21, 13%) and hypotension (n=11, 7%). Other reasons noted included allergy, advanced CKD, renal artery stenosis and other. The category ranking was consistent for patients in each stage of CKD.

Conclusions: This study suggests that a large percentage of patients with CKD and an indication for AI therapy may not be not receiving such treatment. However, our findings also suggest that there may be a substantial opportunity to increase use of AIs. An increased understanding of the reasons for nonuse of AIs in patients where it is indicated may be helpful in designing interventions to optimize their use and delay or prevent the development of ESRD.

PUB189

Statins Role in Kidney Disease André Fragoso, Ana Paula Silva, Pedro Neves. *Nephrology Dept, Hospital de Faro, Faro, Portugal.*

Background: Patients with chronic kidney disease (CKD) have a high risk of cardiovascular disease (CVD). The effects of statins therapy in patients with CKD remain uncertain. The purpose of this study was to evaluate the role of statins in CKD progression and CVD.

Methods: In this observational study we included 349 CKD patients (f=191, m=158) with a mean age of 74.7 years and a mean eGFR (MDRD) of 19.9 ±9,9 ml/min followed in our outpatient predialysis clinic during 124 weeks. At baseline, the patients underwent a complete clinical history and physical examination and several laboratory parameters were analyzed. Our population was divided in two groups: G-I (n= 192) without statins therapy and G-II (n=157) with statins.

Results: We found that patients under statins therapy (G-II) showed higher levels of eGFR (MDRD 21.58 versus 18.53; p=0.004), calcium (9.35 versus 9.11; p=0.004), albumin (4.04 versus 3.91; p=0.018) and lower levels of phosphorus (4.01 versus 4.18; p=0.044), iPTH (206.08 versus 280.68; p=0.0001) and pulse pressure (59.64 versus 64.13; p=0.012) at baseline. In a multivariate cox proportional hazard stepwise model to identify independent risk factors of renal survival male gender (HR=2.41, 95% CI, 1.39 to 4.17; p=0.002), Hg (HR=0.623, 95% CI, 0.50 to 0.78; p=0.0001), eGFR (HR=0.891, 95% CI, 0.81 to 0.98; p=0.015), albumin (HR=0.663, 95% CI, 0.46 to 0.96; p=0.028) and statins (HR=0.607, 95% CI, 0.544 to 0.91; p=0.007) were found to predict renal survival. We also found that CVD (HR 4.08, 95% CI, 2.06 to 8.09; p=0.0001), Hg (HR 0.65, 95% CI, 0.48 to 0.87; p=0.004), iPTH (HR 1.171, 95% CI, 1.00 to 1.40; p=0.044), albumin (HR 0.482, 95% CI, 0.31 to 0.75; p=0.001) and statins (HR 0.615, 95% CI, 0.30 to 0.76; p=0.032) predict overall survival. Using a Kaplan Meier analysis we found that the overall survival of the G-I and G-II at 124 weeks was respectively 78,6% and 91,7% (Log-rank= 5.968; p=0.015) and that renal survival of G-I and G-II was respectively 60,4% and 84,1% (Log-rank= 6.639; p=0.01).

Conclusions: Our results suggest that statins therapy reduce overall mortality and extend renal survival in CKD patients. Further studies are needed to validate the clinical role of statins therapy.

PUB190

Evaluation of Anemia Management in Nephrology Fellow Chronic Kidney Disease Clinic Vikas K. Kalra, Yuvraj Sharma, Charuhas V. Thakar. *Nephrology, Univ of Cincinnati, Cincinnati, OH.*

Background: When defined as hemoglobin (Hb) < 13g/dL in males and < 12g/dL in females, the prevalence of anemia is >60 % in patients with Chronic Kidney Disease (CKD) stage IV or V, according to Kidney Early Evaluation Program (2012) data. Untreated iron deficiency is an important cause of hypo-responsiveness to erythropoiesis stimulating agent (ESA) treatment. Supplementation of iron, when indicated, may potentially decrease the need for ESA, which is important given the potential safety concerns associated with ESA use. As a part of clinical quality improvement project, we assessed Fellows' CKD clinics, within two different healthcare systems, for parameters of anemia management in patients with CKD stage IV or V.

Methods: We retrospective selected a cohort of first 120 patients (60 patients per location) with CKD stage IV or V, who were seen by Nephrology Fellows from March 2014 to May 2014. Patients on dialysis were excluded. Data was reviewed to answer two questions: 1.) Was Hb measured within a period 3 months prior or 1 week after the Renal Clinic visit; 2.) In patients with anemia, were iron stores evaluated within a period 6 months prior or 1 week after the clinic visit? Physicians conformity to these questions across clinic sites was assessed by Fisher's exact tests.

Results: The cohort was 73 % men, mean age (+/- standard deviation) was 65.2 (+/- 13.4) years, mean estimated glomerular filtration rate was 19.7 mL/min and 5 patients were on ESA. Hb was checked in 96 out of 120 patients (80%) of which 85 patients (88.5 %) had anemia. Within the target period, iron stores were not evaluated in 36 out of 85 (42.4 %) patients with anemia. Average Hb for patients whose iron stores were evaluated versus not evaluated was 9.8g/dL versus 11.3g/dL. There was statistically insignificant difference among the two clinics in the proportion of patients with Hb checked (p= 0.25), and iron panel checked when anemic (63.2% versus 50 %, p= 0.27).

Conclusions: There is room for improvement in physician's conformity to anemia management guidelines regardles of healthcare systems. Peer review of performance during fellowship, and provider education may be the key in achieving desired quality improvement.

PUB191

Proton Pump Inhibitors Are Associated with Increased Odds of Development of Chronic Kidney Disease and Death Pradeep Arora,[1,2] Nilang G. Patel,[3] Mojgan Golzy,[4] Rajiv Ranjan,[1,2] Randy L. Carter,[4] James W. Lohr.[1,2] *[1]Medicine, VAMC, Buffalo, NY; [2]Medicine, SUNY at Buffalo, Buffalo, NY; [3]Medicine, VAMC, Richmond, VA; [4]Biostatistics, SUNY at Buffalo, Buffalo, NY.*

Background: Proton pump inhibitors (PPI) are associated with increased risk of AKI due to acute interstitial nephritis (AIN). As clinical manifestations of PPI induced AIN may be subtle, many patients who develop AKI with PPI are missed. These patients may present later with chronic kidney disease (CKD). However, data is lacking on the association of PPI use and CKD.

Methods: This retrospective study was conducted using 2001-2008 data extracted from the VA Health Care Upstate New York (VISN 2). Out of 99,381 individuals with at least one observed outpatient eGFR, we excluded patients with eGFR<60 at entry (CKD patients). To estimate the effect of PPI on outcome (development of CKD), we used case-control logistic regression modeling with PPI covariate, controlling for age, sex, race, time history, and comorbidities(HTN, DM, Vascular, Cancer and COPD) and all two way significant interactions of comorbidities. We also controlled for time history which is the history time prior to developing CKD. Similarly we performed multivariate case-control logistic regression modeling for death as an outcome.

Results: The sample size for analysis of CKD outcome is 71,438 individuals. There are 24,149 individuals in case group (developed CKD), and 47289 in control group (with no CKD). Total of 20,657 were on PPI (6,214 in case group and 14,443 in control group). PPI use was associated with increased odds of CKD and death.

Variable	Odd ratios for CKD with 95% CI	Odd ratios for Death with 95% CI
Age (1Year Increase)	1.05 (1.04-1.50)	1.06 (1.059-1.064)
Female vs Male	1.25 (1.15-1.37)	0.63 (0.54-0.73)
Black (W)	0.88 (0.82-0.93)	1.35 (1.24-1.48)
PPI	1.16 (1.11-1.21)	1.58 (1.50-1.66)
Vascular Disease	1.43 (1.22-1.65)	1.52 (1.44-1.60)
DM	7.52 (6.6-8.43)	1.50 (1.40-1.57)
HTN	4.01 (3.80-4.30)	1.60 (1.48-1.71)
COPD	1.41 (1.22-1.60)	2.26 (2.14-2.39)
Cancer	1.46 (1.27-1.64)	2.34 (2.25-2.49)

Conclusions: Use of PPI is associated with increased odds of CKD and death. Judicious use of PPI may decrease incidence of CKD.

PUB192

Serum Albumin, but Not Glycated Albumin Was a Potent Factor Affecting the Performance of GFR Equation Based on Serum Creatinine Masaru Horio,[1] Enyu Imai,[2] Yoshinari Yasuda,[3] Tsuyoshi Watanabe,[4] Hitoshi Yokoyama,[5] Hirofumi Makino,[6] Seiichi Matsuo.[3] *[1]Osaka Univ Graduate School of Medicine; [2]Nakayamadera Imai Clinic; [3]Nagoya Univ Graduate School of Medicine; [4]Fukushima Medical Univ; [5]Kanazawa Medical Univ School of Medicine; [6]Okayama Univ Graduate School of Medicine.*

Background: In CKD patients with diabetes, hgh glycated albumin (GA) was assumed to a major factor in overestimation of GFR by serum creatinine (Cr) (Diabetes Care. 2014 37:596). Effect of GA levels on the estimated GFR (eGFR) by Japanese GFR equation (Eq-cr) was evaluated in 715 Japanese subjects.

Methods: GFR was measured by inulin clearance (Cin). The subjects were divided into two groups by upper limit of the GA reference range (GA-1: GA <16.3% and GA-2: GA>16.4%). Factors affecting the ratio of eGFR to Cin (eGFR/Cin) was evaluated using multivariate analysis. New equations based on creatinine and albumin (Eq-cr-alb) and based on creatinine, albumin and GA (Eq-cr-alb-ga) were developed from 382 subjects and validated in 333 subjects.

Results: Correlation coefficients between eGFR and Cin were 0.839 and 0.914 in GA-1 and GA-2, respectively. Slopes (95 % CI) of the regression lines with zero intercepts

were 1.013 (0.991 to 1.036) and 0.997 (0.951 to 1.043), respectively. Both slopes were not significantly different from 1.0. Biases (eGFR minus Cin) were -2.3±19.0 and 0.2±11.7 ml/min/1.73m^2, respectively. There was no significant difference in biases between the two groups, indicating a reasonable accuracy of Eq-cr in GA-1 and GA-2. Multiple regression analysis showed that lower serum albumin and higher GA were associated with higher eGFR/Cin. Albumin was a more potent factor affecting eGFR/Cin than GA. Precisions of Eq-cr-alb were significantly better compared with Eq-cr.There was no significant diference of precision between Eq-cr-alb and Eq-cr-alb-GA.

Conclusions: Eq-cr has a reasonable accuracy in GA-1 and GA-2. Lower serum albumin and higher GA were significantly associated with higher eGFR/Cin. The former was a more potent factor affecting eGFR/Cin. Eq-cr-alb showed better performance compared with Eq-cr, suggesting Eq-cr-alb should be used in patients with low serum albumin.

Beliefs and Experiences of Pregnancy in Women with Chronic Kidney Disease: Systematic Review of Qualitative Studies Allison Tong,[1,2] Shilpa Jesudason,[3,4] Jonathan C. Craig,[1,2] Wolfgang C. Winkelmayer.[5] *[1]School of Public Health, The Univ of Sydney, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Australia; [3]Central and Northern Adelaide Renal and Transplantation Service, Royal Adelaide Hospital, Australia; [4]Dept of Medicine, Univ of Adelaide, Australia; [5]Div of Nephrology, Stanford Univ.*

Background: Achieving parenthood in women receiving renal replacement therapy is challenging due to reduced fertility and the substantially higher risk of adverse outcomes. We aimed to describe the perspectives and experiences of pregnancy in women across all CKD stages.

Methods: Electronic databases were searched to April 2014. Studies were imported into HyperRESEARCH and synthesized thematically.

Results: From 11 studies (n=250 women with CKD), we identified five themes. *Failure and blame* described the guilt of being unable to conceive and fulfil a social role which diminished their sense of self-worth. *Fear of birth defects* was mostly attributed to the potential side effects of immunosuppression in kidney transplantation. *Insecurity in decision making* encompassed the uncertainties of prioritizing pregnancy as this meant sacrifices had to be made in their family life and work to minimize their risk of pregnancy complications. Kidney transplant recipients were concerned about the increased risk of graft loss. For patients with autosomal dominant polycystic kidney disease, the chance of genetic transmission influenced decisions regarding childbearing. *Withholding emotional investment* was protecting against the disappointment of inability to conceive, miscarriage or stillbirth. *Control and autonomy* reflected their capacity to choose to accept the risks of pregnancy, while some felt traumatized when advised against pregnancy.

Conclusions: Decisions about pregnancy can be emotionally complicated by the threat to their own health, burden on their family, and the perceived risk of delivering a malformed baby. Multidisciplinary care involving nephrologists, reproductive and obstetrics specialists, and access to psychological support, are suggested to help patients resolve decisional conflict and improve their confidence in managing pregnancy issues in CKD.

PUB194

Chronic Kidney Disease in Familial Dysautonomia: Role of Nocturnal Hypotension and Proximal Tubule Injury Howard Trachtman,[1] Suzanne M. Vento,[1] Horacio Kaufmann,[2] Lucy J. Norcliffe-Kaufmann,[2] Cristina Fuente Mora,[2] Debra J. Morrison,[1] Rachel Brody.[3] *[1]Pediatrics, NYU Langone Medical Center, New York, NY; [2]Neurology, Dysautonomia Center, NYU Langone Medical Center, New York, NY; [3]Pathology, NYU Langone Medical Center.*

Background: With improved survival of patients with familial dysautonomia (FD), new complications have emerged. Approximately 40% of young adults with FD develop chronic kidney disease (CKD). This study was designed to identify prognostic biomarkers of early renal injury and to distinguish between glomerular and tubular damage.

Methods: Eligibility criteria included: (1) confirmation of a genetic mutation in IKAP or ELP-1 associated with FD; (2) Age ≥2 yr; (3) eGFR≥60 mL/min/1.73 m^2. Follow-up included a baseline assessment and visits every 6 months. Clinical assessment included height, weight, BP, 24-hr ambulatory blood pressure monitoring (ABPM). Laboratory testing included serum creatinine and cystatin C levels, eGFR, urine total protein, albumin, and creatinine concentration. Urinary KIM-1, NGAL, and TGF-β excretion (pg/mL) were determined by ELISA.

Results: 33 patients (18 M: 15 F), age 24±11 yr, were included in this analysis. The serum creatinine, cystatin C, and eGFR were 0.94±0.42 mg/dL, 1.07±0.34 mg/L, and 82±34 mL/min/1.73 m^2, respectively. The degree of elevation in urinary KIM-1 excretion was correlated with the magnitude of the nocturnal drop in diastolic BP (P=0.024) and with diastolic blood pressure at night (P=0.040) in the ABPM testing. NGAL, and TGF-β urinary levels did not correlate with diastolic blood pressure at night or with diastolic BP dipping. There was minimal evidence of glomerular barrier dysfunction because only 2 patients had microalbuminuria.

Conclusions: Our findings indicate that patients with FD have evidence of proximal tubular injury based on elevated urinary KIM-1 excretion prior to the development of stage 3 CKD. The primary locus of injury appears to be the tubulointerstitium and the damage may be mediated by excessive decline in nocturnal BP. This 24-hour BP pattern, which is unique to FD compared to other causes of autonomic dysfunction, may represent a potentially remediable target for therapeutic intervention, to prevent CKD.

Research Priority Setting in Kidney Disease: A Systematic Review Allison Tong,[1] Shingisai Alice Chando,[1] Sally Crowe,[2] Braden J. Manns,[3] Wolfgang C. Winkelmayer,[4] Brenda Hemmelgarn,[3] Jonathan C. Craig.[1] *[1]School of Public Health, The Univ of Sydney; [2]Crowe Associates Ltd; [3]Dept of Medicine and Community Health, Univ of Calgary; [4]Div of Nephrology, Stanford Univ.*

Background: Research priority setting typically lacks transparency and patient engagement. This has raised concerns that scarce resources may not be efficiently allocated and important areas of research most relevant to patients are potentially neglected. We aimed to describe research priorities of patients with kidney disease, their caregivers and healthcare providers, and policy makers involved in their care.

Methods: Medline, Embase, PsycINFO, and CINAHL were searched to May 2014. Studies that assessed patient, healthcare provider and policy maker priorities for research in kidney disease were included.

Results: We included 16 studies (n=1923 participants) conducted in the United States (8 studies), internationally (5 studies), Netherlands (1 study), Australia (1 study), and Canada (1 study). Three (19%) studies involved patients with kidney disease and/or caregivers. Priority setting methods included the Delphi technique, expert panels, consensus conference, ranking or voting surveys, focus groups and interviews; of which the process was described in detail by 11 (69%) studies. The priority areas for research most frequently identified across studies were prevention of acute kidney injury, prevention of CKD progression, fluid and diet restrictions, improving vascular access, graft survival, access to transplantation, patient education, and psychosocial impact of CKD.

Conclusions: Research priority setting has covered a broad range of topics pertinent to kidney disease but patient involvement in research priority setting is rare and the prioritization processes are varied and sometimes opaque. Establishing research priorities using a transparent process that engages patients, caregivers, healthcare providers are needed so that resources are invested into areas that address the shared priorities and needs in kidney disease.

PUB196

The Survey on General Well-Being of Recipients after Spousal Donor Kidney Transplantations: A Case Control Study Ma Dengyan, Ping Fu. *Nephrology Dept, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: To investigate the general well-being of recipients after spousal donor kidney transplantations (SDKT) and to discuss influence factors might involved in.

Methods: From January 2006 to May 2012, 100 recipients who received kidney transplantations (KT) were assessed utilizing the General Well-being Schedule (GWBS). All recipients were divided into 2 groups according to the source of graft: Group 1, the SDKT recipients (n=41); Group 2, the living related donor kidney transplantation (LRDKT) recipients (n=59). A complete demographic profile of the samples was taken.

Results: The score of GWBS has a significant difference between two groups: recipients in group 1(SDKT) has a higher mean score than group 2. Of the six factors in GWBS, the third factor (the energy level) has a significant difference between the two groups. There were no significant differences between two groups with other 5 factors.

Conclusions: SDKT recipients had a higher score of GWB, which might be associated with the stable relationship and the common family and healthy goal.

PUB197

Serum Beta Trace Protein Before and After Traumatic Amputation in Male Soldiers: A Case-Control Study Dustin J. Little,[1] Sonia Q. Doi,[2] Alison L. Pruziner,[3] Verena Gounden,[4] Brett J. Theeler,[5] Stephen W. Olson.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Nephrology, Uniformed Services Univ, Bethesda, MD; [3]DoD-VA Extremity Trauma Center of Excellence, Walter Reed National Military Medical Center, Bethesda, MD; [4]Clinical Center, National Institutes of Health, Bethesda, MD; [5]Neurology, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: In a previous study, we determined serum creatinine (SCr) levels to be significantly decreased following traumatic amputation in otherwise healthy male subjects; suggesting that SCr-based equations may overestimate glomerular filtration rate (GFR) in this population. We used specimens from our original analysis to compare pre and post amputation serum beta trace protein (βTP) levels, since βTP is produced predominantly in the central nervous system and traumatic amputation would thus not be expected to result in a loss of βTP producing cells.

Methods: We used the Department of Defense Serum Repository to compare pre and post traumatic amputation serum βTP levels in 33 male soldiers. Results were analyzed for small (3-5.9% estimated body weight loss), medium (6-13.5%), and large (>13.5%) amputation subgroups; and for a control group matched 1:1 to the 12 large amputation subjects on the basis of age, sex, race, and timing of serum collection. Serum βTP was measured using the N Latex βTP assay (Siemens Diagnostics). Paired Student's t-test was used for comparisons. Osterkamp estimation using DEXA scan measurements was used to establish %ESBL.

Results: Mean serum βTP (mg/L) levels were unchanged in controls; all amputees (0.57±0.18 versus 0.55±0.16; p=0.48); and the small (0.51±0.19 versus 0.49±0.20; p=0.63), medium (0.55±0.14 versus 0.60±0.14; p=0.38), and large (0.65±0.18 versus 0.57±0.15; p=0.06) amputation subgroups. Mean SCr (mg/dL) was significantly lower post

amputation overall (1.04±0.18 versus 0.84±0.14; p<0.001) and in the medium (1.09±0.17 versus 0.84±0.12; p<0.001) and large (0.97±0.17 versus 0.76±0.11; p<0.001) amputation subgroups; and unchanged in controls and following small %ESBL amputation.

Conclusions: Serum βTP may be superior to SCr as a filtration marker for the estimation of GFR in adult male amputees without comorbidities.

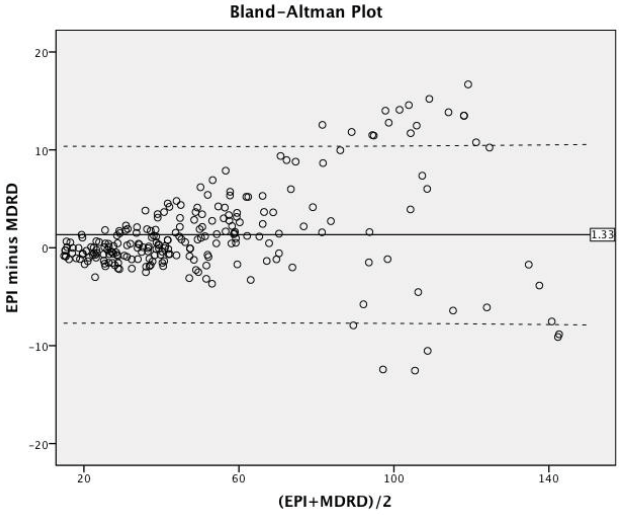
PUB198

Comparison of Creatinine-Based eGFR Equations as Predictors of Renal Events in a Portuguese Cohort of CKD Patients Andreia Campos, Jorge Malheiro, Sofia Santos, Josefina S. Lascasas, A. Castro, António Manuel Nunes Cabrita. *Nephrology Dept, CHP, Porto, Portugal.*

Background: Glomerular filtration rate (GFR) correct assessment is crucial for therapy guidance and decision-making in patients with chronic kidney disease (CKD). We compare the ability of creatinine-based MDRD and CKD-EPI equations as predictors of renal events in a cohort of patients with CKD 1-4.

Methods: A cohort of 234 patients followed in our Nephrology ambulatory unit was selected and eGFR was calculated using MDRD and EPI equation at baseline. Patients were followed until last consultation appointment with a serum creatinine evaluation. Renal event(E) was defined by an increase of 30%in creatinine serum. Category-free net reclassification index(cfNRI) was calculated for EPI in comparison with MDRD.

Results: During the follow up period (median 5 years), 65E(28%)were recorded. The mean baseline eGFR according to MDRD and EPI was respectively 42 versus 44. EPI reclassified 9% to less advanced GFR categories and 2% to more advanced ones.



Event cfNRI was +20%(95%CI 11-29) and non-event(NE) cfNRI was +24%(95%CI 18-31), when EPI equation was compared with MDRD. Mean annual event-rate(AER) was 6,4% patient/year, being greater in patients with diabetes(8%), hypertension(7%) and proteinuria(10%). Considering MDRD equation, there was no significant difference between the AER in stage 2 and 3a (3.7%/4.3% p>0.05). According to EPI, the AER was greater in stage 3a than stage 2 (6,3%/2,2%, p0.04). Considering patients classified as stage 3a by MDRD, those reclassified by EPI to stage 2 had an AER reduction from 5.2 to 0.35 patient/year(p0.004), in comparison with those not reclassified.

Conclusions: Reclassification by EPI, particularly in stage 2-3a, was clinically meaningful. Use of EPI alternatively to MDRD in mild-to-moderate CKD may allow a more adequate referral to a nephrology evaluation, with improvement in means allocation.

PUB199

Normative Surveillance and Treatment Patterns in Real World Chronic Kidney Disease Practice Scott Sibbel, Carey Colson, Mahesh Krishnan, Steven M. Brunelli. *DaVita Clinical Research, Minneapolis, MN.*

Background: There is a paucity of normative data regarding frequency of follow up, surveillance laboratory testing, and drug treatment for chronic kidney disease (CKD) patients in real-practice settings. We sought to clarify the frequency of such data from nephrology practices using the Falcon CKD electronic health record (EHR) system.

Methods: Data were obtained from 4,291 patients treated at 44 qualifying practices who had at least 2 visits after an eGFR<60 ml/min/1.73m^2, excluding those with acute kidney injury and end-stage renal disease. Patients were followed until the last nephrology visit occurring before 01Mar2012-30Jun2013. Patient time and events were ascribed to CKD stage based on the most antecedent eGFR and expressed as rate per 90 days.

Results: Higher CKD stage was associated with older age, male sex, black race, and lower BMI. Nephrologist visit rates (per 90 days) were between 1.06 and 1.25 for stages 1-3B, 1.48 for stage 4, and 3.31 for stage 5 CKD. Rates of eGFR measurement ranged between 0.53 to 0.60 for stages 1-3B, 0.75 for stage 4, and 0.80 for stage 5; potassium measurement frequency was similar to eGFR except for stage 5 where it was higher (1.77 per 90 days). Hemoglobin, phosphate, and PTH measurement were less frequent than eGFR; all were more common in stage 5 versus other stages. Treatment with phosphate binders and erythropoiesis-stimulating agent was rare except in stage 5 (14.9% and 4.2% of patients treated, respectively).

Conclusions: Frequency of testing and medication use are consistent with national CKD guidelines (Kidney Disease Quality Index, 2012 update, Kidney Disease: Improving Global Outcomes 2012 Clinical practice guideline). However, because adoption of the Falcon EHR is not universal, analyses should be updated when additional data become available. We acknowledge the contributions of the Physician Research Consortium.

Table. Patient Characteristics, Surveillance, and Treatment Frequency Among Patients With CKD Stages 1-5

	Stage 1 eGFR ≥ 90 n = 56 89.1 pt-q	Stage 2 eGFR 60-89 n = 253 435.2 pt-q	Stage 3A eGFR 45-59 n = 10,366 1678.6 pt-q	Stage 3B eGFR 30-44 n = 1,516 2511.5 pt-q	Stage 4 eGFR 15-29 n = 1,169 1913.6 pt-q	Stage 5 eGFR < 15 n = 261 447.8 pt-q

Novel Prediction Model of Postoperative Renal Function From Automated Renal Volumetry with Preoperative Multi Detector Computed Tomography Shuji Isotani,[1] Hirofumi Shimoyama,[2] Masaki Kimura,[1] Hisamitsu Ide,[1] Satoru Muto,[1] Shigeo Horie.[2] *[1]Urology, Teikyo Univ, Tokyo, Japan; [2]Urology, Jyuntendo Univ, Tokyo, Japan.*

Background: The predictive model of postoperative renal function may impact on planning nephrectomy. To develop the novel predictive model using combination of clinical indices with computer-volumetry to measure the preserved renal cortex volume (RCV) using multi-detector computed tomography (MDCT), and to prospectively validate performance of the model.

Methods: Total 60 patients undergoing radical nephrectomy from 2011 to 2013 participated, including a development cohort of 39 patients and an external validation cohort of 21 patients. RCV was calculated by voxel count using software (Vincent, Fujifilm). Renal function before and after radical nephrectomy was assessed via the estimated glomerular filtration rate (eGFR).

Results: The postoperative eGFR value was associated with age, preoperative eGFR, preserved renal parenchymal volume (RPV), preserved RCV, % of RPV alteration, and % of RCV alteration (p<0.01). The significant correlated variables for %eGFR alteration were %RCV preservation (r=0.58, p<0.01) and %RPV preservation (r=0.54, p<0.01). We developed our regression model as follows: postoperative eGFR = 57.87 – 0.55(Age) – 15.01(BSA) + 0.30(preoperative eGFR) + 52.92(%RCV preservation). Strong correlation was seen between postoperative eGFR and the calculated estimation model (r=0.83; p<0.001). The external validation cohort (n=21) showed our model outperformed previously reported models. Main limitations were retrospective small cohort, and requirement of semi-automated segmentation in 13% cases.

Conclusions: Combining CT renal volumetry and clinical indices might yield an important tool for predicting postoperative renal function.

PUB201

Neurogenic Lower Urinary Tract Dysfunction and Chronic Kidney Disease in Spinal Cord Injury Patients Hyunjin Na, Hye Min Choi, Dong-Jin Oh. *Dept of Internal Medicine, Myongji Hospital, Goyang-si, Korea.*

Background: It is believed that patients with neurogenic lower urinary tract dysfunction (NLUTD) have a significantly higher risk of developing chronic kidney disease (CKD) than the general population. However, data are limited except a few studies that examined the incidence of renal failure in spina bifida or myelomeningocele in pediatric patients. In addition, serum creatinine is not a reliable marker for renal function in NLUTD patients because they present muscle wasting due to disuse or denervation. We examined the prevalence of CKD in NLUTD patients from spinal cord injury using cystatin-C, and the risk factors for progression to CKD.

Methods: This was a cross sectional study in Korea workers' compensation and welfare Hospital, which is a specialized center for patients from industrial accident. Patients with NLUTD were under regular examination including regular laboratory test and urologic study such as urodynamic study, Sonography and voiding cystourethrography. Patients who visited urology department for routine check-up underwent additional measurement of serum cystatin-C for 3 mo.

Results: Serum cystatin-C was checked in 314 patients (mean age 58.1±8.8 yr, mean time period after injury 18.9±9.3yr). Detrusor hyperreflexia and areflexia accounted for 66.0% and 22.2%, respectively. The overall prevalence of CKD, defined as estimated

glomerular filtration rate (eGFR) < 60ml/min/1.73m^2 was 22.4% and 8.0% by cystatin-C and creatinine-based CKD-EPI equation, respectively, and was greater than age-matched general population (Korean National Health and Nutritional Examination Surveys). Initial eGFR, co-morbid diabetes, proteinuria, bladder volume and the presence of recurrent urinary tract infection (UTI) were the independent risk factors for CKD development in the multivariable analysis.

Conclusions: The prevalence of CKD is higher in NLUTD patients than in the general population, and cystatin-C was more sensitive than creatinine for detecting CKD in NLUTD patients. Co-morbid diabetes, proteinuria, bladder volume and the presence of recurrent UTI seem to be the important risk factors for CKD development in NLUTD patients.

PUB202

High-Density Cholesterol Subclass Distribution in Patients with Chronic Kidney Disease Eliza Samouilidou, Chrisoula Pipili, Kiriaki Vasiliou, Manolis Papamanolis, Eirini Boudou, Eirini Grapsa. *Nephrology, Aretaieion Univ Hospital, Athens, Greece.*

Background: Dyslipidemia and alteration in serum lipoprotein subclass distributions contribute considerably to atherosclerosis in patients with chronic kidney disease (CKD). The shift in the size of HDL-C from larger and more atheroprotective HDL2-C to small dense HDL3-C subclass, predicts the development of oxidative stress in CKD. The aim of this study was to compare HDL-C subclasses in non-dialyzed (stages 2-5) and hemodialysis (HD) patients.

Methods: : Twenty-seven patients with CKD (51±17 years, mean ±SD, 14 males, 13 females), thirty- four patients on HD for 73±16 months (58±15 years, mean ±SD, 19 males, 15 females) and 21 controls (NC) (49±10 years, mean ±SD, 11 males, 10 females) were studied. HDL2 and HDL3-C subclasses were isolated from serum according to a single-step precipitation method following by homogenous HDL-C assay.

Results: Total cholesterol and LDL-C was increased only in non-dialyzed patients compared to NC ($p<0.01$), whereas triglycerides were high both in non-dialyzed (122±62 mg/dl) and HD (138±52 versus 82±32 in NC). HDL-C was decreased in patients compared to NC but this decrease was more profound in HD patients (40±12 md/dl) compared to non-dialyzed patients (53±16, $p<0.01$). Regarding HDL-C subclasses, HDL3-C was dramatically lower in HD patients (11±3 mg/dl) compared to non-dialyzed patients (25±3) and NC (23±4, $p<0.001$). HDL2-C did not differ between patient groups, but was marginally lower in non-dialyzed patients (24±13) compared to NC (33±9, $p<0.05$).

Conclusions: In non-dialyzed CKD patients, a progressive increase of total cholesterol and LDL-C together with a decrease of HDL-C values are observed compared to patients on HD. Hemodialysis does not seem to affect HDL2-C subclass levels, however the significant decrease in HDL3-C may be relevant of a persistent loss of antioxidant capacity of HDL-C in this modality.

PUB203

Standardization Program in Chaco, Argentina: Difficulties in Random Error Correction Maria Eugenia V. Bianchi,[1] Nicolás Ernesto Meier,[1] Mayra Florencia Valdez,[1] Ana M. Cusumano,[3] Gustavo A. Velasco.[2] *[1]Physiology, School of Medicine. Northeast National Univ, Corrientes, Corrientes, Argentina; [2]Biochemical Clinic Studies, Ministry of Health . Chaco Province., Resistencia, Chaco, Argentina; [3]Univ Institute, CEMIC, CABA, Buenos Aires, Argentina.*

Background: Early diagnosis of chronic kidney disease (CKD) is based on the estimation of glomerular filtration rate (eGFR) by MDRD formula, but it is recommended that the determination of creatinine in clinical laboratories must be standardized previously, so that the variations inherent to the laboratory do not affect the result of eGFR and patient classification. The aim of this paper is to describe the creatinine standardization program in Chaco (Argentina) which began in 2010.

Methods: 39 laboratories have participated (public and private), serum panels with certified concentrations of creatinine between 0.65 and 2.28 mg / dl were used. In the first stage, in 2011,the Random Error (RE), Systematic Error (SE) and Total Error (TE) were determined according to EP-10Clinical and Laboratory Standards Institute (NCCLS).

Results: An average of 15.2CV %was obtained, it was concluded then that the most important problem of the program was the RE. In the second stage, during 2012, 37 laboratories participated in the evaluation of the total imprecision of the determination, according to the NCCLS protocol EP -5A, as well as in the reduction of it. In 2013 the laboratories that participated in both stages were categorized: Group I, 19 (48.7%) laboratories that met the desired objectives for EA and Group II, 15 (38.5 %) who failed to reduce imprecision maintaining RE values ≥4.0 %. The mean ± SD values of RE in Group I was 3.99 ± 0.92 in Group II and 11.9 ± 6.31 ($p=0.0001$). Analyzed the strengths,we found that Internal and External Control tools were used in 12 (63.2 %) laboratories in the GI and 4 (36.4 %) in the GII ($p = 0.018$); as well as 10 (27 %) GI laboratories had Homogeneous analytical systems.

Conclusions: After three years of the program only 48.7% of the laboratories can move towards standardization itself, however, the results allow us to state that the lack of control tools and analytical homogeneous systems are the main difficulties.

PUB204

Primary and Recurrent Focal Segmental Glomerulosclerosis Closely Link to Serum Soluble Urokinase Receptor Levels Juan Jin,[1] Yiwen Li,[1] Qiang He.[1] *[1]Nephrology, Zhejiang Provincial People's Hospital, Hangzhou, Zhejiang, China; [2]The Kidney Disease Center, The 1st Affilliated Hospital, Medical College, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Serum soluble urokinase-type plasminogen activator receptor (suPAR) is implicated in the pathogenesis of native and recurrent FSGS. It is elevated in two-thirds of subjects with primary FSGS, but not in people with other glomerular diseases which can differentiate FSGS from other glomerular diseases.

Methods: We measured soluble urokinase receptor levels in the resum of patients with primary focal segmental glomerulosclerosis (FSGS) and determined their association with clinical and pathological data in 86 patients with primary FSGS, 5 repeat renal biopsy FSGS and 6 recurrent FSGS posttranplantation, healthy controls and patients with minimal change disease, andmembranous nephropathy were used as controls. The resum-soluble urokinase receptor levels, measured by commercial ELISA kits.

Results: Of patients with primary FSGS (median:4232, interquartile range 1299-9714 pg/ml) were significantly higher than those of patients with minimal change disease (median 2784pg/ml), membranous nephropathy (median 3478 pg/ml), andhealthy individuals (median 1994 pg/ml). There was no significant difference in suPAR levels between the 65 patients with minimal change disease and 85 patients with membranous nephropathy. The soluble urokinase receptor levels increased in the 5 repeated renal biopsy FSGS and 6 recurrent FSGS posttranplantation. The suPAR levels were significantly but positively correlated with FSGS, not only primary FSGS but also recurrent FSGS posttransplantation, but negatively correlated with other flomerular diseases.

Conclusions: Thus, suPAR levels can differentiate primary FSGS from other glomerular diseases.

PUB205

Markers of CKD in HIV+ Patients Pedro Pereira Campos,[1] Clara Dias,[3] Fernando G. Pereira,[1] Alberto Ortiz,[2] Ana Luisa Papoila,[3] Karina Soto.[1,3] *[1]H. Fernando Fonseca, Portugal; [2]Fundacion Jimenez Diaz, Madrid; [3]Univ Nova Lisboa.*

Background: Traditional markers of kidney function are not accurate for early diagnosis of CKD in HIV patients. Cystatin C (SCysC) was claimed as a good GFR marker. Fractional excretion of phosphate (FePi) and uric acid (FeUrAc) were proposed as tubular markers for early dysfunction together with the urinary albumin/creatinine ratio (UACR). Aim: Determine the usefulness of these associated markers on CKD diagnosis.

Methods: Cross-sectional analysis in 946 consecutive HIV+ outpatients. Demographic, clinical and laboratorial data were recorded. Primary endpoint: CKD (GFR<60ml/min/1.73m2 as assessed by CKD-EPI based on serum creatinine (SCr) or SCysC or by MDRD. McNemar, Chi-squared test and a logistic regression model were used**.** Significance was set at $\alpha=0.05$.

Results: Among 946 patients, mean age 46.1±11.5; 54.4% male; 45.9% Africans; 92.5% HIV1; 23.3% Hypertensive; 11.1% HCV+ and 7.4% Diabetic. Median CD4 count=478 cells/μL and viral load=309 cop/mL. Median eGFR=103 (84-118)mL/min/1.73m^2. CKD distribution was 72.3; 23.8; 3.4; and 0.5% for I; II; III; and IV+V stages respectively. CKD rates were 3.8, 3.9 and 7.5% with MDRD, CKD-EPI-SCr and CKD-EPI-CysC, respectively. Univariate logistic regression showed that FePi [OR 1.1 (CI 1.0-1.1) p= 0.002]; UACR [OR 7.6 (1.1-46.7) p=0.040]**;** HCV+ [OR 3.6 (1.3-9.9) p=0.013] and age [OR 1.1 (1.0-1.1) $p<0.001$] were associated with CKD. For each 1.0 of FePi increase, the odds of CKD increase by 8.6%. There was an inverse correlation between FePi and eGFR based on SCysC. A trend was observed for Atazanavir [OR 2.5 (1.0-6.4) p=0.054]. No association was found with other antiretroviral drugs. In multivariable regression analysis excluding UACR only FePi remained a significant determinant for CKD (p=0.002). Tenofovir was not associated with variations on eGFR, nor FePi, FeUrAc. Although UACR was not included in multivariable analysis, there is a significant difference between CKD and no-CKD patients, $p<0.001$.

Conclusions: Prevalence of CKD in HIV patients is higher than in the general population. Atazanavir, a drug associated with crystaluria, had the closest association with CKD. Of tubular markers, FePi, but not FeUrAc, was associated with CKD.

Classification Tree Models for Predicting the Risk of the Progression of Diabetic Nephropathy Wenbo Zhao,[1] Lin Wei,[2] Ming Li,[1] Jun Zhang,[1] Hui Peng.[1] *[1]Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Neuropathy, Guangdong Province Traditional Chinese Medical Hospital, Guangzhou, Guangdong, China.*

Background: To establish models for predicting the risk of progression of diabetic nephropathy, and to explore the related factors for type 2 diabetes patients with early renal damage using the classification tree model.

Methods: The 256 cases of the hospitalized patients with type 2 diabetes are enrolled. According to GFR installments and urine albumin quantitative,the patients were divided into proteinuria group (73 cases) and early diabetic kidney damage group (183 cases). The clinical data of the patients were recorded to analyze the main factors for the progression of diabetic nephropathy using the Exhaustive CHAID classification tree algorithm.

Results: Classification Tree model has screened out four important explanatory variables from the 34 candidate variables, including course of hypertension, CysC levels, WHR(Waist/Hip Ratio) and ALB(serum albumin). CysC levels and WHR (Waist/Hip

Ratio) were the main factors. The patients with microalbuminuria as CysC>1.53 mg/L and WHR>0.99 with high risk, occurred macroalbuminuria; The risk of disease progression was also significantly increased in CysC>1.53 mg/L and ALB<39.5 g/L group. CysC was 1.13-1.53 mg/L and duration of hypertension 0-3 years group significantly increasing; The model predicted progression of diabetic nephropathy patients from microalbuminuria to macroalbuminuria; The correct rate is 85.9%. The probability of misclassification(Risk values) was 0.207.

Figure 1 Classification Tree Model

(Microalbuminuria, mAlb; Albuminuria, Alb; WHR, Waist/Hip Ratio)

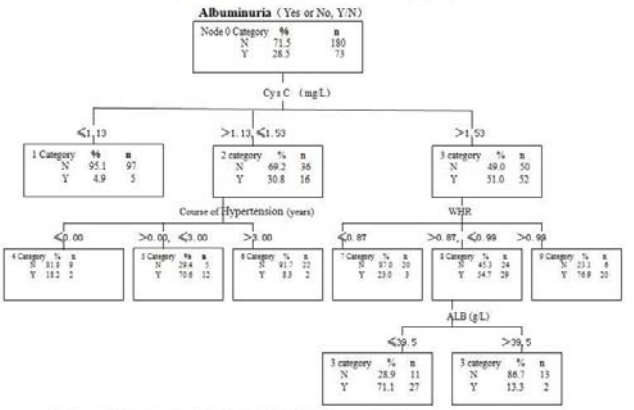

Table 1 Misclassification Matrix and Classified Forecast Table

Classification

Observed	predicted		
	mAlb	Alb	Percent Correct
mAlb	161	22	88.0%
Alb	14	59	80.8%
Overall Percentage	68.4%	31.6%	85.9%

Growing Method: EXHAUSTIVE CHAID
Dependent Variable: Albuminuria

Conclusions: The classification tree model could screen out the major effecting factors of the progression of diabetic nephropathy effectively, and it could help to develop the prevention and treatment methods. Classification Tree Models can be for predicting the risk of the progression of diabetic nephropathy.

Multiple Myeloma with Amyloidosis Aggravates Patients' Survival in Plasma Cell Disorder Seon Deok Hwang, Ji Hyun Yu, Wooyeong Park, Byung Ha Chung, Bum Soon Choi, Chul Woo Yang, Yong-Soo Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, Seoul, Korea.*

Background: Renal failure is a common complication of multiple myeloma and other plasma cell dyscrasias. The presence of coexistent kidney disease is associated with increased mortality. The aim of this study is to investigate the survival effect of multiple myeloma with amyloidosis, renal failure in plasma cell disorder patients.

Methods: Between Dec. 2001 and Feb. 2013, 285 plasma cell disorder Diagnosed patients were included. The median age was 57.32 ± 9.563 years. Male was 126 patients (52.9%). The median GFR 69.26±33.72. 47 patients were excluded because missing data. 10 patients was Amyloid light chain (AL) amyloidosis, 11 patients was multiple myeloma (MM) with amyloidosis, 212 patients MM without amyloidosis and 5 patients others. Kaplan Meier survival curve was used to compare mortality between different groups.

Results: Between AL amyloidosis and MM with amyloidosis, no difference was found in baseline characteristics such as age, sex, transplantation, Hb, MDRD-GFR. The Kaplan Meier showed that AL amyloidosis group were associated with higher survival as compare to MM with amyloidosis group(P-value: 0.013). MM with Amyloidosis patients groups was lower survival in multiple myeloma patients (MM with amyloidosis mortality; 7/11(63.6%) versus MM without amyloidosis; 50/212(23.6%), P<0.001). And also 75 renal failure patients were lower survival than 137 non-renal failure patients in MM without amyloidosis patients (Non renal failure mortality 25/137(18.2%) versus Renal failure 25/75(33.3%), P=0.002).

Conclusions: In plasma cell disorder patients, the prognosis of MM patients with amyloidosis was worse than those of AL amyloidosis patients and MM patients without amyloidosis. MM patients without amyloidosis and AL amyloidosis patients were not associated with the worsening of kidney function. But, MM patients with amyloidosis were associated with the worsening of kidney function and also Renal failure (GFR<60ml/min) is important factor of mortality in MM patients without amyloidosis.

PUB208

Application of Iohexol Plasma Clearance in Chinese Chronic Kidney Disease Children Baobao Wang, Yuan Wu, Mengchun Gong, Xuemei Li, Yan Qin. *Dept of Nephrology, Peking Union Medical College Hospital, Chinese Academic Medical Science and PekingUnion Medical College, Beijing, China.*

Background: Iohexol Plasma Clearance has been validated as a satisfactory reference method for GFR measurement in adult and child. However it has not been applied in China.We therefore propose to develop the method for the quantification of iohexol in serum by high performance liquid chromatography. And then to evaluate the accuracy and practicability for iohexol plasma clearance from the serum and dried bood spots in chronic kidney disease (CKD) children.

Methods: After obtaining informed consent, forty-five CKD children were included and examined by ^{99m}Tc-DTPA plasma clearance and iohexol plasma clearance simultaneously. Blood samples were obtained at 2,4 and 5hours after injection respectively. In the meantime, we also evaluated the efficacy of single blood sample method and dried blood spots method in iohexol plasma clearance. The study was approved by the ethics committee of the Peking Union Medical College Hospital.

Results: Our study established and optimized the measurement of the serum iohexol concentration by HPLC. The standard curve showed a good linearity (the correlation coefficient r>0.999). The RSD% of intra-assay and inter-assay were lower than 5%, the recovery rate was more than 96%. The correlation coefficient between ^{99m}Tc-DTPA plasma clearance and iohexol plasma clearance was 0.94. The correlation between iohexol single sample plasma clearance and double samples was also strong (r=0.96). The iohexol clearance by dried blood spots showed a good correlation with the serum iohexol clearance (r=0.96). Only one 14-year-old boy showed slight scattered red rash in 12 hours after iohexol injection, no other adverse reaction was observed.

Conclusions: The method based on HPLC to measure the serum iohexol concentration is accurate and stable. Iohexol plasma clearance showed a good agreement with ^{99m}Tc-DTPA plasma clearance, which will be an ideal method to measure GFR in CKD children. The single sample method and dried blood spots method make iohexol plasma clearance more convenient and practical.

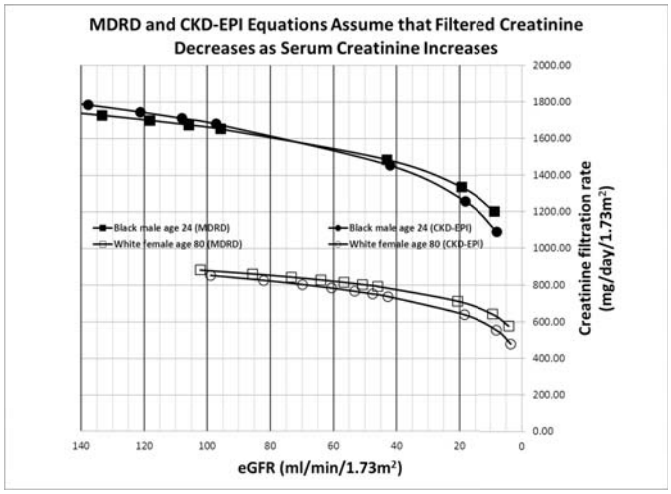
Modeling of Creatinine Kinetics by MDRD and CKD-EPI Equations Includes Non-Renal Creatinine Disposition Karo Torosian,[2] Robert W. Steiner.[1] *[1]Medicine, Univ of California, San Diego, School of Medicine, San Diego, CA; [2]Medicine, Scripps Mercy Hosptial, San Diego, CA.*

Background: The MDRD and CKD-EPI equations are computer-derived, best-fit expressions that predict eGFR from serum creatinine (Cr) and race, gender, and age. We studied how these equations model Cr physiology.

Methods: We compared MDRD and CKD-EPI eGFRs when both were calculated using the same Cr, age, race, and gender, as each of these variables was uniquely varied. We then calculated Cr filtration rates (CrFR, mg/day/1.73m2) as the product of the calculated eGFRs and the serum Cr values used to determine those eGFRs.

Results: At age 24, CKD-EPI estimated up to a 10% higher eGFR than did MDRD, particularly in nonblacks. At age 80, MDRD eGFRs were up to 10% higher, particularly in blacks. Calculated CrFRs varied from 800 to 1700 mg/1.73m2/day at normal eGFRs. At

low eGFRS it was 85-90% of total urine Cr excretion as derived from CKD populations (Ix, CJASN,2011) that we size-normalized for comparison. Both equations predicted an accelerated decrease in CrFR at an eGFR of about 30 ml/min/1.73m2. This curve was closely approximated by subtracting a load-dependent extrarenal Cr clearance of 3L/day,perhaps by bowel flora (Mitch, Nephron,1978), from a constant rate of Cr production.



Conclusions: MDRD and CKD-EPI equations use age and race somewhat differently when estimating eGFR. Both assume an accelerated decrease in CrFR as serum Cr rises. The decrease in CrFR parallels similar decreases in total urinary Cr that are observed CKD populations. Extrarenal Cr disposition at low eGFRs may explain the nonlinearity in eGFR equations, which are challenged to reflect changing Cr kinetics as serum Cr increases. As results were size-normalized and unaffected by age, gender, or race, a major influence of muscle mass is unlikely. The Cr physiology that is implicit in these expressions deserves further study.

PUB211

Is the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) Equation Useful in Chinese Diabetic Patients? Jin-Xia Chen,[1,4] Yanni Wang,[1] Xun Liu,[1,2] Chenggang Shi,[1] Zhenda Zheng,[3] Tan-Qi Lou.[1] *[1]Div of Nephrology, Dept of Internal Medicine, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [2]Div of Nephrology, Tufts Medical Center, Boston, MA; [3]Dept of Cardiology, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [4]Institute of Nephrology, Affiliated Hospital of Guangdong Medical College, Zhanjiang, China.*

Background: The prevalence of diabetic kidney disease(DKD) is escalating and it has become the main cause of end stage renal diseases in western countries. Thus it is essential to present an accurate and convenient glomerular filtration rate estimation for diabetes. Many studies indicated that the Cockcroft-Gault equation and Modification of Diet in Renal Disease equation showed great bias in diabetes. Yet whether the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation demonstrates less accuracy in diabetes is still controversial. In this study We aim to compare performance of the CKD-EPI equation between diabetic and non-diabetic population.

Methods: 1189 subjects were enrolled, and were divided into diabetic group (n=548) and non-diabetic group (n=641). 99mTc-DTPA-GFR revised by dual sample method was referred as the gold standard. Multivariate logistic regression was used to analyze the factors affecting the 30% accuracy of the CKD-EPI equation. The predictive performance of the equation was assessed by bias, precision and 30% accuracy.

Results: Renal dynamic imaging-GFR was revised as the following equation: Dual plasma sampling 99mTc-DTPA-GFR (ml/min/1.73 m^2)= 3.706+1.039×99mTc-DTPA renal dynamic imaging-GFR (ml/min/1.73m^2) (R^2=0.879, P<0.001). Multivariate logistic regression indicated that diabetic status affected the 30% accuracy of the CKD-EPI equation. The diabetic and non-diabetic group were matching to sex, age, body mass index (BMI) and chronic kidney disease (CKD) categories. After matching, the performances of the CKD-EPI equation in the diabetic group were worse in both precision (inter-quartile range of median difference, 28.4 versus 19.9 ml/min/1.73m^2, P<0.001) and accuracy (30% accuracy, 58.3 versus 67.1%, P=0.02) comparing with the non-diabetic group.

Conclusions: The CKD-EPI equation is less accurate in Chinese diabetic patients comparing with the non-diabetes.

PUB212

Developing New Glomerular Filtration Rate Estimating Models for Chinese Diabetic Patients Jin-Xia Chen,[1,4] Xun Liu,[1,2] Linsheng Lv,[3] Chenggang Shi,[1] Yanni Wang,[1] Tan-Qi Lou.[1] *[1]Div of Nephrology, Dept of Internal Medicine, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [2]Div of Nephrology, Tufts Medical Center, Boston, MA; [3]Operating Room, the Third Affiliated Hospital of Sum Yat-sen Univ, Guangzhou, Guangdong, China; [4]Institute of Nephrology, Affiliated Hospital of Guangdong Medical College, Zhanjiang, China.*

Background: The estimation of GFR in diabetes is of great significant. However, reports have identified the current equations all showed less accurate in the diabetes.

Methods: 519 diabetic patients were enrolled. The development dataset was based on patients enrolled from January 2005 through December 2012. And data were randomly divided into the training data set (276) and testing set (138). Data obtained from January 2013 to June 2013 were used as the external validation dataset (n=105). 99mTc-DTPA-GFR revised by dual sample method acted as the gold standard. Multiple regression analysis was used to establish new regression equations and MATLAB 2011A software was adopted to establish the artificial neural network (ANN) models.

Results: Subjects who undergone 99mTc-DTPA renal dynamic imaging and dual plasma sampling ^{99m}Tc-DTPA in the same day were enrolled. 99mTc-DTPA-GFR was revised by the following equation in diabetic patients: Dual plasma sampling ^{99m}Tc-DTPA-GFR (ml/min/1.73m^2) =6.442+1.071×^{99m}Tc-DTPA renal dynamic imaging-GFR (ml/min/1.73 m^2) (R^2=0.703, P<0.001). 8 new regression models and 8 new artificial neural network models were established on the base of sex, age, serum creatinine and by adding BMI, HbA1C, and ACR separately or in combination. Performance of all new models in diabetes were compared with the CKD-EPI equation in the external validation group. Bias between new predicting models and the CKD-EPI equation were not significant. All models had higher precision (P<0.001) than the CKD-EPI equation despite ANN6 (P<0.001). Only ANN3 had higher accuracy than CKD-EPI equation (30% accuracy, 88.6 versus 80.6%, P=0.02). In each original external validation data set, 30% accuracy of the ANN3 had improvements of 4.5% versus the CKD-EPI equation and 8.0% versus the MDRD equation.

Conclusions: ANN3 based on sex, age, serum creatinine and BMI seemed to offer a more accurate and convenience GFR estimation in diabetic patients.

Burden of Chronic Kidney Disease (CKD) in Peru Elizabeth Francis,[1,2] Chin-Chi Kuo,[2] Antonio Bernabé Ortiz,[3] Lisa C. Nessel,[4] William Checkley,[2] Bob Gilman,[2] Harold I. Feldman,[4,5] Jaime Miranda.[2,5] *[1]Weill Cornell Medical College; [2]Johns Hopkins School of Public Health; [3]La Univ Peruana Cayetano Heredia; [4]Univ of Pennsylvania School of Medicine; [5]Co-Senior Authors.*

Background: CKD's silent progression, association with chronic disease, and high treatment costs make it a global public health concern.

Methods: The Peruvian CKD burden has yet to be fully described. To provide insight, we completed a cross sectional study of CKD prevalence among 404 participants in Lima and Tumbes between 2/11-6/11 who were enrolled in the Peruvian CRONICAS Cohort Study. Factors potentially associated with CKD were explored with Poisson regression.

Results: In the total study population, the diabetes and hypertension prevalence was 9.9%(95% CI 7.4-13.3%) and 29.2%(95% CI 25.1-34.0%), respectively, median age was 55.34yrs. 68(16.8%, 95% CI 13.5-20.9%) met CKD criteria; proteinuria 60(15%), eGFR <60 ml/min/1.73m^2 4(1%), or both 4(1%). A greater CKD prevalence was noted in Lima, females, and older age median 59.6 yrs, IQR 50.5-69.2). Among participants with CKD, the prevalence of diabetes and hypertension was 19.1% and 42.7%, respectively. After multivariable adjustment, CKD remained associated with older age, female sex, greater wealth, living in Lima, diabetes and hypertension.

Conclusions: The high prevalence of CKD identified in Lima and Tumbes is similar to that in the U.S. These findings highlight the need to identify occult CKD and implement strategies to prevent disease progression and secondary morbidity.

Age (years)	Male (case/n)	Estimated prevalence (95% CI)	Female (case/n)	Estimated prevalence (95% CI)
35-44	3/51	5.8 (1.9-17.8)	5/51	9.8 (4.2-22.7)
45-54	5/54	9.2 (4.0-21.5)	12/51	23.5 (14.3-38.8)
55-64	6/51	11.8 (5.5-25.1)	9/48	18.8 (10.3-34.0)
≥ 65	7/47	14.9 (7.4-29.7)	21/51	41.2 (29.6-57.3)
Overall	21/203	10.3 (6.9-15.5)	47/201	23.4 (18.2-30.1)
p-value for trend	0.13		0.001

Is Obstructive Sleep Apnoea a Risk Factor for Chronic Kidney Disease?

Jennifer Kerks,[1] David M. Comer,[2] Mohammed Awais Hameed,[1] Rahul Mukherjee,[2] Indranil Dasgupta.[1] *[1]Renal Dept, Heart of England NHS Trust, Birmingham, West Midlands, United Kingdom; [2]Respiratory Dept, Heart of England NHS Trust, Birmingham, West Midlands, United Kingdom.*

Background: Obstructive sleep apnoea (OSA) is associated with intermittent hypoxaemia which leads to activation of a number of pathways including oxidative stress, sympathetic nervous system, endothelial dysfunction and inflammation which in turn lead to hypertension and atherosclerosis. There is some evidence that the same process may predispose to renal dysfunction. In this study, we have compared a group people with hypertension and OSA on continuous positive airways pressure therapy (CPAP) with matched control group not known to have OSA.

Methods: Patients with known OSA and the age, sex and BMI matched control groups were selected retrospectively from a hypertension clinic database. The 2 cohorts were compared in terms of mean 24 hour blood pressure (BP, mmHg), mean serum creatinine (micromol/l) and mean urine albumin creatinine ratio (ACR. mg/mmol).

Results: Forty eight patients were identified with confirmed OSA on CPAP; 6 were excluded due to insufficient data. Of the 42 remaining patients, 34 were male. The mean age was 53.5, the mean BMI was 34.6 kg/m^2. The mean 24 hour systolic BP was 143 (±25.6) in patients with OSA and 135 (±16.7) in the controls (p=0.097). The mean serum Creatinine was 94.0, median 95.0 (range 110) in patients with OSA and mean 93.4, median 93.0 (range 99) in the control (p=0.981). The mean ACR was 2.50, median 0.0 (range 33) in patients with OSA and mean 0.63, median 0.00 (range 7.6) in the control group (p=0.577).

Conclusions: This case control study shows that there is no significant difference in blood pressure, Creatinine or ACR in people with treated OSA and people without although there were trends towards higher BP and ACR in the OSA group. This may be due to CPAP treatment reducing the oxidative stress caused by hypoxaemia. A larger prospective study looking at parameters before and after treatment is needed to confirm this hypothesis.

PUB215

Racial Disparities in End-of-Life (EOL) Preferences in Chronic Kidney Disease (CKD) Patients due to Low Health Literacy

Nwamaka Denise Eneanya, Ravi I. Thadhani. *Nephrology Div, Massachusetts General Hospital, Boston, MA.*

Background: Few patients with CKD document what their preferences are for EOL care and minority and low-income populations are disproportionately impacted when accessing effective supportive care. Additionally low health literacy, which contributes to numerous disparities throughout healthcare, has been shown to affect up to 32% of patients with CKD. We investigated whether health literacy is a mediator of racial disparities in EOL preferences and knowledge.

Methods: Cross-sectional study of CKD patients in nephrology outpatient clinics affiliated with two large academic centers in Boston, MA. Inclusion criteria include: i) Age ≥ 50 years, ii) English-speaking during clinical encounters, iii) self-identification with Black or White race, and iv) Stage 4 or 5 CKD (defined by eGFR ≤ 30 ml/min/1.73m^2). Patients listed for kidney transplantation or with history of dementia are not eligible. Confidential structured interviews are performed with all participants. Health literacy is assessed via the validated Rapid Estimate of Adult Literacy in Medicine. Variables of interest include: 1) health literacy (predictor), 2) preference for care at the EOL, and 3) advance care planning (ACP) preferences. Information regarding spiritual/cultural influences on EOL preferences, hospice knowledge and physician distrust are also collected.

Results: 44 participants have completed the study. Black and White patients differ on health literacy and many aspects of EOL care preference.

	Black (N=12)	White (N=32)
Low Health Literacy	75%	13%
Mean age (years)	70 (+/- 12)	72 (+/- 8)
Male	58%	66%
CPR - Prefer to be revived	92%	88%
Critically ill - Prefer to stay in hospital	34%	25%
Critically ill - Prefer comfort care	50%	69%
Completed living will/Do-not-resuscitate form	17%	53%
Completed health care proxy form	67%	69%

Note - Frequencies listed as percentages. Means listed as (+/- SD).

Conclusions: Black and White patients prefer different care at the EOL with less Black patients having completed ACP. Future analysis will determine whether health literacy contributes to disparities and potentially sets the premise for interventional studies aimed at improving EOL care for all CKD patients.

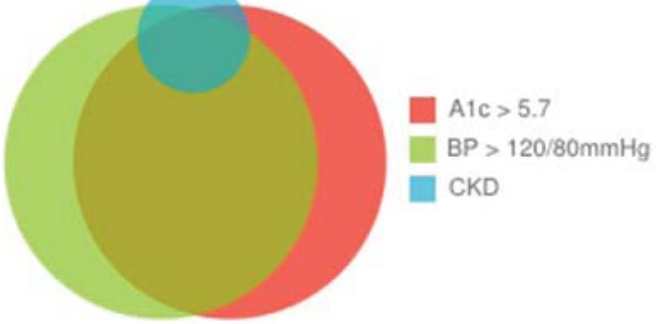
Prevalence of Chronic Kidney Disease in India and Implications for Cardiovascular Disease: The Cardiometabolic Risk Reduction in South Asia Surveillance Study

Shuchi Anand,[1,2] Roopa Shivashankar,[2] Mohammed K. Ali,[3] Dimple Kondal,[2] B. Binukumar,[2] Maria E. Montez-Rath,[1] V.s. Ajay,[1] R. Pradeepa,[4] M. Deepa,[4] Ruby Gupta,[2] V. Mohan,[4] K.M. Venkat Narayan,[3] Nikhil Tandon,[5] Glenn M. Chertow,[1] Dorairaj Prabhakaran.[2] *[1]Medicine/Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [2]Center of Excellence-CARRS, Centre for Chronic Disease Control, New Delhi, India; [3]Rollins School of Public Health, Emory Univ, Atlanta, GA; [4]Madras Diabetes Research Foundation, Chennai, India; [5]Endocrinology, All India Institute of Medical Sciences, New Delhi, India.*

Background: Data on the prevalence of chronic kidney disease (CKD) in India are sparse.

Methods: Using data from the Center for Cardiometabolic Risk Reduction in South Asia surveillance study—a population-based survey of Delhi and Chennai (n=12,271)—we estimate the overall, and the age-, sex-, city-, and diabetes-specific prevalence of CKD. We present the distribution of the population per the KDIGO CKD classification. We compare ten-year likelihood of a cardiovascular event in participants with and without CKD using the Framingham Risk Score.

Results: 9797 participants (80%) had complete data on serum creatinine and albuminuria. Age-standardized prevalence of CKD and albuminuria were 8·8% (95% CI: 8·1-9·6%) and 7·1 (95% CI 6.5-7·7%). Eighty percent of patients with CKD had HbA1c in the diabetes or pre-diabetes range.



Using KDIGO criteria, 7%, 1%, and 0·6% of study participants are at moderate, high, or very high risk for experiencing CKD-associated adverse outcomes. Ten-year probability of cardiovascular events was high for 43% (95% CI 38-48%) of participants with CKD, compared with 15% (95% CI 13-17%) of participants without CKD.

Conclusions: One in twelve people living in two of India's major metropolitan cities have evidence of CKD, with features that put them at high risk for CKD progression and cardiovascular events.

Management Differences of Acute Coronary Syndrome among Patients with Chronic Kidney Disease, End Stage Renal Disease, and Normal Kidney Function Geovani Faddoul, Ninad D. Parekh, Marc M. Saad, Youssef El Douaihy, Iskandar Barakat, Suzanne E. El Sayegh. *Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Background: Chronic kidney disease (CKD) and acute coronary syndrome share common pathophysiology, intersecting management and use of medication like angiotensin converting enzyme inhibitor. This study looks at the management of CKD and end stage renal disease (ESRD) patients in the setting of myocardial infarction (ST and non-ST elevation types: STEMI and NSTEMI) with regards to percutaneous coronary intervention (PCI), coronary artery bypass (CABG) and medical therapy.

Methods: Retrospective cohort analysis of all acute coronary syndrome charts between January 2005 and December 2012 of patients aged more than 18. Exclusion criteria were non cardiac chest pain, AKI at time of admission (history of CKD included). The primary outcome was interventions. The interventions were PCI, CABG and change in medication regimen. The secondary outcomes were length of stay, mortality and left ventricular function ejection fraction percentage (LVEF).

Results: We analyzed 334 patients with STEMI (50.3%) and NSTEMI (49.7%) and compared subgroups of normal glomerular filtration rate (GFR), CKD (III to V) and ESRD. The patients with STEMI had an left ventricle ejection fraction of 37%±10 ($p<0.05$). The length of stay was not significantly different between the different subgroups. CKD patients had less PCI in a STEMI setting and ESRD patients had less PCI overall ($p<0.05$). ESRD patients also had less CABG interventions than normal GFR group ($p<0.05$). The analysis did not however show any difference in medical therapy (aspirin, beta-blocker, ACE inhibitor or angiotensin receptor blocker, clopidogrel or equivalent, statins). Results about mortality were controversial since they showed worse mortality for CKD compared to normal GFR in STEMI and compared to ESRD in NSTEMI.

Conclusions: The CKD and ESRD subgroups benefit less of PCI and CABG than normal GFR patients but have the same medical therapy.

PUB218

Chiral Amino Acid Metabolomics for Novel Biomarker Screening in CKD Yoshitaka Isaka,[1] Tomonori Kimura,[1] Ryohei Yamamoto,[1] Hiromi Rakugi,[1] Masashi Mita,[2] Kenji Hamase.[3] *[1]Dept of Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Shiseido Co., Ltd, Tokyo, Japan; [3]Graduate School of Pharmaceutical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: D-Amino acids are the enantiomers of L-amino acids, and increasingly recognized as novel physiologically active molecules and biomarkers. Their distribution and regulation are totally different from those of L-forms, however, the amounts of D-amino acids are usually small in humans, and the determination is frequently interfered by various intrinsic substances. Therefore, chiral amino acid profile remains unknown in CKD patients.

Methods: More than 100 patients recruited from a single center comprised of chronic kidney diseases stage 3-5. Serum D-amino acids were analyzed using a two-dimensional HPLC system with fluorescence detectors and an ESI-tandem mass spectrometer. For the improvement of detection sensitivity and also of chromatographic retention, amino acids were pre-column derivatized with 4-fluoro-7-nitro-2,1,3-benzoxadiazole (NBD-F). The NBD-amino acids were separated by areversed phase column (capillary monolithic ODS, 0.53 mm i.d. x 1000 mm) in the first dimension, and the D- and L forms of target amino acids were separated by enantioselective columns (1.5 mm i.d. x 250 mm) in the second dimension.

Results: The 2D-HPLC-FL/MS/MS system could successfully determine all proteinogenic amino acid enantiomers without interference from intrinsic substances in human serum. We found small amounts of D-Ala, D-Pro and D-Ser in the sera of healthy volunteers. On the contrary, CKD patients exhibited significantly increased amounts of serum D-amino acids, and these values were correlated with their creatinine and estimated glomerular filtration rate.

Conclusions: D-Amino acids estimated using 2D-HPLC-FL/MS/MS system may be novel biomarkers in CKD patients.

PUB219

Hemodialysis Staff and Caregivers Burnout a Single Center Experience Konstantina Trigka,[1] Periklis Dousdampanis.[1] *[1]Hemodialysis Unit, Kyanous Stayros Patron, Patras, Achaia, Greece; [2]Univ New Mexico.*

Background: The number of dialysis patient's increases and the trend is towards extended hours of HD sessions, the psychological strain by personnel and caregivers is important. We investigated the impact of job psychological stress of HD personnel by obtaining measurements of burnout, examined the burden of family members who provide care for HD patients and correlations with patient's co-morbidities and depression.

Methods: We administered ProQOL5 questionnaire to HD staff, American Medical Association's Caregiver Health Self-assessment Questionnaire to family members and applied the BDI questionnaire to the aforementioned patients and measured their co-morbidities utilizing the Charlson Co-morbidity Index.

Results: The majority did not experience burnout (mean score 23.2±4.9), without statistical difference between physicians and nurses. 2 stressors categories emerged: duration of working practice and age of HD providers. Staff with higher qualifications, working full-time were more likely to be dissatisfied. Staff's sex, marital status and number of children were insignificantly related. 48.45% caregivers responded -mean age: 59±1). Found no significant difference between caregiver's age and stress degree. 70.2 % of caregivers - mean age 58±13, experienced moderate stress. The remaining 29.8 %-mean age 64±12, experienced higher degree stress. Statistical analysis did not indicate correlation of caregivers' and staff"s burnout levels with patients' co-morbidities- CCI or patients' depression- BDI score. There was no correlation regarding inter-dialysis weight gain, dialysis modality, number of daily administered-or psychiatric drugs, dialysis shift, cerebrovascular or cardiac diseases, causes of CKD, anemia, renal osteodystrophy, albumin, cholesterol, arterial hypertension or diabetes mellitus.

Conclusions: HD workers are not exposed to above-average levels of stress. Older personnel with greater length of service and HD staff with occupational seniority have higher burnout levels. Older caregivers tend to report greater degrees of stress, whereas no relationship was revealed between caregiver's stress degree and patient's depression level or co-morbidities.

PUB220

Associations of Depression and Pain with Quality of Life and Satisfaction in Chronic Hemodialysis Patients Linda Yick Belayev,[1] Maria K. Mor,[3,4] Paul M. Palevsky,[1,2] Robert M. Arnold,[5,6] Steven D. Weisbord.[1,2,3] *[1]Renal-Electrolyte Div, Univ of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Renal Section, Medicine Service Line, VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]Center for Health Equity Research and Promotion, VA PIttsburgh Healthcare System, Pittsburgh, PA; [4]Dept of Biostatistics, Univ of Pittsburgh, Pittsburgh, PA; [5]Div of General Internal Medicine, Univ of Pittsburgh School of Medicine, Pittsburgh, PA; [6]Div of Palliative Care, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The impact of depression and pain on health related quality of life (HRQOL) and satisfaction with care is not fully understood in hemodialysis (HD) patients. We sought to characterize the associations of these symptoms with HRQOL and satisfaction with care.

Methods: We prospectively assessed depression using the Patient Health Questionnaire-9 and pain using the Short-Form McGill Pain Questionnaire on a monthly basis in patients on chronic HD. We assessed HRQOL and satisfaction with care quarterly using the Short Form 12 and Patient Satisfaction Questionnaire, respectively. Random effects linear regression was used to analyze associations.

Results: Among 286 patients, depression was reported on 18% and pain on 79% of monthly assessments. Depression was independently associated with decreased SF-12 physical health scores (B= -0.31; 95% CI: -0.43, -0.20); decreased SF-12 mental health scores (B= -0.91; 95% CI: -1.02, -0.79); and decreased satisfaction with care (B = -0.14; 95% CI: -0.17, -0.12). Pain was independently associated with decreased SF-12 physical health scores (B= -0.23; 95% CI: -0.29, -0.17); decreased SF-12 mental health scores (B= -0.16; 95% CI: -0.23, -0.09); but not with decreased satisfaction with care (B = -0.03; 95% CI: -0.01, 0.04).

Conclusions: Depression and pain are associated with reduced physical and mental HRQOL. Depression is also associated with decreased satisfaction of care. Symptom alleviating interventions may improve these patient-centered outcomes.

Cardiovascular and Renal Risk Factors in Wichi Aborigines from Chaco, Argentina Maria Eugenia V. Bianchi,[1] Germán Darío López,[1] Lucas Leonardo Suarez,[1] Katya Carolina Polischuk,[1] Ana M. Cusumano,[2] Gustavo A. Velasco.[3] *[1]School of Medicine., National Northeast Univ, Corrientes, Corrientes, Argentina; [2]Univ Institute, CEMIC, CABA, Buenos Aires, Argentina; [3]Biochemistry, Hospital Julio C Perrando, Resistencia, Chaco, Argentina.*

Background: The Province of Chaco, Argentina, was inhabited since ancient times with gathers and hunters ethnic groups. Wichí aborigines (ab) live near Bolivia, far from urban settlements. The contact with white population and salt began in late 19th century. There are no official records about anthropometric characteristics, blood pressure and social economic state of this ab. National Northeast University designed a program to educate about cardiovascular and renal risk factors (CVRRF). The wichi ab in community meetings were encouraged to create neologisms for diabetes mellitus, hypertension (HT) and Chronic Kidney Disease and trained ab to detect CVRRF. The aim of this work is to show the results obtained by wichi ab health workers in detection of CVRRF.

Methods: This is a descriptive, observational, cross-sectional study. Data collection was conducted using a semistructured survey translated to their own language in presence of medical doctors. VII JC and WHO classifications were adopted for HT and Central Obesity.

Results: A total of 156 ab were surveyed 91(58,3%) men and 65(41,7%) women, mean age of 34,26±11,8 years (range 18-76). The mean (sd) weight was 72,79±14,6 and mean height of 1,63±0,1. Nutritional status showed: overweight in 26,92%(CI95% 21,1-34,6), obesity in 39,1%(CI95% 31,4-47,2), central obesity, 40,15%(CI95% 31,7-49), sedentarism 83,33 %(CI85% 78,2-93,8). HT, 10,9%(CI95% 6,5-16,9), Glycemia > 200mg/dl in only one ab and Proteinuria in 14,6%(CI95% 8,21-23,3). The socioeconomic status was mainly marginal 61,73%(CI95% 50,2-72,3). There were differences by sex in central obesity: 50,9% versus 32,5% (p=0,033) and height 1,56±0,14m versus 1,67±0,06m (p=0,00) for women and men respectively.

Conclusions: These are the first data describing CVRRF in wichi ab from Chaco Argentina. They showed a high rate of obesity with low rates of HT. The cohort will be followed to observe the evolution of CVRRF.

PUB222

Absence of a Strong Correlation Between Obesity and Systolic Hypertension in Korean and Chinese Populations of Greater Boston Michael Ho-Young Ahn,[1] Andrew J. Pan,[1] Ryan Lindeborg,[1] Laura C. Polding,[1] Enchi K. Chang,[1] Anita Xu,[1] Rayhnuma Ahmed,[1] Supisara Tintara,[1] Tzongshi Lu,[2] Jennie Kuo,[2] Li-Li Hsiao.[2] *[1]Harvard College; [2]Renal Div, Brigham and Women's Hospital.*

Background: Obesity is an established risk factor for developing hypertension. Yet very few studies have examined the relationship between obesity and hypertension in Asian populations in North America. This observational study investigates the relationship between obesity (as quantified by BMI) and systolic hypertension in Korean and Chinese participants of free kidney health screenings hosted by the Kidney Disease Screening and Awareness Program (KDSAP).

Methods: In Korean and Chinese populations in Greater Boston, KDSAP held kidney health screenings that included body mass index (BMI) and blood pressure (BP) measurements. Participants were asked to report their ethnicity. Subsequent data analysis accounted for different BMI standards for Asian populations, with a BMI of 24 or above classified as "overweight" and a BMI of 27 or above as "obese". A systolic BP of 140 or above was considered to be hypertensive.

Results: Among 138 Korean participants, 32 had systolic hypertension, of which 8 were overweight and 8 obese. Among 137 Chinese participants, 55 had systolic hypertension, of which 19 were overweight and 15 obese. BMI and BP were weakly correlated in both Asian populations (r = 0.215 for Koreans; r = 0.254 for Chinese). Differences between mean hypertensive and non-hypertensive BMIs were insignificant in Koreans (p = 0.13) and significant in Chinese (p = 0.015).

Conclusions: Our findings contradict those found for BMI and BP in non-Asians by demonstrating a weak correlation. Further studies are warranted to assess the influence of other factors such as diet, smoking, and socioeconomic status on hypertension in Asians. KDSAP fills a unique niche in collecting data from these populations as an organization dedicated to reducing health disparities in medically underserved communities. Identifying the key social determinants and risk factors for chronic kidney disease and elucidating their relationships will be crucial to improve preventive screenings.

PUB223

Patients with Chronic Kidney Disease and Their Intention to Use Electronic Personal Health Records Tyrone Harrison,[1] James Wick,[1] Min Jun,[1] Braden J. Manns,[1] Sofia B. Ahmed,[1] Robert R. Quinn,[1] Marcello Tonelli,[2] Brenda Hemmelgarn.[1] *[1]Dept of Medicine, Univ of Calgary, Calgary, AB, Canada; [2]Dept of Medicine, Univ of Alberta, Edmonton, AB, Canada.*

Background: Strategies to enable patient self-management have been advocated in a movement towards patient-centered care. Electronic personal health records (ePHRs) give patients access to their health information, and may facilitate their self-management. The purpose of our study was to describe the perceptions of patients with chronic kidney disease (CKD) about ePHRs, and characteristics associated with their intent to use ePHRs.

Methods: We surveyed consecutive outpatients with non-dialysis CKD (eGFR <30 mL/min/1.73m^2) in Calgary, Canada over a three-month period. Patients were invited to complete a paper-based survey at their routine nephrology clinic visit. Data obtained included patient demographics, intent to use an ePHR, and perceived benefits and concerns about ePHR use. Multivariable logistic regression was used to determine characteristics associated with intent to use an ePHR.

Results: 67 patients with CKD completed the survey. Most patients were over 65 years old (55%), male (74%), and had access to the internet (72%). The majority of respondents (82%) agreed that patients should have access to their personal health information and 70% indicated they would use an ePHR if available. Perceived benefits of ePHR access included greater involvement in personal health care (50%), and better access to lab results (72%), though 40% reported concerns about privacy of their health information. In a multivariable analysis, only "interest in regular monitoring of their health" was associated with an increased likelihood of intent to use ePHR (OR=11.7, 95%CI: [1.2-110], p=0.031).

Conclusions: Patients with CKD are interested in accessing their personal health information and intend to use ePHRs if offered. Factors such as security, anxiety about results, and lack of internet access did not affect their intent to use ePHRs. Our results are limited by the small sample size and single centre nature of the study. Further research is needed to determine whether use of ePHRs improves patient outcomes.

PUB224

Comparison of Quality-of-Care Indicators in Patients with End-Stage Renal Disease due to Lupus Nephritis versus Other Causes Laura Plantinga, Rachel E. Patzer, Cristina Drenkard, Stephen O. Pastan, Jason Cobb, William M. McClellan. *Emory Univ, Atlanta, GA.*

Background: Patients with end-stage renal disease (ESRD) due to lupus nephritis (LN) may be treated by multiple specialty providers and, thus, have greater opportunities for high-quality pre-ESRD care than patients with other causes of ESRD.

Methods: In U.S. patients initiating treatment for ESRD (7/05-9/11), we examined whether quality-of-care indicators (receipt of pre-ESRD nephrology care, access to transplant, and permanent access placement for dialysis) were better among those with ESRD due to LN (*n*=6,594) versus other causes (*n*=669,295) using national surveillance data (United States Renal Data System). Logistic and Cox proportional hazards models were used to estimate odds ratios (ORs) and hazard ratios (HRs) of each quality-of-care indicator, with adjustment for age, sex, and race.

Results: Among those with ESRD due to LN versus other causes, 71% versus 66% received pre-ESRD nephrology care; 85% versus 79% were informed of transplant options; and rates of waitlisting were 206 versus 96 per 1000 patient-years. With adjustment, those with LN were more likely to receive pre-ESRD care (OR=1.52, 95% CI 1.49-1.56), be informed of transplant options (OR=1.12, 95% CI 1.04-1.21), and be waitlisted (HR=1.46, 95% CI 1.40-1.53) than those with ESRD due to other causes. However, only 24% versus 36% patients with ESRD due to LN versus other causes had a permanent vascular access (fistula or graft) used or in place at the start of dialysis; with adjustment, those with ESRD due to LN were 40% less likely to have a permanent access (OR=0.62, 95% CI 0.58-0.66).

Conclusions: Patients with ESRD secondary to LN are more likely to receive pre-ESRD care and have better access to transplant—but are less likely to have a permanent vascular access for dialysis—than patients ESRD due to other causes. While there is room for improvement in all quality-of-care indicators among LN patients approaching ESRD, further studies are warranted to specifically examine barriers to permanent vascular access placement and morbidity and mortality associated with temporary access in this population.

PUB225

Ace Inhibitors Slow Down Renal Damage Progression Even in Chronic Kidney Disease Stage 5 Pietro Claudio Dattolo, Elena Romoli, Fiammetta Ravaglia, Elisa Ferrari, Marco Allinovi, Giuseppe Ferro, Marco Amidone, Francesco Pizzarelli. *Nephrology, Internal Medicine, S.M.Annunziata Hospital, Firenze, Italy.*

Background: It is a time-honoured knowledge that ACEi slow the progression of kidney damage; if this effect persists in patients with CKD as advanced as stage 5 is less well known. To verify this, we analyzed clinical and laboratory data of patients referred to our outpatient CKD stage 5 clinics from 2001 to 2010.

Methods: We analyzed data of 313 patients (M 60 %, age 72 ± 14 years), 65% with cardiovascular disease, 35% with diabetes and 50% with other comorbidities (cancer, chronic diseases). At first visit the average eGFR (MDRD formula) was 9.5 ml/min/1,73m2 (IQR: 7.9-11.4), and proteinuria was 1.5 g/day (IQR: 0,6-3). During a median 2 year follow-up, 62 patients died and 198 started dialysis. Data are expressed as mean ± standard deviation, median and interquartile range; primary end point was dialysis start. We used ANOVA, t-test and Cox regression for statistical analysis.

Results: The 195 patients treated with ACEi showed a flat eGFR slope significantly lower than 118 patients not treated with ACEi (0,48 ± 1,08 ml/min/1,73 m2/year versus 3,12 ± 3,00 ml/min/1,73 m2/year, p=0.04). Cox regression analysis identified the use of ACEi and age as the only independent factors of protection from renal injury, while proteinuria and phosphorus were independent factors of progression.

	WALD	p	Hazard	95% CI
ACEi (yes)	6,7	0,013	0,69	0,50-0,92
AGE (years)	15,6	0,000	0,98	0,97-0,99
PHOSPHATE (mg/dl)	9,1	0,002	1,20	1,10-1,30
U-PROT (g/die)	35,0	0,000	1,21	1,15-1,30

Conclusions: Our study shows that treatment with ACEi slows down the renal damage progression in patients with advanced CKD stage 5, allowing us to safely delay the start of dialysis treatment.

PUB226

Catheters May Be Associated with Modestly Increased Risk of Poor Outcomes in Patients Transplanted Early Laura Plantinga, Rachel E. Patzer, Stephen O. Pastan. *Emory Univ, Atlanta, GA.*

Background: Clinical guidelines recommend placement of a permanent vascular access (fistula or graft) in all incident dialysis patients, but providers may rely on temporary catheters when patients are expected to receive a transplant imminently. Whether this practice is associated with increased risk of poor outcomes among these patients, as in the overall ESRD population, is unknown.

Methods: Using United States Renal Data System data, we examined mortality (all-cause, infectious), hospitalizations, and transplant failure in 8,617 U.S. incident dialysis patients (7/05-5/11) aged 18-69 who received a transplant within 1 year of their dialysis start date. Follow-up was defined from ESRD start (mortality, hospitalizations; median, 3.5 years) or transplant (transplant failure; median, 2.7 years) to death or end of follow-up (9/11). Catheter use was defined as not having a fistula or graft in place at start of dialysis. We used Cox proportional hazards and Poisson models with adjustment for age, sex, and race to estimate hazard ratios (HRs) and incidence rate ratios (IRRs) for catheter use versus permanent vascular access used/in place.

Results: Overall, 4,861 (56.4%) started dialysis with a catheter. After adjustment, catheter use was associated with 16% and 53% increased all-cause and infectious mortality risk among these patients, respectively, although the associations were not statistically significant (HR=1.16, 95% CI, 0.97-1.39; and HR=1.53, 95% CI, 0.86-2.71). Only 4 (0.7%) of 609 total deaths (5.4% of 74 infectious deaths) were attributed to vascular access. The association between catheter use and hospitalizations was modest, at 5% increased hospitalization rate for patients with catheters versus permanent access (IRR=1.05, 95% CI, 1.01-1.08). Finally, transplant failure was 16% more likely among those recipients starting with a catheter (HR=1.16, 95% CI, 1.01-1.32).

Conclusions: More than half of patients who receive a transplant within 1 year of starting dialysis do not have permanent vascular access in place. Providers should weigh potential modestly increased risks of mortality and morbidity in shared decision making regarding vascular access for dialysis patients who are likely to receive a transplant early.

PUB227

Timely Data Reporting Is Associated with Improved Blood Pressure Control and Reductions in Interdialytic Weight Gain in Dialysis Patients

Patricia McCarley, Karen G. Butler, Alex J. Rosenblum, Portia R. Scott, Terry Ketchersid, John W. Larkin, Len A. Usvyat, Norma J. Ofsthun, Jeffrey L. Hymes, Evan Norfolk, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Uncontrolled blood pressure and fluid overload are challenging to clinically manage in the renal dialysis patient population. In December 2013, Fresenius Medical Care North America (FMCNA) initiated a Weekly Snapshot Report pilot program designed to identify uncontrolled systolic hypertension and fluid overload in dialysis patients. This analysis investigated whether the provision of weekly data for elevated systolic blood pressure (SBP) and fluid overload is associated with improvements in clinical management.

Methods: This study analyzed data from two clinics enrolled in the Weekly Snapshot Report pilot program since December 30, 2013. Clinics participating in the program had weekly identification of patients with high SBP (>160 mmHg pre- and post-dialysis) and fluid gains (i.e. interdialytic weight gain (IDWG) > ultrafiltration volume (UFV)) during the preceding week. Patient clinical data was captured for 30 days before and after enrollment. Comparisons were performed using paired t-test analysis.

Results: Overall, 119 patients were enrolled into the Weekly Snapshot Report program. This investigation found the potential impacts of the program to be reductions in the percent of treatments with post-dialysis SBP >160 mmHg and IDWG > UFV. However, no comparisons were identified to be statistically significant.

Figure 1:	30 days before	30 days after	Percent change
IDWG (kg)	3.33 (SD±1.48)	3.26 (SD±1.23)	-2.2%
Pre-dialysis SBP (mmHg)	150.51 (SD±24.82)	149.59 (SD±23.69)	-0.6%
Treatment time (mins)	207.69 (SD±37.86)	213.9 (SD±50.06)	3.0%
Post weight (kg)	85.04 (SD±23.08)	84.93 (SD±23.28)	-0.1%
% with pre-dialysis SBP>160	37.3%	36.0%	-3.3%
% with post-dialysis SBP>160	17.6%	15.5%	-12.0%
% of tx with IDWG>UFV	48.8%	45.4%	-6.9%

Conclusions: Timely data reporting through the Weekly Snapshot Report pilot program had trending associations with improvements in uncontrolled systolic hypertension and fluid overload. Further studies are needed with larger patient numbers to better identify the potential impacts of timely data reporting.

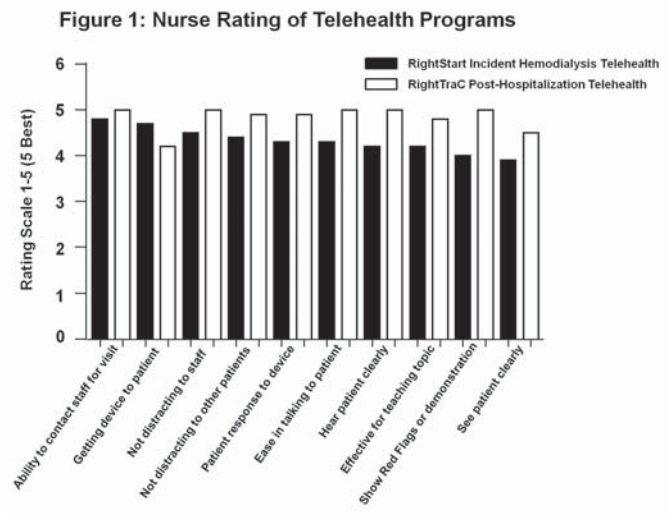
Bridging the Gap between Face-to-Face and Telephonic Case-Management: Use of Telehealth Visits

Billie Axley, Rebecca L. Wingard, Kathryn A. McDougall, Jonathan Nichols, John W. Larkin, Len A. Usvyat, Alexis Porras, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: One in three dialysis patients are readmitted within 30 days of discharge from the hospital according to USRDS data. Since March 2014, this challenge is being addressed via the Right TraC™ (RT) care transitions program, which is a population based case-management approach for patients post-hospitalization. The aims of this pilot study were to understand if telehealth is effective for engaging patient management.

Methods: The RT telehealth visit initiative is based upon framework from the Right Start (RS) program, whereby case managers provide specialized management and education to 1-120 day incident dialysis patients. In the RT program, case managers telephonically deliver targeted interventions designed to promote 0-30 day post-hospitalization patients' self-management skills and interdisciplinary healthcare. This process utilizes a video- and tele-communication device configured to allow for use of a secured Skype application. Comparisons have been performed between the objective ratings in key elements of the RS and RT telehealth programs in 48 and 11 patients respectively.

Results: Results from the RS and RT televisit nurse rating of key elements to assist in its evaluation can be seen in Figure 1. Performance ratings in both programs were similar with ranges from 3.9-5.0, with 5.0 as the best possible score. The RT telehealth visits were found to have excellent ratings for key areas of performance.



Conclusions: Based upon the RT case managers' evaluations, use of telehealth technology can successfully enhance the ability of the case manager to engage their patients through virtual evaluation and integrated self-management tools. Use of telehealth visits may be the bridge in the gap between face-to-face encounters and telephonic case management.

Direct Healthcare Costs Related to End Stage Renal Disease in Patients New to Haemodialysis: The FARO2 Study

Daniela Paola Roggeri,[1] Diego Brancaccio,[2] Mario Cozzolino,[7,8] Piergiorgio Messa,[4] Giuseppe Cannella,[5] Alessandro Roggeri,[1] Anna Maria Costanzo,[6] Sara Di Fino,[6] Umberto Di Luzio Paparatti,[6] Vincenzo Festa,[6] Sandro Mazzaferro.[3] *[1]ProCure Solutions, Nembro, Bergamo, Italy; [2]Dialysis Unit, Simone Martini Hosp., Milan, Italy; [3]Card. Resp. Nephr. Dep., Sapienza Univ, Rome, Italy; [4]Nephrology Dialysis and renal Transplant, Fondazione Ca'Granda IRCCS-Policlinico, Milan, Italy; [5]Dep. of Nephrology, San Martino Hosp., Genoa, Italy; [6]AbbVie, Campoverde, Latina, Italy; [7]Health Sciences, Univ. of Milan, Italy; [8]Renal Div, San Paolo Hosp., Milan, Italy.*

Background: Objective of this analysis was to estimate direct healthcare cost of end stage renal disease (ESRD) in naïve haemodialysis (HD) patients enrolled in the FARO2 study.

Methods: The FARO2 retrospective observational study conducted in Italy aimed to evaluate patterns of treatment of SHPT and healthcare costs in a subgroup of patients who started HD during the FARO study. Observational period: 2006-2008. Costs were measured in 2008 Euros; no discount rate was applied. Resource consumption evaluated for the first two semesters of HD were: reimbursed SHPT drugs, phosphate binders and erythropoietin stimulating agents (ESA), HD sessions and ESRD-related hospitalizations. The analysis was performed from the Italian National Health Service (INHS) perspective.

Results: 567 patients had at least two semesters of observation (average age: 65.5 years). For the first year after HD entrance average direct healthcare costs accounted for 31,677€/patient.

	Semester 1 (€)	Semester 2 (€)
Vitamin D+cinacalcet	324	381
Phosphate Binders	283	364
ESA	3,005	2,941
HD	11,276	11,695
Hospitalizations	749	659
Total	15,637	16,040

These costs were estimated considering: average weekly frequency of HD, for drugs the percentage of patients treated and the average daily dosages and for inpatients the percentage and type of hospitalizations.

Conclusions: Patients naïve to HD have a significant impact on INHS expenditure even if, such in this study, only costs related to treatment of ESRD and its complications were considered. The major cost drivers were HD and ESA (91% of total costs) while SHPT drugs and phosphate binders accounted for only 4% of direct healthcare expenditure.

PUB230

An Updated Assessment of CKD Management in the Primary Care Setting David M. Dewolfe,[1,2] George P. Bayliss.[1,2] *[1]Medicine, Rhode Island Hospital, Providence, RI; [2]Alpert Medical School, Brown Univ., Providence, RI.*

Background: We sought to determine factors associated with nephrologist referral and whether nephrology co-management of CKD patients had a positive effect on adherence to KDOQI guidelines for CKD management and short-term clinical outcomes.

Methods: A retrospective cohort study of 147 patients receiving continued care at the Rhode Island Hospital Resident Medical Clinic between Feb 1 2012 and Feb 1 2014 with an eGFR <60 ml/min/1.73m² on two lab draws at least 3 months apart. Variables include age, gender, CKD severity, presence of CKD ICD-9 code, nephrology referral, consultant correspondence; KDOQI guideline annual assessments include serum Cr, albuminuria, nutrition, bone health, electrolytes, ACE/ARB use and anemia; Clinical outcomes include average blood pressure and rate of decline of GFR.

Results: Of the patients analyzed, 90% had stage III and 10% had stage IV CKD; only 26% were co-managed by a nephrologist. Variables associated with referral to a nephrologist were higher serum Cr, lower eGFR, higher CKD stage and presence of a CKD ICD-9 code in the patient's problem list. Patients co-managed by a nephrologist were more likely to be screened annually for albuminuria (P< 0.0102), electrolyte/bone health (Ca P= 0.0012; Phos P= 0.0012; Vit D P= 0.003; PTH P< 0.001) and anemia (P = 0.031). From Feb 2012 to Feb 2014, median decline in eGFR was 4% for all patients. For those co-managed by a nephrologist the median decline in eGFR was 11.5% versus 2.1% for those not managed by a nephrologist (P= 0.0328), and this difference remained on multivariate analysis. 63% of patients co-managed by a nephrologist met the KDOQI blood pressure goal of <130/80 while only 50% of patients not co-managed did, though this difference did not reach statistical significance (P= 0.15).

Conclusions: Nephrology co-management was associated with greater short-term decline in eGFR despite increased compliance with KDOQI guidelines, in part explained by more advanced CKD at baseline in referred patients, but also perhaps indicating that patients are being referred too late in the clinical course of kidney disease to alter outcomes. Earlier referral may be an area for improvement.

PUB231

Association Between Oral Hygiene Behavior and Hypertension Prevalence, Awareness, Treatment and Urine Sodium Excretion Jun-Beom Park,[1] Hye Min Choi.[2] *[1]Dept of Periodontics, Seoul St Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Myongji Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: A positive association has been reported between hypertension, kidney disease and periodontal disease. Oral health promotion activities appeared to produce improvements in periodontal health, and may result in changes to systemic markers of inflammation and endothelial function. Therefore, this study was performed to assess the association of oral health behaviors, hypertension and sodium intakes in a large probability sample of the Korean population using the data from Korea National Health and Nutrition Examination Survey (KNHANES).

Methods: The data from KNHANES conducted between 2008 and 2010 were used. The tooth brushing frequency and the use of secondary oral products were evaluated. Multivariate logistic regression analyses were used to assess the associations of oral hygiene behaviorwith the hypertension prevalence, awareness, treatment and sodium intakes.

Results: An association between hypertension and oral hygiene behavior could be seen after adjustment for variables. Adjusted odds ratios An association between hypertension and oral hygiene behavior could be seen after adjustment for variables. Adjusted odds ratios and their 95% confidence intervals of hypertension prevalence were 1.231 [1.040-1.457] for individual who brushed none for controlling for age and sex, smoking, drinking, exercise, education, income, energy intake, fat intake and periodontitis. An association between urine sodium excretion and oral health behaviors could be seen in female. Adjusted odds ratios and their 95% confidence intervals of tooth brushing ≥ 3 per day in the highest quartile for urine sodium excretion group were 0.783 [0.608-1.010] after controlling for variables.

Conclusions: Individuals with poor oral hygiene habit were more likely to have higher hypertension prevalence. This study also showed the association between urine sodium excretion and oral health behaviors in female. Within the limits of this study, oral hygiene habit may be considered a potential risk indicator for hypertension.

PUB232

Impact on Estimated Glomerular Filtration Rate (eGFR) in Treatment of Multidrug-Resistant Tuberculosis (MDR-TB) Gustavo Alejandro Casas-Aparicio,[1] Isabel Maria Leon-Rodriguez,[1] Gustavo Reyes-Teran.[1] *[1]CIENI, Instituto Nacional de Enfermedades Respiratorias, México D.F., Ciudad de Mexico, Mexico; [2]CIENI, Instituto Nacional de Enfermedades Respiratorias, México, D.F., Ciudad de México, Mexico; [3]CIENI, Instituto Nacional de Enfermedades Respiratorias, México, D.F., Ciudad de México, Mexico.*

Background: MDR-TB treatment is nephrotoxic, due to use of injectable aminoglycosides(aIY).

Methods: A retrospective study of MDR-TB patients treated with aIY agent at National Health Respiratory Institute in Mexico City between 2009-2013 was performed. Demographics, serum chemistry, hematological testing were recorded at baseline(BL) and End of treatment. Nephrotoxicity was defined as increase in the Creatinine(Cr) level >0.3 mg/dL compared with BL. CKD-EPI was used to calculate the eGFR, KDOQI was used to stage CKD. Results are expressed by means (min, max), Fisher´s exact test and U Mann-Whitney were performed to compare categorical and continues variables respectively. Analysis were obtained using SPSS v15.0, p <0.05 were considered significant.

Results: We evaluated 41 cases with diagnosis MDR-TB confirmed. Age 42 years (19,70). Male 26(62%), Diabetes Mellitus 20(48%), Hypertension 5(12%), HIV 1(2.4%), Kidney Transplant 1(2.4%), Smoke 13(31%). BMI 24.5(13. 34), Antihypertensives 6(14%), AINES 1(2.4%). Anti-TB aIY drugs used were Amikacina 21(51.2%), Kanamicina 2(4.9%), Capreomicina 17(41.5%). Months with aIY drugs 6.29(5, 8), Glucose 146(70, 525), Albumin 3.53 (2.06-4.56), Hemoglobine 13.3(6.9, 18.5). Cr 0.75(0.32, 1.70), eGFR CKD-EPI 108 ml/min/1.73m2 SC(40.5, 150.8). K-DOQI at BL were: Stage 1: 31 (75.6%), 2: 8 (19.5%), 3: 2 (4.9%). Decrease renal function was observed at the end of treatment: CKD-EPI 108.18 (100.51-115.84) versus 91.62 (83.09-100.17) ml/min/1.73 m2 SC p=<0.001. Cr 0.75(0.61-0.78) versus 0.94(0.81-1.06) mg/dL p=0.01. At the end of treatment K-DOQI stages were: Stage 1: 22(55%), 2: 12(30%), 3: 6(15%). Nephrotoxicity was present in 23(56%) of cases, 7 (30.4%) recovered BL renal function. Factors associated with toxicity or loss of eTFG were not found. At analysis all cultures were negative with treatment.

Conclusions: MDR-TB treatment is effective but highly nephrotoxic. Strategies to prevent loss of eTFG are necessary.

PUB233

Improving Quality of Life in Elderly Hemodialysis Patients: A Single Center Prospective Study Sangeetha Murugapandian,[1] Omid Bakhtar,[1] Natasha Sharda,[1] Bijin Thajudeen,[1] Amy Nicole Sussman.[1] *[1]Nephrology, Univ of Arizona Medical Center, Tucson, AZ; [2]Nephrology, Southern Arizona VA Health Care System, Tucson, AZ.*

Background: Quality of life (QOL) is an important factor determining morbidity and mortality in Elderly Hemodialysis patients. Identification of factors like functional decline, frailty, depression, delirium, cognitive decline and malnutrition early in the course of end-stage renal disease (ESRD) helps in improving QOL.

Methods: We did a prospective interventional study in patients on hemodialysis above the age of 65 at SAVAHCS, Tucson, AZ. The following information was obtained at baseline and 6 months.

Baseline	6 months
Physical Exam (PE), Frailty Phenotype (FP)	PE, FP
Surveys:Qualiy of life (QOL), Activities of daily living (ADL),Nutritional Status (NS)	QOL,ADL,NS
Mini-mental status Examination (MMSE) confusion asessment method (CAM), Geriatrics Depression scale(GDS)	MMSE,CAM,GDS

Depending on initial assessment patients were referred to physical rehab, psychology, psychiatry,neurology or dietician as needed.

Results: A total of 14 patients were enrolled in the study with mean age 75.23±8.89 years. We used CAM, ADL, MMSE, GDS, nutrition and Handy Helper score at baseline and 6 months. Initial scores were 3.42±1.02, 0, 80.10±4.44, 27.35±2.82, 6.64±1.40, 22.57±4.67,45.71±7.07 respectively. At six months the corresponding scores were 3.14±1.19, 0, 86.92±3.38, 26.35±3.53, 4.50±1.41, 23.42±3.53 and 48.92±7.25 respectively. GDS was the only variable which showed a statistically significant difference (p value =0.044). QOL assessment at 6 months showed improvement in all variables physical functioning, physical role, emotional role, energy, general health and emotional well-being) except social functioning.

Conclusions: A comprehensive evaluation of all factors which can affect the QOL in ESRD patients should be carried out early and at regular intervals with timely interventions. Depression is a major under diagnosed problem in patients and early recognition and treatment of depression could improve QOL especially in elderly patients.

PUB234

Prevention of Iodinated Contrast Media Nephrotoxicity in Patients with Renal Insufficiency in an Outpatient Basis Maite Rivera, Nuria Rodriguez Mendiola, Victor Burguera, Rodrigo Hernandez Loyola, Viviana Raoch Michaels, Fernando Liano, Carlos Quereda. *Nephrology, Hospital Ramón y Cajal. UAH Univ. IRyCis, Madrid, Spain.*

Background: Prophylaxis of contrast media nephrotoxicity consists of intravenous hydration before and after the radiological procedure, which carries the need of hospitalization. Our aim was to analyze the efficiency of a preventive protocol consisting of a unique dose of intravenous saline hydration and intravenous acetylcysteine before the administration of the iodinated contrast on an out-patient basis.

Methods: Between January and December 2013, 28 patients with chronic renal insufficiency (GFR<60 ml/min/1,73 m2) were treated with this preventive protocol. The radiological exploration in all of them was a computed tomography (CT). Contrast dose:100 ml of Iohexol (concentration of 350 mg/ml). All patients had a stable renal function. Serum creatinine (SCr) before and in the following ten days was recorded. The explorations with iodinated contrast were programmed in the afternoon. During the previous morning, the patients received between 500 and 1000 ml of 0.9 percent saline (according to their hydration grade and / or cardiologycal situation) plus 1 gram of acetylcysteine. Hydration after the iodinated contrast was not prescribed. The treatment was administered in our Nephrology Day hospital, therefore patients were not hospitalized.

Results: Mean age: 62 years. 71% male. 82% hypertense, 39% diabetic and 25 % had vascular peripheral disease. The average Charlson index:6.1 ± 2.5 (2-11). 74% had treatment with ACE i orARB II. 9 patients (32%) had renal chronic disease stage 3; 7 patients (25%) stage 4; and 12 patients (43 %) stage 5. Mean basal SCr was 3.9 ± 2.7 mg/dl and 4.2 ± 2.9 mg/dl after the CT (p=0.09). According contrast nephrotoxicity criterium by KDIGO (relative increase of at least 25 % on the basal level of creatinine) only one patient worsened renal function, that recovery 60 days later.

Conclusions: The administration one dose of 0.9 percent saline with acetylcysteine in an outpatient basis before iodinate contrast in patients with renal insufficiency and risk factors, without posterior hydration, is sure and cheaper since it avoids hospitalization.

PUB235

Infections in the Chronic Kidney Disease Population Sameena Z. Iqbal,[1] Jiajia Liu,[2] Paul E. Barre,[1] Murray L. Vasilevsky.[1] *[1]Medicine, McGill Univ Health Centre, Montreal, QC, Canada; [2]Medicine, McGill Univ, Montreal, QC, Canada.*

Background: Chronic Kidney Disease (CKD) is associated with an increased risk of infections. Infections are one of the leading cause of death in end stage kidney disease. The prevalence of infections in Stage 3-5 CKD and the effect of infections on the rate of GFR decline was assessed.

Methods: In a retrospective cohort study of a university center, we randomly identified 202 patients followed in the CKD clinics between 2006 and 2012. Eleven subjects were excluded because of acute kidney injury. Study population demographic data, date of diagnosis of CKD, cause of renal disease, mean change in eGFR using CKD epi formula, any infection requiring antibiotics, genitourinary infections and Charlson comorbidity score (CCS) obtained from hospital charts. All subjects were divided into two groups, those who had at least one infection and those who had no infections during the study period. Generalized estimating equations with poisson distribution were applied to assess the association of GU infections and rate of decline in renal function.

Results: One hundred and ninety one subjects were followed for 2.8 (0.5-11.1) years. The median age was 73 (19-107), 59.7% were male and the median CCS was 4 (1-12). The overall rates of all infections treated with antibiotics and GU infections were 30.7 (26.3-35.1 and 22.8 (19-26.5) per 100 patient years, respectively. The median rate of eGFR decline was 3.9 ml/min/1.73m^2/year (-25-37). The occurrence of at least one or more GU infection was associated with an increased rate of eGFR decline (RR1.5: 95%CI 1.3-1.8) unadjusted and (RR 1.4: 95%CI 1.2-1.6) adjusted for CCS, age, baseline eGFR, renal disease and gender.

Variable	RR (95% CI)
Baseline eGFR per 1 ml/min/1.73m^2	1.016 (1.010-1.022)
Age	0.985 (0.981-0.989)
Gender	0.88 (0.77-1.00)
CCS	1.10 (1.07-1.13)
Ttubulointerstitial disease (ref Diabetes and hypertension)	0.49 (0.38-0.64)
at least one GU infection	1.4 (1.2-1.6)

Conclusions: Based on these results a significant association of GU infections and the rate of decline in eGFR is noted. Future studies should assess the role of the prompt treatment of such infections and the potential contribution to renal protection.

PUB236

Analysis of Clinical Features in Relapsing MPO-ANCA-Positive Eosinophilic Granulomatosis with Polyangiitis Soko Kawashima, Shinya Kaname, Kazuhito Fukuoka, Yoshinori Komagata, Yoshihiro Arimura. *First Dept of Internal Medicine, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by precedent bronchial asthma, eosinophilia and vasculitis, with about half of the cases being MPO-ANCA positive. However, clinical features of relapsed cases with EGPA are not well investigated.

Methods: Fifteen patients with MPO-ANCA -positive EGPA (8 male and 7 female) who were admitted to our hospital after 1998 were followed up. At the onset, all patients fulfilled the Chapel Hill Consensus Conference (CHCC) classification criteria for EGPA. The relapse was defined as the occurrence of >1 BVAS items caused by active vasculitis after having achieved remission. We analyzed the clinical features including renal and neurological involvement at the time of relapse with respect to the presence or the absence of MPO-ANCA and eosinophilia.

Results: During the study period, 15 relapses were observed in 8 of the 15 patients investigated, with an average time interval from the onset for 47.8 months. At the time of relapses, serum MPO-ANCA was positive in 13/15 (87%), associated with (7/13; 54%) or without (6/13; 46%) eosinophilia. There were two relapses with negative MPO-ANCA titers (2/15 relapses), one of which associated with eosinophilia. Bronchial asthma was seen in 6/15 episodes, and peripheral neuropathy in 8/15 episodes. In 5 patients who initially complicated crescentic glomerulonephritis, one patient led to end-stage renal failure and 4/5 patients achieved renal remission, only one of which (1/4) showed 2 episodes of renal relapses with MPO-ANCA positive and negative, respectively.

Conclusions: The patients with MPO-ANCA-positive EGPA may see relapses within several years by variable clinical findings and even in the absence of an increase in MPO-ANCA titers and eosinophilia.

PUB237

Anti-Phospholipase A2 Receptor Antibody Is a Useful Biomarker for Screening of Hidden Idiopathic Membranous Nephropathy behind Diabetes with Nephrotic Syndrome in Japanese Patients Reiko Muto, Shin'ichi Akiyama, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: We have shown that the anti-phospholipase A2 receptor antibody (aPLA2R) was also powerful differential biomarker of idiopathic membranous nephropathy (iMN) in Japanese patients. On the other hand, in the usual case of Japan, a patient with diabetes mellitus and nephrotic syndrome (DM-NS) is diagnosed with diabetic nephropathy solely based on clinical features such as a presence of retinopathy or long duration of diabetes without renal biopsy. Therefore, we infrequently overlooked the hidden iMN in DM-NS. Here, we tried to screen the iMN behind DM-NS by the aPLA2R test.

Methods: This study recruited three patients with DM-NS (case 1-3). Case 1 was a-48-year-old female under medication with DPP-4 inhibitor who had 5-year-diabetic history and no retinopathy. Her HbA1c and urinary protein were 6.5% and 5.26g/gCr, respectively. Case 2 was a-49-year-old male. His diabetes history was unknown, but HbA1c was 15.4% at the initial visit. He had proliferative retinopathy and 14.7g/gCr of urinary protein. Case 3 was a 54-year-old male with 9-year-diabetic history and simple retinopathy. His HbA1c and urinary protein were 7.2% and 6.75g/gCr, respectively. An aPLA2R in plasma samples from these patients were tested by Western blot analysis with recombinant PLA2R protein under non-reducing condition.

Results: We specifically identified aPLA2R in plasma from case1. Then, we performed a renal biopsy. Light microscopy revealed capillary wall thickening and spikes. Immuno fluorescence (IF) showed a fine granular and peripheral capillary loop staining for IgG and C3. Electron microscopy showed sub-epithelial immunedeposits. Additionally IF showed IgG4-dominant deposition in the glomerular basement membrane. Gastrofiberscopy and thoraco-abdominal computed tomography showed no abnormalities. On basis of these results, she was diagnosed with iMN.

Conclusions: This study demonstrated that the aPLA2R test enabled us to discover the hidden iMN behind DM-NS in Japanese patients and suggested that the aPLA2R test was noninvasive diagnostic methodology for iMN which was complicated with DM-NS.

PUB238

The Level of Urinary α1 Microglubulin Excretion Is a Useful Marker to Indicate Existence of Peritubular Capillaritis in Antineutrophil Cytoplasmic Antibody Associated Vasculitis Naro Ohashi,[1] Tomoyuki Fujikura,[1] Takayuki Tsuji,[1] Yukitoshi Sakao,[2] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Antineutrophil cytoplasmic antibody (ANCA) associated vasculitis causes a vasculitis of small vessels in the kidney (i.e. arterioles, glomerular or peritubular capillaries, or venules). Although crescentic glomerulonephritis is a common histological finding, the incidence of peritubular capillaritis (PTC) or arteriolitis has not been fully known. Moreover, the laboratory data that reflects the degree of renal histological damage and that distinguishes PTC or arteriolitis has not been clarified.

Methods: We investigated the laboratory data and histological findings in 11 patients (2 men and 9 women, mean age: 70.3±3.3 years) whose renal biopsies were performed from 2009 to 2014 and whose disease was diagnosed as ANCA associated vasculitis. PTC was defined by the histological findings that infiltrated cells were accumulated in the peritubular capillary associated with the disruption of the capillary wall that was stained by anti-CD34 antibody.

Results: Myeloperoxidase (MPO)-ANCA was positive in all patients. PTC and arteriolitis were detectedin 6 patients (54.5%), respectively. There was only significant positive relationship between the levels of urinary α1 microglobulin (u-α1MG) excretion and the percentage of tubular atrophy and interstitial fibrosis (r=0.67, p=0.035) between the laboratory data and the histological findings. No significant differences were found among the laboratory data with or without arteriolitis. However, the levels of u-α1MG excretion with PTC were significantly higher than those without PTC (75.2±19.5 mg/dl versus 15.0±3.6 mg/dl, p=0.035).

Conclusions: PTC or arteriolitis is caused at a high rate independently of crescentic glomerulonephritis in ANCA associated vasculitis patients. The levels of u-α1MG excretion reflect the degrees of tubular atrophy and interstitial fibrosis. Moreover, high levels of u-α1MG excretion suggest that it is possible that PTC not arteriolitisexists in ANCA associated vasculitis patients.

PUB239

Can Rhabodomyolysis Be the First Manifestation of HIV? Rhea Bhargava,[1] Abdelrahman Abdallah Abohashem Aly,[1] Christine Corbett,[2] Jim I. Mertz,[2] Reem Mustafa.[2] *[1]Internal Medicine, Univ of Missouri, Kansas City, MO; [2]Nephrology, Univ of Missouri, Kansas City, MO.*

Background: Renal complications in patients infected with HIV are usually secondary to the virus infectivity or toxicity from the HIV treatment. Renal tubular acidosis (RTA) is a known complication of some of the antiretroviral medications. The presence of RTA in HIV patients without treatment is rare with very few cases reported.

Methods: A 49-year-old Caucasian woman with no significant past medical history except admitting to abusing intravenous drugs in the past. She presented to the emergency room with a 3 week history of muscle cramps, weakness and dark urine along with nausea, vomiting and decreased urine output in the last 3 days. She was not taking any medications at home. Physical examination was unremarkable, except for diminished reflexes in the lower extremities. Initial Laboratory data revealed extremely low K of 1.3, Na of 124, Cl of 83, HCO3 of 13, Cr of 6.7, BUN of 65 and CK of 54,275. ABG showed pH 7.38, PaCO2 27, PaO2 64.8. Urine pH was 6.5 and urine anion gap was positive. The patient's rapid HIV testing was positive and UDS was positive for amphetamine. Patient was admitted to the ICU and treatment was started with aggressive hydration, IV bicarbonate and potassium replacement along with temporary hemodialysis with high K bath. Even after resolution of her rhabdomyolysis, her electrolyte levels never fully corrected and she was discharged on bicarbonate and potassium supplements. Unfortunately, the patient was readmitted for severe hypokalemia 3 months later but without rhabdomyolysis or renal failure and was discharged with a higher dose K replacement. Diagnosis of acquired distal RTA was made in the follow up visits due to the persistent hypokalemia, normal anion gap metabolic acidosis, alkaline urine, with the absence of features suggestive of chronic RTA.

Conclusions: To the best of our knowledge, based on literature review, this is the first case of HIV diagnosed with an initial presentation of rhabdomyolysis. We believe that acute renal failure was due to hypokalemia precipitating rhabdomyolysis caused by HIV-induced dRTA which was further exacerbated by amphetamines.

PUB240

Eculizumab in Pregnancy-Associated Atypical Hemolytic Uremic Syndrome

Abdelrahman Abdallah Abohashem Aly,[1] Aref A. Bin Abdulhak,[1] Mohammed Waseemuddin Ansari,[1] Rhea Bhargava,[1] Ahmed Elkhanany,[1] Hassan A. Salameh,[1] Ryan Lustig,[2] Rakesh Gaur.[3] *[1]Internal Medicine, Univ of Missouri-Kansas City; [2]Nephrology, Univ of Missouri-Kansas City; [3]Hematology, Univ of Missouri-Kansas City.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease resulting from dysregulation of the alternative complement pathway and is characterized by microangiopathcic hemolytic anemia, thrombocytopenia and renal failure. Pregnancy-associated aHUS (P-aHUS) is rare, occurring in about 4% of cases, with outcome being poor for both mother and fetus. The monoclonal antibody Eculizumab (ECU) has induced durable response in treatment of nonpregnant patients with aHUS. We report a case of P-aHUS that benefited from ECU.

Methods: 30-year-old 22 weeks pregnant woman with past medical history of hypertension and systemic lupus erythematosus presented with 1 week history of abdominal pain and leg swelling. She denied any recent diarrhea. On exam, patient had 3+ pitting edema of her legs. Laboratory findings were notable for Hemoglobin 4 and Platelets of 54,000. Reticulocyte count was 4.8%, INR 1.0, PTT 29. LDH was 4664 with Creatinine 9.5, K+ 5.6 and GFR 6. Patient's kidney function was normal 4 months before. Liver enzymes, C3 and C4 levels were normal. ADAMTS13 activity was normal at 67%. ANA titer was 1:80 and DNA antibody was negative. Due to the concern of aHUS in setting of volume overload, anuria and a history of SLE, plasma exchange (PEX) and hemodialysis (HD) were started along with red cells transfusion and IV steroids. Following 2 weeks of treatment, patient remained anuric, had elevated LDH and thrombocytopenia. ECU therapy was started with rapid recovery of platelet count, LDH and Hemoglobin. Patient delivered a healthy 25 week baby by C-section and was discharged on ECU and prednisone taper.

Conclusions: Thrombotic microangiopathies during pregnancy are rare and life-threatening with poor response to PEX. In our case, treatment with ECU was well tolerated by both mother and fetus and resulted in cessation of the disease process, supporting the use of ECU as a therapeutic option in P-aHUS. Role of timing of ECU therapy in preventing need for HD in P-aHUS remains to be elucidated.

PUB241

Surimposed Paraneoplastic Minimal Change Disease with Nephrotic Syndrome in an Elderly Woman on the Course of a Sarcoma : A Rare Association

Achour Laradi,[1] Stephanie Lanoiselee,[1] Philippe Poret,[2] Anne Croue,[3] Alain Cremault,[1] Francois Babinet.[1] *[1]Néphrologie-Dialyse, ECHO CMCM-Pôle Santé Sud, Le Mans, France; [2]Cardiologie, ECHO CMCM-Pôle Santé Sud, Le Mans, France; [3]Pathologie Cellulaire, CHUd'Angers, Angers, France.*

Background: Minimal Change Disease (MCD) accounts for 20% of all cases of idiopathic nephrotic syndrome (NS) in elderly patients (pts) .And about 25% of pts have an underlying malignancy, must often lymphomas.We report the case of a NS with MCD associated with a sarcoma in an elderly woman.

Methods: An 72- year old white female with a history of hypertension and thyroid insufficiency developped a rhabdomyosarcoma in June 2012 on her inner face of the left thigh and was treated by curative surgical removal and radiotherapy.Two pulmonary nodules were present with a deep venous thrombosis of the inferior vena cava treated .In October 2013 she exhibits NS with heavy proteinuria (10 gr/day), microscopic hematuria, severe hypoalbuminemia (15g/L) and an increased GFR (hyperfiltration).The Bence-Jones proteinuria was négative.Possible causes of primary or secondary proteinuria were ruled out.A kidney biopsy was performed and showed minimal glomerular changes (MCD). Methylprednisolone (0.5 mg/kg/day) was initiated (30 mg/day) with low molecular-weight heparin and diuretics.

Results: Sustained remission was induced and the pt was clear of symptoms except persistant microscopic hematuria and hyperfitration syndrome with actually 10 mg /day of prednisone with a serum Albumin of 40 g/L and proteinuria of 0.15g /day.

Conclusions: Few cases of Paraneoplastic MCD have been reported in pts with solid tumors (1).The pathogenic linkage between the two diseases is a possible tumor-induced elaboration of glomerular damaging factors.On the other hand, MCD is frequent and accounts for 20 % of idiopathic NS in Caucasian adults .The overall prevalence of malignancy in pts with NS is 22 % .The association of Hodgkin's disease with MCD is well documented .Sarcomas rarely,if ever,are a cause of MCD(2) and makes this case unsual. (1)Meyrier A and al : Minimal change NS revealing solid tumors,Nephron.1992,61 (2):220-3 (2)RichardJ.Glassock :Secondary MCD, Nephrol Dial Transplant(2003) 18 [Suppl 6]:vi52-vi58.

PUB242

Lupus Nephritis and Autoantibody Characteristics of a Single Center Cohort of Male Pediatric SLE Patients

Scott E. Wenderfer,[1] Debra Canter,[2] M. John Hicks,[3] Eyal Muscal,[2] Marietta De Guzman.[2] *[1]Pediatrics-Renal, Baylor College of Medicine, Houston, TX; [2]Pediatrics-Rheumatology, Baylor College of Medicine, Houston, TX; [3]Pathology, Baylor College of Medicine, Houston, TX.*

Background: Males represent 4–22% of all SLE patients, but it is unclear if gender should influence management. Studies of mostly adult patients suggest genetic, hormonal and environmental aspects of gender differences contribute to differences in presentation, clinical course and outcome, including a positive association between male gender and nephritis and a negative association with disease activity and outcome. While differences may exist, these findings are supported by limited evidence, particularly for children and adolescents with SLE.

Methods: We retrospectively reviewed records of the nearly 297 pediatric SLE patients followed in the TCH rheumatology and renal clinics between 1990 and 2014 to identify males with pSLE. Autoantibody features and renal involvement were collected.

Results: We identified 39 males (44% Hispanic, 21% Black, 15% Asian). The mean age of onset of disease was 11.9 ± 3.3 yrs old. The cumulative incidence of positive autoantibodies included 51% anti-dsDNA, 70% anti-phospholipid, 44% wanti-RNP, 33% anti-Ro (SS-A), 16% anti-Smith, 10% anti-La (SS-B), and 5% rheumatoid factor. Nearly half (n=20, 56%) developed lupus nephritis (LN), the majority of whom had class V lesions (70%). Class IV lesions were seen in 9 patients, including 4 with mixed histopathology. LN was a presenting symptom in all patients. Of these, 30% had acute kidney injury and 2 required hemodialysis. The proportion of boys with LN and anti-dsDNA antibodies was not significantly different from boys without LN (74% versus 50%, $p = 0.17$).

Conclusions: Although SLE predominately affects females, males with SLE represent an important subset of patients about which little is known. In our male cohort, rates of kidney disease and autoantibody positivity were similar to those published for females. However, autoantibody profiling may not be as useful in predicting kidney involvement in boys. Additional research is of upmost importance to improve quality of care and outcomes of male SLE patients.

PUB243

Un Unusual Presentation of Gaucher Disease with Renal Envolvement

Monica Patricia Calvo Abeucci,[1] Vanina Vazquez,[1] Graciela Alfonso,[2] Alejandro Iotti.[3] *[1]Nephrology, Hospital Simplemente Evita, G.Catán, Bs.As.; [2]Haematology, Hospital Posadas, Palomar, Bs.As.; [3]Patologia Dres.Iotti, CABA, Argentina.*

Background: Gaucher Disease(GD) is an autosomal recessive disorder due to β-glucocerebrosidase deficiency wich results in lysosomal accumulation of glucosylceramide,leading to hepatosplenomegaly,blood cytopenia,and bone,pulmonary and neurological manifestations.Renal involvement reports are limited.We present a GD case with proteinuria as first manifestation of illness.

Results: 45-year-old man with proteinuria detected in World Kidney Day renal disease screening,GD and endogamy family history. He complained of left hip pain and spontaneous bruising in the past. Unremarkable physical examination. Laboratory:platelet count 95.000/mm3, normal renal function, uric acid(Ua)5.1 mg%,calcium(Ca) and phosphate(P)9.1 and 2.1 mg% respectively,IgG 1973 mg/dL,IgA 362 mg/dL,IgM 302 mg/dL, β_2 microglobulin1.6 µg/mL, Chitotriosidase 627.3nmol/l/h. 24-hour urine(U) collection: 1.31 g of proteinuria, P 1.69 g,Ca 220 mg,Ua 700 mg, P tubular reabsortion 70.2, ratio UCa/creatinine 0.18. Diagnosis of incomplete Fanconi Syndrome was done. S protein electrophoresis:elevated monoclonal γ protein and elevated β_1 globulin. Enzymatic diagnosis by dried blood spot test:βglucosidasa 1.5 nmol/l/h. Leukocytes-βglucosidasa activity:3.5nmol/mg/h. Genotyping: Patogenic variants in exon 9, p.N409S, heterozygous. S immunofixation electrophoresis: Monoclonal immunoglobulins IgG and IgA kappa (λ) light chains. U Immunofixation: No abnormal chains. Bone marrow biopsy:Gaucher Cells infiltration and myelofibrosis. Treatment with enzyme replacement therapy (Imiglucerase,60 U/Kg dosis) was initiated and 6 months after,renal biopsy disclosed no abnormalities (optical,immufluorescence and electronic microscopy).

Conclusions: We report an unusual GD presentation,with proteinuria and renal tubular functional alterations.The absence of tubular changes in renal biopsy could show that manifestations of tubular alteration were not due to disproteinemia but GD and the Imiglucerase therapy could improve potential accumulation of glucocerebroside in the lysosomes of tubular renal cells.

PUB244

Clinical Efficacy of Glucocorticoids and Immunosuppressive Treatment for Patients with Lupus Podocytopathy Zhihong Liu, Weixin Hu, Ying-Hua Chen, Hao Chen, Lihua Zhang, Zheng-Zhao Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing Univ School of Medicine, Nanjing, Jiangsu, China.*

Background: Lupus podocytopathy is a newly recognized subtype of lupus nephritis, buttheclinical efficacy of glucocorticoids (GC) and immunosuppressant treatment for the patients have not been well assessed.

Methods: Thirty-seven SLE patients (34 females, 3 males, mean age 31.1 ± 11.6 years) with nephrotic syndrome and biopsy-provenpodocytopathy were recruited. The patients were given prednisone alone (GC group) or GC plus immunosuppressant (Combination group) during induction or maintenance treatment. The remission and relapse rates were retrospectively analysed.

Results: Initial treatment led to remission in 97.4% of thepatients. The complete remission (CR, defined by normallevels of urine protein, serum albumin and SCr) rates were similar in the two groups (81.5% versus 81.8%), while the median treatment duration to achieve CR was much shorter in GC group (4 versus 12 wk in combination group, p<0.05). In the first maintenance phase, the relapse rate was much higher in GC group (81.8% versus 38.5% in combination group, p<0.05). All relapsed patients achieved remission after thesecond GC or combination therapy, and the CR rate was 83.3%. The patients were followed up for 6 to 125 months (median 62), during which 20 patients (52.6%) experienced one or more relapses. In the totalof68 maintenance treatments (16 in GC group, 52 in combination group) during the follow-up, relapse rate was much higher in GC group (75.0% versus 40.4% in combination group, p<0.05). Allfour patients with GC+MMF maintenance treatmentdid not relapseduringthe24-46mfollow-up,incontrastwiththe relapse ratesinthe patientswith GC plus FK506(58.3%), AZA(50%), Tripterygium wilfordii(42.9%) or Leflunomide(33.3%). Re-biopsy in 9 patients after relapse showed histologic changes in 2 patients and notin the other 7.

Conclusions: GC may be the first-line therapy for remissioninduction in thepatients, while GCcombined with immunosuppressant may be used in the maintenance for a lowerrelapse rate. Whether GC+MMF is an optimal maintenance regimen needs prospective studies.

PUB245

Anti-C5 Monoclonal Antibody - Eculizumab: Use in the Treatment of Life Threatening ANCA Associated Vasculitis with Pulmonary Hemorrhage and Profound Anemia John Niles, Karen A. Laliberte, Andrew P. Murphy, Katherine M. Cosgrove, Robert Makar. *Nephrology /Medicine, Massachusetts General Hospital, Boston, MA.*

Background: We report the first case of active vasculitis treated with anti-C5 monoclonal antibody (anti C5). Animal models show the importance of C5 in the development of ANCA injury. We describe the results using anti-C5 to treat a patient with immediate life threatening ANCA vasculitis. Due to religious beliefs, she refused blood products and severe anemia prevented the use of cyclophosphamide and plasma exchange.

Methods: Case description: 61 yo woman with new ANCA vasculitis (MPO), diffuse alveolar hemorrhage, glomerulonephritis and life threatening anemia. Her creat was 0.95, hct 20.2, UA with RBCs and protienuria. She required high flow O2 to maintain an O2 sat > 90%. Treatment: In place of cyclophosphamide and plasma exchange, she was given methylpredisolone 250mg IV Q6 hours x 9.5 days, Rituximab 1000mg IV on days 0 and 49, followed 8 hours later with the 1st dose of Eculizumab 900mg IV. She received a total of 3 doses of Eculizumab: #2 on day 7 and #3 on day 14. Blood draws were limited. Aminocaproic acid 1000mg IV /hour was given days 1-5. EPO 40K units SC x4 doses, and Venofer 1000mg IV were given to stimulate erythropoiesis.

Results: Clinical course: Her pulmonary function remained precarious, but did not progress. Her hematocrit held at 17.4%. On day 5 her oxygenation improved. Her anemia improved to 23.8% at discharge. Her last dose of anti-C5 was day 14. Daily cyclophosphamide 100 mg was added on day 18. She was discharged on day 19. Between day 18 and day 49 her creat rose from 1.04 to 3.03. ANCA level remained high. Her B cells remained zero.

Conclusions: The patient was treated for 3 weeks with Rituximab, Eculizumab and steroids, during which time her lungs improved, her Cr remained stable and anemia started to improve, but her ANCA remained high. After fininshing Eculizumab, her renal function deteriorated despite cyclophosphamide, continued B cell depletion and continued high dose steroids. The findings suggest that Eculizumab was highly effective in blocking active vasculitis, but that active vasculitis returned rapidly when Eculizumab was discontinued.

PUB246

Lupus Vasculitis with Clinical Features of HUS/TTP Akinari Sekine, Yoshifumi Ubara, Junichi Hoshino, Masahiro Kawada, Koki Mise, Kenmei Takaichi. *Nephrology, Toranomon Hospital, Minato-ku, Tokyo, Japan.*

Background: D'Agati classified the vascular lesions of lupus nephritis into 5 categories in Heptinstall's pathology of the kidney. Noninflammatory necrotizing vasculopathy (called lupus vasculopathy) and thrombotic microangiopathy were distinguished from each other as the vascular lesions of lupus nephritis. In both types, there is severe narrowing or occlusion of preglomerular arterioles. The former type shows positive staining for immunoglobulin G (IgG) and/or complement components (C3 or C1q), and clinically progresses to severe renal insufficiency. The latter type is negative for IgG or complement, and presents with distinct clinical syndromes such as HUS/TTP.

Methods: We evaluated 4 patients with histological lupus nephritis (Class III in 1, Class IV in 2, and Class V in 1) and clinical features of TTP/HUS such as acute renal failure, microangiopathic hemolytic anemia, thrombocytopenia, fever, and neurologic symptoms.

Results: Immunosuppressive therapy with plasmapheresis was performed for 4 patients. Two patients progressed to end-stage renal failure requiring dialysis and one of them died, while the disease subsided in two patients. The two refractory patients showed positive staining for IgG and C3 along the walls of small arteries, while intraluminal material was negative for IgG and C3 (although it showed positive staining for PTAH indicating fibrin deposition). The two patients who responded to therapy showed positive staining of intraluminal material for IgG, C1q, and C3, as well as staining along small arterial walls, while intraluminal material was negative for PTAH.

Conclusions: These findings indicate that immunosuppressive therapy can control this disease when intravascular thrombosis is closely related to immune complexes associated with activation of the early complement components C1q and C4. However, when intravascular thrombosis is not closely related with these factors and involves fibrin deposition, immunosuppressive therapy will not be effective. Lupus vasculitis with clinical features of HUS/TTP syndrome should be kept in mind.

PUB247

Usefulness of Birmingham Vasculitis Activity Score after Initial Treatment as a Predictor for Renal Prognosis in ANCA-Associated Vasculitis Ryusuke Yotsueda,[1] Akihiro Tsuchimoto,[1] Shunsuke Yamada,[1] Kosuke Masutani,[1] Kazuhiko Tsuruya,[1,2] Takanari Kitazono.[1] *[1]Depts of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Birmingham vasculitis activity score (BVAS) is used to evaluate activities of ANCA-associated vasculitis (AAV). However, it is not clear whether BVAS can be a useful predictor of renal prognosis in AAV patients.

Methods: In this retrospective study, we reviewed 70 AAV patients with 32 males and 38 females, who were treated in our hospital from 1989 through 2013. We identified BVAS ver. 3 at admission and at one month after diagnosis, and evaluated the association between BVAS at each points and renal prognosis.

Results: At diagnosis, 68 patients showed renal impairment and 35 showed pulmonary complications. The median value (interquartile range) of BVAS at admission was 16 (13-20). Fifty-nine and 11 patients were treated with steroid pulse therapy followed by oral corticosteroid and oral corticosteroid only, respectively, while 45 patients were treated with additional immunosuppressants. After the initial treatment, BVAS at one month decreased to 5 (5-5). During a median (interquartile range) follow-up of 731 (58-2,324) days, 17 patients reached end-stage renal disease (ESRD). The likelihood of reaching ESRD within one year was not associated with BVAS at diagnosis, but significantly associated with BVAS at one month (area under the curve 0.78, sensitivity 56%, specificity 91%, cut off 6). In the Cox's hazard models, the group with BVAS at one month ≥6 showed a significantly higher risk of ESRD, independent of renal function at diagnosis; hazard ratio (95% confidence interval), 4.0 (1.4-11.3) (p = 0.010).

Conclusions: BVAS at one month was a useful predictor for renal prognosis in AAV patients. This finding suggests that evaluation of disease activity using BVAS after initial treatment might be important to determine the maintenance treatment for AAV.

PUB248

Percutaneous Kidney Biopsy Performed by Nephrology Fellows in Academic Center: High Efficacy and Low Complication Rates Alcino Pires Gama, Elerson Costalonga, Lilian Carmo, Renato Antunes Caires, Janaina De Almeida Mota Ramalho, Vivian Lumi Onusic, Cristiane B. Dias, Luis Yu, Lectícia Jorge, Viktoria Woronik. *Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Previous studies showed that complications occur in about 15% of percutaneous kidney biopsies. In University of Sao Paulo, fellows perform all kidney biopsies under supervision. The aim of this study is to evaluate incidence of biopsy-related complications performed by non-experienced professionals in an academic center.

Methods: Kidney biopsies between 2009 and 2013 were retrospectively analyzed. All procedures were performed on an inpatient basis, ultrasound guided and subjects fulfilled these criteria: BP<140/90mmHg, Hb>10g/dl, platelet>100k, urea<140mg/dl and INR>1.2. After the procedure, the patients were observed for 24h.

Results: 668 procedures were performed and 94% of the samples were satisfactory. The main clinical indication was nephrotic sd.(38%), followed by nephritic sd.(19%), and lupus nephritis(12%). A post biopsy Hb decline≥1.5g/dL was observed in 69 subjects(10%). This group had a higher serum creatinine levels(sCr) and an increased risk of major complications(hematuria, symptomatic hematoma or blood transfusion). Three subjects(0.45%) underwent arteriography and there was no death related to the procedure.

	ΔHb≥1.5 (n=69)	ΔHb<1.5(n=599)	p
Age/y	41.8±19	40.5±16	ns
%Male	35%	41.2%	ns
Hbpre(g/dl)	11.9±1.7	11.8±1.7	ns
sCr(mg/dl)	2.57±1.7	2.07±1.6	0.015
%Major complication*	26.2%	6.3%	<0.001

Table 1. Clinical features on subgroups.
* symptomatic hematoma, macroscopic hematuria or blood transfusion.

Based on the ROC curve (AUC 0.81, CI 0.78-0.84), the best SCr cutoff value to identify patients with increased bleeding risk was 1.5 mg/dl.

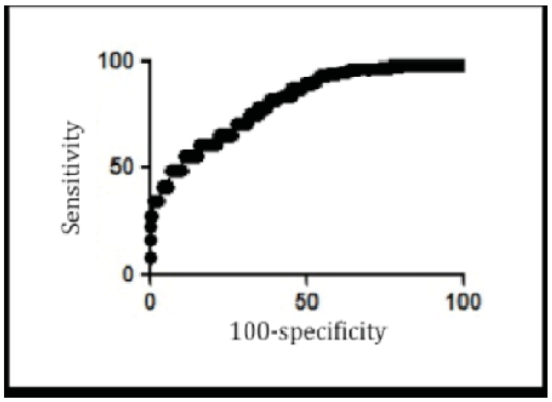

Figure 1: Serum creatinine vs ΔHb≥1.5 g/dl. When sCr≥1.5mg/dl S:87% e E:55%. AUC 0.81.

Conclusions: Renal fellows can safely perform percutaneous kidney biopsy with low rates of complications.

Funding: Government Support - Non-U.S.

PUB249

Tonsillectomy and IgA Nephropathy: Insights Into the Modifications of Innate Immunity and Regulatory T Cells Induced By Tonsillectomy in Children with ENT Indications to Tonsil Ablation Luca Vergano, Elisa Loiacono, Licia Peruzzi, Alessandro Amore, Massimiliano Bergallo, Rosanna Coppo, Vincenzo Landolfo, Paolo Tavormina, Roberto Albera. *Citta della Salute, Turin, Italy.*

Background: The role of tonsillectomy as immune suppressive tool in IgA nephropathy is debated. Comparison of results between Asian and European cohorts is biased since tonsillectomy is performed because of the diagnosis of IgAN in Asia, while in Europe it strictly follows Otolaryngology (ENT) indications.

Methods: To address the effect of tonsillectomy "per se" in subjects with ENT indication to tonsillectomy we investigated mucosal immunity activation, including Toll-like receptors (TLRs 2,3,4,9), which trigger T cell response via proteasome (PS) to immunoproteasome (iPS) switch and T regulatory cells (FoxP3/Th17) in mononuclear cells from 25 children before (T0) and 15 days (T1) after tonsillectomy and 30 healthy controls (HC).

Results:

mRNA	HC	T0	T2	Kruskall-Wallis test p
TLR2	0.98 (0.59-1.68)	1.86 (1.19-2.85)	1.30 (1.06-2.72)	P 0.0061
TLR3	0.86 (0.52-1.43)	1.96 (1.31-2.99)	1.45 (1.07-2.66)	P 0.0004
TLR4	1.03 (0.65-1.64)	4.07 (2.43-6.38)	3.47 (1.36-9.10)	p< 0.0001
LMP2/ β1	0.78 (0.60-0.97)	3.00 (1.17-3.67)	1.96 (1.08-4.07)	p< 0.0001
LMP7/ β5	1.03 (0.83-1.29)	2.18 (1.54-2.38)	2.01 (1.45-2.83)	p< 0.0001
MECL1/β2	0.96 (0.75-1.16)	1.31 (0.83-1.61)	0.99 (0.87-1.41)	P 0.047
IL17	0.85 (0.24-1.56)	3.08 (0.62-4.53)	2.15 (0.85-6,65)	P 0.003

A strong activation of innate immunity with increased expression of TLR2, TLR3, TLR4, TH17 and switch Ps-iPS was observed at T0, with significant improvement at T1.

Conclusions: Tonsillectomy can improve over a short time the hyperactive mucosal immune system which is detected in patients with ENT indication to tonsillectomy. Whether this benefits will last over years during the follow-up of IgA nephropathy and contribute to final clinical outcome remains a matter to be elucidated.

PUB250

The Long-Term Prognosis of Idiopathic Membranous Nephropathy Patients Treated By New Algorithm Including Ponticelli Protocol Daigo Nakazawa, Saori Nishio, Junya Yamamoto, Sekiya Shibazaki. *Dept of Medicine II, Hokkaido Univ School of Medicine, Sapporo, Hokkaido, Japan.*

Background: Idiopathic membranous nephropathy (IMN) patients are treated by the combination therapy with steroid and immunosuppressive agents based on the prognosis in the world. Contrastively, most IMN patients in Asia including Japan reveal good prognosis and steroid alone therapy is empirically used. However, the treatment is not effective for some patients, and the immunosuppressive therapy should be used restrictively. We decided a new restrictive algorithm including modified Ponticelli protocol (PCP) in Japanese patients with IMN.

Methods: We have identified all 35 patients with biopsy-proven idiopathic membranous nephropathy in 3 Hokkaido university affiliated hospitals from 2004 to 2013. We established therapeutic algorithm that IMN patients predicted poor prognosis are treated with PCP (methylprednisolone 0.5 g intravenously for 3 days followed by oral prednisolone; 0.5 mg/kg for 27 days alternated every other month either with cyclophosphamide; 1.2 mg/kg for 30 days. The whole treatment lasted 6 months). Poor prognosis patients defined as patients who had renal insufficiency or intolerable edema. In addition, we referred to poor prognosis factors (male, older age, hypertension, urinary IgG,β_2MG, FSGS and tubulointerstitial fibrosis). While, good prognosis patients are treated with supportive therapy. We retrospectively evaluated the renal survival rate and remission rate.

Results: 19 IMN patients who were diagnosed as poor prognosis treated with PCP and the complete remission (CR), partial remission (PR), and stable disease (SD) rate at the last visit was 42.1%, 52.6%, 5.3%, respectively. 16 IMN patients who were diagnosed as good prognosis treated with supportive care and the CR, PR, and SD rate at the last visit was 37.5%, 37.5%, 33.3%, respectively. In both groups, 10-year survival rate was 100%.

Conclusions: This is the first report that modified Ponticelli protocol could improve the long-term prognosis for Japanese patients with severe IMN and this algorithm could lead to the avoidance of unnecessary immunosuppressive agents for good prognosis IMN patients.

PUB251

Clinical Significance of Glomerular IgG Deposits in IgA Nephropathy Anthony Alvarado,[1] Sergey V. Brodsky,[2] Tibor Nadasdy,[2] Alice Hinton,[3] Brad H. Rovin.[1] *[1]Faculty of Medicine, Nephrology Dept, The Ohio State Univ, Columbus, OH; [2]Pathology Dept, The Ohio State Univ, Columbus, OH; [3]Div of Biostatistics, College of Public Health, The Ohio State Univ, Columbus, OH.*

Background: It has been suggested that the prognosis of IgA nephropathy (IgAN) is adversely affected if there is significant co-deposition of IgG in the glomeruli. We conducted this study to test whether Ig G deposition may help guide therapy by indicating poor clinical outcomes.

Methods: IgAN biopsies and their associated clinical data found in our biopsy archives between 2004 and 2013 were retrospectively reviewed. Patients were divided into groups showing only IgA deposition in their glomeruli and patients who had IgA+IgG deposition. Change in serum creatinine (SCr) over time, need for renal replacement therapy, and death were assessed in these groups. Covariates used were: proteinuria at biopsy, length of follow-up, treatment, degree of interstitial fibrosis, sex, age at biopsy and race. Univariate differences were evaluated with T-tests or univariate logistic regression. Multivariate linear regression was used to model changes in SCr over time.

Results: This cohort had 29 patients with IgA deposits and 18 patients with IgA+IgG depositis. The patients were mostly male (66%) and Caucasian (79%). Only 13% were Asian. On univariate analysis there were no differences in SCr, initiation of dialysis, kidney transplant or death between the groups. The change in SCr over time was not different between the groups using multivariate modeling (P=0.35), however proteinuria (P<0.001), length of follow-up (P<0.001) and treatment with corticosteroids and/or a cytotoxic agent (P=0.011) were all significant covariates for change in SCr.

Conclusions: Co-deposition of IgG with IgA in the glomeruli of IgAN patients did not affect the prognosis or outcome of the disease. A potential explanation of the difference between this study and other studies that did find an association of IgG deposits with worse outcomes may be that our cohort was predominantly Caucasian and others included 50 to 100% Asian population.

PUB252

Diffuse Extracapillary Crescentic Glomerulonephritis: Analysis of 106 Cases. A Single Center Experience Federico Varela,[1] Gustavo Cristian Greloni,[1] Diego Serra,[1] Griselda Bratti,[1] German Barrera Hugalde,[1] Silvia Beatriz Christiansen,[2] Guillermo Javier Rosa Diez.[1] *[1]Nephrology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [2]Pathology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.*

Background: Rapidly progressive glomerulonephritis (RPGN) is defined by increase of creatinine twice from baseline in a no longer period than three months. Diffuse extracapillary crescentic glomerulonephritis (DECG) that cause RPGN has crescent formation in more than 50% of glomeruli. Objetive: Analyze prevalence, clinical findings, treatment and outcome of DECG in our rneal biopsies data.

Methods: Data was obteined from medical record during the period 1/1/1990 to 31/12/2011. We used a minimun count of 5 glomeruli for DECG diagnosis. They were classified into 3 types described by Glassock. In each group we analyzed, prevalence, degree of proteinuria and serum creatinine at renal biopsy. Variables were considered in 3 age groups: GI (< 40 years), GII (40-65 years) and GIII (> 65 years).

Results: We performed 2098 renal biopsies in this period. Prevalence of DECG was 5.2 %. Mean age was 53 +/- 21 years and 65% were female. DECG type I represent 5.6 % (6 cases), type II 50% (53 cases) and type III 44% (47 cases). Higher levels of creatinine were observed in DECG type I (mean 10 mg/dl) (p 0.0334) as well as alveolar hemorrhage and a greater number of affected glomeruli ($p < 0.05$). Value of proteinuria in nephrotic levels was observed in DECG type II (mean 4.4 gr/day) (p 0.0069). We found an increased frequency of diagnosis DECG type III (57,04 %) in elderly people and DECG type II in person under 40 years (45.2%) ($p>0.001$) We can´t found any variable statistics with anti-nuclear antibodies, rheumatoid factor or cryoglobulins. Treatment performed consisted steroids (92% IV), cyclophosphamide in 80% of patients and plasmapheresis in 8 %. The year of biopsy 45.8 % of patients were out of dialysis and 34.8 % remained on dialysis. Mortality was 17 % and there was no difference between the mortality by type.

Conclusions: Prevalence DECG in our renal biopsies data was similar that reported in the literature. Although clinical findings are similar to others authors, DECG type II was the most frequently found.

PUB253

Learning Points From 2 Cases of Eculizumab Responsive, Pediatric C3Nef Positive C3 Glomerulopathy Basema I. Dibas,[1] Hsiao Ling Lai,[2] Deborah E. Westbrook,[3] Leonard Curtis Hymes,[1] Benjamin L. Laskin,[4] Guillermo Hidalgo.[1] *[1]Pediatrics, ECU, Greenville, NC; [2]Internal Medicine and Pediatrics, ECU, Greenville, NC; [3]Pediatric Nephrology Section, VMC, Greenville, NC; [4]Pediatrics, Children's Hospital of Philadelephia, Narberth, PA.*

Background: We describe treatment success of 2 children with C3 glomerulopathy with eculizumab.

Methods: Case 1. 12 yrs old AAF who presented with stage 2 hypertension, anasarca and secondary enuresis. A renal biopsy showed exclusively C3 GN. She received methylprednisolone followed by prednisone.(HD) was initiated (s.cr 2.24 mg/dL, BUN 127mg/dL).

Labs	Admission labs (normal range)	Labs (in the interim) Day #	Current labs
BUN	29 mg/dL	↑ 127mg/dL (D #20)	19 mg/dL
s.Creatinine	1.58 mg/dL	↑ 2.45 mg/dL (D #20)	1.03 mg/dL
S. Albumin	1.9 gm/dL	Fluctuates	2.5 gm/dL
Urine protein/creatinine	4.6 mg/mg (<0.2)	↑17 mg/mg (mean ~6mg/mg)	2.3 mg/mg
C3	12 (80-150)	persistently low	30
C5	3.8 (6-20)	Normal then high	46.5
CH50	<10 (31-60)		<10
C_3Nephritic factor	0.69 (0.0-0.30)	Normal	0.28

She received 3 PE sessions. She had no improvement,D#29 she received 900 mg Eculizumab q wk for 3 doses and dose increased to 1200 mg.After 2 doses of eculizumab, she did not need HD or PE.

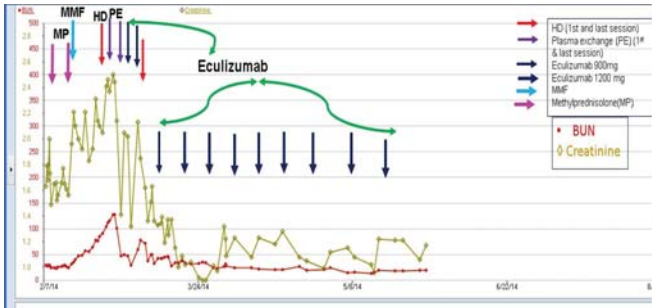

Figure 1. Serum Creatinine, BUN, Hemodialysis, Plasma exchange, Mycophenolate Mofetil, Methylprednisolone and Eculizumab treatment .

Results: Case2. 10 yrs old WF who presented at 6 yrs of age with acute post Strept. GN. Kidney biopsy showed dense deposit disease. First Lisinopril maintained normal u. P/C and renal function for 2.5 yrs. However, she developed new onset severe nephrotic syndrome and her kidney function worsened. She received MP, CRRT, PE and MMF. She received eculizumab,her kidney function recovered.

Conclusions: Eculizumab can be used in treatment of C3 glomerulopathy in pediatric patients and help recovery of renal function. Eculizumab dose, frequency and eculizumab trough level still need to be determined.

PUB254

A Pooled Analysis of Early Use of Adrenocorticotropic Hormone in Nephrotic Syndrome Kenneth V. Lieberman,[1] Anna Pavlova-Wolf.[2] *[1]Hackensack Univ Medical Center, Hackensack, NJ; [2]Questcor Pharmaceuticals, Inc., Hayward, CA.*

Background: The emergence of adrenocorticotropic hormone (ACTH) as a treatment for nephrotic syndrome (NS) in the late 1940s dramatically altered NS management. The current analysis synthesizes the efficacy and safety of ACTH in NS presented in this early work.

Methods: MEDLINE was searched using the MeSH terms 'adrenocorticotropic hormone' and 'nephrotic syndrome,' with the limits of 1945 (the era of ACTH introduction) to 1965 (ACTH was largely replaced by synthetic oral steroids by this time) and English. Relevant studies also were identified from the reference lists of reviewed papers. From 61 papers found, 14 studies met the inclusion criteria of >5 patients treated, defined remission criteria, and report of safety outcomes. The early clinical experience with short-term ACTH treatment is reported in 9 studies, and 5 studies depict longer-term maintenance treatment. The primary short-term outcome of attaining remission assessed diuresis. The primary long-term aim of sustained remission examined proteinuria.

Results: The patients were predominantly pediatric (88%; 349/395 with ages given) across the 14 studies. The 9 studies examining short-term ACTH treatment included 332 patients. ACTH dose ranged from 20 mg/day to 160 mg/day. Mean treatment duration was about 12 days, ranging from 4 to 28 days. Diuresis resulting in loss of edema was reported in 70% (249/356) of patients or ACTH courses. The 5 studies examining long-term ACTH treatment evaluated 96 patients. ACTH maintenance regimen doses typically ranged from 100 mg to 200 mg and included ACTH treatment for 3 successive days repeated weekly. Remission of proteinuria was reported in 66% (63/96) of patients at last follow-up. Complications of treatment included signs and symptoms of hyperadrenocorticism.

Conclusions: There is a re-emergence of interest in ACTH as a second-line therapy for the reduction of proteinuria in the treatment of NS, yet current clinical research is limited. The analysis of the early clinical literature detailing ACTH in the treatment of NS during the 1950s can provide guidance on ACTH efficacy and safety for today's clinicians.

Association of PreS1-Ag, HBeAg, HBV-DNA in the Serum of Patients with Hepatitis B Virus-Associated Glomerulonephritis Chenggang Shi, Xun Liu, Cailian Cheng, Qiong-Li Yin, Mei Li, Weizhao Mo. *Dept of Nephrology, the Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: To investigate the relationship between the serum PreS1-Ag, HBeAg, HBV-DNA and Hepatitis B Virus-associated Glomerulonephritis **(**HBV-GN).

Methods: Baseline data, biochemical data and serum virological indicators were analyzed retrospectively among the HBV-GN group, HBV and chronic kidney disease (not HBV-GN) group, chronic kidney disease without HBV group.

Results: 76 patients were enroll as HBV-GN group (experiment group), 85 patients as HBV and chronic kidney disease(control group 1), 70 patients as chronic kidney disease without HBV group(control group 2). Serum albumin and the incidence of ascites had significant differences between the experimental group and control group 1. Gentle, liver functional indicators, serum albumin, the incidence of liver cirrhosis and ascites had significant differences between the experimental group and control group 2; The percentage of high HBV-DNA copy ($>1\times10^5$IU/ml)($P<0.001$), the positive rates of PreS1 ($P=0.005$) and HBeAg($P=0.002$)had significant differences between the experimental group and control group 1. In total, there were 40 cases (52.36%) of membranous nephropathy (MN) in the experimental group, and 20 cases (26.32%) of membranoproliferative glomerulonephritis (MPGN). And in the control group 1, there were 35 cases of IgA nephrosis(41.18%), in the control group 2, there were 25 cases of IgA nephrosis(35.71%). Multivariate analysis showed that serum albumin and the positive of PreS1 were the correlation factors for the progress of the disease. The predictive value regression equation: $P = 1/[1+e^{-(0.841+1.309\,X1-0.078\,X2)}]$ The under area of the ROC curve was 0.765. The maximum Value of Youden index was 0.567 and obtained 0.3696454 as the diagnosis point.

Conclusions: The percentage of high HBV-DNA copy ($>1\times10^5$IU/ml)and the positive percentage of HBeAg and PreS1 is higher of patients with HBV-GN. The serum albumin and the positive rates of PreS1-Ag could help diagnose the HBV-GN.

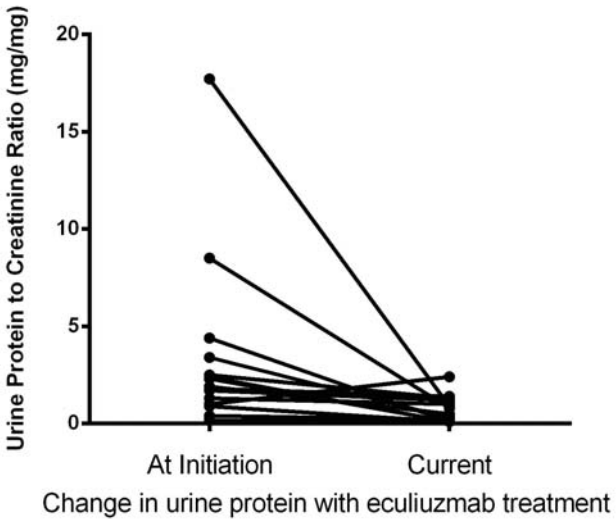
Renal Outcome in Eculizumab-Treated Patients: A Single Center Experience Melissa A. Muff-Luett,[1] Jennifer G. Jetton,[1] Christie P. Thomas,[2] Patrick D. Brophy,[1] Carla M. Nester.[1,2] *[1]Dept of Pediatrics, Univ of Iowa Children's Hospital, Iowa City, IA; [2]Dept of Internal Medicine, Univ of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Eculizumab ®, a first in class complement blocker, has been shown to be a very effective treatment for atypical hemolytic uremic syndrome (aHUS). Clinicians have begun to use it for other disorders that are believed to involve complement dysregulation.

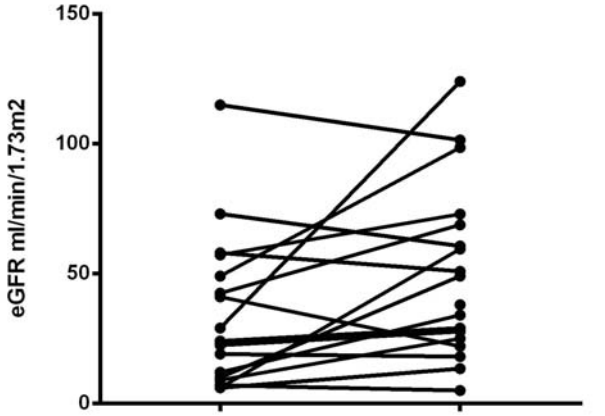
Methods: We performed a retrospective chart review of all patients treated with eculizumab at the University of Iowa. AMR patients were excluded. The major focus was on renal outcomes and patient morbidity. Data collection is ongoing.

Results: The age range of treated patients was 52 days to 64 years. The average length of therapy was 11 months (range 1-47 months) for five diagnoses: 12 with aHUS, 3 with C3G, and 3 with thrombotic microangiopathy from other causes. Nine of the 16 patients

had complement mutations. Two were found to have CFH autoantibodies. The average eGFR at initiation of eculizumab was 43.6ml/min/1.73^2; this improved to 59.1ml/min/1.73^2 at recent evaluation. The urine protein decreased from an average of 3.11mg/mg to 0.71. Anti-hypertensive therapy decreased from an average of 2.7 to 2.1 medications. Reported infections included central line infections, UTIs, parvovirus infection and 1 death following a severe RSV-B infection.



Change in urine protein with eculiuzmab treatment



Change in creatinine with eculiuzmab treatment

Conclusions: Eculizumab appeared to be well tolerated in all age groups. There were no obvious trends in morbidities. Neither the presence nor the type of mutation predicted the renal outcome. aHUS patients demonstrated the most striking improvements. The most significant change for all groups was noted in urine protein reduction.

PUB257

ANCA Vasculitis and Thyroid Disease Treatment in Children: The Chicken, the Eggs or Two Eggs in a Basket: A Case Series of Three Patients Seen at Lebonheur Children's Hospital, TN and West Virginia University Children's Hospital Oulimata K. Grossman, Alimirza Onder. *Pediatric Nephrology, WVUH, Morgantown, WV.*

Background: ANCA vasculitis can be seen during the course of thyroid disease treatment. We report 3 cases in children.

Kidney pathology: Pauci immune	44 gloms, 65 % crescents	36 gloms, 25% crescent	8 gloms, 50% crescents
Pulse solumedrol with cyclosphosphamide	+	+	+
Induction with monthly cyclosphosphamide	+	+	+
Maintenance	Cellcept	Azathioprine	Cellcept
Thryroid Medication	None	None	None

Results: All 3 patients improved clinically and had a normalization of ANCA levels and serum creatinine as well as thyroid markers. One with Hashimoto thyroiditis and transient lupus anticoagulant never required thyroid medication. None of them had required further thyroid disease treatment after diagnosis and management of vasculitis.

Conclusions: ANCA vasculitis has been well described to be secondary to Methimazole, PTU. The two diseases have coexisted in one patient who was not on thyroid medication and had lupus anticoagulant. Our data is too small however one could start questioning the causality of thyroid medication on concomitant ANCA vasculitis.

PUB258

Anti-Neutrophil Cytoplasmic Antibodi-Associated Vasculitis. Clinical and Survival Study of 84 Patientes from a Single Center Federico Varela,[1] Valeria Scaglioni,[2] Gustavo Cristian Greloni,[1] Griselda Bratti,[1] German Barrera Hugalde,[1] Silvia Beatriz Christiansen,[3] Enrique Roberto Soriano Guppy,[2] Guillermo Javier Rosa Diez.[1] *[1]Nephrology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [2]Rheumatology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [3]Pathology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.*

Background: Epidemiology of ANCA-associated vasculitis (AAV) is not entirely known. There are few studies published in Latin America. Our objective was to describe the clinical, serological features and outcomes of patients with AAV and renal involvement.

Methods: Electronic medical records from 2000 to 2013 with diagnosis of Wegener's granulomatosis (WG), Churg Strauss (CSS), microscopic polyangiitis (GPA) or renal-limited vasculitis (RLV), were reviewed, and those patients with ANCA-posive.

Results: 84 patients (WG n=34, MPA n = 12, CSS n = 14 and RLV n = 24) were included. Sex, age, progression to renal failure and dialysis, mortality, relapse after induction and remission are summarized.

	WG (n=34)	MPA (n=12)	CSS (n=14)	RLV (n=24)
Women, n (%)	20 (58,8)	10 (83,3)	11 (78,6)	17 (70,8)
Age	58,4	65,7	60,9	66,3
ANCA C +, n (%)	26 (78,8)	1 (8,3)	2 (15,4)	2 (8,3)
ANCA P +, n (%)	3 (9,1)	10 (83,3)	6 (42,3)	21 (87,5)
Involvement, n (%) - Pulmonary - Renal - Pulmonary/Renal	 21 (61,7) 18 (52,9) 3 (8,8)	 4 (33,3) 8 (66,7) 3 (25)	 2 (14,2) 4 (28,6) 0	 0 23 (95,8) 0
ESRD, n (%)	4 (11,8)	0	1 (7,1)	3 (12,5)
Remission after incution, n (%) - No - Partial - Complete Currently treated	 7 (20,6) 10 (29,4) 15 (44,1) 2 (5,9)	 1 (8,3) 6 (50) 4 (33,3) 1 (8,3)	 1 (7,1) 8 (57,1) 4 (28,6) 1 (7,1)	 4 (16,7) 8 (33,3) 11 (45,8) 1 (4,2)
Relapses	13 (39,4)	4 (33,3)	7 (50)	4 (16,6)
Follow up, yeas (DS)	5,5 (6,1)	2,8 (2,3)	4 (2,9)	4,1 (3,8)
Death	3 (8,8)	3 (25)	1 (7,1)	2 (8,3)

Median follow-up was 3.9 years (IQR 1.2 to 7.8). Nine patients died (11%). Overall survival at 10 years was 85% (95% CI 71-93).

Conclusions: The WG and RLV were the most frequent AAV in our cohort. Latter group were at high risk for developing CKD (p = 0.008 versus WG). Acceptable 10-year survival was observed. High percentage of patients showed disease relapse after achieving complete remission. Lower percentage did not achieve remission after the induction.

PUB259

Zoledronic Acid Induced Acute Interstitial Nephritis: Two Cases in One Institute and Literature Review

Titi Chen, Subramanian K. Kumar. *Nephrology, Gosford Hospital, Gosford, NSW, Australia.*

Background: Zoledronic acid is a highly potent intravenous form of bisphosphonate, widely used for treatment of osteoporosis and malignancy associated bone diseases. Its nephrotoxicity, which is dose and infusion rate dependent, has been observed in multiple clinical trials. However, these trials do not usually provide information on renal biopsy findings. A literature search has shown that to date, only eleven patients in four studies had renal biopsies to confirm the etiology of Zoledronic acid induced renal dysfunction. Nine had acute tubular necrosis (ATN), one had focal segmental glomerulosclerosis (FSGS) and one had acute interstitial nephritis (AIN). AIN occurred in a patient with bone metastasis from breast cancer when treated with a high dose of Zoledronic acid (4mg/month).

Methods: We reported two cases of AIN caused by Zoledronic acid, with both patients having normal renal function prior to treatment and both having received the low treatment dose of 4mg/year. Both of these patients developed AIN confirmed by renal biopsy requiring hemodialysis. To our knowledge, these are the first two case reports of biopsy proven AIN requiring dialytic support caused by low dose yearly Zoledronic acid treatment in patients with normal baseline renal function.

Conclusions: Zoledronic acid induced AIN is not uncommon and can occur at a low treatment dose. Renal function should be monitored closely when patients are treated with Zoledronic acid. If acute kidney injury does occur, AIN should be included in the differential diagnosis, in addition to ATN and FSGS as previously reported in the literature. Prompt renal biopsy should be considered to confirm the diagnosis, as the treatment of these conditions are different.

PUB260

Rituximab-Induced Continuous B Cell Depletion for Durable Remission in 32 Consecutive Patients with Idiopathic Membranous Nephropathy

John Niles, Andrew P. Murphy, Katherine M. Cosgrove, Karen A. Laliberte. *Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Many groups are working on the optimal strategy for induction and maintenance of remission. Immunosuppression may be valuable to preserve renal function and to reduce the exposure to the nephrotic state thus reduce the complications of membranous nephropathy. In the past, induction with cytoxic agents and glucocorticoids were found to be effective; however, as data continues to grow, Rituximab may be even more efficacious in induction and short term maintenance therapy to achieve sustained remission.

Methods: We performed a retrospective analysis of clinical data from patients with biopsy-proven idiopathic membranous treated by our group with continuous B cell depletion.

Results: 32 patients: 16 men and 16 women with a mean age of 56.3 received induction and maintenance therapy for idiopathic membranous nephropathy with Rituximab. All but 1 patient received corticosteroids. 20 patients received cyclophosphamide and rituximab. 2 patients received MMF and rituximab. 12 patients received rituximab without concumitant cyclophosphamide or MMF. Mean duration of therapy was 669 days (22 months). Mean spot urine protein/creatinine ratios went from 11.3 prior to therapy to 1.2 at most recent follow up. One patient in the Rituximab only group died five months into therapy with advanced alzheimer's and one patient in the Rituximab only group developed GCSF-responsive neutropenia.

Conclusions: We have seen an increase in the number of new cases each year. Combined induction therapy with cyclophosphamide, corticosteroids and rituximab followed by 2 years of continuous B cell depletion was effective in achieving and sustaining a complete, long term remission. Safety of Rituximab has been well demonstrated in other patient populations. Proteinuria is reduced, renal function is preserved and complications from membranous nephropathy were absent.

PUB261

Rituximab for Antineutrophil Cytoplasmic Antibody-Associated Vasculitis, Hepatitis C Virus-Associated Cryoglobulinemic Vasculitis, and Membranous Nephropathy: One Center Experience

Elena Zakharova. *Nephrology, City Clinical Hospital n.a. s.P. Botkin, Moscow, Russian Federation.*

Background: Rituximab, which is currently used as a treatment option for several autoimmune diseases, was approved for usage in ANCA-associated vasculitis (AAV) in Russian Federation in March 2013. We use rituximab as a rescue therapy for AAV, HCV-associated cryoglobulinemic vasculitis (CCV), and idiopathic membranous nephropathy (IMN) since 2010, and aimed to evaluate treatment results in our patients.

Methods: Using electronic clinical and pathology database for we searched patients with severe AAV and CCV with biopsy-proven kidney damage, and also IMN, treated with rituximab in our unit during 2010-2013. Treatment regimens were either four weekly infusions (375 mg/m^2), or two 2-weekly infusions (1g per infusion).

Results: Study group included 14 patients, 6 (42.8%) male and 8 (57.2%) female, median age 53.5 [25;79] y.o. Patients presented with rapidly progressive glomerulonephritis (RPGN) or with severe nephrotic syndrome (NS) plus arterial hypertension, those with vasculitis had also multiple life-threatening extra-renal manifestations. Kidney pathology showed crescentic glomerulonephritis (CGN), membranoproliferative glomerulonephritis (MPGN), or membranous nephropathy (MN). Main diagnosis, kidney clinical presentation and pathology, indications for rituximab and short-term outcomes are shown in table.

Main diagnosis	AAV	CCV	IMN	Total
Number of patients	6	4	4	14
RPGN	6	2	0	8
NS	0	2	4	6
CGN	6	0	0	6
MPGN	0	4	0	4
MN	0	0	4	4
Refractory disease	3	0	2	5
Relapse	3	3	2	8
First-line tharapy	0	1	0	1
Complete remission	3	3	0	6
Partial remission	3	0	4	7
No remission	0	0	0	1
Relapses after rituximab	0	1	0	1

Conclusions: Rituximab as a rescue therapy was effective in all patients in our group, treated for refractory or relapsing ANCA-associated vasculitis, HCV-associated cryoglobulinemic vasculitis, and idiopathic membranous nephropathy, and presenting with rapidly progressive glomerulonephritis or severe nephrotic syndrome. First-line therapy used in single case of CCV failed. We intend to use rituximab also for maintenance treatment at least for AAV, and evaluate long-term results.

PUB262

Paraneoplastic Glomerulonephritis with Acute Renal Failure in a Patient with Myeloproliferative Disorder Associated with Eosinophilia

Zeljka Veceric Haler, Spela Borstnar, Andreja Ales Rigler, Nika Kojc, Kovac Damjan, Marko Malovrh, Jelka Lindic. *Nephrology, Univ Clinical Centre Ljubljana, Slovenia.*

Background: We report a rare case of crescentic GN superimposed to membranous nephropathy (MN) in a patient with myeloproliferative disease (MPD) and marked eosinophilia.

Methods: Six years before admission 66-year old woman with nephrotic syndrome (NS) was diagnosed with MN. Secondary causes of MN and systemic disease were excluded, her renal function and blood smear were normal. She achieved spontaneous remission. After 5 years she was diagnosed with myelodisplastic syndrome (MDS). At the time of admission she presented with two months lasting diarrhea, dyspnea, weight loss and extensive sweating, anaemia, trombocytopenia and eosinophilia. She also presented with rapidly progressive GN with concomitant NS and needed hemodialysis. Immunoserologic tests were negative. History of parasitic infection, drug reaction, asthma or allergy was negative. She had acute respiratory failure and her CT revealed dense infiltration of right lower lobe. Bronchoscopy revealed eosinophilic bronchitis, bronchial lavage was sterile. Bone marrow biopsy revealed MDS with blasts in excess. Renal biopsy revealed crescentic GN and mixed cell tubulointerstitial nephritis with acute tubular injury and obturatory erythrocyte casts

superimposed on late stage MN. Immunofluorescent analysis revealed modest IgG and C3 immune complex deposition. Diagnosis of hypereosinophilic syndrome associated with MPD and concomitant paraneoplastic crescentic GN was made. Patient was treated with high dose steroids and intravenous immunoglobulins, diarrhea and respiratory insufficiency disappeared, lung infiltrate partially retracted, but patient still remained dialysis dependent. After azacitidine therapy partial resolution of eosinophilia and complete disappearance of lung infiltrate was achieved and renal function started to improve continually.

Conclusions: In our patient with 6-years long history of MN, paraneoplastic GN with hypereosinophilic syndrome associated with MPD was revealed. Appropriate treatment of the underlying disease resulted in marked improvement of renal function with resolving of NS.

PUB263

Percutaneous Renal Biopsy of Native Kidneys Using Real Time Ultrasound: Adequacy and Complications Rates with 14 versus 16 Gauge Automated Needles Svetha Chunduri, William Luke Whittier, Stephen M. Korbet. *Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: The use of a 16 gauge automated biopsy needle has been recommended when performing percutaneous renal biopsy (PRB) of native kidneys. We compare the adequacy and safety of PRB with a 14-gauge or 16-gauge automated needle.

Methods: PRB of native kidneys was performed in 137 adult patients from 1/2010 to 12/2012 using real-time ultrasound guidance. Clinical, laboratory and outcome data (renal US 1-hr post-biopsy, adequacy and safety) was collected prospectively and compared between biopsies performed randomly with a 14-gauge (82 biopsies) or 16-gauge (55 biopsies) automated needle.

Results: Biopsies done with a 14-gauge versus a 16-gauge needle were compared. There were no differences in age (47±17 versus 48±19 yrs), gender (30% versus 35% male), race (41% versus 49% AA) or blood pressure. The creatinine (2.2±1.8 versus 2.1±1.7 mg/dl), bleeding time (8.0±1.8 versus 7.8±1.8 min), the proportion with a normal bleeding time (83% versus 74%) or PTT (90% versus 82%) were similar at the time of PRB. The pre-PRB hemoglobin (Hgb)(11.3±1.9 versus 11.4±2.0) and post-PRB drop in Hgb (1.0± versus 0.8±0.9) were also similar. There were no differences in the number of passes taken (3.0±0.9 versus 2.7±0.8) or cores obtained (2.3±0.6 versus 2.4±0.6) per biopsy. The number of glomeruli obtained per biopsy (light + fluorescence microscopy) was similar (29±11 versus 31±14) and adequate tissue for diagnosis was obtained in 99% and 100% of biopsies. A hematoma by renal US 1-hr post-PRB was demonstrated more often in biopsies done with the 14-gauge needle (39% versus 22%, P 0.04). However, a hematoma at 1-hr post-PRB had a positive predictive value of only 22% with a negative predictive value of 98% in predicting a post-PRB complication. Thus, the complication (8.5% versus 9.1%), transfusion (7.3% versus 7.2%) and embolization (3.7% versus 1.8%) rates were not significantly different for 14 versus 16-gauge needles.

Conclusions: While a hematoma was observed by renal US 1-hr post-PRB more frequently when using the 14-gauge needle, the overall safety and adequacy of PRB of native kidneys using real-time ultrasound was similar using either a 14 or 16-gauge automated needle.

PUB264

Recurrent Lupus Nephritis in a Kidney Allograft Jianping Lin,[1] Talal A. Khan,[2] Sirma H. Koutzaki,[1] Alden Michael Doyle,[2] Yelena Piazza,[1] Suganthi Soundararajan.[1] *[1]Dept of Pathology and Laboratory Medicine; [2]Dept of Medicine, Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia.*

Background: Lupus nephritis (LN) is a common yet serious complication of systemic lupus erythematosus (SLE). It affects 50 percent of SLE patients who may progress to end stage kidney disease (ESKD). Patients who receive renal transplants are thought to be somewhat protected from recurrent lupus nephritis primarily due to the use of immunosuppression. However, the risk of recurrent LN following transplantation is found to be higher in younger African American female patients. Herein we report a case of a biopsy proven recurrent lupus nephritis in a kidney transplant recipient.

Methods: The patient is a 35-year-old Caucasian female with a history of ESKD from lupus nephritis, who received a living unrelated renal transplant in August, 2006. She had induction immunosuppression with basiliximab. She was maintained on standard triple regimen including tacrolimus, mycophenolate and mofetil. The patient was doing well without any complications until August 2013, when she developed kidney allograft dysfunction associated with non-nephrotic range proteinuria. Her urinalysis showed no evidence of RBCs cast, donor specific antibodies were negative, and her complement levels were normal. Her allograft biopsy revealed double contour glomerular basement membrane with electron lucent subepithelial, subendothelial and mesangial deposits. Tubular reticular inclusions were noted. Immunohistochemical stain showed no C4d deposits. All of these observations were consistent with recurrent lupus nephritis against a background of chronic allograft nephropathy. Based on the biopsy findings, patient's mycophenolate dose was increased and high dose prednisone was added. Her proteinuria improved and the kidney function stabilized.

Conclusions: This case illustrates recurrent lupus nephritis in a kidney allograft in a stable kidney transplant recipient who presented with elevated serum creatinine and new proteinuria. Although rare, recurrent LN should be considered in the differential of kidney transplant dysfunction, even in the absence of other clinical evidence of SLE.

PUB265

Morphometry on Baseline Biopsies Predicts Early GFR Change in Nephrotic Syndrome (NEPTUNE) Kevin V. Lemley,[1] S. Bagnasco,[2] Cynthia C. Nast,[3] L. Barisoni,[2] Catherine M. Conway,[4] Stephen M. Hewitt,[5] Peter X.K. Song.[6] *[1]Pediatrics, Univ. of Southern California, Los Angeles, CA; [2]Pathology, Univ. of Miami, Miami, FL; [3]Pathology, Cedars Sinai Med Ctr, Los Angeles, CA; [4]Leica Microsystems, Dublin, Ireland; [5]National Cancer Institute, Bethesda, MD; [6]Biostatistics, Univ. of Michigan, Ann Arbor, MI.*

Background: NEPTUNE is a 21-center consortium undertaking a longitudinal study of nephrotic syndrome due to FSGS, minimal change disease (MCD) and membranous nephropathy (MN) in children and adults.

Methods: From incident diagnostic biopsies, morphometric assessment was done on digital images of 65 cases and correlated with longitudinal change in estimated GFR (eGFR) over 18 months using generalized estimating equations (GEE) method. Three morphometric variables were estimated in the biopsy images on a SlidePath platform (Leica Biosystems): average glomerular tuft cross-sectional area (AG) and cortical glomerular density (NA) were determined by digital planimetry; fractional interstitial area (FIA), a marker of interstitial fibrosis, by point counting. All measurements were done by a single investigator (KVL) who was blind to all other patient characteristics. Eight potential confounding variables (e.g. race, age, sex, baseline level of proteinuria) were included in the GEE analysis.

Results: The subjects studied were 34% African-American, 68% male and 63% adult; disease category was FSGS in 32, MCD in 20 and MN in 11 ('other' in 2). NA and FIA were the strongest predictors of change in eGFR (P=0.003 and P=0.0001), followed by baseline patient age (P=0.019). No other variables had a significant effect in the multivariate longitudinal analysis. AG was significant as a single predictor, but not in the multivariate analysis, possibly due to strong collinearity with NA (r=-0.56, P<0.0001).

Conclusions: All 3 morphometric variables may be considered as markers of glomerulopenia. Thus, their predictive power may reflect the deleterious effects of a congenital low nephron endowment in patients who later develop nephrotic syndrome (low FIA) or reflect preceding glomerular loss, even in these early, diagnostic biopsies.

PUB266

The NEPTUNE Digital Pathology Protocol Increases Accuracy in Glomerular Number Assessment Avi Z. Rosenberg,[1] M. Palmer,[2] L. Merlino,[3] J. Troost,[4] A. Gasim,[5] S. Bagnasco,[6] C. Avila-Casado,[7] D. B. Johnstone,[8] Jeffrey B. Hodgin,[4] Catherine M. Conway,[9] Jeffrey B. Kopp,[10] Cynthia C. Nast,[11] L. Barisoni,[3] Stephen M. Hewitt.[1] *[1]NCI; [2]U of Pennsylvania; [3]U of Miami; [4]U of Michigan; [5]U of North Carolina; [6]Johns Hopkins Univ; [7]Univ Health Network, Toronto; [8]Temple U; [9]Leica; [10]NIDDK; [11]Cedars Sinai.*

Background: Standardized review of renal biopsies are central to kidney diseases diagnosis/prognosis. Reproducibility is a challenge for basic metrics. The NEPTUNE digital pathology protocol (NDPP) seeks to standardize this by refining scoring reproducibility. Glomerular number (GN) reported by light microscopy (LM) versus enumeration by digital annotation were compared using glomerular annotation of histologic levels on whole slide images (WSI).

Methods: 9,379 glomeruli in 274 cases were annotated at all levels. Total GN/case or average GN/slide, and total number with glomerular sclerosis (GS) were enumerated on WSI; reported GN (total or average) and glomerular number with GS were excerpted from the reports.

Results: The discrepancy between reported total (total and GS) versus annotated glomeruli increased proportionally to the total GN. This difference was disease-dependent for GS glomeruli (IgA NP 5.9; FSGS 3.7; MN 1.6; MCD 0.03 (p<0.01)). There was a mean discrepancy up to 14.6% (<0.0001) in % GS reported versus annotated in 30 - 80% GS bracket.

Summary of variation in glomerular enumeration (#range, mean)

	Reported#	Annotated#	Correlation	Difference#	Significance of difference
Average per slide (n=134)	4 – 125 21.7	1.4 – 135 16.7	0.95	-17 to 15 -1.5	0.002
Total per case (n=140)	2 - 71 18.3	3 – 149 30.8	0.87	-11 to 78 12.4	<0.001
Sclerotic (total, n=140)	0-50 2.7	0-99 4.9	0.89	-6 to 72 2.2	<0.001
% Sclerotic (total, n=140)	0-100 15	1-130 17	0.84	-73 to 93 2.2	0.007

Conclusions: Enumeration of GN on WSI provides an accurate assessment of glomerular lesions. Average glomerular profiles/level are more reproducible, allowing better determination of glomerular injury. Further work into the role of WSI will assess reproducibility/accuracy of involvement by subtler lesions and determine the impact on ennumeration versus estimation has on diagnosis and prognosis.

PUB267

Trefoil Factor 3 Expression in Immunoglobulin A Nephropathy Derya Guler, Izzet Hakki Arikan, Dilek Barutcu Atas, Ebru Asicioglu, Arzu Velioglu, Mehmet Koc, Serhan Tuglular, Cetin Ozener. *Nephrology Div, Marmara Univ Hospital, Istanbul, Turkey.*

Background: Trefoil factor 3 (TFF3) is a small peptide that is secreted from mucous producing cells. It plays an important role in mucosal protection, cell proliferation and migration. Increased plasma or urine TFF3 levels have been reported in patients with acute or chronic kidney disease. However, there is no renal tissue expression in healty kidneys. We aimed to investigate the possible TFF3 expression and its role in pathogenesis of human IgA nephropathy.

Methods: Twenty eight patients with biopsy proven IgA nephropathy (16 women, mean age 37 ± 13.8 years) included to this study. Kidney biopsy materials of these patients were re-evaluated according to the Oxford classification. Patients' demographic, clinical and laboratory data were collected. TNF-α, IL-10, TGF-β, and TFF3 expressions were investigated on renal biopsy specimens. The possible correlations between clinical data and the expressions were assessed by SPSS version 15.0.

Results: The mean follow-up time of the patients was 4.8±2.7 years. None of the patients have reached end-stage renal failure. The uric acid level was higher in patients with messengial hypercellularity (p=0.04). Sitoplasmic TFF3 expression was observed in 19 patients (%67.9). Nuclear TGF-β expression was demonstrated in 20 (71.4%) patients in tubular epithelial cells. IL-10 expression was also observed in majority of the patients (89.3%). There was a positive correlation between TGF-β and TFF3 expression in the tubular epithelial cells (P=0.005). Patients with nuclear TGF-β expression have most likely to show glomerular and tubular IL-10 expression (p=0.015). There were no correlations between clinical or histopathological findings and TFF3 expression.

Conclusions: We have demonstrated TFF3 expression on kidney tissues in patients with IgA nephropathy. The presence of TFF3 expression in tubular epithelial cell but not in glomeruli suggests that TFF3 may contribute in tubular injury rather than spesific pathogenetic role in IgA nephropathy. The correlation between TGF-β and TFF3 expression in tubular epithelial cells may support our hypotesis that TFF could have a role in inflammatory process.

PUB268

Significance of Intrarenal Arteriolar Lesions in the Patients with IgA Nephropathy with or without Hypertension Tian-Yi Chen, Hong Cheng, Yi-Pu Chen. *Div of Nephrology, Beijing Anzhen Hospital,Capital Medical Univ, Beijing, China.*

Background: To develop quantitative criteria for evaluating intrarenal arteriolar lesions, and to investigate the effect of arteriolar lesions on the patients of IgAN.

Methods: 50 non-IgAN cases with normal small arteries in our hospital were analyzed. patient's arteriolar inside diameters and outside diameters were measured by indirect method. Average value of arteries' inside diameters/outside diameters were calculated and the degrees of severity of arteriolar lesions were evaluated. The criteria for evaluating intrarenal arteriolar lesions were developed, base on the data. According to the criteria, we analyzd 305 cases of IgAN with or without hypertension.

Results: The average ratio of arteriolar inside/outside diameters of all non-IgAN cases was 0.52±0.05. The criteria of arteriolar lesions were defined as follows: >0.48 was normal; 0.45-0.48 was mild; ≤0.45 was severe. Among 305 IgAN, the prevalence of arteriolar lesions was 36.4% and 13.3% of those patients with severe lesions. The cases of intrarenal arteriolar lesions had significantly higher systolic blood pressure (SBP), diastolic blood pressure (DBP), serum creatinine level (SCr), proportion of ischemic glomerulosclerosis (PIG) and lower urine osmotic pressure (UOP) compared with normal cases (P<0.05). The severe lesion group had higher DBP, SCr and PIG, compare with mild lesion group (P<0.05). Through variables selected for the logistic regression model we found that SBP, SCr, UOP and PIG associated with arteriolar lesions independently. Among the 147 IgAN cases with normal blood pressure, 26.5% of them with arteriolar lesions and 7.5% with severe lesions. Compare with normal group, the cases of intrarenal arteriolar lesions had significantly higher SCr and PIG compared with normal cases (P<0.05). The significantly lower UOP only appeared in the cases of severe arteriolar lesions (P<0.05). Among the IgAN cases with normal blood pressure,UOP and PIG associated with arteriolar lesions independently.

Conclusions: Intrarenal arterial lesions appeared in IgAN patients with or without hypertension, and the arteriolar lesions are frequently associated with more severe glomerular and tubular dysfunction.

PUB269

RENAL AID, a Newly Established Biorepository Is a Unique Platform for Conducting CKD Research Alan Perlman,[1,2] James M. Chevalier,[1,2] Thomas Parker,[2] Surya V. Seshan,[3] Daniel Levine.[2] *[1]Nephrology, Weil Cornell Medical College, NY, NY; [2]The Rogosin Institute, NY, NY; [3]Pathology, Weil Cornell Medical College, NY, NY.*

Background: RENAL AID (Repository of Novel Analytes Leading to Autoimmune, Inflammatory and Diabetic nephropathies) is a unique dual function data registry and tissue repository designed as a platform to conduct research relating to the correlation between tissue diagnosis, histology patterns and gene expression from renal biopsies relative to subjects clinical characteristics, disease course, serum/urine biomarkers and blood/urine gene expression. The goal of the bio-repository is to collect data from subjects with diabetic, inflammatory and autoimmune renal conditions in order to ascertain factors that predict disease progression, response to therapy and assess for discriminating noninvasive features that predict biopsy findings.

Methods: RENAL AID is able to capture biopsy findings in a retrievable electronic database. Typically, biopsy results are reported in descriptive prose that is useful to the practicing physician but limits the ability to associate biopsy findings with other variables for the purpose of translational research. RENAL AID electronically stores pathology descriptions using a data collection instrument that is objective, quantifiable and retrievable. Pathology details are stored in the same database as all other clinical and laboratory data thereby facilitating straightforward detection of associations between these variables. Follow-up occurs at regular intervals with updated clinical/laboratory data. RENAL AID also serves as a tissue repository for renal biopsy, urine, blood and serum specimens for future comparative analysis between any combination of variables including tissue, blood and urine gene expression, histopathology, pathologic diagnosis, serum/urine biomarkers and clinical variables.

Conclusions: RENAL AID is a unique dual function bio-repository platform designed to study associations between clinical, biochemical, histology and genetic data in subjects with diabetic, inflammatory and autoimmune nephropathies. As data from these sets are stored in a single database, the discovery of novel associations is facilitated.

PUB270

The Effect of Anemia on Complication Rate after Percutaneous Renal Biopsy William Luke Whittier, Khaleel Sayeed, Stephen M. Korbet. *Nephrology, Rush Univ Medical Center, Chicago, IL.*

Background: A percutaneous renal biopsy (PRB) complication has been defined by bleeding resulting in the need for an intervention, and the degree of anemia pre-PRB has been shown to be a risk factor for a complication. As the most common intervention is a blood transfusion, the purpose of this study was to determine if anemia is truly a risk factor for bleeding, or if anemic patients are simply more likely to receive a transfusion after a PRB.

Methods: PRB of native kidneys was performed in 910 adults using real-time ultrasound and automated 14 gauge biopsy needles from 1/1990 to 4/2014. All patients were prospectively monitored for a bleeding complication in the hospital for 24 hours and evaluated based on the post-PRB drop in hemoglobin concentration (Δ Hgb). A complication was defined by bleeding resulting in an intervention (transfusion, embolization or cystoscopy), re-admission due to post-PRB complication, or death. Patients were divided into 3 groups based on the pre-PRB Hgb (<9, 9-11 and >11 g/dl).

Results: Complications occurred in 71(7.8%) of 910 biopsies, and the majority of these (57/71, 80%) resulted in a transfusion (6.3% overall). Biopsies with complications had a lower pre-PRB Hgb than those without complications (10.3 ± 2.0 g/dl versus 12.0 ± 2.1 g/dl, p < 0.0001) and a greater Δ Hgb (2.1 ± 1.6 versus 1.0 ± 0.8 g/dl, p < 0.0001). Patients with a pre-PRB Hgb < 9 g/dl were significantly more likely to receive a transfusion but had a smaller Δ Hgb and experienced fewer hematomas compared to patients who received a transfusion but started with a higher pre-PRB Hgb.

Pre-PRB Hgb (g/dl)	<9	9-11	>11	P value
N	79	266	565	
Transfusion	19 (24%)	23 (9%)	15 (3%)	< 0.0001
Δ Hgb in Transfusion patients (g/dl)	1.3± 1.0	1.8± 0.8	3.2± 1.6	< 0.0001
Hematomas in transfusion patients	58%	83%	87%	0.04

Conclusions: While severely anemic patients have a higher transfusion rate and thus by definition a higher complication rate, this appears to be due to a lower threshold for transfusing as these patients actually have less clinical evidence of bleeding. Thus, the complication rate may be falsely elevated as an artifact of its definition.

PUB271

Incidental Tubulo-Reticular Inclusions in Allograft Biopsies of Five Kidney Transplant Recipients without Clear Etiology Talal A. Khan,[1] Sirma H. Koutzaki,[2] Alden Michael Doyle,[1] Ying Lu,[2] Suganthi Soundararajan.[2] *[1]Div of Nephrology and Hypertension; [2]Dept of Pathology and Laboratory Medicine, Drexel Univ College of Medicine, Philadelphia.*

Background: Tubulo reticular inclusions (TRIs) are organized subcellular structures within cisternae of endoplasmic reticulum and are considered footprints of interferon activity (IFNα and INFβ). These structures have been described with collagen vascular diseases [SLE(systemic lupus erytheromatosus),systemic sclerosis etc], viral infections (HIV, HBV,HCV) and during systemic treatment with interferons.Incidental findings of TRIs in kidney transplant recipients may suggest underlying pathology. They usually occur in endothelial cells in glomeruli of kidney transplants with underlying SLE or viral infection. However in some cases they occur without any underlying etiology. Herein we report 5 cases of kidney transplant recipients who were found to have incidental TRIs on kidney biopsy specimens examined by electron microscopy.

Methods: We retrospectively reviewed five cases of kidney transplant recipients who had biopsy proven TRIs.Most (4/5) of the patients had biopsies performed to evaluate acute kidney injury, while the other was performed as part of a surveillance. Four were from deceased donors, one was from a living donor. We reviewed these cases for any evidence or history of SLE, HIV, Hepatitis B and C virus infection or BK virus nephropathy.

Results: None of the patients had any evidence or history of SLE, HIV, Hepatitis B and C virus infection or BK virus nephropathy.No patients had been exposed to interferon therapy at any time.Two patients had evidence of chronic rejection, while 1 patient was diagnosed with IgA nephropathy and 1 patient had recurrent FSGS. No patient had evidence of acute rejection.

Conclusions: We report 5 cases of incidental TRIs found in kidney allograft biopsy specimens in patients with no clear reason. We hypothesize that these may be related to the production of cytokines in the recipient's allo-immune response and that these may be of some utility in diagnosis or prognosis. We encourage nephropathologists to be aware of their possible presence and encourage further study into this intriguing histopathological phenomena.

PUB272

Renal Arterial Perfusion Ratio Reflects Cardiac and Renal Functions in Chronic Kidney Disease and Hypertension

Arkadiusz Lubas, Robert Ryczek, Jerzy Smoszna, Stanislaw Niemczyk. *Internal Medicine, Nephrology and Dialysis, Military Institute of Medicine, Warsaw, Poland.*

Background: Cardiac hemodynamic function is crucial for maintaining renal perfusion. On the other hand renal tissue alterations corresponding to chronic kidney disease (CKD) ameliorate perfusion of the organ. The aim of the study was to evaluate whether Renal Arterial Perfusion ratio (RAP) could reflect both cardiac and renal functions in patients with stable CKD and hypertension.

Methods: Forty five patients (5 F; 40 M; age 52 ±16) with stable CKD (Cys-CreCKD-EPI 54.4 ±27.8 ml/min/1,73m^2) and hypertension were enrolled in the study. Serum Creatinine (Cre), Cystatin C (Cys), NT-pro brain natriuretic peptide, Troponin I (TnI) were tested. Renal function was estimated according to Cys-Cre based CKD-EPI formula. Echocardiographic examination, ABPM, ultrasound estimation of Intima-Media Thickness (IMT) and Renal Resistive Index (RRI) were collected. RAP was calculated as a ratio of Proximal (PPI) to Distal (DPI) arterial Perfusion Intensity in renal cortex assessed in Color Doppler (PixelFlux, Chameleon Software, Germany).

Results: DPI was lower than PPI (0.077 ±0.072 cm/s versus 0.427 ±0.284 cm/s; p<0.001). Median RAP was 7.00 (range: 0.93 - 12.30). RAP was significantly correlated with mean arterial pressure (MAP)(r=0.33; p=0.031) and left ventricle hemodynamic parameters: stroke volume (LVSV) (r=0.38; p=0.009) and cardiac index (CI) (r=0.37; p=0.014), but not with left ventricular mass index, nor with parameters of renal function. In the model of stepwise multiple regression analysis (Cys, Cys-CreCKD-EPI, TnI, LVSV, IMT, RRI, MAP and PP) LVSV and Cys-CreCKD-EPI as well as RRI and pulse pressure together independently influenced RAP (R^2=0.46; p<0.001).

Conclusions: Renal Arterial Perfusion ratio is significantly influenced by cardiac and renal functions in hypertensive CKD patients. RAP could be considered a new tool in diagnosing cardio-renal interactions.

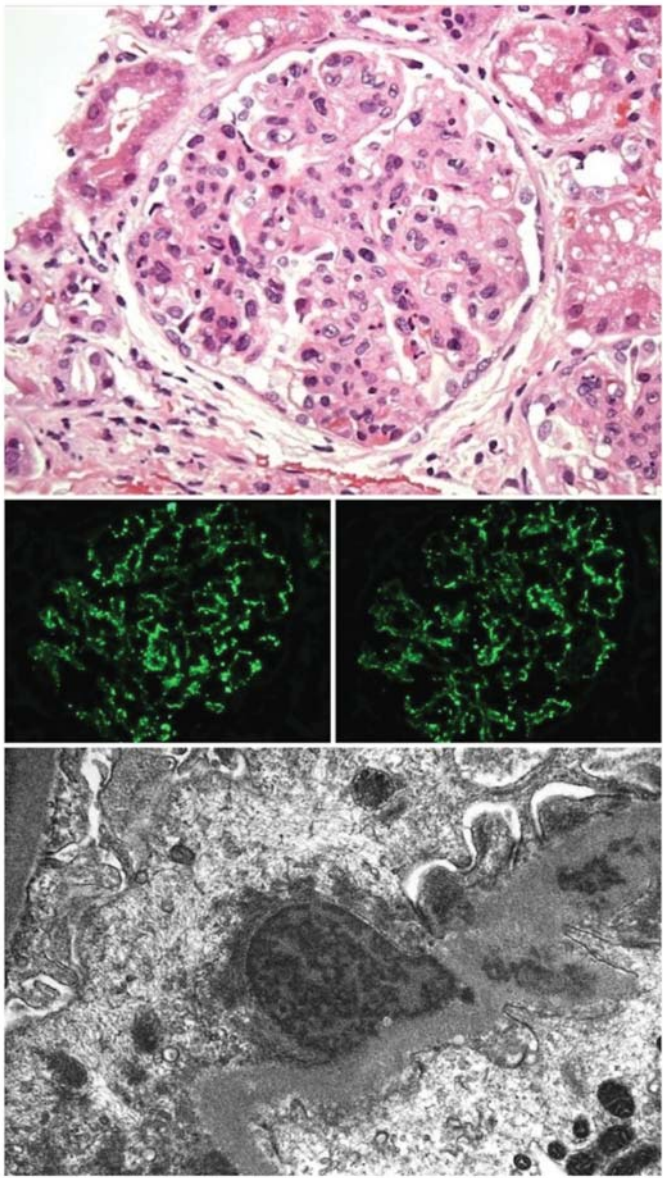
PUB273

Proliferative Glomerulonephritis with Monoclonal IgG Deposit an Atypical Presentation of Acute Post Infectious Glomerulonephritis

Elie El-Charabaty,[1] Leal C. Herlitz,[2] Suzanne E. El Sayegh.[1] *[1]Nephrology, Staten Island Univ Hospital, Staten Island, NY; [2]Pathology, Columbia Univ Medical Center, New York, NY.*

Background: Pathologocal labeling of a glomerulonephritis into a specific entity can be challenging. We present below a rare case.

Methods: This is a case of a 20-yo female with PMH of tonsillectomy presenting for evaluation of proteinuria. She had lethargy, weakness, fever of 102, cough, sputum production 2 weeks prior. She gained 25 lbs,had facial, and lower extremities edema.No hematuria,diarrhea or rash.No OTC medications. No drug abuse. On exam she had +3 edema of lower extremities. The rest was normal. Dipstick showed hematuria with 3+ protein. Her Creatinine was 1.1 mg/dl, CBC was normal .Albumin was 2.2 mg/dl. Urine Pr/Cr was 11 g/g and no RBC casts on urine microscopy, C3, C4 normal, ANA, DsDNA, ANCA, cryoglobulins,RF,viral serologies and cultures were negative.She was started on steroids and a kidney biopsy was done



It showed diffuse proliferative GN with exudative features and IgG3- Kappa deposits. LM shows an acute proliferative and exudative GN and EM shows subepithelial hump-shaped immune type electron dense deposits. These findings are consistent with APIGN. The lack of low C3,C4 argues against that. The IF finding of apparent monoclonal IgG3-Kappa restricted deposits raises the possibility of PGNMID. The patient SPEP, UPEP, serum free light chain were negative.She was started on prednisone at 1mg/kg for a period of 1 month and tapered rapidly over 4 weeks .She is clinically asymptomatic, her last UPr/Cr is 1g/g of creatinine.

Conclusions: Our case is unusual because PGNMID patients tend to be older (80%>40yrs) and the predominance of hump shaped deposits is not characteristic of it. While both APIGN and PGNMID are in the differential, this case appears to be unique and defies definitive classification as a specific entitiy.

PUB274

Renal Involvement as the First Symptom of Multiple Myeloma

Wei Wang, Li Wang. *Renal Dept, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Renal involvement is a common complication of multiple myeloma (MM). However, most studies have focused on renal failure in MM, and little information is available about the other renal manifestations in MM and their association with immunophenotypes.

Methods: We retrospectively analyzed the clinical and laboratory data of 213 MM patients treated in Sichuan Provincial People's Hospital, West China, between January 1990 and May 2012. The patients were divided into a renal involvement group (n = 150) and a non-renal involvement group (n = 63).

Results: In the renal involvement group, 67 (44.7%) patients were diagnosed with MM in the Nephrology Department, and isolated proteinuria, renal failure and nephrotic syndrome were detected in 76 (50.7%), 77 (51.3%) and 44 (29.3%) patients, respectively. 85 patients with renal involvement underwent immunofixation electrophoresis, and IgG,

IgA, IgD, pure light chain and nonsecretory MM were detected in 34 (40%), 25 (29.4%), 1 (1.2%), 22 (25.9%) and 3 (3.5%) patients, respectively. 27 patients without renal involvement also underwent immunofixation electrophoresis, and IgG and IgA MM were found in 15 (55.6%) and 12 (44.4%) patients, respectively. Severe anemia and hypertension and pure light chain disease were more frequent in patients with renal involvement ($P < 0.05$). Serum globulin level was higher in patients without renal involvement ($P < 0.05$).

Conclusions: Renal involvement was common at MM diagnosis and had diverse clinical manifestations. Nephrologists should rule out MM in patients presenting with renal involvement.

PUB275

Identification of Double Negative αβ T Cells in Human Kidney

Maria Noel Martina Lingua,[1] Samatha Bandapalle,[2] Sanjeev Noel,[2] Mark Ball,[3] Abdel Hamad,[1] Mohamad Allaf,[3] Hamid Rabb.[2] *[1]Pathology, Johns Hopkins Univ, Baltimore, MD; [2]Medicine, Johns Hopkins Univ, Baltimore, MD; [3]Urology, Johns Hopkins Univ, Baltimore, MD.*

Background: We found a large population of the unconventional T cell subset, the TCRαβ+CD4-CD8- double negative (DN) T cell, in mouse kidneys during studies of acute kidney injury (J Leuk Biol 2008). To evaluate the human relevance of the mouse findings, we studied human kidneys removed for renal cell carcinoma (RCC). Furthermore, given the role of immune system in RCC, intra-renal lymphocytes may play an important role in disease pathogenesis. In this study we hypothesized that DN T cells are present in human kidney. We also hypothesized that kidney lymphocyte numbers and function correlate with RCC stage.

Methods: We used a strategy to enrich hematopoietic cells from 6 human kidney modified from our mouse protocol. Briefly, we positively selected pure CD45+ lymphocytes from kidney mononuclear cells. Phenotypic characterization and cytokine analysis of purified CD45+ cells was performed by flow cytometry and data analyzed by Flow Jo software.

Results: We study 6 patient nephrectomy; 4 patients had clear cell, 1 patient had hybrid tumor and 1 patient had papillary RCC. We found DN T cells in all samples (7-55% of T cells). We also analyzed for CD4 (17-49%), CD8 (6-72%) and double positive (DP) CD4+/CD8+ T cells (3-22%). Only one patient had metastasis (patient number 2), who showed the lowest DN T cell infiltration and the highest CD8 T cell infiltration. DN T cells together with CD8 T and DP T cells express high values of IFN-γ (11.5%, 16% and 12% respectively).

Case	Age / Gender	Diagnosis / Tumor Diameter (cm)	% DN	% CD4	% CD8	% DP	Clinical Stage
1	77 M	Clear Cell / 4	**55**	32	6	3	cM0
2	55 M	Clear Cell / 8	**7**	17	72	4	cM1
3	68 M	Clear Cell / 3.5	**13**	49	11	22	cM0
4	63 M	Hybrid (RCC + oncocytoma) / 4	**22**	32	35	4	cM0
5	69 M	Papillary / 3.5	**13**	35	50	6	cM0
6	56 F	Clear Cell / 3.5	**13**	32	33	8	cM0

Conclusions: These data demonstrate that TCRαβ+CD4-CD8- double negative cells are present in human kidneys, validating findings in mouse kidney. Human kidney T cells may participate in regulating RCC.

PUB276

Spectrum of Native and Transplant Histological Features Seen in the Presence of Tubuloreticular Inclusions

Chang-Ho Yoon, Michelle Willicombe, Jill Moss, Linda Moran, Tom Cairns, H. Terence Cook. *Imperial College Kidney and Transplant Centre, London.*

Background: The presence of tubuloreticular inclusions [TRIs] in glomerular endothelial cells is pathognomic of SLE and viral infections, particularly HIV. However, the spectrum of histological findings in patients with TRIs is not well defined. Furthermore, the relevance of TRIs in renal transplant biopsies is not known. The aim of our study is to determine the co-existing histopathological findings in patients with TRIs in native and transplant biopsies.

Methods: We retrospectively analysed all patients who underwent a native or renal transplant biopsy with TRIs on EM examination between 2005 and 2013.

Results: 290 patients had a native renal biopsy with TRIs. 211/290 [72.8%] were females. 83/290 [28.6%] were Caucasoid. The mean age at biopsy was 41.6 ± 15.6 years. The mean follow up was 3.9 ± 2.5 years. Renal survival post biopsy was 91.5%. Lupus was diagnosed on 206/290 [71.0%] biopsies. The remaining diagnoses are shown below:

Non-lupus histological diagnoses			
Immune complex GN	**N=35[12.1%]**	**Non-immune complex GN**	**N=49 [17.9%]**
Membranous	12 [4.1]	TMA	3 [1.0]
IgA	9 [3.1]	DM nephropathy	9 [3.1]
IgM	4 [1.4]	Pauci-immune GN	5 [1.7]
MPGN	5 [1.7]	FSGS	5 [1.7]
C3 glomerulopathy	2 [0.7]	TIN	5 [1.7]
HIVAN/HIVICK	3 [1.0]	TI Scarring	8 [2.8]
		Other	14 [4.8]

40 patients had TRIs on renal transplant biopsy. 16/40 [40.0%] were female. 19/40 [47.5%] were Caucasoid. The mean age at transplant was 52.6 ± 12.9 years. 4/40 [10.0%] had an underlying diagnosis of SLE. The mean follow up post biopsy was 2.3 ± 1.9 years. Allograft survival post biopsy was 50.7%. The distribution of histological diagnosis was as follows: alloimmune injury 17 [42.5%], glomerulonephritis (recurrent or de novo) 11 [27.5%], tubulo-interstitial scarring 6 [15.0%], vascular changes/hyalinosis 4 [10%], pyelonephritis 2 [5%].

Conclusions: This study shows the diversity of native renal pathology which can be seen in patients with TRIs. The lack of 'traditional' associations seen in transplant recipients with TRIs warrants further investigation.

PUB277

Focal Segmental Glomerulosclerosis in Patients Aged 40 Years and Older

Cristiane B. Dias,[1] Lectícia Jorge,[1] Luis Yu,[1] Leonardo Abreu Testagrossa,[2] Denise M.A.C. Malheiros,[2] Viktoria Woronik.[1] *[1]Nephrology, Hospital das Clínicas da Univ de São Paulo, São Paulo, Brazil; [2]Pathology, Hospital das Clínicas da Univ de São Paulo, São Paulo, Brazil.*

Background: The focal segmental glomerulosclerosis (FSGS) in Brazil corresponds to 29.7% of primary glomerulopathies and 9.7% of biopsies of elderly patients. The aim of this study was to evaluate the clinical, laboratory characteristics and etiologies of FSGS aged 40 years and older.

Methods: This is a retrospective single-center study of FSGS patients diagnosed from 2000 to 2013. There were 257 patients from all ages and 26.8% over 40 years old, while 5.6% were over 60 years old.

Results: Clinical characteristics of FSGS patients over 40 years are in Table 1.

Characteristics	Patients n= 69
Age (years), mean ± SD	52.6 ± 10.8
Serum creatinine (mg/dL), median and interquartile range	1.4 (1.0-4.0)
Proteinuria (g/day), median and interquartile range	4.0 (2.0-7.5)
Serum albumine (g/dL), median and interquartile range	1.4 (1.0-3.1)
Male (%)	63.7
White race (%)	46.3
Nephrotic syndrome (%)	62.3
Hypertension (%)	74
No family history of kidney disease (%)	97
Hematuria (%)	53.6

Eleven patients (16%) showed association with viral infection, 2 patients (2.8%) with long standing hypertension and 1 (1.4 %) with schistossomose. The remaining 55 patients (79.7%) were classified as idiopathic form. Columbia classification was performed in 50 patients, 31 (62%) NOS, 10 (20%) collapsing, 6 (12%) TIP, 2 (4%) perihilar and 1 (2%) celular. Fifteen patients had diagnosis over 60 years and were idiopatic forms.

Conclusions: The patterns of FSGS secondary to metabolic and hypertensive disease were infrequent based on clinical criteria and not indicating kidney biopsy. The idiopathic form occurred in 79.7% of cases and the types of FSGS based on Columbia classification were similar to published data in young patients under 40 years old.

PUB278

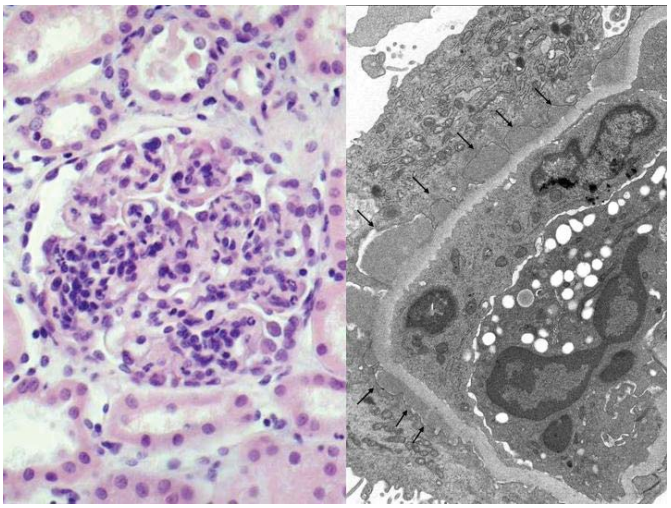
Henoch Schonlein Purpura Renal Biopsy Showing Features of IgA Dominant Post Infectious Glomerulonephritis Requiring Transplantation Followed by an Early IgA Nephropathy in the Renal Allograft

Sami S. Zarouk,[1] Sruthi Jinna,[1] Ping L. Zhang,[2] Michele T. Rooney.[2] *[1]Dept of Nephrology, William Beaumont Hospital, Royal Oak, MI; [2]Dept of Pathology, William Beaumont Hospital, Royal Oak, MI.*

Background: A 38-year-old Caucasian male had lower extremity rash, abdominal pain, and sore throat. Laboratory values revealed acute kidney injury and an elevated anti-streptolysin-O titer, negative anti-nuclear antibody, anti-neutrophil cytoplasmic antibody, and normal complement levels.

Methods: Skin biopsy revealed IgA positive leukocytoclastic vasculitis. Kidney biopsy revealed diffuse "exudative" glomerulonephritis, with endocapillary proliferation

and marginated neutrophils. Immunofluorescence revealed IgA predominance, C3, and light chain with fluorescence for lambda greater than kappa. Electron microscopy showed numerous large epimembranous bell-shaped "hump-like" deposits.



Results: This patient's renal failure progressed in spite of immunosuppressive therapy. Seven months post presentation, he received a preemptive kidney transplant from his wife. He developed hematuria soon after, with findings of IgA nephropathy in his allograft biopsy at one month post transplantation. He is currently 5 years post-transplant with unchanged creatinine at 2.2 mg/dl.

Conclusions: Our case is suspected to be from streptococcus infection as opposed to staphylococcal infection associated IgA nephropathy (APIGN). It highlights the possibility of recurrence of IgA deposit in the renal allograft in a patient with clinical presentation of HSP and renal biopsy compatible with APIGN. The recurrence of IgA deposit in the renal allograft of this patient early on post-transplant is similar to primary cases of IgA nephropathy. Infection has been implicated in the pathogenesis of both of these entities. They may ultimately prove to be ends of a spectrum rather than two distinct entities.

PUB279

Serum LDH Level Is Associated with Decreased eGFR and Proteinuria in Patients with Glomerulonephritis Seong Kwon Ma,[1] Chang Seong Kim,[1] Ha Yeon Kim,[1] Hoon In Choi,[1] Jung Sun Park,[1] Eun Hui Bae,[1] Jongun Lee,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea; [2]Dept of Physiology, Chonnam National Univ Medical School, Gwangju, Republic of Korea.*

Background: Although LDH is expressed in the kidney, the relationship between serum LDH and renal expression of LDH in kidney diseases has not yet been established. We investigated the relationship between serum LDH level and estimated glomerular filtration rate (eGFR) or proteinuria in patients with glomerulonephritis (GN). We also investigated the protein expression of LDH in the kidney of experimental renal ischemia/reperfusion (I/R) injury and puromycin aminonucleoside (PAN)-induced nephrotic syndrome.

Methods: We conducted a retrospective study of patients with GN diagnosed by kidney biopsy (n=104) and control patients (n=28). We analyzed clinical parameters including serum LDH, CKD-EPI eGFR, serum albumin and proteinuria by using one-way ANOVA, post hoc Tukey HSD test, Pearson's correlation coefficient, stepwise multiple linear regression. Renal I/R injury in mice was induced by clamping of both renal pedicles for 25 min. PAN-induced nephrotic syndrome in rats was induced by a single intravenous injection of PAN via the femoral vein.

Results: Serum LDH level is increased in patients with severe proteinuria compared with the control patients (358.4 ± 9.3 versus 515.0 ± 24.0 U/L, $p<0.05$). Serum LDH is also increased in patients with eGFR less than 60 mL/min/1.73 m^2 (358.4 ± 9.3 versus 523.0 ± 26.2 U/L, $p<0.05$). Serum LDH level was correlated with eGFR ($r = -0.433$, $p<0.001$), 24 h urine protein ($r = 0.478$, $p<0.001$), and serum albumin ($r = -0.432$, $p<0.001$). Linear regression analysis showed eGFR and proteinuria were independent predictors of serum LDH level. The protein expression of LDH was increased in the kidney of mice with renal I/R injury and rats with PAN-induced nephrotic syndrome.

Conclusions: In conclusion, serum LDH level is increased in patients with decreased eGFR and severe proteinuria, which may be attributed to increased renal expression of LDH during renal injury.

PUB280

Possible Involvement of von Willebrand Factor in TTP Secondary to SLE Miho Karube, Shinya Kaname, Yoshinori Komagata, Yoshihiro Arimura. *First Dept of Internal Medicine, Kyorin Univ School of Medicine, Tokyo, Japan.*

Background: Although SLE is known to be one of the common causes that may complicate thrombotic microangiopathy (TMA), its pathogenetic mechanism is still unclear.

Methods: We conducted clinical and histological study for two SLE patients with concomitant TMA in the kidney. Immunohistochemical analysis for von Willebrand factor (VWF) was also performed.

Results: Case 1 was a 44-year-old woman with a history of SLE for 12 years with lupus nephritis class V+III. Thrombocytopenia and hemolysis suddenly developed with AKI in the absence of the increased disease activity. ADAMTS13 activity was markedly decreased at 1.6% with an increase in anti-ADAMTS antibody titers, indicating the diagnosis of thrombotic thrombocytopenic purpura (TTP). Renal biopsy revealed class V lupus nephritis with TMA and glomerular endothelial injury. Interestingly, VWF showed strong granular staining along the glomerular capillary loops. After administration of glucocorticoid, TTP findings quickly improved. Case 2 was a 41-year-old woman with a history SLE for ten years. Thrombocytopenia, hemolysis and AKI developed in association with a relapse of SLE, but ADAMTS13 activity was normal. Renal biopsy showed lupus nephritis class IV+V with TMA lesions, but no staining of VWF was observed in contrast to Case 1. The patient was treated with glucocorticoid and plasmapheresis with a good response.

Conclusions: From these results, it is suggested that VWF may be involved in the development of renal TMA in patients with lupus nephritis associated with TTP, but not in those with renal TMA from unknown causes other than TTP.

PUB281

Possible Involvement of von Willebrand Factor in TTP Secondary to SLE Miho Karube, Shinya Kaname, Yoshinori Komagata, Yoshihiro Arimura. *First Dept of Internal Medicine, Kyorin Univ School of Medicine, Tokyo, Mitaka, Japan.*

Background: Although SLE is known to be one of the common causes that may complicate thrombotic microangiopathy (TMA), its pathogenetic mechanism is still unclear.

Methods: We conducted clinical and histological study for two SLE patients with concomitant TMA in the kidney. Immunohistochemical analysis for von Willebrand factor (VWF) was also performed.

Results: Case 1 was a 44-year-old woman with a history of SLE for 12 years with lupus nephritis class V+III. Thrombocytopenia and hemolysis suddenly developed with AKI in the absence of the increased disease activities. ADAMTS13 activity was markedly decreased at 1.6% with an increase in anti-ADAMTS13 antibody titers, indicating the diagnosis of thrombotic thrombocytopenic purpura (TTP). Renal biopsy revealed class V lupus nephritis with TMA and glomerular endothelial injury. Interestingly, strong granular staining for VWF was observed along the glomerular capillary loops. After administration of glucocorticoid, TTP findings quickly improved. Case 2 was a 41-year-old woman with a history SLE for ten years. Thrombocytopenia, hemolysis and AKI developed in association with a relapse of SLE, but ADAMTS13 activity was normal. Renal biopsy showed lupus nephritis class IV+V with TMA lesions, but there was no staining for VWF in contrast to Case 1. The patient was treated with glucocorticoid and plasmapheresis with a good response.

Conclusions: From these results, it is suggested that VWF may be involved in the development of renal TMA in patients with lupus nephritis associated with TTP, but not in those with renal TMA from unknown causes other than TTP.

PUB282

The Clinicopathologic Study of Renal Diseases in High Altitude Population Zhangxue Hu, Jiachuan Xiong, Zhaoxia He, Ping Fu, Ye Tao. *Dept of Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: Little is known about the renal biopsy spectrum of high altitude patients with kidney disease. It is unknown whether high altitude affect the structure of the kidney, too. This study aimed to analyze renal disease spectrum in patients living in high altitude area, and to explore the effect of high altitude on kidney.

Methods: We retrospectively enrolled 111 patients from high altitude area(mainly from Tibet), who underwent renal biopsy in West China Hospital since January,2012 to December, 2012. Thirty MCD patient from normal altitude area were also included. Demographic and clinical information were collected from each patient's clinical record. The glomerular volume and thickness of glomerular basement membrane(GBM) were measured in 41 patients diagnosed minimal chang disease(MCD) and IgA nephropathy(Lee classification 1 grade, M0E0S0T0) from high altitude area and 30 MCD patient from normal altitude area.

Results: In this study, membranous nephropathy (24.3%) was the most common diagnosis in the primary glomerular diseases. Henoch-Schoenlein purpura nephritis (10.8%) accounted the most frequent in the secondary glomerular diseases while lupus nephritis was second cause. High altitude patients have a high prevalence of hyperuricemia and hypertension. Although there was no difference of the glomerular volume between patients with MCD or mild IgAN from high altitude area and those from normal altitude area ($P = 0.27$), GBM was significantly thicker than those from normal altitude area ($P = 0.005$).

Conclusions: There are differences in renal disease spectrum between high altitude population and normal altitude population. Lupus nephritis is not the leading cause in secondary glomerular diaseses. GBM was thicker in high altitude population compared to normal altitude population, which could be the early change caused by high altitude. Further detailed study should be conduct to clarify the mechanism how high altitude circumstances affect renal structure and function.

PUB283

Endothelial Nitric Oxide Synthase Gene Expression Is Associated with Hypertension in Autosomal Dominant Polycystic Kidney Disease

Ismail Kocyigit,[1] Serpil Taheri,[2] Elif Funda Sener,[2] Aydin Unal,[1] Eray Eroglu,[3] Fahir Ozturk,[3] Kezban Korkmaz,[4] Murat H. Sipahioglu,[1] Bulent Tokgoz,[1] Oktay Oymak.[1] *[1]Dept of Nephrology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [2]Dept of Medical Biology, Erciyes Univ Medical Faculty, Kayseri, Turkey; [3]Dept of Internal Medicine, Erciyes Univ Medical Faculty, Kayseri, Turkey; [4]Dept of Medical Genetics, Erciyes Univ Medical Faculty, Kayseri, Turkey.*

Background: Early occurrence of hypertension is the prominent feature of autosomal dominant polycystic kidney disease (ADPKD). The role of angiotensin converting enzyme (*ACE*) gene polymorphism and endothelial nitric oxide synthase (*eNOS*) gene polymorphism on the clinical course ADPKD has not been well understood. Thus, we aimed to investigate both *ACE* and *eNOS* genes polymorphisms and expressions that affect hypertension in ADPKD.

Methods: ACE and eNOS gene polymorphism and their expressions were analyzed in 78 ADPKD patients and 30 controls. The 24-hour blood pressure monitoring was performed for the diagnosis of hypertension in all study participants.

Results: In ADPKD patients, *eNOS* expression and eGFR were found statistically higher in patients without hypertension compared to hypertensive ADPKD patients. Each unit of the increase in *eNOS* expression led to a 0.88fold decrease (95%CI, 0.80-0.96) in multiple logistic regression analysis.

Conclusions: *eNOS* gene expression is independently predicting hypertension in ADPKD population. This study, for the first time, showed a novel link between *eNOS* gene expression and hypertension in ADPKD.

PUB284

Development of ADPKD Cell Lines and CXCL12 Up-Regulation in ADPKD

Sun Ae Han,[1] Joon Young Jang,[1] Ah-Young Kang,[1] Hayne C. Park,[2] Chang-Seok Ki,[3] Young-Hwan Hwang,[4] Curie Ahn.[1,2] *[1]Transplantation Research Institute, Seoul National Univ Medical Research Center, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ Collage of Medicine, Seoul, Korea; [3]Dept Laboratory Medicine and Genetics, Samsung Medical Center, Seoul, Korea; [4]Dept of Internal Medicine, Eulji General Hospital, Seoul, Korea.*

Background: Human primary cells or tissues are also good tools for studying autosomal dominant polycystic kidney disease (ADPKD). Each cyst from one patient is thought to have a different somatic mutation, developing various ADPKD cell lines with a different cyst origin is necessary to understand heterogeneous nature of the disease.

Methods: Primary cells were obtained from several single cysts of 1-3 cm in diameter were transfected with a plasmid pRNS-1 and the SV40 large T antigen by lipofectamine. After establishment of cell lines, expression of SV40 antigen and cytokeratin was identified by immunocytochemistry. cDNA microarray was performed using Agilent SurePrint G3 Human GE 8x60K array and results were analyzed using GeneSpring GX 7.3.1. Candidate genes were validated by using Western blot and immunohistochemistry (IHC).

Results: Three normal cell lines and 6 ADPKD cell lines were established. All of our ADPKD cell lines were found to be LTL-positive and DBA-negative indicating proximal tubule origin. Germline and somatic mutations in PKD1 were identified by direct sequencing of genomic DNA from blood paired with cell lines. In microarray analysis, commonly changed genes in ADPKD cell lines with greater than 2 fold changes were total 842 genes: 319 up-regulated and 523 down-regulated ($p<0.01$). We found top 25 up- and down-regulated genes in ADPKD cell lines compared to nRTEC cell lines. Among them, CXCL12 and CXCR4/7 were examined as a possible candidate pathway. Expression of CXCL12 significantly increased in ADPKD by Western blot and IHC.

Conclusions: All of our PKD cell lines were found to have PKD1 gene defects, and originated from proximal tubules. This study showed up-regulation of CXCL12 in ADPKD, and further study will be required to show its possibility as a therapeutic target for ADPKD.

PUB285

Patient Experience with Pain Related to Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Dorothee Oberdhan,[1] Andrew C. Palsgrove,[2] Jason C. Cole,[2] Jaime Blais,[1] Rebecca Cheng.[2] *[1]Otsuka Pharmaceutical Development and Commercialization, Rockville, MD; [2]Covance Inc., San Diego, CA.*

Background: ADPKD leads to kidney enlargement and worsening kidney function due to cyst development, expansion, infection, and rupture, increasing patients' need for medical care. Patients with ADPKD typically experience pain related to these symptoms (Gabow 1991 and Grantham 1992). The pain experienced by ADPKD patients is complex and multifaceted with acute and chronic episodes which complicates adequate characterization. As a result the ADPKD Pain and Discomfort Scale (ADPKD-PDS) was developed to help assess disease impact and treatment effectiveness as well as inform treatment decisions.

Methods: Focus groups with adult ADPKD subjects (N = 168) and interviews with adolescent ADPKD subjects (N = 22) were performed across Europe, North America, South America, Australia, and Asia. In these interactions, disease symptoms and impacts of ADPKD-related pain on a patient's daily life were discussed.

Results: Adult patients consistently reported three distinct types of ADPKD-related pain: dull pain in the lower back or waist, sharp pain in the kidneys, and fullness or discomfort. They described that pain interfered with routine and leisure activities, relationships, mood, physical activities, and sleep. Adolescents primarily reported the impact of pain and discomfort on their daily activities including physical activities like playing sports, anxiety about their future, and decreased school attendance. Overall pain reported by adolescents was similar in nature to adults but the frequency of their symptoms was more intermittent.

Conclusions: Pain is an important symptom of ADPKD with measurable impacts on the daily lives of adult and adolescent patients. Increasing the understanding of this ADPKD-specific pain and its impact on health related quality of life through the development of tools like patient-reported outcome questionnaires could facilitate the assessment of treatment effectiveness and inform treatment decisions. Such a tool, the ADPKD-pain and discomfort scale, is currently under development.

PUB286

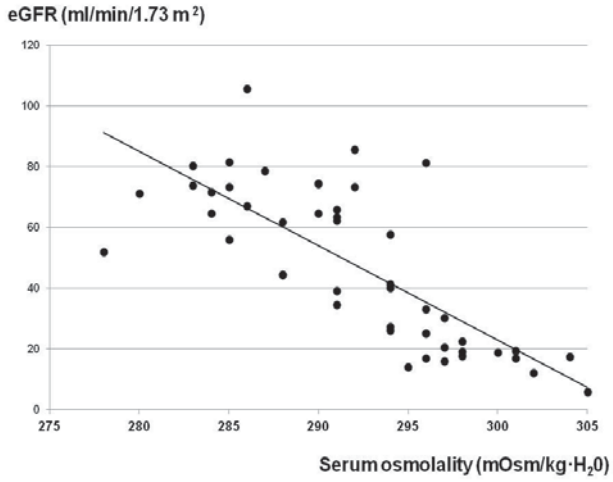
Serum Osmolality Has Much More Effective as Biomarker of Renal Function Than Urine Cyclic AMP or Copeptin in ADPKD Patients

Satoru Muto,[1] Yan Lu,[1] Haruna Kawano,[2] Masaki Kimura,[1] Keisuke Saito,[1] Shuji Isotani,[1] Hisamitsu Ide,[1] Raizo Yamaguchi,[1] Shigeo Horie.[2] *[1]Urology, Teilyo Univ, Tokyo, Japan; [2]Urology, Juntendo Univ, Tokyo.*

Background: In Japan, the novel treatment of V2R antagonist for ADPKD was started at a month ago. In this era, we have a great desire for precise and easy-to-use biomarker of progression of disease associated with arginine vasopressin-cyclic AMP pathway. However, it is unknown whether copeptin concentration is associated with disease severity in patients with ADPKD.

Methods: Urine cyclic AMP and copeptin concentration were measured in 52 ADPKD patients (24 females and 28 males, mean age; 51.8 years) by an immunoassay. Plasma and urinary osmolarity were also measured. To assess disease severity, we compared these markers with BUN, serum Cr, cystatin C, eGFR and total renal volume by magnetic resonance imaging predicted from the conventional ellipsoid method.

Results: The median eGFR and cystatin C were 48.3 ml/min/1.73 m^2 (range; 5.4-105.8) and 1.34 mg/l (range; 0.72-4.81), respectively. The median kidney volumes (TKV) were 1099.8 ml (range; 38.1-16298.2). Although Urine cyclic AMP/urine Cr and copeptin concentration were not significantly correlated with eGFR (cyclic AMP; R^2=0.474, p=0.107, copeptin; R^2=0.427, p=0.218) and TKV (cyclic AMP; R^2=0.132, p=0.273, copeptin; R^2=0.200, p=0.537), serum osmolality was significantly correlated with serum Cr (R^2=0.641, p=0.001), cystatin C (R^2=0.651, p=0.001) and significantly inversely correlated with eGFR (R^2=-0.140, p=0.004).



Conclusions: Although, prognostic and diagnostic properties of copeptin were recently reported in ADPKD patients as a marker of endogenous AVP secretion, serum osmolality may have much more effective as biomarker of renal function than copeptin in ADPKD patients.

PUB287

Clinical Characteristics and Disease Predictors of a Large Chinese Cohort of Patients with Autosomal Dominant Polycystic Kidney Disease

Changlin Mei,[1] Rudolf P. Wuthrich,[2] Shengqiang Yu,[1] Dongping Chen,[1] Yiyi Ma.[1] *[1]Dept of Nephrology, Shanghai Changzheng Hospital, Shanghai, China; [2]Div of Nephrology, Univ Hospital, Zürich, Switzerland.*

Background: The aim of this study was to characterize Chinese patients with autosomal dominant polycystic kidney disease (ADPKD) and to identify the factors which predict the disease progression.

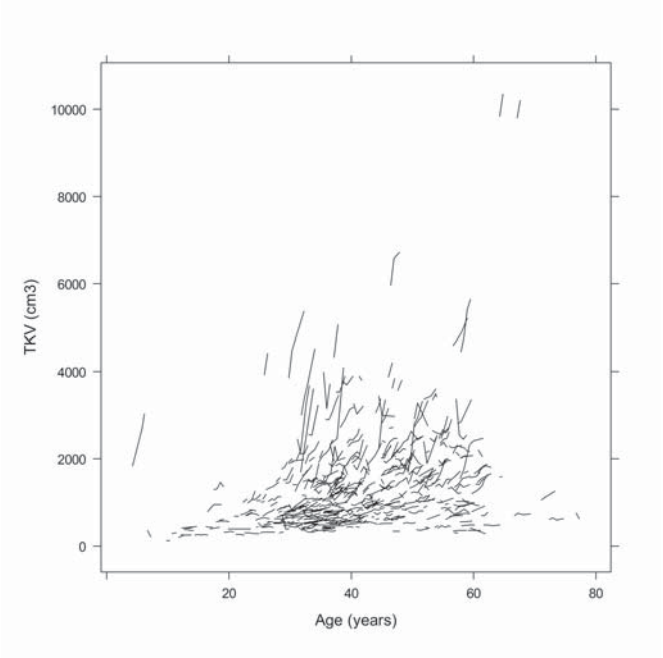
Methods: A prospective longitudinal observational study in a cohort of 541 Chinese patients with ADPKDwas performed. Patients were followed clinically and radiologically with sequential abdominal magnetic resonance imaging (MRI). Clinical characteristics

and laboratory data were related to changes in estimated glomerular filtration rate (eGFR) and total kidney volume (TKV). A linear regression model was developed to analyze the risk factors.

Results: The age range of this unselected cohort ranged from 4 to 77 years. Baseline parameters are listed in table 1.

Characteristics	N	Total
Age (years)	541	39.7±12.1
Height (cm)	539	167.5±9.7
History of hypertension	531	67.2%
Family history for ADPKD	509	75.4
eGFR(ml/min/1.73m)	502	100.4±20.1
Yearly eGFR change(ml/min/1.73m)	416	-0.9±9.6
TKV(cm^3)	532	1265±1002
Yearly TKV growth	421	4.6±10.2%
Protein creatinine ratio	324	0.21±0.32

Median follow-up time was 14.3±10.6 months. Spaghetti plot for TKV over time in individual patients is showed in figure1.



There was a consistent link between eGFR and TKV. Baseline log10-transformed TKV and urinary protein/creatinine ratio were identified as the major predictors for a faster eGFR decline and a higher TKV growth rate. Interestingly, a lower thrombocyte count correlated significantly with lower eGFR (r=0.222) and higher TKV (r=0.134).

Conclusions: This large cohort of Chinese patients with ADPKD provides unique epidemiological data for comparison with other cohorts of different ethnicity.

PUB288

Plasma Pentraxin3 and Arterial Stiffness in Autosomal Dominant Polycystic Kidney Disease Abdulmecit Yildiz,[1] Cuma Bülent Gül,[2] Nimet Aktas,[3] Osman Z. Sahin.[4] *[1]Uludag Univ Medical School, Bursa, Turkey; [2]Sevket Yilmaz Research and Training Hospital, Bursa, Uganda; [3]Bilecik State Hospital, Bilecik, Turkey; [4]Recep Tayyip Erdogan Univ Medical School, Rize, Turkey.*

Background: Cardiovascular disease is leading cause of morbidity and mortality in patients with Autosomal dominant polycystic kidney disease (ADPKD), with over 80% of deaths attributable to coronary artery disease. Pentraxin3 (PTX3), a recently discovered inflammatory mediator, is produced abundantly in various cells in atherosclerotic lesions, and therefore, its plasma level could reflect local inflammation at the site of atherosclerotic lesion. The present study evaluated PTX3 levels in in the early stage of ADPKD and sought their association with arterial stiffness.

Methods: 54 ADPKD patients with preserved renal functions and 26 healthy subjects were included. Arterial elasticity was assessed and serum PTX3 level was measured. Comparison of the groups was performed with Student t or Mann Whitney U test and correlation analysis was done with Pearson or Spearman test as needed.

Results: In the ADPKD group, 23 patients were hypertensive (HT). The mean levels of PTX3 were higher in ADPKD patients compared to controls. PTX3 levels were similar in HT-ADPKD and normotensive (NT)-ADPKD patients (n=31). Large and small vessel compliances (C1 and C2, respectively) were lower in the ADPKD patients compared to controls. NT-ADPKD patients had lower C2 and tended to have lower C1 compared to controls. HT-ADPKD patients tended to have lower C1 and C2 compared to controls. HT-ADPKD and NT-ADPKD patients had similar) arterial function values. There was no correlation between arterial elasticity parameters and PTX3 levels.

Conclusions: Vascular inflammation that is evaluated with PTX3 is evident in ADPKD patients with preserved renal function, however vascular inflammation is not associated with arterial stiffness in ADPKD.

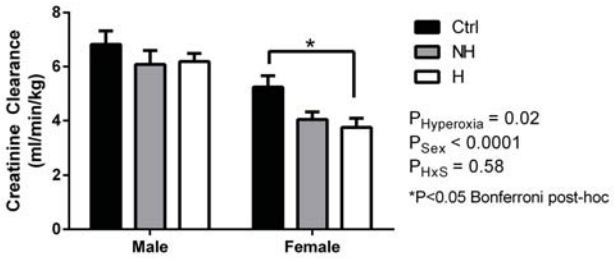
PUB289

The Long-Term Impact of Neonatal Hyperoxia Exposure on Renal Function Megan R. Sutherland,[1,2] Marie-Amélie Lukaszewski,[1,2] Anik Cloutier,[1,2] Mariane Bertagnolli,[1,2] Anne Monique Nuyt.[1,2] *[1]CHU Sainte-Justine Research Center, Montréal, QC, Canada; [2]Univ of Montréal, Montréal, QC, Canada.*

Background: Neonates born preterm are exposed to high oxygen levels relative to the intrauterine environment, when nephrogenesis is ongoing. We have previously shown that hyperoxic gas exposure impairs renal development in neonatal rats and results in a reduced nephron number in adulthood. The aim of this study was to determine the long-term effects of neonatal hyperoxia exposure on renal function.

Methods: Hyperoxia-exposed Sprague-Dawley pups were raised in 80% O_2 from P3 - P10 (H; n=8 litters). To prevent maternal O_2 toxicity, H dams were interchanged every 12 hours with a dam with pups raised in room air (NH; n=8 litters). Control litters were kept in room air (Ctrl; n=8 litters). At 1, 5, and 11 mo (1 male and 1 female /litter/age), animals were placed in metabolic cages with urine collected for 16h overnight; plasma and kidneys were collected the following day.

Results: There was no difference in body or kidney weights between groups. Hyperoxia exposure resulted in a significantly reduced urine output in animals at 5mo of age, but not at 1mo or 11mo. There was no difference in creatinine clearance (Cl_{Cr}) between groups at 1mo and 11mo; at 5mo, however, Cl_{Cr} was significantly reduced following hyperoxia exposure (Figure 1). There was also a trend at 5mo for increased fractional sodium excretion (p=0.09). Urine albumin/Cr levels increased with age, but there was no difference between groups.



Conclusions: In younger and older rats (likely with lower renal functional demand), kidney function was not significantly affected by neonatal hyperoxia exposure. Importantly, however, there was an adverse impact on creatinine clearance at 5 months of age. Overall, these findings suggest that individuals exposed to high oxygen levels during development may have a reduced renal functional capacity in adulthood.

Amniotic Fluid Stem Cells Transplantation in the Fetal Kidney to Regenerate Nephrons Loss during Nephrogenesis Luc Behr,[1] Sebastien Sammut,[1] Mehrak Hekmati,[1] Agnieszka Anna Ksiazek,[4] Benedikt Weber,[4] Martine D. Lelievre-Pegorier,[2] Kathleen Laborde.[3] *[1]IMMR, Paris, France; [2]INSERM U872, Paris, France; [3]Necker Hospital, Paris-5 Univ, Paris, France; [4]Swiss Center for Regenerative Medicine, Zurich, Switzerland.*

Background: Amniotic fluid stem (AFS) cells are pluripotent and harbour the potential to differenciate upon renal lineages and contribute to the development of primordial kidney structures. The aim of the present study was to investigate AFS cells contribution to the formation of renal tissue when placed in a kidney context of relevance for regenerative medicine, during the window of active nephrogenesis, in a model of subtotal nephrectomy in the fetal sheep.

Methods: Ovine amniotic fluid-derived stem cells (AFSd) were isolated, labelled with GFP and selected using cell surface marker c-kit. When cultured in the absence of LIF, AFSd formed embryonic bodies which cultured in an optimized medium generated renal progenitor population, expressing PAX-2 (AFSr). Subtotal nephrectomy (5/6NX) was performed at 70 days of gestation in 11 fetal lambs among which 5 were treated with intra-renal injection of AFS in the caudal (AFS) and cranial (AFSr) kidney poles. Control fetuses were sham-operated and did not received AFS (SHAM, n=5). At 134 days of gestation, the fetuses were euthanized, the kidneys removed and processed.

Results: Among the fetuses, 3 died before 134 day, one (1/6) in the 5/6NX and 2 (2/5) in the 5/6NX+AFS group. Body weight did not differ significantly between the different groups. Compensatory renal growth was observed in all 5/6NX fetuses, displaying in all cases the striking budding pattern previously described. In spite of AFS injection, catch-up growth was similar in the 5/6NX+AFS and the 5/6NX groups (SHAM: 2.7±0.4; 5/6NX: 4.7±2; 5/6NX+AFS: 5.52±1.44 KW/BW). Renal cranial and caudal budding sizes were similar, and not related to the differenciation status of the AFS injected. GFP cells were present in the kidney parenchyma and appeared integrated in the renal structures.

Conclusions: Amniotic fluid-derived stem cells may represent a potentially source of cells for kidney regeneration but do not seem to restore completely kidney damage, even when injected during nephrogenesis.

Reno Protective Activity of Esculetin in Insulin Resistant and Type 2 Diabetic Rats

Almesh Mallappa Kadakol, Santosh Kumar Goru, Anuradha Pandey, Anil Bhanudas Gaikwad. *Pharmacy, BITS Pilani, Pilani, Rajasthan, India.*

Background: Diabetic nephropathy is the leading cause among the all renal failure in patients. There is a need of better therapeutic agent to prevent initial causes and further worsening of renal failure under type 2 diabetic conditions. Several attempts have been made to improve existing treatment hence, in this study Esculetin which has been recognized as inhibitor of lipoxygenase was used as a therapeutic intervention against type 2 diabetic nephropathy.

Methods: Insulin resistance and Type 2 diabetes was induced by High Fat Diet (HFD) feeding and low dose (35mg/kg, *i.p.*) of Streptozotocin in Wistar rats (140g-150g). In brief, animals were grouped into normal control, high fat diet control, diabetic control and diabetic control treated with Esculetin. The rats were allowed to feed on HFD till end of the study (24 weeks). Rats were treated with Esculetin 50 and 100 mg/kg/day, *per oral* and control with Vehicle (0.5% sodium carboxy methyl cellulose) for 7 days prior to end of the study. Body and organ weights were measured and different biochemical estimations to access insulin resistance, diabetes and diabetic nephropathy were carried out at the end of study.

Results: High fat diet control developed insulin resistance, whereas high fat diet fed animals treated with low dose of STZ exhibited the type 2 diabetes. There was a significant increased in blood urea nitrogen (BUN) level in insulin resistant animals compared to normal control animals. Treatment with Esculetin to diabetic animals was resulted in significant reduction in BUN (18.96±0.37 to 6.52±0.50mmol/l, $p<0.05$) and PCr (11.37±0.05 to 2.42±0.04mg/dl, $p<0.05$), and increase in PA (18.48±1.44 to 37.68g/l, $p<0.05$) levels compared to diabetic control. Further, two folds of the kidney weight and kidney/body weight ratio were also reduce. In addition, the level of MDA (15.73±1.04 to 9.492±0.83, $p<0.001$) was reduced and the level of GSH (1.475±0.21 to 7.420±0.73µg/mg protein, $p<0.001$) level was increased in Esculetin treated HFD+STZ rat kidney compared to HFD+STZ rats.

Conclusions: These observations demonstrated that 100mg/kg dose of Esculetin has better reno protective activity.

The Effect of Nigella Sativa Extract on Diabetic Nephropathy

Rumeyza Kazancioglu, Banu Buyukaydin, Siddika Kesgin, Elif Kilic, Mehmet Zorlu, Muharrem Kiskac, Abdurrahim Kocyigit. *Bezmialem Vakif Univ, Istanbul, Turkey.*

Background: *Nigella sativa* has been studied for its biological impacts and therapeutic potential. We investigated the possible renoprotective effects of this plant seeds on diabetic nephropathy.

Methods: Male Sprague-Dawley rats were randomly divided into:Group1;diabetes (6), group2;diabetes+*N.sativa* (8), group3;only *N.sativa.* (8) and group4;control (8). Diabetes was induced by streptozotocin. 50g *N.sativa* seed was subjected with methanol for 24 hours at 40°C. Methanol was evaporated and extract was obtained with lyophilization at -85°C. Diluted extract was administered 200mg/kg/day i.g for 5 weeks. Serum glucose, urea and creatinine were measured before extract administration and sacrification.Transforming Growth Factor Beta (TGF-β_1)(pg/ml), type IV collagen(ng/ml), superoxide dismutase(ng/ml) and hydroxyproline(ng/L) were measured in the obtained tissue by Elisa.

Results: Glucose and urea levels did not change in all groups throughout the study. Serum creatinine was significantly decreased in groups 3 and 4. Results of tissue parameters and variations between groups are presented in Table1

Effects of SAA and AGE to Activate PKC-β-Mediated Podocyte Inflammation and Apoptosis

Rick L. Meek,[1] Robert J. Anderberg,[1] Sheryl K. Cooney,[1] Katherine R. Tuttle.[1,2] *[1]Providence Sacred Heart Mediacal Center and Children's Hospital, Spokane, WA; [2]Div of Nephrology, Univ of Washington School of Medicine, Spokane and Seattle, WA.*

Background: Serum amyloid A (SAA) is increased in the kidneys of humans and mice with diabetic kidney disease (DKD). Advanced glycation end-products (AGE) are metabolic mediators of DKD that produce glomerular damage by podocyte injury and loss. Protein kinase-beta (PKC-β), a central signal for cellular inflammation and death, is activated by ligand engagement with the receptor for AGE (RAGE). The aim of this study was to determine if SAA mediates podocyte inflammatory and apoptotic responses by activation of PKC-β in a manner similar to AGE.

Methods: Mouse podocytes were cultured with human SAA protein or AGE. β-isoform specific (LY-379198) and general (calphostin C) PKC inhibitors were added to media at 100 nM. Inflammatory mediator mRNA expression (SAA3, Cxcl5, Ccl5, Ccl2) was assessed by RT-PCR after 24 hours. Apoptosis was measured by TUNEL assay after 48 hours. PKC-β activation was measured by phosphorylation.

Results: PKC-β inhibition reduced SAA-induced SAA and Cxcl5 mRNA (51±17 %, 68±19 % relative to control; both $p<0.001$, n=8). General, but not PKC-β, inhibition reduced SAA-induced Ccl2 (54±15 % relative to control; $p<0.001$, n=8). However, Ccl5 was not reduced by either inhibitor. PKC-β inhibition reduced AGE-induced mRNA for SAA3, Cxcl5, Ccl2, and Ccl5 (25±15 % relative to control, p=0.019; 75±6 %, $p<0.001$; 27±16 %, p=0.017; 44±20 %, p=0.004, n=6-8). SAA- and AGE-induced podocyte apoptosis were reduced by PKC-β inhibition (93±2 % relative to control, p=0.005; 62±10 %, $p<0.001$, n=6). Phosphorylated-PKC-β was increased by both SAA and AGE.

Conclusions: PKC-β mediated up-regulation of 2 of 4 inflammatory mediators in podocytes exposed to SAA, whereas AGE-induced expression of all 4 mediators was at least partly-dependent on PKC-β. Both SAA and AGE-induced apoptosis were highly-dependent on PKC-β. Effects of SAA and AGE to activate PKC-β-mediated podocyte inflammation and apoptosis are similar but not identical, indicating that SAA acts via pathways that are not entirely comparable to AGE-RAGE interactions.

PUB294

PPARα/γ Agonism Confers Partial Improvement in the BTBRob/ob Mouse Model of Diabetic Nephropathy

Anette E. Ericsson,[1] Pernilla Håkansson,[1] Ann-Katrin Andersson,[1] Ann-Cathrine Jönsson-Rylander,[1] Gerhard Bottcher.[2] *[1]Bioscience, AstraZeneca R&D Molndal, Molndal, Sweden; [2]Pathology, AstraZeneca R&D Molndal, Molndal, Sweden.*

Background: The BTBRob/ob mouse model have been shown to mimic progressive albuminuria and morphologic lesions of advanced human diabetic nephropathy (DN). The enalapril renoprotective effect is limited in the BTBRob/ob mouse whereas leptin replacement was found to reverse damage (1).

Methods: To further investigate renoprotection and improved metabolic control in BTBRob/ob mice the PPARα/γ agonist AZD6610 (10.25mg/kg diet, n=8) were used from 17 to 24 weeks of age and compared with BTBRob/ob without treatment (n=12) or with enalapril treatment (200mg/l water, n=7) from 14 to 24 weeks of age. Lean BTBR mice were used as healthy controls (n=5).

Results: AZD6610 significantly lowered plasma glucose (median 11.3 versus 23.8mM) and triglycerides (median 1.0 versus 2.0mM), and increased liver growth (median 6.5 versus 4.0g) in BTBRob/ob. Urine albumin excretion rate (UAER) at 24 weeks age was increased in BTBRob/ob compared to lean controls (median 1206 versus 39µg/13h). AZD6610 had no effect on UAER whereas enalapril appeared to lower UAER but this did not reach statistical significance. In contrast, morphological semi-quantitative assessment of glomerula demonstrated mesangial matrix expansion in BTBRob/ob that was reduced by AZD6610 treatment but not by enalapril. Immunohistochemical podocyte markers nephrin and WT-1 showed a reduction in BTBRob/ob, but neither enalapril or AZD6610 treatment improved these markers. Furthermore, an expected but slight increase (+10%) in thickness was observed in the glomerular basement membranes in the BTBRob/ob, with no treatment effects.

Conclusions: PPARα/γ agonism improves metabolic control and reduces mesangial matrix expansion, but without positive effects on albuminuria or immunohistochemical podocyte markers. We have reproduced the previously reported effects of enalapril in this mouse model (1) and show that late intervention with PPARα/γ agonism can only partially improve hallmarks of DN.

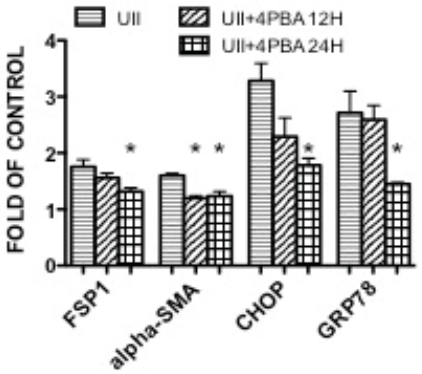
Urotensin II Can Induce EMT via Triggering Endoplasmic Reticulum Stress in Diabetic Nephropathy Aihua Zhang, Qiong Bai, Minhua Fan. *Dept of Nephrology, Peking Univ Third Hospital, Beijing, China.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease. Urotensin II (UII) and its receptor are highly expressed in the kidney tissue of patients with DN. We presume that UII may cause endoplasmic reticulum (ER) stress. This will in turn induce Epithelial-Mesenchymal Transition (EMT) in renaltubular epithelial cell of DN, which can eventually cause renal tubule injury and interstitial fibrosis.

Methods: Kidney tissues were collected from ten diabeticnephropathy patients and ten healthy control subjects. The expression of UII, UII receptor (GPR14), CHOP, and GRP78 in kidney were detected by immunohistochemistry. HK-2 cells in vitro were cultured and treated with different concentrations of UII, UIIcombined with antagonist of ER stress (4PBA), and PBS solution. Markers of ER stress,CHOP and GRP78, and markers of EMT,α-SMA and FSP1,were then detectedby real-time PCR.

Results: UII,UII receptor (GPR14), GRP78, and CHOP were highly expressed in the kidney tissue of DN than those of normal healthy controls, which were mainly localized in renal tubulointerstitium. Expression of UII was positively correlated with the expression of CHOP and renal fibrosis in DN patients' kidney tissue. In HK-2 cells, the amount of UII present was shown to correspond to the level of induced ER stress and EMT. 4PBA, an antagonist of ER stress, can inhibit the mRNA expression of α-SMA and FSP1 when UII was incubated with HK-2 cells.ID tag.



Conclusions: We first verify the expression of UII and its receptor are positively correlated with ER stress and renal fibrosis in DN, UII can trigger ER stress pathway which will induce EMT in renal tubular epithelial cell in vitro. ER stress pathway of renal epithelial cell may be involved in the UII induced renal fibrosis in DN.

PUB296

CCR2+ Inflammatory Monocytes Contribute to Early Graft Dysfunction of MHC Mismatched Islet Transplants Ke Vin Chow,[1,2,3] Robyn M. Sutherland,[1] Yifan Zhan,[1] Andrew M. Lew.[1] *[1]Immunology, Walter and Eliza Hall Institute of Medical Research, Parkville, Victoria, Australia; [2]Medical Biology, Univ of Melbourne, Parkville, Victoria, Australia; [3]Nephrology, Royal Melbourne Hospital, Parkville, Victoria, Australia.*

Background: Islet transplantation provides a potential cure for patients with type 1 diabetes, and is associated with reduced long-term complications and improved quality of life. Despite this, its use is limited by a lack of supply of donor organs and issues with poor primary engraftment. CCR2+ monocytes are actively involved in the inflammatory response and are capable of differentiating into monocyte derived dendritic cells, which may play a role in islet transplantation.

Methods: To determine the role of CCR2+ monocytes in this setting, we transplanted 400 MHC mismatched islets from BALB/C mice (H-2d) under the kidney capsule of C57BL/6 hosts (H-2b). Host mice had been genetically modified to express the primate diphtheria toxin receptor under the control of the CCR2 promoter (CCR2.DTR) allowing for diphtheria toxin induced conditional depletion of CCR2+ cells. Host mice were rendered diabetic by the administration of streptozotocin prior to transplantation. Nine doses of diphtheria toxin 20 ng/g (DT+) (n=10) or normal saline (control) (n=9) were administered between day -4 and day 15. Graft function was determined by measuring blood glucose (BG) via tail bleed.

Results: DT+ mice showed complete absence of CCR2+ monocytes in peripheral blood with normal populations of CD4+ T cells, CD8+ T cells, CD19+ B cells and Ly6G+ neutrophils. Pre-transplant BGs between DT+ and control mice were equivalent (27.0 ± 1.3 mmol/L versus 29.6 ± 1.1 mmol/L, P = 0.159). DT+ mice achieved higher rates of normoglycemia than control mice at day 1 (11.0 ± 1.8 mmol/L versus 19.1 ± 1.4 mmol/L, P = 0.004) and day 3 (7.1 ± 0.8 mmol/L versus 15.4 ± 2.0 mmol/L, P = 0.003). Despite this, there was no significant difference in long-term graft survival between the two groups.

Conclusions: CCR2+ monocytes appear to be involved in an innate immune response that mediates early graft dysfunction of transplanted islet allografts. Further studies are required to determine the mechanism of this effect and the role of these cells in the adaptive immune response.

PUB297

Diabetic Nephropathy Is Attenuated after 8 Weeks of Resistance Exercise Training (RET) Kleiton Augusto Santos Silva,[1] Luciana Jorge,[1] Rafael Luiz,[1] Rodolfo Rosseto Rampaso,[1] Ralmony Santos,[2] Tatiana Sousa Cunha,[2] Nestor Schor.[1] *[1]Medicine, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Science and Technology Institute, Federal Univ of Sao Paulo, Sao Jose dos Campos, SP, Brazil.*

Background: Kidney is impaired in Diabetes mellitus condition. RET normally used against skeletal muscle atrophy has unclear effects on kidney function and thus, we assessed kidney from diabetic rodents under RET.

Methods: Wistar rats were submitted to RET (50 – 80% of maximal load test). After diabetes establishment (Streptozotocin, 50 mg/kg i.v.), animals were divided into four groups. Two control groups (non-exercised and exercised) and two diabetic groups (non-exercised and exercised) in 4 – 6 rats/group. We measured parameters as body weight and proteinuria; we also measured protein level by Western blot and multiplex technology assay.

Results: It was found that RET does not protected skeletal muscle from atrophic process in exercise diabetic group. Extensor digitorium longus weight – EDL were: 0.36±0.20 mg/g versus 0.33±0.53 mg/g ($p>0.05$) in non-exercised and exercised diabetes groups, respectively. Additionally, maximal load test demonstrated no significant different among diabetic groups. Regarding kidney, it was found that KW was preserved in exercised diabetic animals (5.7±2.72 mg/g diabetic versus 4.7±2.01 mg/g exercised diabetic, $p<0.05$); moreover, proteinuria was lower in exercised diabetic group compared to diabetic group ($p<0.05$) and podocin expression was increased in exercised diabetic animals. We assessed the mTOR signaling pathway and found significant decreases in PI3K, p-Akt and p-4EBP1 in exercised diabetic animals ($p<0.05$). Additionally, we found that TGFβ-1 was markedly decreased in exercised diabetic animals (437±13 pg/mL diabetic versus 325.8±21 pg/mL exercised diabetic, $p<0.05$).

Conclusions: Kidney may be functionally protected and mTOR signaling pathway plays important role on renal environment. However, skeletal muscle might have no improvement under this program. Thus, a different effects under RET affect skeletal muscle and kidneys but since a decrease in proteinuria was observed, a potential protection against progression of diabetic nephropathy with RET could be a strategic complementary therapy.

PUB298

Advanced Glycation End Products Impaired Diabetic Muscle Function via AMP-Activated Protein Kinase-Mediated Muscle Atrophy Signaling Pathway Chih-Kang Chiang,[1,2,3] Chen-Yuan Chiu,[1] Yuan-Siao Chen,[2] Shing-Hwa Liu.[1] *[1]Graduate Institute of Toxicology, National Taiwan Univ, College of Medicine, Taipei, Taiwan; [2]Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan; [3]Dept of Integrated Diagnostics and Therapeutics, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Advanced glycation end products (AGEs) are the etiology of Diabetes mellitus (DM)-related complications via crosslinking proteins and tissue accumulation. DM has become near a half the primary etiology of incident dialysis. AGEs-induced muscle weakness or wasting has become a critical issue in maintenance dialysis patients. Here, we investigated whether the AGEs accumulation impaired diabetic skeletal muscle function.

Methods: Adult male ICR mice were peritoneally injected with 100 mg/kg streptozotocin to induce type 1 DM. The expression of AGEs in the soleus muscles were determined by immunohistochemistry. Muscle function was examined by the fatigue task using a Rota-Rod, and we also measured the weights of gastrocnemius muscles and soleus muscles in glycerol-induced muscle injury. Moreover, the C2C12 myoblast-differentiated myotubes were used to test the *in vitro* effects of AGEs. The myotubes were determined morphologically by H&E staining. The expressions of proteins (Atrogin-1, MuRF-1, phospho-Akt, phospho-FoxO3a, phospho-AMPK) were determined by Western blotting.

Results: Diabetic mice with/without intra-muscular injection of glycerol had less skeletal muscle mass and lower muscular endurance. To explore the mechanism of AGEs on skeletal muscle atrophy, the myotubes were exposed to AGEs in the differentiation media for 48 h. AGEs significantly and dose-dependently reduced numbers and diameters of C2C12 myotubes at 48 h. As expected, AGEs stimulated AMPK and the muscle atrophy-related protein expressions (Atrogin-1, MuRF-1, phospho-FoxO3a), and inhibited the muscle hypertrophy-related protein expression (Akt phosphorylation).

Conclusions: Modulation of AMPK is linked to AGEs accumulation and AGEs-related impaired diabetic skeletal muscle function. We concluded that AGEs may up-regulate AMPK expression via an atrophy-related signaling pathway, leading to induction of diabetic muscle wasting.

Atrasentan, a Specific ET-A Blocker, Improves Podocytes Survival and Ameliorates Diabetic Kidney Glomerular Injury in the db/db Mouse

Syed K. Haque,[1] Minghao Ye,[1] Jan A. Wysocki,[1] Jonathan Chou,[2] Yashpal S. Kanwar,[1] Amani Fawzi,[2] Daniel Batlle.[1] *[1]Div of Nephrology and Hypertension, Feinberg School of Medicine, Chicago, IL; [2]Dept of Ophthalmology, Feinberg School of Medicine, Chicago, IL.*

Background: The endothelin(ET) system is chronically activated in diabetic nephropathy and retinopathy. We have shown that atrasentan administration to db/db mouse ameliorates the retinal vascular pathology while increasing the number of pericytes, a cell with similarities to podocytes. Here we report the effect of atrasentan on glomerular podocyte counts and glomerular injury.

Methods: Diabetic mice, 23 weeks old, were given either atrasentan or vehicle in drinking water for 8 weeks. At the end of the treatment period, kidneys were harvested for PAS staining for morphometric analysis and for WT-1 staining to perform podocyte count. Mesangial matrix expansion, glomerular cellularity and glomerular size were evaluated in PAS stained sections.

Results: In atrasentan-treated db/db mice, glomerular mesangial matrix and glomerular cellularity decreased significantly as compared to vehicle-treated db/db mice. Glomerular size decreased in atrasentan-treated db/db mice (Table). Atrasentan-treated diabetic db/db mice showed significantly higher podocyte counts per glomeruli as compared to vehicle-treated db/db mice ($p < 0.01$).Preliminary work in cultured podocytes suggests that atrasentan reduces glucose-induced apoptosis as a potential mechanism of increased podocyte survival (not shown).

Group	Db/m	Db/db	Db/db, atrasentan
Mesangial matrix expansion	1 ± 0	2.7 ± 0.3*	1.4 ± 0.2†
Glomerular cellularity	1.0 ± 0	2.1 ± 0.1*	1.3 ± 0.2†
Glomerular size	0.0031 ± 0.0001	0.0048 ± 0.0002*	0.0039 ± 0.0006≥†
Podocyte Count (per glomeruli)	13.1± 0.3	10± 0.4*	12.1± 0.4†

Conclusions: Atrasentan ameliorates glomerular diabetic lesions in the db/db mouse and has a protective effect on podocytes, similar to our finding of increased retinal pericyte counts.The dual protective effect of atrasentan for diabetic retinopathy and nephropathy involves enhanced pericyte and podocyte survival.

Down-Regulation of Transient Receptor Potential (TRP) M6 Channel as a Cause of Hypermagnesiuric Hypomagnesemia in Obese Type-2 Diabetic Rats

Kaori Takayanagi,[1,2] Taisuke Shimizu,[2] Minoru Hatano,[2] Shimpei Okazaki,[2] Naohiko Anzai,[3] Tota Kiba,[2] Yuta Kogure,[2] Yuichiro Kawai,[2] Tomonari Ogawa,[2] Akihiko Matsuda,[2] Hajime Hasegawa.[2] *[1]Ishikawa Kinenkai Kawagoe Ekimae Clinic, Kawagoe, Saitama, Japan; [2]Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan; [3]Pharmacology and Toxicology, Dokkyo Medical Univ School of Medicine, Shimotsuga, Tochigi, Japan.*

Background: Hypomagnesemia is found in 30-40% of diabetic patients and is associated with the risks of the development of insulin-resistance and the coronary artery disease. The establishment of hypomagnesemia in diabetes is principally caused by the excess excretion of Mg from kidney which is apparent even in the early nephropathy. The purpose of this study is to understand the underlying mechanism causing the increase in excretion of Mg in diabetic nephropathy, and the association with tubulo-interstitial nephropathy (TIN) that is known for the increase in excretion of Mg will be discussed additionally.

Methods: Kidneys were obtained from male OLETF (F) and LETO (L) rats of 16, 24, and 34 weeks-old. Expression profile of Mg transporting molecules and the development of TIN were assessed by immunohistochemistry and RT-PCR.

Results: Renal Mg excretion in F, assessed by UMgV and FEMg, was significantly higher than L in the weeks of 24 and 34. mRNA and protein expression of transient receptor potential (TRP) M6, Mg pathway in DCT, in F was down-regulated in all weeks, which was synchronized with down-regulation of thiazide-sensitive NCC, one of principal regulator of TRPM6 expression. However, expression of claudin-16, the other principal Mg pathway in tight junction of TAL, was not altered in F at all weeks. Development of TIN assessed by the ratio of interstitial area, expression of fibrosis-related molecules was not significant in both F and L at all weeks.

Conclusions: Decreased Mg reabsorption in DCT by the down-regulation of TRPM6 might be a principal cause for hypomagnesemia in diabetes patients being independent from TIN. The down-regulation of NCC might be involved in the altered TRPM6 expression. Assessment of Mg excretion might be useful to evaluate the functional abnormalities of tubules in early diabetes.

PUB301

Role of the Inflammasome and Interleukin-33 in Diabetic Nephropathy Pathogenesis

Sonay Guven Karatas,[1] Hakki Yilmaz,[2] Zehra Firat,[3] Umran Yildirim,[4] Kadir Demircan,[5] Ayse Mukadder Bilgic,[2] Nuket Bavbek,[2] Ali Akcay.[2] *[1]Internal Medicine, Turgut Ozal Univ School of Medicine, Ankara, Turkey; [2]Internal Medicine, Section of Nephrology, Turgut Ozal Univ School of Medicine, Ankara, Turkey; [3]Ankara Univ, Biotecnology Institue, Ankara, Turkey; [4]Pathology, Turgut Ozal Univ School of Medicine, Ankara, Turkey; [5]Medical Biology and Genetics, Turgut Ozal Univ School of Medicine, Ankara, Turkey.*

Background: Diabetic nephropathy is the leading cause of end-stage renal disease. Therefore, investigations into the mechanisms that underlie intrarenal inflammation may provide new therapeutic targets for anti-inflammatory strategies against diabetic nephropathy. We aimed to explore the roles of NLRP3, the inflammasome and IL-33 in the pathogenesis of diabetic nephropathy in a streptozotocin-induced diabetes mouse model.

Methods: To generate an experimental diabetes model in mice, 50 mg/kg of streptozotocin was administered intraperitoneally. Kidney tissues were obtained via sacrifice in the 1st, 2nd, 3rd, 4th and 6th months. Immunohistochemical staining was performed to visualize IL-33. IL-33, anti-ASC, IL-1β, caspase-1 and NLRP-3 protein analyses were performed in the kidney tissues using the western blot method and ELISA (only for IL-33).

Results: IL-33 expression was typically located in the peritubular and intraglomerular capillaries, according to the results of immunostaining experiments.Consistent with our immunohistochemical data, we found significant 6-fold (diabetic mice 4th month versus control, $p<0.01$) and 5.8-fold (diabetic mice 6th month versus control, $p<0.01$) increases in IL-33 protein expression in western blots of whole kidney tissue and assessment of IL-33 with ELISA also confirmed our results (IL-33 levels 0.409pg/µg diabetic mice 6th month versus 0.164pg/µg control, $p<0.01$). No significant differences in the expression of the anti-ASC, IL-1β, caspase-1 and NLRP-3 proteins were observed between diabetic mice and controls.

Conclusions: These results reveal that IL-33 may participate in the pathogenesis of diabetic nephropathy. The recognition of IL-33 as a significant pathogenic mediator in diabetic nephropathy provides the opportunity to identify new potential therapeutic targets.

PUB302

Role of Innate Immunity Activation in Experimental Diabetic Nephropathy

Orestes Foresto-Neto, Amanda H. Albino, Simone C.A. Arias, Lisienny C.T. Rempel, Viviane D. Faustino, Gizely C.S. Moreira, Camilla Fanelli, Claudia R. Sena, Vivian L. Viana, Victor F. Avila, Ricardo P. Mazzonetto, Denise M.A.C. Malheiros, Niels O.S. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

Background: Innate immunity activation by hyperglycemia has been pointed out as a potentially important event in the pathogenesis of diabetic nephropathy (DN). We investigated whether innate immunity and inflammasome assembly are activated in streptozotocin (STZ)-induced diabetic rats developing DN, as compared to those failing to develop renal injury.

Methods: Adult male Munich-Wistar rats (N=18) received STZ, 65 mg/kg, and daily insulin injections to keep blood glucose (BG) moderately elevated. Nondiabetic rats (N=5) served as controls (C). At 12 months, urinary albumin/creatinine ratio (U_{alb}/U_{cr}) was determined and kidneys were harvested to determine % glomerulosclerosis (%GS). Diabetic rats with the 4 highest %GS values were considered as DN+, whereas those with the 4 lowest %GS values were considered as DN-, serving as a more specific control. Renal TLR4, Caspase-1 and NLRP3, components of innate immunity, were assessed by qRT-PCR (Tlr4, Casp1, Nlrp3) and Western blotting (TLR4, Caspase-1). In addition, serum MCP-1 was evaluated by ELISA.

Results:

	BG	U_{alb}/U_{cr}	%GS	MCP-1
C	101±2	1.5±0.3	1.5±0.2	1056±60
DN-	430±23[a]	2.7±1.3	1.4±0.2	958±30
DN+	385±32[a]	6.7±4.3	14.6±3.6[ab]	1416±140[ab]

Mean±SE, [a]$p<0.05$ vs. C, [b]$p<0.05$ vs. DN-.

Group DN- showed no significant changes in the expression of innate immunity components compared to C. Despite similar hyperglycemia, glomerular lesions in DN+ were accompanied by a significant ($p<0.05$) increase in Tlr4 (50%), Casp1 (80%) and Nlrp3 (110%) mRNA, compared to C. The renal abundance of TLR4 and Caspase-1 increased numerically and serum MCP-1 was significantly elevated in DN+ ($p<0.05$). Of note, %GS correlated positively with the expression of Tlr4 ($r=0.82$), Casp1 ($r=0.57$), Nlrp3 ($r=0.58$) and serum MCP-1 ($r=0.75$).

Conclusions: Activation of innate immunity and inflammasome assembly may play an important role in the development of DN in STZ diabetes. Such activation may be independent of hyperglycemia. FAPESP/CNPq.

PUB303

Immunoglobulin G Fc Receptors with an Immunoreceptor Tyrosine-Based Activation Motif Promote Diabetic Nephropathy in the Early Stage Fei Liu. *Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: Diabetic nephropathy(DN) is a low grade inflammatory disease trigged by metabolic disorder. Inflammation has played an important role in the early stage of DN pathogenesis.Inflammatory cytokines, such as C-reactive protein(CRP), have contributed to inflammation through binding immunoglobulin G Fc receptors (FcγRs)in the surface of cell. We previously found that the expression of FcγRs with an immunoreceptor tyrosine-based activation motif(ITAM-FcγRs) increased in the kidney of diabetic CRP-Tg mouse induced by STZ. The present study investigated the potential role of ITAM-FcγRs in the early stage of DN.

Methods: Diabetes was induced by streptozotocin in Sprague Dawley(SD) rats for assessment of kidney injury at 2,4,8weeks by real-time PCR, immunohistochemistry and western blot analysis.

Results: Compared with control, urinary albuminexcretion was significantly increased in diabetic SD rats at 2,4 and 8 weeks after STZ injection. Diabetic rats developed severe renal inflammation with enhanced infiltration of macrophages and T cells, and upregulation of pro-inflammatory cytokines (IL-1β, TNFα). Enhanced renal inflammation in diabetic rats was associated with upregulation of ITAM-FcγRs(CD64, CD16), and over-activation of the nuclear factor κB signalling pathway.

Conclusions: These findings suggested that ITAM-FcγRs(CD64, CD16) may be mediators in the early stage of DN. Enhanced activation of nuclear factor κB signalling pathway may be the mechanism by which ITAM-FcγRs promote renal inflammation under diabetic conditions.

PUB304

Atrasentan Ameliorates Proteinuria and Cardiovascular Complications in Diabetic Nephropathy Wai W. Cheung,[1] Shiping Li,[4] Sujana S. Gunta,[1] Nancy Dalton,[2] Katayoon Shayan,[3] Robert H. Mak.[1] *[1]Pediatrics, Rady Children's Hospital, Univ of California, La Jolla, CA; [2]Dept of Medicine, Univ of California, San Diego, La Jolla, CA; [3]Pathology, Rady Children's Hospital, Univ of California, La Jolla, CA; [4]Yangzhou Univ, Yangzhou, Jiangsu, China.*

Background: Diabetic nephropathy (DN) presents with progressive chronic kidney disease (CKD) and cardiovascular complications. We investigate the effects of Atrasentan (AT), an endothelin A receptor antagonist, in mice with DN with CKD.

Methods: DN with CKD was induced by streptozotocin and 5/6 nephrectomy in CD1 male mice. DN/CKD mice were treated with vehicle (V), AT (6 mg/kg/day), enalapril (EN) (10 mg/kg/day) or both AT and EN while sham (S) mice were treated with V. DN/CKD+V mice were fed *ad libitum* while other groups of mice were pair-fed to DN/CKD+V mice for 90 days.

Results: DN/CKD mice had higher BUN and serum creatinine levels than S+V mice ($p<0.001$). Weight gain was reduced in DN/CKD+V mice relative to S+V mice ($p<0.01$) and was normalized in DN/CKD+AT and DN/CKD+AT+EN mice. Urine output was increased in DN/CKD+V mice (6.3±2.1 ml/24hr, $p<0.01$) but was normalized in DN/CKD+AT+EN mice (2.7±0.6 ml/24hr) relative to S+V mice (1.6±0.3 ml/24hr). Urine albumin and urine protein/creatinine ratio were elevated in DN/CKD+V mice relative to S+V mice ($p<0.001$). AT+EN normalized urine albumin concentrations and also reduced urine protein/creatinine ratio in DN/CKD mice. Left ventricular mass/left tibiae length ratio was increased in DN/CKD+V mice (5.1±0.3 mg/mm, $p<0.01$) but was normalized in DN/CKD+AT+EN mice (4.1±0.2 mg/mm) relative to S+V mice (3.7±0.3 mg/mm). Systolic blood pressure was elevated in DN/CKD+V mice (145.4±6.8 mm Hg, $p<0.001$) but was normalized in DN/CKD+AT+EN mice (110.8±4.4 mm Hg) relative to S+V mice (100.2±3.6 mm Hg). TNF-α, IL-6 and IL-1α mRNA were increased in kidney and heart of DN/CKD+V mice than S+V mice ($p<0.001$). AT+EN decreased the expression of these cytokines in DN/CKD mice ($p<0.01$).

Conclusions: Atrasentan alone or in combination with Enalapril ameliorates proteinuria and cardiovascular complications in diabetic nephropathy.

mPGES-2 Deletion Attenuates Obesity, Extends Lifespan and Improves Glucose Metabolism in a High-Fat Diet Mouse Model Zhanjun Jia, Ying Sun, Tianxin Yang. *Internal Medicine, Univ of Utah, Salt Lake City, UT.*

Background: By now, there's no report regarding the in vivo phenotypes of PGE2 synthase 2 (mPGES-2). mPGES-2 Arg298his polymorphism is reported to be associated with metabolic syndrome in human subjects. Present study is to elucidate the role of mPGES-2 in obesity.

Methods: mPGES-2 WT (n=39) and KO (n=37) mice were treated with high fat diet (HFD) for 15 months. Then bodyweight, lifespan, glucose metabolism, energy expenditure, and fat tissues were analyzed.

Results: In this mouse strain with a mixed genetic background (C57BL/6X129), 50% mice developed obesity (obesity prone, OP) and 50% remained lean (obesity resistant, OR). The bodyweight (BW) was blocked by more than 60% in KO/OP mice compared to WT/OP group contrasting to the similar BW between KO/OR and WT/OR mice. In line with BW, white fat mass was remarkably reduced in KO/OP contrasting to the increased weight of brown adipose tissue (BAT). In BAT, there is a large amount of lipid accumulation in WT/OP mice but not KO/OP mice. Using metabolic chamber, KO/OP mice showed higher energy expenditure than WT/OP group accompanied with higher UCP1 in BAT and higher UCP3 in skeletal muscle, without affecting food intake and locomotor activity. As control, the OR mice showed no any difference in energy expenditure between genotypes. As expected, the KO/OP mice also displayed improved glucose tolerance test (GTT) and insulin tolerance test (ITT), and such improvement of glucose metabolism was also found in normal diet-treated KO mice in parallel with enhanced plasma insulin level and activated liver insulin signaling. More interestingly, mPGES-2 deficiency led to markedly extended lifespan under long term HFD condition in both OP and OR mice (WT:16 of 39 died; KO: 3 of 37 died) in accordance with markedly up-regulated longevity genes.

Conclusions: mPGES-2 deletion blunted HFD-induced obesity possibly through increasing energy expenditure of BAT, enhanced glucose metabolism possibly via increased plasma insulin and activated liver insulin signaling, and extended lifespan possibly by modulating longevity genes. These findings demonstrated a novel target for the treatment of obesity, type-2 diabetes, and metabolic syndrome.

Beta2 Adrenergic Receptor Regulates High Glucose or Diabetes-Induced Pro-Inflammatory Response in Monocytes/Macrophages Hyunjin Noh,[1,2] Mi Ra Yu,[2] Hyun Joo Kim,[2] Jee Wan Wee,[1] Sang Heon Lee,[1] Jin Seok Jeon,[1,2] Dong-Cheol Han.[1,2] *[1]Internal Medicine, Soon Chun Hyang Univ, Seoul, Republic of Korea; [2]Hyonam Kidney Lab, Soon Chun Hyang Univ, Seoul, Republic of Korea.*

Background: Activation of monocytes/macrophages has been shown to be increased in diabetes and correlated with vascular complications. In this study, we investigated whether β2 adrenergic receptor (β2AR) agonists have therapeutic potential targeting monocyte/macrophage activation.

Methods: The effect of β2AR agonists on pro-inflammatory responses was examined using primary rat bone marrow (BM)-derived macrophages (Mph), THP-1 cells, and peripheral blood (PBMC) and BM mononuclear cells (BMMC) from types 1 and 2 diabetic rats.

Results: In Mph and THP-1 cells, high glucose (HG, 30 mM) up-regulated the expression of tumor necrosis factor (TNF)-α, monocyte chemoattractant protein (MCP)-1, interleukin (IL)-1β, and CD36, which were blocked by β2AR agonists, metaproterenol and salbutamol. The activation of nuclear factor κB (NFκB) and phosphorylation of inhibitor of NFκB (IκBα) induced by HG were markedly decreased by both β2AR agonists. The expression of β-arrestin 2 that regulates β2AR signaling and stabilizes cytosolic IκBα and the interaction of β-arrestin 2 and IκBα were significantly decreased by HG. Metaproterenol and salbutamol reversed these changes. Ex vivo treatment of metaproterenol for 16 hours also significantly reduced diabetes-induced TNF-α production in PBMC from streptozotocin-induced diabetic rats. However, metaproterenol failed to reduce TNF-α production when the cells were co-treated with selective β2AR blockade, suggesting that the anti-inflammatory effect of metaproterenol was truly mediated by β2AR. PBMC and BMMC from Zucker diabetic fatty (ZDF) rats showed enhanced expression of CD11b/c and C-C chemokine receptor 2 which was significantly decreased by chronic treatment (12 weeks) with salbutamol. Salbutamol also attenuated monocyte adhesion to endothelium and the expression of CD36 upon lipopolysaccharide stimulation.

Conclusions: These findings suggest that β2AR agonists have novel anti-inflammatory properties and might therefore have protective effects against diabetic vascular complications.

LncRNAs Expression Profiling in Diabetic Nephropathy Mouse Model Zhigui Li, Zhuo Yang. *College of Medicine, Tianjin Key Laboratory of Animal Models and Degenerative Neurological Diseases, State Key Laboratory of Medicinal Chemical Biology, Tianjin, China.*

Background: Long non-coding RNAs (lncRNAs) are functional RNAs longer than 200 nucleotides in length.LncRNAs play important roles in a variety of biological functions; however, few have been identified that regulate renal function in diabetic nephropathy. In this study, we described lncRNAs profiles in a leptin receptor deficient BKS.Cg-*m*$^{+/+}$ *Lepr*^{db}/J type 2 diabetic nephropathy (T2DN) mouse model by microarray.

Methods: Three Diabetic *db/db* (BKS.Cg-*m*$^{+/+}$ *Lepr*^{db}/J) mice and three age-matched C57BLKS/J mice (10 wk old, male) were included. Body weight, water intake and blood sugar were measured. Expression of lncRNAs and mRNAs in renal cortex were determined using Agilent microarray. 10 aberrantly expressed lncRNAs ($p < 0.05$, FC ≥ 2 and regardless of sample signal value) and 6 aberrantly expressed lncRNAs ($p < 0.05$, FC ≥ 2 and at least one group of sample signal value was greater than 7) were validated by qRT-PCR.

Results: QRT-PCR assay showed that, comparing with the result of lncRNA microarray, only 5 of the 10 lncRNAs ($p < 0.05$, FC ≥ 2 and regardless of sample signal value) were validated to be differentially expressed in *db/db* mice. All of the 6 lncRNAs ($p < 0.05$, FC ≥ 2 and at least one group of sample signal value was greater than 7) were successfully validated. So we defined differentially expressed genes as those having a p value < 0.05, fold change ≥ 2 and at least one group of sample signal value was greater than 7. Comparison between *db/db* and control mice revealed that 951 lncRNAs were differentially expressed. The principal component analysis showed the ability of these lncRNAs to distinguish the two groups. The result of mRNAs microarray revealed that 926 mRNAs were aberrantly expressed in *db/db* mice.

Conclusions: Our data suggested that numerous lncRNAs may function in the development of DN. Identifying potential reasons, especially a potentially interaction with the candidate mRNAs, will require further analyses.

Roles of CD80, CD86 and CTLA-4 in the Pathogenesis of Mouse Diabetic Nephropathy Sonay Guven Karatas,[1] Hakki Yilmaz,[2] Zehra Firat,[3] Umran Yildirim,[4] Kadir Demircan,[5] Ayse Mukadder Bilgic,[2] Nuket Bavbek,[2] Ali Akcay.[2] *[1]Internal Medicine, Turgut Ozal Univ School of Medicine; [2]Internal Medicine, Section of Nephrology, Turgut Ozal Univ School of Medicine; [3]Biotechnology, Ankara Univ, Institute of Biotechnology; [4]Pathology, Turgut Ozal Univ School of Medicine; [5]Medical Biology, Turgut Ozal Univ School of Medicine.*

Background: Diabetic nephropathy (DN) has become a major health problem in recent years due to the increasing prevalence of diabetes. It is a well known fact that, inflammation plays a key role in the development and progression of DN. Our aim in this study is, to investigate the roles of CD80, CD86 and CTLA-4,which are crucial in T cell-related inflammatory responses, in the pathogenesis of DN.

Methods: To generate an experimental diabetes model, 50 mg/kg of streptozotocin was administered for 5 consecutive days. A total of 36 mice with blood glucose levels >250 mg/dl were included in the study. Kidney tissues were obtained via sacrifice in the 1st, 2nd, 3rd, 4th and 6th months. Diabetic nephropathy was confirmed by examination of histopathology. Immunohistochemical staining was performed to visualize CD80, CD86 and CTLA-4. CD80, CD86 and CTLA-4 protein analysis was performed in the kidney tissues using the western blot method.

Results: CD80, CD86 and CTLA-4 positive immunostaining was observed in the intraglomerular and peritubular capillary areas. Western blot analysis revealed greater CD80 protein levels in the DN group in the 6th month than in the healthy controls (p=0.003). These levels were also greater than those observed in the DN group in the 1st (p=0.006) and 4th months (p=0.009). In addition, CTLA-4 and CD86 protein levels were increased in the 4th and 6th months in the DN group compared to the healthy controls (All p <0.05).

Conclusions: These results suggest that the costimulatory molecules CD80, CD86 and CTLA-4 may be associated with DN pathogenesis and may represent a new treatment approach.

PUB309

Development and Progression of Renal Functional Decline in the ZSF1 Rat Model of Diabetic Nephropathy Kathleen A. Lincoln, Paul Harrison, Damian C. Matera, Hongxing Chen, Hu Sheng Qian, Chung-Wein Lee, Nicholas F. Brown, Susan Goldrick, Steven S. Pullen, Glenn A. Reinhart, Carine Boustany. *Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.*

Background: The ZSF1 obese rat closely approximates the pathophysiological conditions of human diabetic nephropathy (DN). We sought to further characterize disease progression in this model with a particular focus on glomerular filtration rate (GFR) and renal biomarkers.

Methods: Male ZSF1 obese rats and their age-matched lean controls were studied from 11 through 41 weeks of age for the development and progression of DN. Starting from week 25, losartan was administered at 3 doses (3, 10, 30 mg/kg QD) for 16 weeks. Mean arterial pressure (MAP) was assessed from week 25 onwards. Weekly measurements of proteinuria were performed. GFR was measured in the conscious rats utilizing the inulin clearance method. Additionally, histologic quantification of glomerular and interstitial lesions were performed at select ages on a subset of rats (11, 25 and 41 weeks) and specific biomarkers were assessed for mesangial proliferation (PCNA, Ki67), myofibroblast activation (α-SMA), macrophage infiltration (ED-1), podocyte (Glepp-1) and tubular damage (Kim-1) by immunohistochemistry.

Results: Proteinuria developed by 16 weeks of age (Lean: 25 ± 1; Obese: 61 ± 6 mg/day) and continued to increase with age. This coincided with increased incidence of glomerular lesions (Lean: 1 ±0.1; Obese: 20 ±0.6 %) and interstitial lesions (Lean: 0; Obese: 77 ± 3.2 total number foci). Furthermore, there was an increase in ED-1 (Lean: 0.2; Obese: 2 ±0.1 %), KIM-1 (Lean: 0; Obese: 4 ±0.4 %), α-SMA (Lean: 0.4; Obese: 2.9 ± 0.3 %) and a decrease in GLEPP1 (Lean: 37 ± 1.0; Obese: 19 ± 0.7 %) renal expression. Losartan dose-dependently reduced proteinuria and MAP. Importantly, GFR was significantly reduced in obese ZSF1 rats versus lean (Lean: 0.7 ± 0.1; Obese: 0.3 ± 0.1 ml/min/100g). This was partially reversed by losartan.

Conclusions: In summary, the ZSF1 obese rat model displays key hallmarks of early DN and progresses towards overt diabetic nephropathy over the course of 11-41 weeks of age.

PUB310

Urinary Excretion of Neutrophil Gelatinase-Associated Lipocalin (NGAL) in Diabetic Rats Horacio Osorio,[1] Abraham Said Arellano-Buendia,[1] Fernando E. García-Arroyo,[1] Maria L. Loredo,[2] Edilia Tapia,[1] L. Gabriela Sanchez-Lozada.[1] *[1]Nephrology, Instituto Nacional de Cardiología "Ignacio Chavez", Mexico, Distrito Federal, Mexico; [2]Histopathology Laboratory, School of Medicine, Univ Panamericana, Mexico, Distrito Federal, Mexico.*

Background: The excessive production of reactive oxygen species (ROS) has been suggested as a mechanism which leading to diabetic nephropathy. On the other hand recent studies suggest that in the progression to diabetic nephropathy the tubular damage precedes to glomerular damage. Therefore, we evaluated the oxidative stress and urinary excretion of tubular proteins in diabetic rats as markers of tubular dysfunction.

Methods: The groups were control (C), diabetic (D) and diabetic-insulin treated (DI). ROS was assessed by catalase (CAT), glutathione peroxidase (GPx), superoxide dismutase (SOD) activities and by 3-nitrotyrosine (3-NT), 4-hydroxynonenal (4-HNE) and oxidized protein (OP) levels. The urinary excretion of neutrophil gelatinase-associated lipocalin (NGAL) (uNGAL), osteopontin (uOPN) and N-acetyl-b-D-glucosaminidase (uNAG) were determined.

Results: At 7 day of diabetes, hyperglycemia, glycosuria and uNGAL was elevated, whereas at 30 days of diabetes, hyperglycemia, low body weight, glycosuria, diuresis, creatinine clearance and glomerular filtration rate were significantly increased compared with C. Further at 30 days in D there was an increase in the CAT and SOD activities, in 3-NT levels and 4-HNE and OP levels in cortex and medulla while the GPx activity was low. The NGAL and OPN levels in serum as well as the uNGAL, uOPN and uNAG were increased in D compared with C. All these alterations were associated with tubular damage which was evidenced in samples at 7th days and aggravated to 30th days post diabetes induction.

Conclusions: The results suggest that tubular dysfunction evidenced by increase in urinary excretion of NGAL, precede to the oxidative stress during diabetes.

PUB311

High Glucose Increases Formation as well as Pro-Oxidative and Pro-Coagulant Activity of Endothelial Microparticles Dylan Burger, Kevin D. Burns. *Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Diabetic subjects exhibit elevated plasma levels of endothelial microparticles (eMPs) which predict risk of cardiovascular events. Emerging evidence suggests that eMPs may influence pathophysiological processes in a paracrine fashion. However the impact of high glucose on the formation and biological activity of eMPs is unknown.

Methods: Human dermal microvascular endothelial cells (ECs) were cultured in media containing normal D-glucose (5.6 mM), 15 mM D-glucose or 25 D-mM glucose, with L-glucose as osmotic control. eMP levels were assessed by flow cytometry (Annexin V labeling) and nanoparticle tracking analysis (NTA). eMPs were isolated from the media of ECs subjected to high glucose and effects on endothelial reactive oxygen species (ROS) formation were assessed by dichlorofluorescin fluorescence. Effects of high glucose on eMP pro-coagulant activity were assessed by a procoagulant activity assay.

Results: Exposure of ECs to high D-glucose caused a dose-dependent increase in eMP formation relative to osmotic controls. At 24 hours, there was a ~2.5-fold increase in eMP release associated with 25 mM D-glucose exposure (P<0.01, n=4-6). eMPs formed in 25 mM D-glucose displayed a greater diameter compared with normal D-glucose osmotic controls (25 mM: 260±14 nm versus 5.6 mM: 203±7nm versus P<0.05, n=6). eMPs generated in 25 mM D-glucose were more potent inducers of EC ROS production than eMPs generated in 5.6 mM D-glucose (~6-fold versus ~2.5 fold increase versus control, respectively; P<0.05, n=4). High glucose eMPs caused a ~3-fold increase in pro-coagulant activity compared with an equivalent amount of normal glucose eMPs (P<0.001, n=4).

Conclusions: Our results suggest that elevated glucose is a potent inducer of endothelial MP formation while also increasing the pro-oxidative effects of endothelial MPs. Such effects may contribute to progressive endothelial injury in diabetes.

PUB312

The Early Renal Pathologic Changes in Diabetic Rats and the Protective Effects of Traditional Chinese Medicine Qingli Cheng, Yang Liu, Guang Yang, Qinglin Li. *Dept of Geriatric Nephrology, Chinese PLA General Hospital, Beijing, China.*

Background: To explore the early renal pathological changes, the expression of ED-1+ cells and toll-like receptor 4 (TLR4) in the renal tubulointerstitium in diabetic rats and the protective effects of Traditional Chinese Medicine (ShenKang Injection, SK) were investigated in this study.

Methods: Thirty SD rats were divided into three groups: diabetic group (DM), DM+SK group (DM+SK) and normal control group (NC). The type 2 diabetic rat models were induced by fed with high-fat diet for 4 weeks, then intraperitoneal injection with streptozotocin (35mg/kg). The insulin resistance of the rats was evaluated using hyperinsulinemic-euglycemic clamp test. Intervention of SK was given by Intraperitoneal injection for 8 weeks. The body weight(BW), kidney index(KI) were recorded; the level of blood glucose (GLu), serum creatinine (Scr), and the level of microalbuminuria (mALB), urinary NAG were tested. The renal pathological lesions were observed using PAS staining. The renal tubular injury were evaluated with Paller's score. The expression of TLR4 and ED-1+ cells in the renal interstitial were detected using the immunohistochemical method.

Results: Compared with the NC group, the level of glucose infusion rate(GIR) decreased markedly in the DM group. The levels of GLu, mALB, urinary NAG, KI, the glomerular volume and the tubular score in the DM+SK group were significantly lower than those of the DM group respectively (P<0.01). Meanwhile, the expression of TLR4 and ED-1+ cells in the rat renal interstitial of the DM+SK group significantly decreased when compared with the DM group (P<0.01). Insulin resistance was also significantly improved in the DM+SK group when compared with the DM group.

Conclusions: The early renal changes in diabetic rats included glomerular volume increase, tubular vacuolar degeneration, and renal interstitial macrophage infiltration. Traditional Chinese Medicine SK Injection could attenuate diabetic tubulointerstitial damage and delay the progression of diabetic nephropathy, which may be associated with the reduced expression of TLR4 and the inhibition of inflammation-mediated macrophage infiltration.

PUB313

Renal Structure-function Relationship in Aging Obese ZSF1 Rats during Progression of Diabetic Nephropathy Jay Kuo, Suzanne Nodop Mazurek, Chung-Wein Lee, Hu Sheng Qian, Ryan M. Fryer. *Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.*

Background: The obese ZSF1 rat is described as a preclinical model of type 2 diabetic nephropathy (DN) with marked renal dysfunction and structural derangement. However, these hallmarks of disease progression have not been evaluated in the same cohort of animals in an age-dependent manner. This study characterizes temporal changes in renal function (GFR) relative to changes in proteinuria and glomerular and tubulointerstitial structure using morphometric techniques to further understand renal disease progression in this model.

Methods: Male obese ZSF1 rats were aged to 20, 25, 30, 35, or 40 weeks of age (n=5-11/group). At each timepoint, proteinuria (UPCR) and GFR (anesthetized, FITC-inulin, kidney weight (KW) normalized) were measured. The left kidney was processed for histopathological analyses of glomerular lesions (% glomerulosclerosis) and interstitial damage (total foci number, interstitial collagen (SRM), myofibroblast encroachment (a-SMA), tubular injury (KIM-1), and macrophage infiltration (ED-1+)).

Results: GFR remained steady from 20 to 30 weeks of age (avg 0.71±0.06 mL/min/g KW). At 35 and 40 weeks, GFR declined markedly to 0.29±0.11 and 0.23±0.05 mL/min/g KW, respectively. The incidence of glomerulosclerosis increased steadily from 12±1% at 20 weeks to 71±2% by 40 weeks of age as did UPCR, and the number of interstitial lesions, a-SMA, and ED-1. In contrast, interstitial collagen increased modestly from 20 weeks (1.3±0.2%) to 30 weeks (3.7±0.3%). However, at 35 and 40 weeks of age, interstitial collagen markedly increased to 8.3±0.6% and 13.3±0.9%, respectively. KIM-1 increased until 30 weeks (7.5±0.6%) before declining at 40 weeks (6.9±0.7%).

Conclusions: In aging obese ZSF1 rats, increases in UPCR and the incidence of glomerulosclerosis occurred prior to the decline in GFR and further increased as GFR fell. The decreased GFR also corresponded with a marked increase in tubulointerstitial fibrosis (collagen deposition) and injury (declining KIM-1 indicative of excessive tubular damage). These results, consistent with observations in human DN, also support the obese ZSF1 rat as a relevant preclinical model of DN.

PUB314

Advanced Glycation End Products Induces Myo-Inositol Oxygenase via Activation of PI3K Pathwayin Proximal Tubular Epithelial Cells Rashmi Santosh Tupe, Tatsuya Tominaga, Yashpal S. Kanwar. *Dept of Pathology, Northwestern Univ, Chicago, IL.*

Background: Pathogenesis ofDiabetic Nephropathy is multifactorial, and the advanced glycation end products (AGEs) have been postulated to play a central role in this process. Conceivably, AGEs induce damage to both the glomerular and tubular compartments of the kidney. Myo-inositol Oxygenase (MIOX)is exclusively expressed in the kidney tubules, where it catabolizes myo-inositol and channels it into xylulose-pentose pathway. MIOX up-regulation is associated with an intra-renal myo-inositol deficiency, which is implicated in the development of nephropathy following increased expression of fibronectin (FN). Previously we observed up-regulation of MIOX in proximal tubular epithelial cells (HK-2) via PI3K pathway under high glucose ambience. However, the association of MIOX with AGEs and the receptor of AGEs (RAGE) in cellular signalling is unknown. We investigated the effect of AGEs, derived from albumin, laminin and Collagen IV, on cellular MIOX regulation and examined the underlying mechanisms.

Methods: HK2 cells were subjected to AGEs treatment and processed for MIOX expression and activity, PI3K signalling, and expression of NF-KB, TGF-β and FN, and status of cellular redox. ECM proteins were also glycated and for their effects on the HK-2 cell viability, adhesion and binding to RAGE, were studied. For the latter studies solid phase ELISA assay was used.

Results: In HK2 cells treated with AGEs- albumin (50-400 μg/ml) for 6- 48 h, MIOX expression and activity was increased in concentration and time dependent manner. In addition, increased expression of PI3K signalling pathway molecules (PDK, Phospho-PDK, AKT, Phospho-AKT); NF-KB, TGF-β, FN and cellular oxidative stress was observed. Glycated ECM proteins – laminin and Collagen IV had increased binding to RAGE and cell adhesion, whereas the cell viability was somewhat reduced.

Conclusions: These results suggest the AGEs, derived from glycated albumin and ECM proteins up-regulate cellular MIOX activity via PI3K pathway and triggers downstream events leading to excessive ECM production, and this may be a novel mechanism by which AGEs induce renal damage.

Mycophenolate Mofetil Attenuates Diabetic Kidney Injury by Modulating Renal Th17 Su-Mi Kim, Jiyun Park, Yang Gyun Kim, Kyung-Hwan Jeong, Sang Ho Lee, Tae Won Lee, Chun-Gyoo Ihm, Ju-Young Moon. *Div of Nephrology, Dept of Internal Medicine, Kyung Hee Univ College of Medicine, Seoul, Korea.*

Background: Recent studies reported that proinflammatory T helper 1 (Th1) and T helper 17 (Th17) cell subsets have been associated with the pathogenesis of metabolic disease. However, the role of Th1 and Th17 cells in the development and progression of diabetic nephroapathy remains unknown. In this study, we investigated the hypothesis that MMF attenuates diabetic kidney injury by modulation of renal T cell proliferation and related cytokine.

Methods: We designed four animal groups as following; 1) C57BL/6 (Control); 2) Control + MMF (30 mg/kg/day); 3) Streptozotocin-induced diabetic mice (STZ); 4) STZ + MMF for 12 weeks. Using immunohistochemistry staining, $CD4^+$, $CD8^+$ T cell infiltration in kidney was measured. Intrarenal $CD4^+$ T cell proliferation was assessed by BrdU stating. IFN-IL-17 producing kidney and spleen mononuclear cell was assessed by flow cytometry.

Results: Urinary albumin excretion, mesangial expansion, and tubulointerstitial fibrosis decreased in STZ + MMF compared to STZ without change of HbA1c level. In immunohistochemistry, increased numbers of kidney interstitial $CD4^+$, $CD8^+$ T cells were identified in diabetic mice. BrdU incorporation was detected by subsequent intracellular staining of single cell suspensions from kidney, and consequently**,** renal $CD4^+$ T cell proliferation was increased in STZ mice and decreased by MMF. In flow cytometry of kidney mononuclear cell, diabetic mice showed an increase of renal Th1 and Th17 cells from 8 weeks after STZ induction. The population of Th1 and Th17 are no difference between control and STZ in spleen. The production of IL-17 was decreased by MMF while no significant difference was observed in IFN- γ production.

Conclusions: Our study results indicated that MMF attenuates diabetic nephoropathy by modulating renal IL-17 production.

PUB316

Vitamin D Receptor Regulates High Glucose Induced Inflammation through Inhibition of NF-κB Pathway Hao Zhang, Jing Huang, Bin Yi, Wei Li. *Dept of Nephrology, The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Vitamin D (VD) and its receptor (VDR) have beneficial function on the pathogenesis of DN by anti-inflammation. This study aims to investigate the underlying mechanism for VD and VDR to modulate inflammation caused by high dose of glucose treatment in Human proximal tubules cell line (HK2), focusing on the NF-κB pathway.

Methods: 1. To investigate the effect of vitamin D on the inflammation induced by high glucose in HK2 cells. HK2 cells were divided into 5 groups: control group, high glucose group (HG), high glucose added with VD group (at concentrations of 10-7 M). 2. To investigate the effect of vitamin D receptor on the inflammation induced by high glucose in HK2 cells. HK2 cells were divided into 4 groups: control group, high glucose group (HG), VDR siRNA group(transfected with VDR siRNA) and blank plasmid group (transfected with scrambled siRNA). 3. The mRNA level of VDR, NF-κB was detected by realtime qPCR. The total protein and nuclear protein level of VDR, NF-κB protein were detected by western Blot. The level of MCP-1 and RANTES was detected by realtime qPCR and western Blot. The level of IκBa and IKK was detected by western Blot.

Results: 1. In high glucose group, the mRNA and protein level of MCP-1 and RANTES are increased compared with control group ($p<0.05$). Meanwhile the protein level of IκBa and IKK are also increased ($p<0.01$, compared with control group). Vitamin D can decrease the expression of MCP-1, RANTES, NF-κB, IκBa and IKK ($p<0.01$, compared with high glucose group). 2. Vitamin supplementation significantly ($P<0.05$) decreased the total and nuclear protein abundance of NF-κB/p65, compared those with high glucose group. Vitamin D supplementation significantly promoted the total and nuclear protein abundance of VDR ($P<0.05$). 3. Treatment with VDR siRNA significantly inhibited the expression of VDR from protein and mRNA levels ($p<0.01$, compared with control group), leading the up-regulation of IκBa, IKK and MCP-1 protein ($P<0.05$, compared with scrambled siRNA).

Conclusions: Vitamin D and VDR regulate high glucose induced inflammation by affecting NF-κB pathway.

PUB317

Berberine Ameliorate Epithelial-Messenchymal-Transition (EMT) in Renal Tubular Epithelial Cells Induced by High Glucose plus Advanced Glycation End-Products Nanmei Liu. *Dept of Nephrology, Jimin Hospital of Shanghai, Shanghai, China.*

Background: Increased glucose and advanced glycation end products (AGEs) are proposed to lead to diabetic kidney disease (DKD). The epithelial-messenchymal-transition (EMT) plays an important role in loss of renal function and progressive of DKD. Since berberine, an herbal compound extracted from Rhizoma Coptidis, can lower blood levels of glucose and improve protenuria, we hypothesised that it might attenuate EMT in tubular epithelial cells induced by high concentration of glucose plus AGE.

Methods: Cultured human renal tubular epithelial cell line (HK-2 cells), treated with high concentration of glucose (50mM), AGE(100ng/ml), Berberine (3uM) respectively for 24h, detected the positive deposit of type IV collagen (Col-IV), α-smooth muscle actin (α-SMA) through immunohistochemistry, measured the protein expression of AGE receptor (RAGE), Col-IV,α-SMA and transforming growth factor--β1(TGF-β1) by Western blot.

Results: After incubated with 50mM glucose or AGE, the cells' shape changed from round into fusiform and hypertrophy. The positive optical density (OD) of type IV collagen was increased, with the expression of α-SMA, TGF-β1 and RAGE up-regulated. Berberine significantly decreased the OD value of type IV collagen and inhibited the expression of α-SMA, TGF-β1 and RAGE.

Conclusions: A continuously stimulating with high glucose plus AGE resulted renal tubular epithelial cells hypertrophy and induced extracellular matrix synthesis or execrations, Berberine improved cell hypertrophy and inhibited cell transdifferentiation. The mechanism might be related to down-regulate the expression TGF-β1.

PUB318

VDR and NF-κB Can Combine with Nup214 in HK-2 Cells Induced by High Glucose Hao Zhang, Jing Huang, Wei Li, Bin Yi, Wei Zhang. *Dept of Nephrology, The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Inflammation plays an important role in the pathegenesis and progression of diabetic nephropathy (DN), recent research has demonstrated that VDR can play anti-inflammatory role by inhibiting the activation of NF-κB: VDR can physically interact with IKKβ, affect IκBα ubiquitination and degradation, form a complex with NF-κB p65 to affect p65 nuclear translocation. These research mostly focus on cytoplasm level, and the condition regarding to cell nucleus level is missing. Our previous clinical research has found significant down-regulation of nuclear VDR expression in type 2 DN patients, which is negatively related with uACR. Nuclear vitamin D receptor(nVDR) protein expressions is negatively associated with NF-κB nuclear protein expression.

Methods: Human proximal tubules cell line(HK2) were divided into 2 groups: control group, high glucose group (HG). Co-immunoprecipitation was used to investigate the correlation between protein and protein.

Results: We found that NF-κB and nVDR can combine with nucleoporin214 (Nup214) in HK-2 cells induced by high glucose, which locates in the nuclear envelope and mediates nucleocytoplasmic transport.

Conclusions: In conclusion, VDR may regulate inflammation by affecting NF-κB pathway during their nucleocytoplasmic transport induced by high glucose. The mechanism about whether there is a competitive inhibition between VDR and NF-κB in the process of nucleocytoplasmic transport remains to be studied further.

PUB319

Activation of RAS in Diabetic Mice as Determined by Increased Urinary Angiotensin II - Two to Tango? Jan A. Wysocki, Minghao Ye, Daniel Batlle. *Div of Nephrology and Hypertension, Northwestern Univ, The Feinberg School of Medicine, Chicago, IL.*

Background: Urinary renin-angiotensin system (RAS) components reflect kidney RAS overactivity and could indicate a risk of developing diabetic kidney disease. Urinary angiotensinogen (AOG) has been found to be increased in urine of diabetic patients with nephropathy. To study RAS activity more directly we measured Ang II, the main active peptide of the RAS, and also urinary renin, another critical component of the RAS cascade.

Methods: We studied urinary angiotensin (Ang) II in conjunction with renin and AOG in the urines from the db/db model of type 2 diabetes at an age when albumin excretion is maximally increased and when glomerular lesions are more established (35-48 weeks of age). Urinary AOG, total renin protein and angiotensin II were measured using ELISA kits. Urinary activity of ACE2 was measured using synthetic fluorogenic substrate.

Results: In db/db mice, there was an almost 10-fold increase in urinary AOG as compared to age-matched db/m controls (165±63 versus 17±5 ng/mg creatinine, $p<0.05$, respectively). Urinary renin in a subset of *db/db* mice of similar age was also significantly increased *as compared to db/m* (1.19±0.74 versus 0.23±0.21 ng/mg creatinine, $p<0.05$, respectively). The increases in urinary AOG and renin levels were paralleled by an increase in angiotensin II in urines from db/db mice as compared to urines from db/m mice (576±230 versus 42±6 pg/mg creatinine, $p<0.05$, respectively). Urinary activity of ACE2, an Ang II-degrading enzyme, was found to be increased in *db/db* mice as well (29±9 versus 6.5±0.8 RFU/ug creat/hr, $p<0.05$, respectively) consistent with our previous findings suggesting a compensatory increase in this enzyme to degrade Ang II more efficiently.

Conclusions: Kidney RAS activation in diabetic mice is best demonstrated from increased levels of urinary Ang II. This results from upstream activation as a result of both increased urinary angiotensinogen and renin.

PUB320

GQ-16, a Partial PPARg Agonist, Decreases Blood Glucose, Visceral Adiposity and Induces the Expression of Beige Fat-Selective Genes in Obese and Diabetic Mice Alexandre Martini, Angélica Amorim Amato, Michela Soares Coelho, Francisco R. Neves, Caroline Lourenço de Lima. *Laboratory of Molecular Pharmacology, Univ of Brasilia, Brasilia, Distrito Federal, Brazil.*

Background: Thiazolidinediones (TZDs) are used for the treatment of type 2 diabetes (T2DM), and their therapeutic actions are mediated via activation of peroxisome proliferator-activated receptor γ (PPARγ). Despite their efficacy, their use is limited by side effects such as weight gain, edema, bone loss, and visceral adiposity. This has prompted the search for novel PPARγ agonists with reduced side effects. We have previously identified a novel PPARγ ligand (GQ-16) with similar anti-diabetic efficacy as rosiglitazone (RSG), yet in the absence of weight gain in obese and insulin-resistant mice. The aim of this study was to evaluate the effects of different doses of GQ-16 on adiposity and expression of PPARγ-dependent genes in mice with obesity and insulin resistance induced by high fat diet (HFD).

Methods: Mice were fed a normal-fat diet (NFD, 10% kcal fat) or HFD (60% kcal fat) since weaning. At the age of 16 wk, they were randomly assigned into six groups and received GQ-16 (5, 10 or 20mgkgd), RSG (4mgkgd) or vehicle by gavage daily for two weeks. Body weight (BW) gain, food and water intake, energy intake, metabolic efficiency, and fasting blood glucose were measured daily or weekly. Two different white adipose depots (subcutaneous and visceral) and interscapular brown adipose tissue (BAT) were harvested for determination of gene expression by quantitative real-time PCR.

Results: BW, BW gain, WAT fat mass content and blood glucose were greater in the HFD group, compared to the NFD group. In HFD-treated mice, weight gain was reduced by all treatments with GQ-16, but increased by. In addition, GQ-16 treatment (20 mg/kg/d) reduced visceral WAT pads, whereas RSG treatment increased them. Brown (UCP1) and Beige (CD40, Tmem26) fat-selective genes were upregulated in WAT in response to GQ-16.

Conclusions: Lower doses of GQ-16 decreased blood glucose and visceral adiposity in mice with obesity and insulin resistance induced by HFD, possibly through the expression of thermogenesis-related genes.

Funding: Government Support - Non-U.S.

PUB321

Post Hoc Analysis of ZEUS and HERAKLES, Two Prospective, Open-Label, Multicenter, Randomized Trials: Onset and Progression of Diabetes in Kidney Allograft Recipients on Standard Cyclosporine or Converted to CNI-Free or CNI-Low Everolimus Regimen Claudia Sommerer,[1,2] Wolfgang Arns,[1,2] Klemens Budde,[1,2] Ingeborg A. Hauser,[1,2] Volker Kliem,[2] Johannes Jacobi,[2] Petra Reinke,[1,2] Barbara M. Suwelack,[1] Anja Susanne Muehlfeld,[1,2] Ute Eisenberger,[1] Rudolf P. Wuthrich,[1] Katharina M. Heller,[1] Hans-Hellmut Neumayer,[1,2] Heiner H. Wolters,[1] Martina Porstner,[3] Daniel Baeumer,[3] Oliver Witzke,[1,2] Martin G. Zeier,[1,2] Frank Lehner.[1,2] *[1]ZEUS Study Group, Germany; [2]HERAKLES Study Group, Germany; [3]Novartis, Germany.*

Background: To compare incidence of NODAT (new-onset diabetes mellitus(DM) after Transplantation(Tx)) and progression of pre-existingDM in de novo kidney(K) allograft recipients after conversion to everolimus(EVR) based regimen and withdrawal or reduction of cyclosporine A(CsA).

Methods: Post hoc analysis on NODAT development or DM progression from ZEUS and HERAKLES, two 12months(Mo), prospective, open-label, multicenter, randomized(rdz) trials. De novo KTx patients (pts) received standard CsA/EC-MPS +steroids since Tx and were rdz to either a) continue CsA regimen or b) convert to EVR/EC-MPS (ZEUS:Mo4.5, HERAKLES:Mo3 post Tx) or c) change to a 3rd arm with low CNI+EVR(HERAKLES).

Results: ZEUS: 8%(25/300) of pts had DM at Tx. To Mo12 NODAT had developed in 8%(22/275) of non-DM pts(EVR14/142, CsA8/133) with 7% before rdz (EVR13/142, CsA7/133); after rzd incidence of NODAT was similar between groups($p=0.97$). Mean blood sugar change from rdz to Mo12 was similar between EVR versus CsA pts, in NODAT and DM subgroups. Mean eGFR (Nankivell[ml/min/1.73m^2]) was similar at rdz and significantly higher at Mo12 for EVR versus CsA pts within all defined subgroups: NODAT: EVR+14.0 versus CsA-9.2; pre-existing DM: EVR+5.5 versus CsA+0.7. HERAKLES results: To Mo12 NODAT occurred in 6.8%(30/438) of all pts (EVR 6.7%[10/149] versus CsA 8.3%[11/133] versus low-CsA 6.3%[9/143]), hence a similar incidence of NODAT in all 3 HERAKLES groups ($p=0.62$).

Conclusions: No difference in NODAT incidence or DM progression after conversion to EVR with CNI elimination or reduction were found until 12Mo post Tx. The benefit on renal function of an early conversion to an EVR-based regimen was seen in the NODAT subpopulation, similar to what was seen in both trials' ITT study results.

Novel Urinary Biomarkers for Early Detection of Kidney Disease in Type 2 Diabetes: A Pilot Study Veeda O. Landeras,[1,3] Jennifer W. Xu,[1,3] Carla Cavallin,[1,3] Mahboob Rahman,[1,2,3] Donald E. Hricik,[1,3] Michael S. Simonson.[1,3] *[1]Medicine, Div of Nephrolohy and Hypertension, Univ Hospitals Case Medical Center, Cleveland, OH; [2]Medicine, Div of Nephrology and Hypertension, Louis Stokes VA Medical Center, Cleveland, OH; [3]Case Western Reserve Univ School of Medicine, Cleveland, OH.*

Background: Kidney disease in type 2 diabetes is difficult to identify at an early stage when treatment to slow progression of renal insufficiency may be most effective. In a pilot cross-sectional study of patients with type 2 diabetes, we measured candidate urinary biomarkers (endothelin-1, ET-1; interleukin-6, IL-6; and macrophage chemoattractant protein-1, MCP-1) to determine whether they discriminate patients with eGFR < > 90 ml/min/1.73 m^2 more accurately than albumin/creatinine ratio (ACR).

Methods: Spot urine specimens were collected from 56 outpatients with type 2 diabetes, and ET-1, IL-6, MCP-1 and albumin levels were assessed by ELISA and corrected for urinary creatinine. Receiver operating characteristic (ROC) regression (Stata 13, Rocreg) was used to determine area under the ROC curve (AUC) for discrimination of eGFR < > 90ml/min/1.73 m^2 and to adjust for covariates with a non-parametric bootstrap.

Results: Nineteen patients had MDRD eGFR > 90 ml/min/1.73 m^2 (109 + 13, mean + SD) and 37 had eGFR < 90 (63 + 22, $P<0.01$). The AUC for ACR was 0.565 (95% CI, 0.413-0.716). AUCs for ET-1, MCP-1 and Il-6 were 0.752 (0.610-0.895, $P= 0.04$ versus ACR), 0.694 (0.541-0.847, $P=0.02$ *versus*. ACR) and 0.833 (0.715-0.952, $P<0.01$ *versus*. ACR), respectively. AUCs for ET-1, MCP-1 and IL-6 were statistically equivalent (all comparisons P > 0.231). AUCs for ET-1, MCP-1 and IL-6 were not significantly affected by covariate adjustment for age (all $P>0.639$), female sex ($P>0.597$), Black race ($P>0.499$), HbA1c ($P>0.593$) or blood pressure > 140/80 mm Hg ($P>0.415$).

Conclusions: Urine levels of ET-1, MCP-1 and IL-6 discriminate type 2 diabetic patients with eGFR < 90 ml/min/1.73 m2 with higher accuracy than ACR independent of covariates. Further evaluation of these candidate biomarkers for early detection of kidney disease is warranted in cohorts with type 2 diabetes.

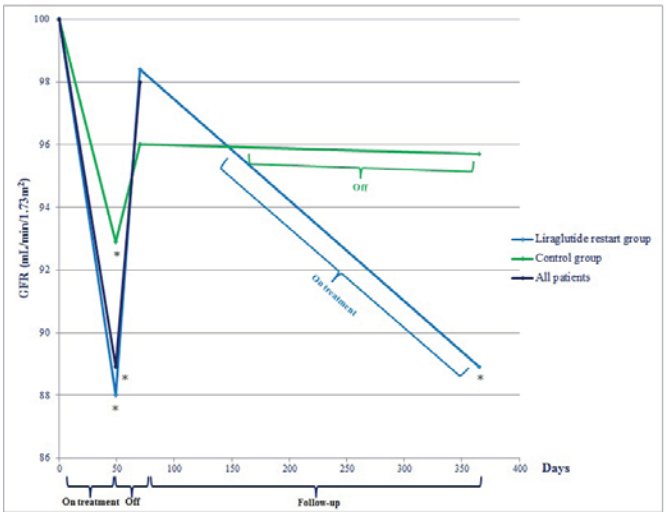
PUB323

Glucagon-Like-Peptide (GLP-1): Long-Term Effect on Kidney Function in Patients with Type 2 Diabetes Bernt Johan Illum von Scholten,[1] Tine Hansen,[1] Frederik I. Persson,[1] Peter Rossing.[1,2,3] *[1]Steno Diabetes Center, Denmark; [2]Aarhus Univ, Denmark; [3]Univ of Copenhagen, Denmark.*

Background: In a short-term study including 31 patients with type 2 diabetes, we observed that glucagon-like-peptide-1 receptor agonist (GLP-1 RA) treatment was associated with a decline in GFR, which was reversed when GLP-1 RA was stopped. The aim of this study was to investigate the effect of long-term treatment on kidney function in patients restarting GLP-1 RA.

Methods: We included 30 patients from our short term study, in an open-label follow-up of one year, 23 restarted with liraglutide and seven control subjects continued without. Primary endpoint was change in GFR (^{51}Cr-EDTA).

Results: Patients were 8 (35%) females, mean (SD) age was 61.5 (10.0) years, HbA_{1c} 60.1 (13.8) mmol/mol and diabetes duration (range) 6 (1-18) years. Baseline GFR was 100.6 (24.9) mL/min/1.73m^2 and treatment was associated with a reduction of 11 (95% CI: 6.6; 15.7) mL/min/1.73m^2 from baseline (p<0.0001), independent of change in 24hour systolic blood pressure (SBP), weight, UAER or HbA_{1c} (p>0.59). Baseline geometric means (IQR) of UAER was 25.5 (9.9-50.9) mg/d and was reduced with 27% (5%-44%, p=0.020) after one year of treatment, independent of change in SBP, weight, GFR or HbA_{1c} (p>0.22). Fractional albumin excretion was reduced by 37% (13%-54%, p=0.007) and 24hour SBP by 8.2 (0.1-16.2) mmHg (p=0.048).



Conclusions: Long-term treatment with GLP-1 RA liraglutide was associated with blood pressure independent changes in measured GFR identical to what was seen during short-term treatment. Moreover, UAER was reduced. Whether this could reflect a renoprotective effect of GLP 1-RA has to be addressed in randomized long-term trials.

PUB324

Relationship Between Urinary N-Acetyl-β-D-Glucosaminidase and 24-Hour Glycemic Profile, or 1,5-Anhydroglucitol in Patients with Type 2 Diabetes Mellitus Motoshi Ouchi,[1] Tatsuya Suzuki,[2] Taro Saigusa,[2] Kenzo Oba,[2,3] Promsuk Jutabha,[1] Naohiko Anzai,[1] Shuichi Tsuruoka.[4] *[1]Pharmacology and Toxicology, Dokkyo Medical Univ School of Medicine, Shimotsuga-gun, Tochigi, Japan; [2]Geriatric Medicine, Nippon Medical School, Bunkyo-ku, Tokyo, Japan; [3]Internal Medicine, Oarai Sea Shore Core Clinic, Higashiibaraki-gun, Ibaraki, Japan; [4]Nephrology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: The serum 1,5-anhydroglucitol (1,5AG) level has been shown to generally reflect postprandial hyperglycemia. Elevated urinary levels of N-acetyl-β-D-glucosaminidase (NAG) indicate proximal tubular damage. The relationship between 1,5AG and urinary NAG levels has been reported by some studies, including our studies, in patients with and without diabetes mellitus (DM). However, no studies have evaluated the relationship between 24-hour glycemic profile and urinary NAG.

Methods: 176 subjects (38-87 years of age) were recruited among inpatients who had received diagnoses of type 2 DM at Nippon Medical School Hospital. Patients who had been brought to our hospital by ambulance were excluded. Other exclusion criteria included severe illness, pregnancy, previous gastrectomy, estimated glomerular filtration rate < 45 (ml/min/1.73 m^2), albuminuria ≥ 300 (mg/g Cr), a history of proteinuria, and kidney disease. The daily profiles of plasma glucose was recorded at 10 time points in the preprandial period (8:00, 12:00, 18:00), and the postprandial period (10:00, 14:00, 20:00), and then at 0:00, 3:00, 6:00, and 8:00 on the next day.

Results: The mean urinary NAG level was 8.24 ± 6.45 U/g Cr. There was weak correlation between urinary NAG and some markers (10:00, 12:00, 18:00 glucose, M-value, mean plasma glucose, area under the curve [AUC] of daily glycemic profile, AUC of postprandial glycemic profile, and 1,5AG). Urinary NAG did not correlate with fasting plasma glucose, HbA1c, and the mean amplitude of glycemic excursions.

Conclusions: This study is the first to show, by means of 24-hour glycemic profile, the relationship between urinary NAG and 1,5AG, or other glycemic markers in patients with type 2 DM. Urinary NAG had stronger associations with 1,5AG, than 24-hour glycemic profile.

PUB325

The Therapeutic Potential of C-Peptide in Kidney Disease: A Systematic Review and Meta-Analysis James A. Shaw, Partha Pradeep Shetty, Kevin D. Burns, Greg A. Knoll. *Div of Nephrology, Dept of Medicine, Kidney Research Centre, Ottawa Hospital Research Institute, Univ of Ottawa, Ottawa, ON, Canada.*

Background: C-peptide, normally released by pancreatic beta-cells along with insulin and in equimolar amounts, has intrinsic biological activity and may be renoprotective. Our major objective was to conduct a systematic review to identify whether C-peptide has an effect on GFR, proteinuria, kidney histology, requirement of renal replacement therapy, and mortality in patients with kidney disease of any etiology.

Methods: MEDLINE, EMBASE, and the Cochrane Central Databases were searched for human and animal studies in which C-peptide was administered and renal endpoints were subsequently measured.

Results: We identified 4 human trials involving a total of 74 patients and 18 studies involving 568 animals, most of which were rat studies. In humans, the renal effects of exogenously delivered C-peptide have only been studied in type I diabetics with either normal renal function, microalbuminuria, or glomerular hyperfiltration, and meta-analysis showed no difference in GFR (mean diff. -1.36 mL/min/1.73 m^2, p=0.72) or renal blood flow (mean diff. 32.53 mL/min/1.73 m^2, p=0.27) in patients receiving C-peptide compared to a control group. One study reported reduced albuminuria in the C-peptide group (p<0.05). Diabetic rodent models revealed C-peptide-induced reduction in GFR (mean diff. -0.62 mL/min, p<0.00001), proteinuria (mean diff. -186.24 mg/day, p=0.05), glomerular volume (p<0.004), and mesangial matrix area (p<0.00001). C-peptide did not affect blood pressure or plasma glucose. Most of the studies were relatively short-term in duration, most falling within a range of 1-2 hours - 4 weeks.

Conclusions: In diabetic animal studies, C-peptide reduces GFR, proteinuria, and mesangial matrix, without affecting blood pressure or plasma glucose. The underlying mechanisms for these effects are unknown. In patients with type I diabetes there is minimal evidence supporting a reduction in albuminuria. Human studies of sufficient sample size and duration are needed to determine if the beneficial effects of C-peptide seen in animal models translate into improved outcomes for patients with chronic kidney disease.

PUB326

Urinary miR-124 Correlated with Albuminuria and Renal Function in Patients with Type 2 Diabetes Mellitus Hui Peng, Meirong Zhong, Yan-Ru Chen, Jun Zhang, Wenbo Zhao, Tan-Qi Lou. *Nephrology Div, Dept of Medicine, the Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: miR-124 may be involved in the pathogenesis of diabetic kidney disease (DKD) by targeting the RhoA/ROCK signal pathway or integrin a3 b1. The study was undertaken to explore the possibility association of urinary miR-124 and renal injury in diabetic mellitus.

Methods: Eighty-three patients diagnosed with type 2 diabetes mellitus were recruited into this cross-sectional study. Urinary miR-124 levels were detected by TaqMan qRT-PCR. Urinary albumin excretion rate, urinary albumin to creatinine ratio and renal functional parameters including the blood urea nitrogen (BUN), serum creatinine, cystatin, β2-microglobulin levels, and estimated glomerular filtration rate (eGFR) were collected as well. They were divided into two groups based urinary albumin to creatinine ratio: patients with albuminuria (n=42) and with normoalbuminuria (n=41).

Results: The miR-124 in urinary supernatant was significantly higher (p = 0.007) in patients with albuminuria than those with normoalbuminuria. However, the expression of miR-124 in urinary sediment was significantly lower (p = 0.021) in patients with albuminuria than others.There was no significant difference in the serum miR-124 level between both groups. The urinary supernatant miR-124 level was significantly correlated with the urinary albumin excretion rate (r = 0.271, p = 0.023), eGFR (r = -0.308, p = 0.005), serum cystatin (r = 0.239, p = 0.042), serum β2-microglobulin (r = 0.307, p = 0.009), BUN (r = 0.239, p = 0.030), and serum creatinine (r = 0.321, p = 0.003).

Conclusions: Urinary supernatant miR-124 is associated with albuminuria and renal function in patients with type 2 diabetes, which may have the potential to serve as noninvasive biomarker for DKD. The implication of miR-124 in the pathogenesis of DKD needs further exploration.

PUB327

Glycoalbumin Is an Accurate Indicator for Postprandial Blood Glucose and Fluctuation Evaluated by CGM (Continuous Glucose Monitoring) in Dialysis Patients Kunihiro Ishioka, Hidekazu Moriya, Takayasu Ohtake, Sumi Hidaka, Shuzo Kobayashi. *Nephrology,Immunology, Vascular Medicine, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan.*

Background: Little data is available concerning blood glucose (BG) monitoring in dialysis patients with continuous glucose monitoring (CGM). CGM is ambulatory and plays an important role for indicating every 5 min BG for 48 hrs, which could show blood

glucose fluctuations, postprandial BG, average BG or area under the curve (AUC). Japanese guideline for BG managements in dialysis patients says that glycoalbumin (GA) should be used instead of HbA_1C because of underestimation of BG due to a short survival of RBCs and ESA usage. With CGM, we evaluate what GA indicates, and reveal relationships between GA, HbA_1C and various kinds of blood glucose indicators.

Methods: We performed consecutive 2-days CGM to monitor glucose levels in 16 HD patients (DM 10 pts, non-DM 6 pts), and studied the association of various CGM indicators (average glucose values ; AG, fluctuations of 24h blood glucose ; FL, and area under the curve for glucose level >180mg/dl ; $AUC_{>180}$) with GA, HbA1c,and postprandial BG (pre-dialysis BG), respectively.

Results: The mean HbA1c, and GA of the subjects were 5.4±1.0 %, and 22.0±5.9 %, respectively. GA is significantly associated with 48hrs average blood glucose levels, postprandial BG (pre-dialysis BG), and AUC180, and FL on non-dialysis day ($r=0.65$, $p<0.01$). However, HbA1C is not associated with neither indicator above mentioned. 24h AG and AUC>180 are significantly correlated with postprandial BG and FL significantly is correlated with GA on non-dialysis day in multiple regression analyses ($p<0.03$).

Conclusions: We showed that GA is more accurate and a useful marker than HbA1C in terms of BG management in dialysis patients because GA is well associated with several indicators, all of which include BG excursion from low to high blood levels. Since postprandial or fluctuations of BG is known to play an important role for the development of cardiovascular events, we emphasize that BG should be managed continuously throughout 48 hrs between dialysis sessions using GA.

PUB328

A Multicenter Clinical Trial of Allopurinol to Prevent Early Renal Function Loss (PERL) in Type 1 Diabetes (T1D) David Cherney,[1] Bruce A. Perkins,[1] Michael Mauer,[2] Alessandro Doria.[3] *[1]Univ of Toronto; [2]Univ of Minnesota; [3]Joslin Clinic. On Behalf of the PERL Consortium.*

Background: Despite improvements in glycemic and blood pressure control and renin angiotensin system blockade (RASB), the incidence of diabetic nephropathy (DN) remains high. The Joslin Kidney Study found that that moderately elevated serum uric acid (UA) is associated with a 2-fold increase in GFR loss in T1D, suggesting that UA lowering may prevent or slow GFR loss in T1D.

Methods: To test this hypothesis, we established a consortium of investigators from 8 centers (U.S.A., Canada, Denmark) with expertise in the conduct of DN clinical trials. Recently fully funded by a 5 year grant from the NIDDK and the JDRF, PERL is proceeding with the pivotal 3-year, multicenter, double-blind, placebo-controlled, randomized clinical trial to evaluate the efficacy of allopurinol, compared to placebo, in reducing GFR loss in T1D.

Results: The trial is targeted to T1D patients with high risk features such as elevated albumin excretion rates or GFR decline and serum UA ≥4.5 mg/dl, since these patients may benefit most from UA lowering. Baseline GFR is being measured by the plasma disappearance of iohexol (iGFR) between 45 and 99 ml/min/1.73m2. Patients will receive full dose RASB with blood pressure targeted at <130/80 mmHg. The primary endpoint of the study will be the iGFR (adjusted for the baseline iGFR) at the end of a 2-month allopurinol wash-out period after the 3-year intervention, thereby demonstrating durability of potential benefits. Sample size calculations suggest that 240 subjects in each treatment arm will provide ≥80% power to detect a meaningful reduction in the rate of iGFR decline in the allopurinol versus the placebo group of 1ml/min/year, which would translate to a 7-10 year delay in end stage renal disease (ESRD).

Conclusions: We anticipate that allopurinol may be a valuable adjuvant therapy to prevent or slow GFR loss in T1D patients with established DN. The reduction in morbidity and mortality associated with the prevention of delay of ESRD due to the use of allopurinol would have a major impact on the lives of T1D patients, significantly reducing the human and financial costs associated with this condition.

PUB329

The Clinical and Pathological Analysis and Prognosis of the Renal Disease in Type 2 Diabetes Mellitus Patients Ming Li,[1] Huiqing Chen,[2] Wenbo Zhao,[1] Canming Li,[1] Tan-Qi Lou.[1] *[1]Dept of Nephrology, The Third Affiliated Hospital, SUN Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Pediatric, The First Affiliated Hospital, SUN Yat-sen Univ, Guangzhou, Guangdong, China.*

Background: Objective To analyze the pathological and clinical characteristics of renal disease in patients with type2 diabetes mellitus(all receive renal biopsy) and evaluate prognosis.

Methods: The cilnical and pathological data of 42 type2 diabetic patients with abnormal urinalysis or increased serum creatinine in our department were studied, who were followed-up for average 4 years.

Results: Among 42 patients, 27 cases(64.3%)were diagnosed diabetic nephropathy (DN), including 3 cases presenting with diabetic nephropathy complicated with non-diabetic renal disease (NDRD), and 15 cases were diagnosed as NDRD (35.7%). Membranous glomerulonephritis was the most common pathological changes in NDRD(33.3%), followed by minimal-change disease (20%) and IgA nephropathy (13.3%). Difference of diabetic duration, hemoglobin level, whether complicated with diabetic retinopathy (DR) or other DM complications between two groups had statistical significance ($P<0.05$).Logistic regression analysis indicate that DR is the independent risk factor for DN.DR had 66.7% sensitivity and 93.3% specificity for diagnosing DN**.** After 4 years follow-up,totally 10 patients(23.8%) progressed to ESRD,8 in DN group, and 2 in NDRD group.Multiple linear regression model indicated renal interstitial fibrosis was the only independent risk factor for progression to ESRD in two groups**.**

Conclusions: The renal disease occured on the patients with type2 diabets sometimes belongs to NDRD. It is necessary to differentiate the renal pathological changes by history,fundus examination, renal biopsy et al.Compared with NDRD patients, prognosis in DN group is worse,and renal interstitial fibrosis is the only independent risk factor for progression to ESRD.

PUB330

Urine AQP5 Is a Potential Novel Biomarker of Diabetic Nephropathy Wenzheng Zhang,[1] Yiyang Lu,[2] Lihe Chen,[1] Zhou Xiao,[2] Ting Meng,[2] Qiaoling Zhou.[2] *[1]Graduate School of Biological Sciences, Univ of Texas Health Science Center at Houston, Houston, TX; [2]Internal Medicine, Central South Univ, Changsha, Hunan, China.*

Background: Although several urine-based proteins have emerged as potential markers of diabetic nephropathy, none of them have been used clinically. Water channel AQP5 functions in the generation of saliva, tears, and pulmonary secretions, but is barely detectable in normal kidneys. Based on our recent findings, we hypothesize that urine AQP5 is a potential novel biomarker of diabetic nephropathy.

Methods: We performed immnunofluorescence staining of kidney biopsies from 15 patients with minimal change disease as normal controls and 17 patients with diabetic nephropathy. Using an AQP5-specific enzyme-linked immunosorbent assay, we measured serum and urine AQP5 in 84 subjects consisting of normal controls (n=26) and patients with diabetes mellitus (n=25) or diabetic nephropathy (n=33). Correlations between urine AQP5 and clinical parameters were calculated as the Pearson's correlation coefficient, using Microsoft Excel. Analyses of ANOVA with Holm-Sidak test, Receiver Operator Curve (ROC), multiple logistic regression, and Bland-Altman agreements were conducted using SigmaPlot 11 (Systat Software). Differences were considered statistically significant at $p<0.05$.

Results: We found that 1) AQP5 exists inside the lumen of the tubules in patients with diabetic nephropathy, but not in patients with minimal change disease. 2) Urine AQP5/creatinine is significantly higher in patients with diabetic nephropathy than in other two groups, and in diabetic nephropathy stage V than in stage III; 3) correlates with serum creatinine, urine microalbumin, and multiple other known risk factors of the disease; 4) improves the clinical models in distinguishing diabetic nephropathy from normal controls and diabetic mellitus; and 5) has a high stability over prolonged frozen storage.

Conclusions: Our data suggest that urine AQP5/creatinine may possess diagnostic and prognostic values as a biomarker of diabetic nephropathy and offer flexibility for reliable measurement in the clinical setting.

PUB331

Oxalate Nephropathy Causing Irreversible Renal Failure following Roux-En-Y Surgery: Recognizing Patients at Risk Jessica M. Nelson, Jamie Alton Green, Maria C. Bermudez. *Geisinger Medical Center, Danville, PA.*

Methods: We present a case of a 51 year old female with medical history significant for hypertension, type 2 diabetes mellitus (DM), chronic kidney disease (CKD) stage III and morbid obesity (BMI 38) status post bariatric surgery complicated by volume depletion and subsequent acute on chronic kidney injury. During her hospitalization she had persistent decline in her renal function prompting further investigation. The work-up revealed normal- large hyperechogenic kidneys, protein-creatinine ratio of 1 gram per day, bland urinary sediment and negative serologic evaluation. Ultimately, a renal biopsy was performed revealing severe tubulointerstitial inflammation, moderate to severe tubular atrophy and interstitial fibrosis with diffuse tubular deposition of Calcium Oxalate (CaOx) crystals consistent with ON. Urine oxalate levels were not measured given oliguria. Despite institution of a low fat-oxalate diet, calcium supplementation and surgical reversal of her bypass, she rapidly progressed towards dialysis with no evidence of renal recovery.

Conclusions: Oxalate nephropathy (ON) is an unrecognized, devastating phenomenon following Roux-En-Y Gastric Bypass (RYGB). ON is the result of iatrogenic fat malabsorption leading to hyperoxalemia, hyperoxaluria and renal deposition of CaOx crystals. Our case illustrates the associated potential complication of ON with RYGB as previously described in the abandoned jejunoileal bypass. This phenomenon has been observed in a few case series with biopsy-proven oxalate nephropathy reported in the literature. Interestingly, the presence of underlying CKD, DM and volume depletion appear to be common risk factors, all of which were present in this patient. Risk stratification and early recognition are mainstays of improved morbidity from this irreversible condition. Renal biopsy, the goal standard diagnostic tool, should be considered in patients at risk in order to institute early treatment which includes consideration of surgical reversal of the bypass. As recurrence of the disease is anticipated after renal transplantation, objective diagnosis and establishment of preemptive strategies are crucial.

PUB332

Beneficial Effect of Polymyxin-B Direct Hemoperfusion for Septic Shock Patients with Low Central venous Pressure: A Retrospective Cohort Study Hiroyuki Yamada, Tatsuo Tsukamoto, Motoko Yanagita. *Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Although fluid resuscitation is a fundamental therapy for severe sepsis or septic shock, positive fluid balance might be associated with adverse outcomes. The direct hemoperfusion with polymyxin B-immobilized fiber column(PMX-DHP) could improve hemodynamic status of septic shock patients without aggressive fluid resuscitation. In

order to examine the beneficial effect of PMX-DHP in patients with chronic kidney disease or chronic heart failure, whose fluid resuscitation has to be limited, we retrospectively compared the hemodynamic improvement and the mortality of patients treated with PMX-DHP by using central venous pressure (CVP) as an indicator.

Methods: 70 patients received PMX-DHP for septic shock between May 2008 and 2013 April were recruited and divided into low CVP group (n=33, CVP<12mmHg) and high CVP group (n=37, CVP≥12mmHg). PMX-DHP was carried out for at least 120 minutes per session. Primary outcome was the change in mean arterial pressure (MAP) and vasopressor requirement, and secondary outcome was the 28-day mortality.

Results: MAP significantly increased after PMX-DHP (66 to 78 mmHg in low CVP group and 62 to 67mmHg in high CVP group; p<0.01), however, the increased MAP was maintained at 24 hours only in low CVP group (to 76mmHg; p<0.01). Inotropic score significantly decreased at 24 hours in low CVP group (20 to 10; p<0.01), whereas no significant change was observed in high CVP group (25 to 22; p=0.11). Vasopressor dependency index also significantly improved at 24 hours in low CVP group (0.33 to 0.16 $mmHg^{-1}$; p<0.01), but not in high CVP group (0.43 to 0.34 $mmHg^{-1}$; p=0.10). The 28-day mortality rate was higher in high CVP group (57% versus 21%: p<0.01), despite the presence of similar comorbidity diseases between two groups.

Conclusions: Our findings indicate that PMX-DHP could provide beneficial effect on both the hemodynamics and the mortality in patients with low CVP group, whose fluid resuscitation was limited. Further study is required to elucidate the mechanism of action of PMX-DHP on sepsis treatment.

PUB333

Disparity between Prescribed Dose Based on Effluent Flow Rate and Actual Delivered Dose in Continuous Renal Replacement Therapy Explained

Minhtri K. Nguyen, Ritu Vahi, Jingbo Huang, Minh Kevin Nguyen, Ira Kurtz. *Div of Nephrology, UCLA, Los Angeles, CA.*

Background: Continuous renal replacement therapy (CRRT) is a dialytic modality commonly used in patients with acute kidney injury. The recommended minimal CRRT urea clearance rate is 20 ml/kg/hr, and it is critical that the prescribed calculated dose is accurate.

Methods: CRRT urea clearance is calculated as the ratio between the [urea] in the effluent and plasma multiplied by the effluent flow rate (EFR). Due to its low molecular weight, the sieving coefficient of urea is one, i.e. the effluent/plasma (E/P) [urea] ratio is equal to 1. The convective clearance of urea is thus equal to the EFR. Hence, the dose of CRRT has been reported as the EFR, which is equal to the ultrafiltration rate in CVVH and sum of ultrafiltrate and spent dialysate in CVVHD and CVVHDF. However, observational studies have shown that the prescribed dose based on EFR significantly overestimates the measured urea clearance. We hypothesized that this difference is due to the fact that E/P [urea] = 1 holds true only for convective solute transport. In diffusive solute transport, the effluent [urea] will be equal to the equilibrated [urea] at diffusive equilibrium, which will always be less than the plasma [urea]. Thus, the E/P [urea] ratio is < 1 and calculation of urea clearance using the EFR will overestimate the actual urea clearance.

Results: Accounting for the fact that the equilibrated effluent [urea] at diffusive equilibrium is less than the plasma [urea], two new equations are derived to accurately calculate urea clearance: CVVHD urea clearance = $(Q_{BW} \times Q_{effluent})/(Q_{BW} + Q_{DFR})$ and CVVHDF urea clearance = $(Q_{BW} \times Q_{effluent})/(Q_{BW} + Q_{RF} + Q_{DFR})$, where Q_{BW} = blood water flow rate, $Q_{effluent}$ = EFR, Q_{DFR} = dialysate flow rate, and Q_{RF} = predilution replacement fluid rate.

Conclusions: The disparity between prescribed dose based on EFR and actual delivered dose in CRRT can be explained by the lower effluent [urea] at diffusive equilibrium. By accounting for the equilibrated effluent [urea], these new equations will provide clinicians with a more accurate guide for calculating the prescribed CRRT dose.

Implementation of Sustained Low Efficiency Dialysis in a Community Hospital without a Chronic Hemodialysis Program

Shelley E. Albert,[1,2] Jo-Ann Fernando,[1] Donna I. Mcritchie,[1,2] Marina Bitton.[1] *[1]North York General Hospital, Toronto, ON, Canada; [2]Univ of Toronto, Toronto, ON, Canada.*

Background: Sustained low-efficiency dialysis (SLED) is a hybrid modality for the management of acute kidney injury in the critical care setting which avoids many of the drawbacks of continuous renal replacement therapy. North York General Hospital is a 420-bed community teaching hospital in suburban Toronto with in-patient volumes of 28,000 per year and a 22-bed Critical Care Unit (CrCU). There is no chronic hemodialysis unit on-site.

Methods: We implemented a SLED program in the CrCU in 2009 performed exclusively by CrCU RNs under the supervision of staff nephrologists and intensivists. Training and technical support was provided by Fresenius Medical Care using the 2008K@ home hemodialysis machine. In the last 5 years, a total of 67 patients, average age 68, have undergone 434 SLED sessions in our CrCU.

Results: Overall in-hospital mortality was 48%. The average MODS score on day 1 of SLED was 8.1. 78% of patients were ventilated at dialysis initiation, and 45% were on pressors. 31% of survivors (11 patients) were still dialysis-dependent at the time of CrCU discharge and were transferred to other hospitals for chronic hemodialysis. The average cost per treatment was CAD$250.

Conclusions: Our experience indicates that SLED is a safe, efficacious and cost-effective option for the management of acute kidney injury in a community hospital lacking chronic hemodialysis facilities. To our knowledge, SLED is not widely practiced in such settings. Our approach avoids both the cost of consummables and other disadvantages of CRRT, as well as the added cost of a hemodialysis nurse traditionally employed in the performance of SLED.

PUB335

Clinical Study of CRRT for 56 Cases of Neonate

Hirotsugu Kitayama. *Dept of Pediatric Nephrology, Shizuoka Children's Hospital, Shizuoka, Japan.*

Background: Recently we could come to perform CRRT for neonates, because recent CRRT device is accurate. CRRT for neonate does not clarify diagnosis, vascular access and so on.

Methods: From 2002 to 2012, these 56 patients were performed CRRT and neonate in NICU. We confirm diagnosis, vascular access, CRRT device, modality of CRRT, mortality of all and mortality of Sepsis.

Results: There are 56 neonate patients performed CRRT. Vascular access are femoral vein, umbilical vein, internal jugular vein, umbilical artery, radial artery and subclavian vein as frequency series. Technical skills of insertion depend on department of pediatric cardiology, neonatologist, cardiac surgeon, critical care and nephrology. CRRT device were perista pump, ACH-07(QB20ml/hr~) and JUN505(QB1ml/hr~). Concerning with modality of CRRT, there are PD(18 cases), CHF(4 cases), CHD(3 cases), CHDF(35 cases), PMX-DHP(13 cases) and PEX(1 case) were also performed. From 2002 to 2007, there are 18 patients with PD out of 30. From 2007 to 2012, there are 5 patients with PD out of 27. In diagnosis as series of high frequency, there are Sepsis, congenital heart disease, congenital diaphragm hernia, digestive system disease (perforation and so on), congenital metabolic disease, persistent pulmonary hypertension of neonate, meconium aspiration syndrome, transient abnormal myelopoiesis, hyperkalemia, kidney disease and fetal hydrops. Mortality was 59.3% in previous term. In following term, mortality was 55.8%. All of the mortality was 57.4%. Mortality of sepsis was 46.2%.

Conclusions: Team medicine, accuracy of CRRT device and technical skills of blood access insertion make it possible to perform CRRT for neonate.

PUB336

Renal Replacement Therapy in Acute-On Chronic Liver Failure – Outcomes and Predictors of Survival

Sivaramakrishnan Ramanarayanan,[1] Rajendra Prasad Mathur,[1] Suman Nayak,[1] Shiv Sarin,[1] Amit Kumar.[2] *[1]Institute of Liver and Biliary Sciences, India; [2]All India Institute of Medical Sciences, India.*

Background: Acute-on chronic liver failure (ACLF) is defined as acute deterioration of preexisting chronic liver disease usually related to a precipitating event. Compared to decompensated cirrhotics with refractory hepato-renal syndrome, patients with acute-on chronic liver failure (ACLF) with acute kidney injury (AKI) have a slightly better chance of survival on renal replacement therapy (RRT). But the data on outcomes and predictors of survival in this subset of patients is lacking.

Methods: We retrospectively analyzed the data of adult (> 18 years) ACLF patients with severe AKI requiring RRT, admitted to our institute between May 2009 to September 2013. We excluded following ACLF patients from our study- patients who had pre-existing chronc kidney disease; patients with following co-morbidities - coronary artery disease or cardiomyopathies, significant structural lung disease; malignancies.

Results: About 170 patients of ACLF had severe AKI requiring RRT during the study period. Out of these, only 117 patients qualified for the final analysis. The study population consisted predominantly males. Median age was 46.9 ± 24.2 years.ACLF patients with AKI requiring RRT had severe liver disease (mean MELD 42.3) and high rate of multi-organ dysfunction (Mean SOFA – 12.8). SLEDD was the modality used for RRT. About 53% of the ACLF patients had some form of intra-dialytic complication. The average number of days ACLF patient survived after initiation of RRT was 11.6±2.02 days. On multi-variable stepwise linear regression analysis, the independent predictors of mortality in this subset were – CTP score (Beta- 0.14, standard error – 0.05) and SOFA score (beta – 0.09; standard error – 0.05).

	Beta	Standard error	P value
SOFA score	0.094	0.18	< 0.001
CTP score	0.14	0.05	0.01

Conclusions: ACLF patients with severe AKI requiring RRT have very high mortality. CTP and SOFA score are independent predictors of mortality among these patients. Prospective studies comparing different modalities of RRT in this subset of patients are needed.

PUB337

The Implication of Reticulocyte Hemoglobin Content in Maintenance Hemodialysis Patients

Hyang Kim, Kyu-Beck Lee, Young Youl Hyun, Hyosun Lee. *Dept of Internal Medicine, Sungkyunkwan Univ School of Medicine Kangbuk Samsung Hospital, Seoul, Korea.*

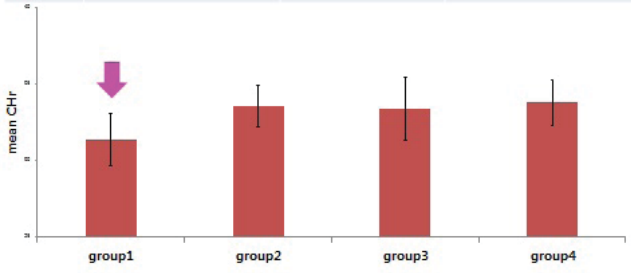
Background: Iron deficiency is one of the most important factors causing erythropoietin hyporesponsivness. According to the K/DOQI guideline, absolute iron deficiency correlates with transferrin saturation(TAST) ≤20% or serum ferritin≤100ng/ml or reticulocyte hemoglobin content (CHr) <29 pg. The aim of this study is to examine the relationship between reticulocyte hemoglobin content and other parameters associated with iron deficiency in maintenance hemodialysis patients.

Methods: Sixty-two patients undergoing hemodialysis were enrolled in this study. Blood samples were obtained prior to the first-of-the-week hemodialysis session. CHr was measured with ADVIA 2120 reticulocyte analysis (SIEMENS, Germany). Correlations among CHr, age, mCHr, Hb, MCV, MCHC, albumin, iron, Kt/V, Hct, ferritin, TIBC and TSAT were analyzed by Pearson correlation coefficient and multivariate linear regression analysis. Patients were divided into 4 groups according to their TSAT and ferritin levels. CHr levels were compared among these 4 groups by ANOVA.

Results: Mean CHr was 33.1±1.9 pg. CHr was related to mCHr($p<0.001$), MCV($p<0.001$), MCHC($p<0.001$), iron($p<0.001$), ferritin($p=0.016$) and TSAT.($p=0.013$) In regression analysis including these variables, MCV($p<0.001$), MCHC($p<0.001$) and iron($p=0.008$) were significantly related to CHr. Mean CHr levels were 31.4 pg(group 1), 33.5 pg(group 2), 33.4 pg(group 3) and 33.8 pg(group 4). The level was significantly lower in group 1. ($p<0.001$).

<Mean CHr of subgrups >

		Mean	Std. Deviation
CHr	Group 1 TSAT<0.2 | ferritin <100	31.4	1.6959
	Group2 TSAT<0.2 | ferritin ≥100	33.5	1.3721
	Group3 TSAT≥0.2 | ferritin< 100	33.4	2.0502
	Group4 TSAT≥0.2 | ferritin ≥100	33.8	1.4642
	Total	33.0	1.9065



Conclusions: Although reticulocyte hemoglobin content is not used in usual clinical practice, it was related to parameters representing iron deficiency in Korean hemodialysis patients. Further research is needed to verify the usefulness of reticulocyte hemoglobin content in predicting iron deficiency in hemodialysis patients.

PUB338

Six Months Intradialytic Aerobic Cycling Program Exerts Beneficial Effects on Haemoglobin Stability in Hemodialysis Patients Treated with ESA

Myriam Rouchon Isnard, Céline Coutard, Marie-Hélène Mosnier, François Jamy. *Aura Auvergne, Chamalieres, France.*

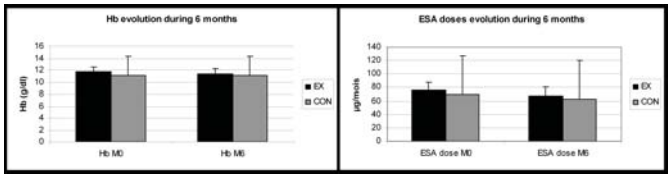
Background: Chronic Kidney Disease (CKD) leads to decrease erythropoietin synthesis. Haemodialysis patients have an unfavourable cardiovascular outcome: the variation of haemoglobin (Hb) is now considered like a cardiovascular risk factor. In clinical practice, the Hb correction with an Erythropoietin Stimulating Agent (ESA) during CKD must be slow and progressive. The morbidity due to quick variations of Hb has been largely studied. This study aimed to determine if physical activity during dialysis (PA) may help to maintain Hb stability in haemodialysis patients treated with Metoxy Polyethylene Glycol Epoetin Beta (MIRCERA*).

Methods: We studied 17 haemodialysis patients treated with MIRCERA in an hemodialysis center. They were voluntarily assigned to either intradialytic exercise training (cycling) group (EX;n=7) or a control group (CON;n=10). Baseline characteristics of the patients:

Groups	%Male	Age	Charlson Index	Time in Dialysis (year)	Diabetes%	Cardiovascular Risk Factors%
EX n=7	71	68 ±10.9	6.4 ± 2.3	4 ± 2.16	57	71
CON n=10	40	67 ± 17.8	5.1 ± 1.66	4.2 ± 2.9	60	70

The Charlson Score is higher in EX: one patient has a score of 11.

Results: Intradialytic training protocol did not modify Hb level, no significant difference between the 2 groups (t=0.21). Hb remains stable in the 2 groups, no supplementary dose during 6 months of follow-up and the doses of ESA diminish in the 2 groups



Conclusions: These results show that: Hb level is stable in the 2 groups, the ESA doses are reduced during the 6 months follow up; no need of supplementary dose. The Hb stability is a protective cardiovascular factor for the haemodialysis patients. It seems that when they practice physical activity it is more stable, so we can encourage patients to do PA. But certainly randomised studies are needed on the subject.

Anemia Management in the Gulf Cooperation Council (GCC) Countries: International Comparisons from the DOPPS Phase 5 Study (2012-2014)

Samra Abouchacra,[1] Maria Larkina,[2] Mohamed Elsayed,[3] Faissal A. Shaheen,[4] Jamal S. Al Wakeel,[5] Mohammad Alazmi,[6] Bruce M. Robinson,[2] Ronald L. Pisoni.[2] *[1]TAWAM Hosp., United Arab Emirates; [2]Arbor Research, MI; [3]Hamad Med. Corp., Qatar; [4]SCOT, Saudi Arabia; [5]King Saud Univ, Saudi Arabia; [6]Dar Alshefa Hospital, Kuwait.*

Background: Managing anemia and iron stores is an important aspect of care for chronic hemodialysis (HD) patients (pts). Here we provide the first detailed comparison of anemia and iron management (mgmt) in HD pts in 6 GCC countries with that in Europe(EUR), Japan(JPN), and North America (NA).

Methods: Data are from DOPPS 5 (2012-2013) initial cross-section of 742 HD pts on dialysis >90 days at 34 randomly selected facilities in the GCC and compared to 3 other regions: JPN, NA, and EUR. Results are weighted for sampling fraction in each unit.

Results: Mean age of GCC HD pts (53.6 yrs) was 8-11 years younger than in JPN, EUR, or NA, 56% were male, with mean dialysis vintage of 4.2 yrs (versus 4.4, 5.6, 9.3 yrs in NA, EUR, and JPN, respectively). Mean hemoglobin (Hgb) was similar in the GCC, JPN, and NA but varied from 10.3-11.2 g/dL across GCC countries (Table); lower Hgb target varied greatly across GCC facilities. Monthly ESA use was highest in the GCC (89%), ranging from 85-100% across GCC countries; 49%, 48%, and 3% of ESA pts used epoetin, darbepoetin, or Mircera, respectively, but ESA type used varied greatly across GCC countries. Mean TSAT and ferritin in the GCC were similar to that in EUR. Monthly IV iron % use in the GCC was lower than in EUR and NA although mean IV iron doses were the highest among DOPPS countries.

Conclusions: Many aspects of anemia and iron mgmt in the GCC are similar to that in EUR, JPN, and NA. However, considerable differences also are seen across GCC countries. Future studies will examine the relationship of anemia control and iron stores with pt outcomes, and reasons for anemia/iron mgmt practice differences within the GCC.

Non-Anemic Dialysis Patients with No Requirement for Erythropoiesis Stimulating Agents: Who Are They?

Mehmet S. Sever,[1] Murvet Yilmaz,[2] Fatih Kircelli,[3] Ozgur Akin Oto,[1] Gulay Asci,[4] Cengiz Dogan,[3] Kutay Gunestepe,[3] Ali Basci,[4] Ercan Ok.[4] *[1]Istanbul Univ School of Medicine; [2]Bakirkoy Dr. Sadi Konuk Training and Research Hospital; [3]Fresenius Medical Care; [4]Ege Univ School of Medicine.*

Background: Not only anemia, but also erythropoiesis stimulating agents (ESA) may adversely affect outcome of hemodialysis (HD) patients. Features of ESA-independent non-anemic cases may be useful for defining pathogenesis and related outcomes of anemia in chronic HD patients.

Methods: Data, retrieved from European Clinical Database (EuCliD)-Turkey, on ESA-independent non-anemic (Hb >11.5 g/dl) prevalent HD patients (n:410) were compared with their counterparts, who needed ESA for anemia treatment (n:3891).

Results: Various parameters are provided in table 1.

Table1. Various features of the patients who did, and did not need ESA treatment

Parameter	*No ESA requirement*	*ESA Users*	*P*
Age (yrs.)	54,6±12,6	57,9±14,8	<0,001
Male (%)	78,7	52,8	<0,001
Dialysis vintage (months)	88,8±62,4	61,4±51,7	<0,001
Diabetic (%)	22,7	32,1	<0,001
Hepatitis C (+) (%)	25,1	13,3	<0,001
Dialysis with a-v fistula (%)	86,1±28,4	81,8±32,3	<0,001
URR (%)	73,8±4,7	76,0±5,3	<0,001
Hb (g/dl)	13,2±0,9	11,4±0,9	<0,001
Ferritin (ng/ml)	428,7±469,3	827,0±493,4	<0,001
CRP (mg/dL)	1,3±1,8	1,7±1,9	<0,001
Vit. D usage (%)	66,3	77,2	<0,001
Carnitene usage (%)	49,3	62,9	<0,001

Survival of ESA-independent non-anemic patients was superior as compared to the ESA users.

Conclusions: Favorable effects of several clinical and laboratory parameters as well as elimination of side-effects of ESAs can play a role in better outcome observed in non-ESA requiring patients.

PUB341

Responses to Erythropoietin in Iron Deficient Hospitalized Hemodialysis Patients

Tanjim Sultana, Muhammad R. Toor, Maria V. DeVita, Michael F. Michelis. *Nephrology, Lenox Hill Hospital, NY, NY.*

Background: Management strategies to correct anemia in hospitalized hemodialysis (HD) patients include therapy with erythropoietin (EPO). The effectiveness of EPO is known to be limited by iron deficiency. Repeated blood studies and blood loss from various procedures can cause or worsen iron deficiency. There is a paucity of data on iron management in hospitalized ESRD patients.We evaluated the EPO responsiveness in iron deficient patients who did and did not receive iron therapy.

Methods: Hospitalized anemic hemodialysis patients who were treated for more than two weeks over an eleven month period were enrolled. Hemoglobin (Hb) levels, iron status, EPO dosage, use of intravenous iron supplementation and transfusion use were observed.

Results: Fifty-seven patients were enrolled during this period. Anemia was present in 29 patients (50.8%). Of these, 15 patients had transferrin saturation (TSAT) < 23%. Ten (66%) iron deficient patients did not receive intravenous iron because there was concern regarding active infection. Among these 10 patients the average dosage of EPO was 9500 units/HD. In the other 5 patients who were given iron therapy, the average administered EPO dose was 8000 u/HD. The difference was not statistically significant (P=0.35). In patients not given iron initial Hb was 9.0±0.8 gm/dl and discharge Hb was 8.9±0.8gm/dl. Those who did receive iron therapy had initial Hb 8.8±1.7gm/dl and discharge Hb 9.8±1.5gm/dl. The changes between initial and discharge Hb level were not different in the two groups (P=0.30). The discharge Hb levels in both groups were also not statistically different (p=0.15). There was no difference in the incidence of transfusion.

Conclusions: Current practice avoids intravenous iron therapy in the setting of infection. There is insufficient data to assess EPO responsiveness to various levels of iron storage and replacement. In this short term evaluation of iron deficiency anemia in hospitalized ESRD patients we found that Hb levels were not different between patients who received or did not receive iron. Our data suggest that patients are able to maintain some responsiveness to EPO despite iron deficiency.

PUB342

Roxadustat (FG-4592) May Lower Cholesterol Through a Mechanism Related to More Efficient Anemia Correction in Patients with Chronic Kidney Disease

Lynda Szczech, Anatole Besarab, Lona Poole, Brian K. Roberts, Gopal Saha, Kin-Hung Peony Yu, Thomas B. Neff. *FibroGen, San Francisco, CA.*

Background: Iron deficiency is associated with higher lipid levels; with iron repletion, lipid levels fall. Roxadustat, a prolyl hydroxylase inhibitor stabilizing hypoxia inducible factor being developed for the anemia Rx in CKD 3-5, decreases total cholesterol (TC). This analysis explored the potential mechanism for this observation.

Methods: Post-hoc analysis of 2 phase II studies evaluated change in total cholesterol (TC) from baseline across treatment arms stratified by concomitant statin use by Spearman rank correlation.

Results: In ESRD subjects randomized to roxadustat or epoetin alfa, roxadustat reduced TC (assessed as mean change from BL to day 43) irrespective of concomitant statin use (p<0.0001 for both). TC on day 43was significantly lower with roxadustat compared to epoetin alfa (Table 1).

Table 1: TC changes from baseline (mg/dL) by treatment group stratified on use of statins: mean (SD)

	FG-4592	N	epoetin alfa	N	p value
Concomitant statin	-37.10 (45.39)	48	6.52 (29.22)	21	<0.0001
No statin	-36.14 (25.56)	56	0.93 (28.40)	15	<0.0001

Similarly, roxadustat reduced TC from BL to week 9 irrespective of concomitant statin use in CKD (-24.8+30.6, p<0.0001,n=88 and -27.7+28.1, p< 0.0001,n=45 respectively). Among subjects receiving roxadustat and statins, TC inversely correlated with MCV at baseline (slope=-0.24, p=0.03), and a decline in TC was associated with a greater increase in TSAT (slope=0.31, p=0.004). Among subjects receiving roxadustat without statins, greater declines in TC were seen among those with greater TC at baseline (slope=-0.38,p=0.007) and associated with greater increases in MCV from baseline to week 9 (slope=-0.33, p=0.02). Decline in TC was not correlated with either baseline or change in CRP but was associated with increased ferritin (slope=-0.42, p=0.003).

Conclusions: In the two studies analyzed, roxadustat reduced TC in patients with or without concomitant statin therapy. TC reduction was correlated with smaller baseline MCV, a greater rise in MCV during therapy, as well as a rise in TSAT and ferritin suggesting improved availability of endogenous iron as a potential mechanism.

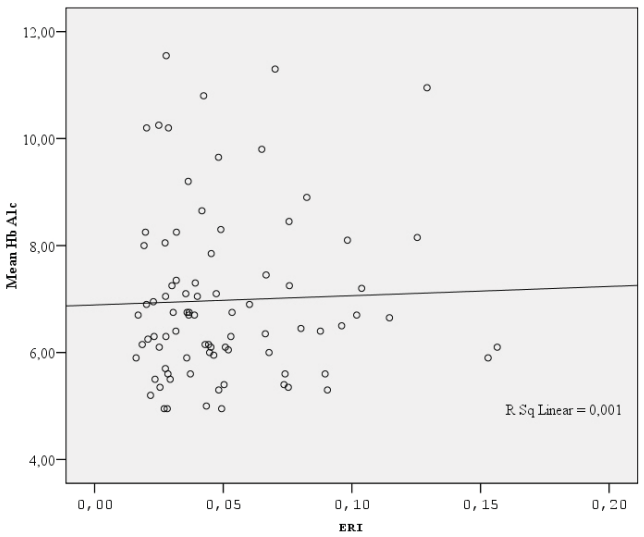
Glycemic Control and Erythropoietin Resistance in Diabetic Hemodialysis Patients

Faruk Turgut,[1,2] Emaad M. Abdel-Rahman,[1] Kline Bolton.[1] *[1]Dept of Nephrology, Univ of Virginia, Health System, Charlottesville, VA; [2]Dept of Nephrology, Mustafa Kemal Univ, School of Medicine, Hatay, Turkey.*

Background: Anemia is very common in patients with chronic kidney disease (CKD) and erythropoiesis stimulating agents (ESA) are often used to treat anemia in these patients. In the course of CKD, diabetic patients tend to develop anemia earlier and to a greater degree than patients without diabetes mellitus. The primary objective of this study was to evaluate the association between glycemic control and ESA dose in diabetic hemodialysis patients.

Methods: This is a cross-sectional study conducted on hemodialysis patients using ESA for anemia. The data between September, 2008 and December, 2008 were investigated retrospectively. Diabetic patients (either type 1 or type 2) receiving darbopoetin alpha and aged ≥18 years were included in the study. To assess ESA responsiveness, an erythropoietin resistance index (ERI) was calculated as weekly ESA dose per kg body weight, divided by the hemoglobin concentration. Erythropoietin resistance was defined as an ERI >0.02 μg/kg/week/g Hb.

Results: A total of 84 diabetic patients of 441 patients on hemodialysis were included in the final analysis. Seventy one patients (84.5 %) had an ERI > 0.02 (patients with ESA resistance). Demographic characteristics were similar in patients with and without ESA resistance. There was a small but significant difference in albumin and Kt/V between the groups (p=0.047, p=0.011, respectively). We found no correlation between ERI and Hb A_{1c} (r= 0.034, p=0.7) (figure1). There was a significant negative correlation between ERI and serum albumin levels (r= -0.273, p=0.012).



Conclusions: We showed that glycemic control may not influence the ESA dose requirement, and there is an association between low serum albumin levels and EPO resistance in diabetic hemodialysis patients.

PUB344

The Sequential Change of Serum Hepcidin-25(HPC) Level and Other Iron Metabolism Markers After Single Intravenous Iron Administration in Hemodialysis (HD) Patients

Noriko Saito,[1] Shigeru Miyazaki,[1] Tetsuo Morioka,[1] Kazuhide Saito,[2] Yuya Sato,[1] Yutaka Tsubata,[1] Kozo Ikarashi,[1] Hisaki Shimada.[1] *[1]Shinraku-en Hospital, Niigata, Japan; [2]Niigata Univ, Niigata, Japan.*

Background: HPC is a crucial player of iron metabolism. Iron-overload and inflammation stimulate HPC production, whereas anemia, iron depletion inhibit HPC production. It is not elucidated that the sequential changes of the relation between HPC level and other iron parameters after single intravenous(IV) iron administration in HD patients.

Methods: 23 HD patients were administered ferric oxide (Fe 40mg) intravenously after HD session. We evaluated the following markers before and at 0.5, 1, 2, 4, 6, 20 and 44 hours after iron administration : HPC, transferrin (Tf), 8-oxo-2'-deoxyguanosine (8-OHdG) and standard hematological parameters including high sensitive CRP (hs-CRP). The transferrin saturation (TSAT) value (%) was calculated from the serum iron and Tf values using the formula : serum iron (μmol / L) / Tf (g/L) x 3.8.

Results: 1. TSAT was immediately increase after IV iron administration (before IV was 20(14-27)% and reached the peak after 0.5 hour at 81(65-100)%), and returned to the same level before IV administration at 44 hours. In 6(26%) patients, TSAT had oversaturated. The data are indicated as medians(interquartile range) or numbers(%). 2. HPC level before IV iron administration was 5.1(0.6-20.3) ng/ml, significantly elevated after 4hours at 15.1(0.8-47.3) ng/ml ($p<0.05$), marked the peak after 20 hours at 36.5(5.5-57.6) ng/ml and gradually decreased to 20.7(3.5-41.8) ng/ml after 44 hours. 3. Ferritin level and 8 OHdG level before IV iron administration were 110(49-216) ng/ml and 0.197(0.120-0.268) ng/ml, significantly elevated after 20 hours at 151(83-222) ng/ml ($p<0.01$) and 0.290 (0.196-0.374) ng/ml ($p<0.01$), respectively. 4. Stepwise analysis indicated that HPC level at 4hr, 8OHdG at 0 hr and TSAT at 2 hr were predictors of ferritin level at 20 hrs.

Conclusions: In HD patients, after single IV iron administration, TSAT level was firstly elevated and then HPC level and lastly ferritin level was increased. HPC, 8OHdG and TSAT could be predictor of ferritin level after IV iron administration.

PUB345

Effectiveness of Biosimilar Epoetin Alfa (HX575): Interim Results from the MONITOR-CKD5 Study of Anemia in Hemodialysis

David Goldsmith,[1] Christian Combe,[2] Adrian Covic,[3] Frank Dellanna,[4] Loreto Gesualdo,[5] Gerard M. London,[6] Johannes F. Mann,[7] Philippe Zaoui,[8] Matthew Turner,[9] Ivo Abraham,[10] Karen Macdonald.[10] *[1]Guy's and St Thomas' NHS Foundation Hospital, London, United Kingdom; [2]Centre Hospitalier de Bordeaux, Univ of Bordeaux, Bordeaux, France; [3]G.I. Popa Univ Hospital of Medicine and Pharmacy, Iasi, Romania; [4]Dialysezentrum, Duesseldorf, Germany; [5]Univ degli Studi di Bari, Bari, Italy; [6]Centre Hospitalier F.H. Manhés, Fleury-Mérogis, France; [7]Friedrich Alexander Univ Erlangen-Nürnberg, Munich, Germany; [8]Univ de Grenoble, Grenoble, France; [9]Sandoz Biopharmaceuticals, Holzkircehn, Germany; [10]Matrix 45, Earlysville, VA.*

Background: MONITOR-CKD5 is a European prospective observational multicenter study of practice patterns and outcomes with HX575 in hemodialysis patients.

Methods: Analysis of 2087 CKD5 patients with renal anemia started on HX575 treatment de novo or by conversion in 10 countries. Interim longitudinal results on HX575 dosing and Hb levels in the first 18 months are presented.

Results: Mean age was 64.8±14.9y. Mean time since first dialysis was 3.7±4.7y. Most patients were male (60%) and converted from a prior ESA (82%). Primary CKD5 etiologies were diabetic nephropathy (25%), glomerulonephritis (21%), vascular disease (16%), tubular interstitial nephropathy (11%). Common comorbidities were hypertension (88%), coronary disease (39%), type 2 diabetes (33%). At enrollment median serum ferritin was 559±574 ng/mL; 73% had adequate iron stores, 22% had functional and 5% absolute deficiency. Across visits, iron supplementation was given in 62-67%, and transfusions were given in 2-9%. At enrollment mean Hb was 11.2±1.2 g/dL and mean weekly HX575 dose was 7532±5342 IU/wk. Hb remained stable over 18 months ($p=0.07$) ranging from 11.2±1.2 to 11.3±1.2 g/dL. Changes in HX575 dose ranged from 7385±6769 to 7721±6393 ($p<0.01$), but ESA resistance index (HX575 dose/Hb) remained stable, ranging from 9.3±8.1 to 10.0±9.8 ($p=0.10$).

Conclusions: Interim analysis of this real-world study reveals that biosimilar epoetin alfa (HX575) dosing is effective in maintaining stable longitudinal Hb outcomes, reflecting the same patterns as known with originator epoetin alfa.

PUB346

The Cost-Effectiveness of Erythropoietin Stimulating Agents for Treating Anemia in Dialysis Patients: A Systematic Review

Ravindi M. Gunasekara,[1] Yang Xu,[1] Thomas W. Ferguson,[2] Blake R. Lerner,[1] Paul Komenda,[1] Claudio Rigatto,[1] Navdeep Tangri.[1] *[1]Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: Anemia is common in patients with chronic kidney disease. Erythropoietin stimulating agents (ESAs) are used to treat anemia and reduce the need for blood transfusions. However, recent evidence suggests that ESAs may increase cardiovascular risks and have no significant effects on quality of life. In light of these findings, treatment with ESAs to current hemoglobin targets, may not be cost-effective. Our objective was to evaluate published studies that determine the cost-effectiveness of ESAs based on relevant costs and benefits in adult patients with CKD.

Methods: We conducted a systematic review of studies evaluating the cost-effectiveness of ESAs in patients on dialysis with no restriction on setting. We searched PubMed, EMBASE, and the Cochrane Library ranged from their establishment until June 2013. The primary outcome was the incremental cost-effectiveness ratio (ICER) of treating anemia with ESA as compared to routine blood transfusion, lower Hb target levels, or no ESA treatment.

Results: Seven studies met our inclusion criteria. Four studies compared ESAs and routine blood transfusion as standard of care, two studies compared the cost-effectiveness between different Hb targets, while one studied compared ESA treatment and no ESA treatment. ESAs were found to be less cost-effective than routine blood transfusions (ICERs > $50,000 USD/QALY) in all studies except one. One study found targeting higher hemoglobin levels to be associated with greater clinical benefits at a lower cost and assumed a mortality benefit from increased Hb targets, while a second study found that aiming for higher Hb levels was not cot-effective and assumed an increase in mortality from targeting higher Hb targets.

Conclusions: Our analysis suggests treatment of anemia with ESAs is not cost-effective without assuming large benefits in utility scores or all cause mortality from ESA treatment. Cost-effectiveness models for ESA treatment need to be updated to reflect current clinical evidence on benefits and risks.

PUB347

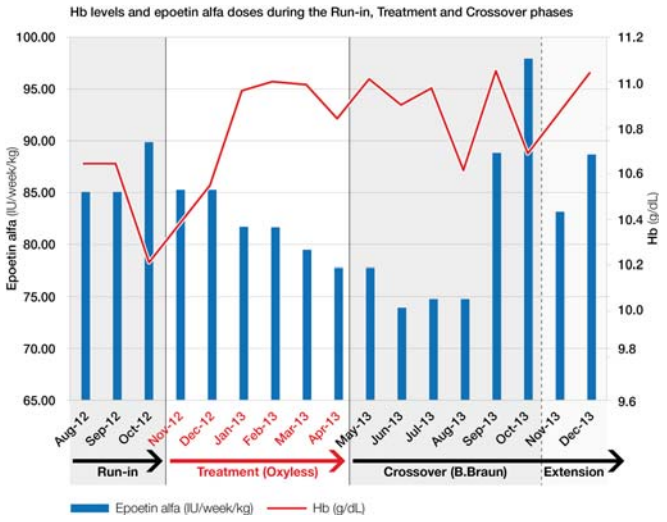
Improving Erythropoiesis Stimulating Agent Therapy in Haemodialysis Patients. A Clinical Audit of a Novel Bloodline

Iain C. Macdougall,[1] Adam Rumjon,[1] Emmanuel Mangahis,[1] Thomas Ryzlewicz,[2] Franz-Ferdinand Becker,[2] William Kilgallon.[2] *[1]King's College Hospital, London, United Kingdom; [2]Oxyless Ltd, Reading, United Kingdom.*

Background: A patented universal bloodline (Oxyless) which greatly reduces the contact between blood and air has been developed for routine haemodialysis (HD). The aim of the investigation was to explore whether the use of the Oxyless bloodline could improve the efficiency of Erythropoiesis Stimulating Agent (ESA) therapy.

Methods: Patients (> 18 years, HD for ≥ 3 months with AV fistulas) were entered into a 12 month open label, single cross-over, cohort prospective pilot audit. Haemoglobin (Hb), epoetin alfa and ESA resistance index (ERI) were reported.

Results: Data from only eight out of fifteen patients were able to be used as a result of drop-outs due to clinical intercurrent events. Haemoglobin increased in the first three months and stabilised during the treatment phase at 11.0 g/dL. Individual patients had Hb increases of more than 1.0 g/dL. Mean peak reduction in epoetin alfa levels were noted in June, ranging from 14% to 67%, representing a total reduction of 12,667 IU/week and a per patient reduction of 2,533 IU/week. In the crossover phase, epoetin alfa levels increased to a mean of 113% of run-in values in response to falling Hb levels (reductions ≤ 1.3 g/dL). These returned to 99%, indicating a rebound effect. Mean Hb returned to 104% of run-in values.



ERI decreased steadily during the treatment phase with a maximum reduction of 16.2%.

Conclusions: There is a small but definite signal that the use of the Oxyless bloodline can improve haemoglobin levels and result in reduced ESA doses. The crossover design allows some confidence in the validity of the data. These results could have potential financial benefits for HD service delivery. A prospective multi-centre European audit (PEMA) is underway to gather more robust clinical and health economic data.

PUB348

Optimizing Anaemia Management and Transfusion Rates in Haemodialysis
Suzanne H. Forbes, Neil Ashman. *Dept of Nephrology and Transplantation, Royal London Hospital, London, United Kingdom.*

Background: The last decade has seen major changes in anaemia management in end-stage renal disease (ESRD) including different iron regimens, advances in erythropoietin stimulating agents (ESA) and altered haemoglobin (Hb) targets. Despite this, red cell transfusions to maintain target Hb are common in hemodialysis (HD) patients, conferring a burden in cost and nursing time, and risk of sensitization for transplantation. We aimed to quantify transfusion rates in our HD patients at 3 time points reflecting historic changes in our practice, with a cohort of PD patients as control.

Methods: We analysed 4 groups retrospectively. We excluded the first 90 days of HD and patients with sickle cell disease (n=13). For each group we determined the number of units of blood transfused over time on dialysis during the specified year, as well as various haematological parameters and cumulative ESA dose. All ESA doses were subcutaneous until 2012 when policy switched to intravenous.

Results: 1958 patient years were studied. Transfusion rates (units/patient year) between the 4 groups were significantly different (p=0.002) with a clear fall over time to rates seen on PD.

Modality	n (pt yrs)	ESA		Transfusion (u/pt/yr)	TimeAve Results					
		% pts taking Darbepoeitin (cumulative dose mcg/kg/yr)	% pts taking NeoRecormon (cumulative dose mcg/kg/yr)		Hb	Plt	Fer	Tsat	TIBC	CRP
HD 2004	340 (301)	49 (28.4)	51 (4784)	2.42	10.9	233	480	-	-	25
HD 2008	757 (637)	46 (49.4)	38 (8579)	1.66	10.7	230	475	28.4	41.2	23
HD 2012	1071 (917)	89 (22.8)	4 (4488)	1.52	10.7	212	493	27.6	45.5	22
PD 2012	164 (104)	80(14.6)	10 (1156)	1.37	10.9	233	358	28.3	41.6	14

All time-averaged haematological parameters were comparable except significantly lower CRP and ferritin levels in PD. Cumulative ESA dose fell over time, particuarly with iv dosing.

Conclusions: Although occasionally required, blood transfusions in dialysis patients should be avoided, particularly if transplantation is anticipated. We show here that with the use of iv iron (fortnightly to a ferritin target of 500mg/l) and iv darbepoeitin at minimal doses on HD, Hb targets can be met with minimal blood transfusion use, providing safer and more cost-effective care.

PUB349

Sleep-Disordered Breathing Is Associated with Low Serum Klotho in Hemodialysis Patients
Takuya Miki,[1] Takahiro Masuda,[1] Tetsu Akimoto,[1] Sumiko Honma,[2] Yuko Watanabe,[1] Kazuhiro Shiizaki,[3] Makoto Kuroo,[3] Eiji Kusano,[4] Yasushi Asano,[2] Daisuke Nagata.[1] *[1]Div of Nephrology, Dept of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [2]Div of Nephrology, Koga Red Cross Hospital, Koga, Ibaraki, Japan; [3]Center for Molecular Biology, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [4]Japan Community Health care Organization Utsunomiya Hospital, Utsunomiya, Tochigi, Japan.*

Background: Sleep-disordered breathing (SDB), characterized by nocturnal intermittent hypoxia, is frequently observed in the aged and in patients with end-stage renal disease (ESRD). The anti-aging protein Klotho is mainly expressed in the kidney and released into the blood, but down-regulated in hypoxic conditions or chronic kidney disease. We therefore examined the relationship between SDB and serum Klotho protein level in ESRD.

Methods: Sixty-three maintenance hemodialysis (HD) patients (male: 50.8%, age: 64.2 ± 1.6 years, body mass index [BMI]: 21.3 ± 0.4, duration of HD: 6.7 ± 0.7 years, diabetes: 33.3%) in Koga Red Cross Hospital were subjected to overnight pulse oximetry on a dialysis day. The SDB group was defined as 3% oxygen desaturation index over five events per hour, and the others were designated as the normal group. Serum Klotho levels were measured by a commercially available sandwich ELISA.

Results: Twenty-four patients (38.1%) were classified into the SDB group. Compared to the normal group, the SDB group exhibited lower serum Klotho (SDB 352 ± 23 versus normal 435 ± 34 pg/ml, P=0.040), but higher serum C-reactive protein and higher blood radical formation potential, which denotes oxidative stress. Serum fibroblast growth factor 23, BMI and frequency of diabetes were similar between the groups. After adjusting for age, gender, BMI, duration of HD and diabetes in a logistic regression analysis, SDB was independently associated with low serum Klotho (odds ratio 0.63; 95% confidence interval 0.33–0.99: P = 0.044).

Conclusions: SDB in HD patients was associated with low serum Klotho. This study suggests that nocturnal intermittent hypoxia may contribute to a decrease in renal Klotho expression.

Proton Pump Inhibitors: An Innocent Bystander in Uremic Cardiovascular Disease?
Kieran Mccafferty, Conor J. Byrne, Magdi Yaqoob. *Dept of Translational Medicine and Therapeutics, Queen Mary Univ, London, United Kingdom.*

Background: It has recently been demonstrated that PPIs inhibit dimethylarginine dimethylaminohydrolase, a key enzyme responsible for the metabolism of the eNOS antagonist asymmetrical dimethylarginine (ADMA). There is evidence in animal and ex vivo human models that PPI treatment leads to increased ADMA levels, reduced NO availability and impaired vascular function. ESRD patients have hugely elevated ADMA levels compared to non-uremic patients. High levels of ADMA are associated with cardiovascular death in dialysis cohorts and as such ADMA is considered a 'uremic toxin'. Our hypothesis is that PPI use, through increased ADMA levels may be associated with altered hemodynamic parameters on dialysis.

Methods: We performed a single center observational cross-sectional study, in a teaching hospital HD unit (n=334), collecting demographic and clinical data and stratifying patients according to PPI use.

Results: When compared to patients not on a PPI (n=180), PPI treated patients (n=154) were older (p=0.009), had a lower serum calcium (p=0.02), were more likely to have diabetes (p=0.03) and to receive aspirin (p=0.01), clopidogrel (p=0.004) and β-blockers (p=0.006). There was no difference between the groups in terms history of ischemic heart disease, dialysis vintage, EPO dose and overall antihypertensive use. There was a slight reduction in mean arterial pressure, which approached statistical significance (p=0.06), but no difference in pulse pressure (p=0.32) with PPI treatment.

Conclusions: Our data do not support the hypothesis that PPI use is associated with significant haemodynamic changes in a haemodialysis cohort. Explanations for this result are: at a physiological dose, PPIs may not inhibit ADMA sufficiently to alter blood pressure (a crude surrogate marker of nitric oxide metabolism); other factors (EPO use, hyperglycaemia, oxidative stress) which lead to increased ADMA levels may overwhelm the signal from PPI use, and the colocalization of PPIs and antiplatelet use for heart disease may lead to confounding. Future prospective studies examining PPI use on ADMA levels in patients with CKD may be of great therapeutic potential.

PUB351

Haptoglobin 2-2 Genotype Is Associated with Pulmonary Hypertension in Diabetic Individuals on Hemodialysis
Farid M. Nakhoul,[1,2] Inbal Dahan,[2] Farber Evgeny,[1,2] Nakhoul Nakhoul,[2] Andy Levy,[3] Rabea Asleh.[3] *[1]Nephrology and Hypertension Div, Baruch Padeh Poriya Medical Center Faculty of medicine Galilee, Lower Galilee, Israel; [2]Diabetic Nephropathy Lab, Poriya Medical Center; [3]Vascular Medicine Lab, Faculty of Medicine Technion, Haifa, Israel.*

Background: Haptoglobin (Hp) is an antioxidant protein by virtue of its ability to bind free hemoglobin (Hb) and prevents heme-iron mediated oxidation.The Hp1 protein is superior to the Hp 2 protein in binding to free Hb and neutralizing its oxidative potential. Pulmonary hypertension (PHT) is an elevation of pulmonary arterial pressure, recently been recognized as a complication of chronic kidney disease and Hemodialysis (HD). The higher PHT is an independent predictor of increased morbidity and mortality in HD patients.

Methods: 29 HD patients with DM (mean age, 66.75 ± 8.94 yrs) and 18 HD patients without DM (mean age, 66.58 ± 16.97 yrs)were included. Exclusion Criteria: severe lung disease or known congestive heart failure. Hp typing was performed. Echo measurments of HD patients included left ventricular end-systolic (LVESD), left ventricular end-diastolic diameter (LVEDD) and estimated systolic pulmonary pressure (e-PASP), by Doppler echocardiography.

Results: 1. The prevalence of PHT in Hp 2-2 DM HD patients is much higher (80%) compared with DM HD patients with Hp 2-1 (44%) or Hp1-1 (25%) genotypes. In the non-DM group only 20% of the patients have PHT with no significant differences between the Hp genotypes. **2.** Hp 2-2 DM patients have a significantly higher e-PASP levels (42.17±9.7) compared with Hp 1-1 DM patients (28±7.16) or Hp 2-1 (35.28±5.65) genotypes. In the non-DM patients we found no significant differences in e-PASP values between the different Hp genotypes. **3.** Hp 2-2 DM HD patients had higher e-PASP (42.17±11.69), LVEDD (54.07±6.18) and LVESD (40±3.16) levels compared with non-DM Hp 2-2 HD patients (28.33±3.42, 46.67±6.08 and 33.67±5.05 respectively).

Conclusions: 1. Hp polymorphism affects the prevalence and the severity of PHT specifically in DM HD patients but not in non-DM HD patients. **2**.DM Hp 2-2 HD patients are with the highest risk for CV event. **3.** DM Hp 2-2 HD patients, should be screened by echocardiogram for PHT before entering the HD program.

PUB352

Low Serum Klotho Level Predicts High Mortality in Hemodialysis Patients
Naoko Otani,[1] Takahiro Masuda,[1] Tetsu Akimoto,[1] Sumiko Honma,[2] Yuko Watanabe,[1] Kazuhiro Shiizaki,[3] Makoto Kuroo,[3] Eiji Kusano,[4] Yasushi Asano,[2] Daisuke Nagata.[1] *[1]Div of Nephrology, Jichi Medical Univ, Shimotuke, Tochigi, Japan; [2]Koga Red Cross Hospital, Koga, Ibaraki, Japan; [3]Center for Molecular Biology, Jichi Medical Univ, Shimotuke, Tochigi, Japan; [4]Japan Community Health Care Organization Utsunomiya Hospital, Utsunomiya, Tochigi, Japan.*

Background: Klotho is a transmembrane protein that is predominantly expressed in the kidney. Its extracellular domain is subjected to ectodomain shedding and released into the blood. Klotho has protective effects against cardiovascular disease (CVD) and death,

but is down-regulated in end-stage renal disease (ESRD). We therefore examined whether low serum Klotho is related to long-term cardiovascular events and mortality in ESRD.

Methods: Sixty three chronic hemodialysis (HD) patients (male 32, age 64.2 ± 1.6 years, BMI 21.3 ± 0.3, follow-up period 60.3 ± 1.6 months) were included in this study. Serum Klotho levels were determined by a commercially available sandwich ELISA. The patients with serum Klotho of less than 350 pg/ml were defined as the low Klotho group, and the others were defined as the high Klotho group. The primary outcome was cardiovascular events and all-cause death. The Kaplan–Meier method and Cox proportional hazard model were used for survival analyses.

Results: Twenty-six patients (41.3%) were classified into the low Klotho group. Age, gender, history of CVD, serum calcium, phosphorus, fibroblast growth factor 23, intact parathyroid hormone, and 1,25-dihydroxy vitamin D3 were similar between the groups. Kaplan–Meier analysis with log-rank test revealed that the low Klotho group had a higher rate of all-cause mortality (P=0.041) and cardiovascular events (P=0.055) than the high Klotho group. In the multivariate Cox regression model including age, gender, serum albumin, and diabetes, low serum Klotho remained an independent predictor for increased mortality (hazard ratio, 3.32; 95% confidence interval, 1.02 to 12.68; P=0.045).

Conclusions: This observational study showed that low serum Klotho is an independent predictor for increased mortality in HD patients. Further studies are required to conclude that low serum Klotho is a cause of poor clinical outcome in HD patients.

PUB353

Effects of Adherence to Anti-Hypertensive Drugs on All-Cause Mortality and Hospitalizations in a Cohort of Prevalent Hemodialysis Patients

Disha Trivedi,[1] Lei Wang,[1] Jim Y. Wan,[1] Csaba P. Kovesdy,[1,2] Elvira Gosmanova.[1]
[1]Univ of Tennessee HSC, Memphis, TN; [2]Memphis VAMC, Memphis, TN.

Background: Poor adherence to anti-hypertensive drugs (AHD) was linked to adverse outcomes in general hypertensive population. However, little is known about effects of adherence to AHD in hemodialysis (HD) patients. We investigated the association between adherence to AHD and all-cause mortality and hospitalizations in a cohort of prevalent HD patients.

Methods: We prospectively studied a cohort of 58 HD patients (mean age 55 years, 96.5% African-Americans, 59.3% males) undergoing HD for at least 12 months under care of a single nephrologist. Adherence to AHD was determined at baseline using analysis of pharmacy dispensation records by calculating proportion of days covered (PDC) in the previous 12 months. Adherence to AHD was considered as good (PDC>80%) and poor (PDC<80%). The association between adherence to AHD and 1-year all-cause mortality and hospitalizations were assessed using univariate analysis and multivariate logistic regression models after adjusting for age, race, gender, and the number of AHD.

Results: At baseline, 10 patients (17.2%) had good adherence to AHD. Among remaining 48 patients, 39.6% had PDC between 40-79% and 60.4% had PDC<40%. During 1-year follow up period, 7 patients (12.1%) died, 41 patients (70.7%) had at least one hospitalization, and 23 patients (39.6%) were hospitalized for cardiovascular causes. In univariate analysis, good adherence to AHD was associated with 89% lower risk of any hospitalizations (OR 0.11, 95% CI 0.03-0.52) and 91% lower risk of all-cause mortality and hospitalization for any cause (OR 0.09, 95% CI 0.02-0.40). In the adjusted analysis, the patients with good adherence to AHD remained at lower risk of any hospitalization (OR 0.16, 95% CI 0.03-0.80) and combined outcome of all-cause mortality and hospitalization for any cause (adjusted OR 0.10, 95% CI 0.02-0.57).

Conclusions: Good adherence to AHD is associated with improved survival and reduced risk of hospitalizations in prevalent HD patients. Therefore, adherence to AHD should be monitored and reinforced in order to improve outcomes in this population.

PUB354

The Correlation of 1,25-Dihydroxyvitamin D with Peripheral Arterial Disease in End Stage Renal Disease Patients on Hemodialysis

Kyung Soo Kim, Bernice Kim, Dong Jun Oh, Sung Joon Shin. *Div of Nephrology, Dept of Medicine, Dongguk Univ Ilsan Hospital, Go-yang, Republic of Korea.*

Background: Vitamin D deficiency is recently regarded as an independent risk factor for peripheral arterial disease(PAD) and frequently occurs in end stage renal disease(ESRD) patients on hemodialysis(HD). However, since most studies are conducted on 25(OH) vitamin D (25(OH)D), the effect of 1,25(OH) vitamin D (1,25(OH)2D) on PAD in ESRD patients has not yet been investigated. The aim of this study is to examine the effect of 1,25(OH)2D on the occurrence of PAD in ESRD patients on HD, similarly to other factors related to bone metabolism.

Methods: Preliminary assessment was carried out on adult patients receiving HD. Patients with ankle-brachial index (ABI) less than 0.9 were defined to have PAD. Concentration of 1,25(OH)2D was measured using radioimmunoassay. Many covariates such as sex, age, body mass index(BMI), serum albumin, intact PTH, calcium and phosphate concentration were simultaneously measured.

Results: Serum 1,25(OH)2D concentration was measured for 40 patients out of 44 patients. The mean concentration was 30.9±6.3 pg/mL. ABI of 15 patients was measured, and PAD was confirmed in 20% of patients. Between the patient groups with and without PAD, no difference was found in sex, age (years, 65.0±11.8 versus 69.1±11.2, p=0.57), BMI (kg/m2, 24.8±2.7 versus 24.0±5.5, p= 0.81), serum calcium (mg/dL, 9.1±1.0 versus 8.5±0.5, p=0.19), phosphate (me/dL, 2.8±0.8 versus 4.6±2.3, p=0.29) and intact PTH (pg/mL, 218.6±85.6 versus 199.5±65.4, p=0.68), as well as 1,25(OH)2D (pg/mL, 27.8±7.0 versus 32.3±6.7, p=0.052). An interesting fact is that the female patient group showed direct correlation of serum 1,25(OH)2D concentration with ABI. Such result was statistically significant (p=0.042) after correcting various covariates.

Conclusions: No difference was found in serum 1,25(OH)2D concentration between the patient groups with or without PAD in this study. The female group on HD had a significant correlation of serum 1,25(OH)2D concentration with ABI. Since this study was a preliminary assessment conducted on a small number of participants, future study should be carried out.

PUB355

Walking Speeds for Reduced Cardio-Cerebrovascular Events in Hemodialysis Patients: A Seven-Year Cohort Study

Yoshifumi Abe,[1] Atsuhiko Matsunaga,[1] Ryota Matsuzawa,[1] Kei Yoneki,[1,2] Manae Harada,[1] Ryoma Ishikawa,[1] Takaaki Watanabe,[1] Atsushi Yoshida,[2] Kouju Kamata.[1] *[1]Kitasato Univ, Sagamihara, Japan; [2]Sagami Junkanki Clinic, Sagamihara, Japan.*

Background: Deterioration in walking ability characterized by slow walking speed is associated with an increased risk of hospitalization and mortality in hemodialysis (HD) patients. However, few studies have focused on walking speeds associated with reduced clinical events. Here we assessed the benefits of a range of maximum walking speeds (MWS) to reduce cardio-cerebrovascular events in HD patients.

Methods: A total of 188 Japanese outpatients (90 men, 98 women; mean, 65±10 years) undergoing maintenance HD 3 times a week were monitored for 7 years. We measured clinical characteristics (age, sex, body mass index, HD duration, comorbid conditions, serum albumin, and serum C-reactive protein) and MWS at baseline, and followed the patients for clinical events. Patients were divided into quartiles (Q1=lowest, Q4=highest) based on MWS for each sex. Kaplan-Meier analysis and Cox proportional hazards regression were used to assess the contribution of MWS to cardio-cerebrovascular events.

Results: During the follow-up period, cardio-cerebrovascular events occurred in 67 patients. Seven-year cumulative incidence rates were 36%, 32%, 13%, and 9% for Q1 through Q4, respectively, and a significant difference across quartiles of MWS was observed (Log rank, $P<0.001$). While the incidence did not significantly differ between Q1 and Q2 and between Q3 and Q4, Kaplan-Meier curves clearly differed between Q2 and Q3.

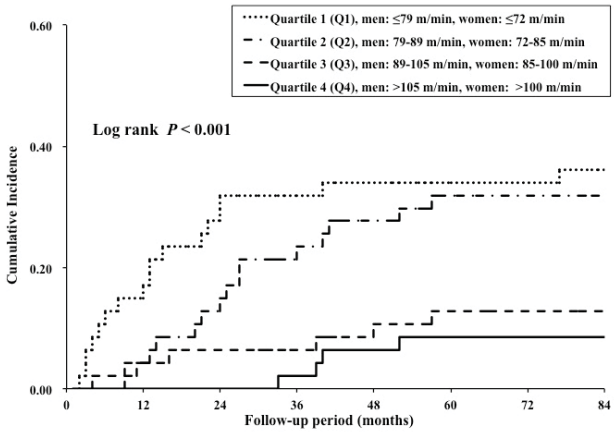

Figure 1. Kaplan-Meier analysis of the number of cardio-cerebrovascular events in 188 hemodialysis patients.

After adjusting for potential confounders, the hazard ratio for events per 10-m/min increases in MWS was 0.71 (95% confidence interval: 0.58-0.86; $P = 0.001$).

Conclusions: Our findings suggest that MWS >89 m/min in men and >85 m/min in women should be maintained in order to reduce subsequent cardio-cerebrovascular events in HD patients.

PUB356

The Effect of Statin for Cardiovascular Prevention in Peritoneal Dialysis Patient

Ping-Hsun Wu,[1,2] Mei-Chuan Kuo,[1,3] Yiwen Chiu,[1,3] Shang-Jyh Hwang,[1,3] Hung-Chun Chen.[1,3] *[1]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [2]Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [3]Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: End stage renal disease is associated with a high risk of cardiovascular event, which is one of the leading causesof death among peritoneal dialysis patients. However, most of the statin treatment randomized studies focus on hemodialysis or chronic kidney disease. The study of statin use for cardiovascular prevention in peritoneal dialysis patients is still sparse and need further investigate. This study aimed to evaluate the efficacy of statin in reducing the subsequent risk of cardiovascular event in a national cohort of Taiwan peritoneal dialysis patients.

Methods: We conducted a nationwide follow-up study, based on the Taiwan National Health Insurance Research Database. We identified incident peritoneal dialysis patients between during 1998 and 2006. Of the peritoneal dialysis patients, 725 received statin with

medication possession ratio (MPR) more than 80% in the first year and 2,114 received statin with MPR less than 80% for hyperlipidemia control. During the 3 years follow up, the primary outcomes of the study was major cardiovascular event, which include hospitalization for acute coronary syndrome and ischemic stroke.

Results: Statin with MPR more than 80% users were not significantly lower hospitalization for major cardiovascular event than statin with MPR less than 80% users (6.34% versus 7.05%), whereas adjusted HR was 0.91 (95% CI: 0.65 to 1.27). The adjusted HRs of hospitalization for acute coronary syndrome and ischemic stroke were 0.9 (95% CI: 0.61 to 1.32) and 0.98 (95% CI: 0.5 to 1.89).

Conclusions: In this retrospective analysis, statin use with MPR more than 80% had no statistically significant effect on the composite end point of hospitalization for acute coronary syndrome and ischemic stroke than statin use with MPR less than 80%.

PUB357

Use of Non-HDL Cholesterol as an Alternative Lipid Panel in Hemodialysis Patients Joannie Lefebvre, Jean-Philippe Lafrance, Vincent Pichette, Martine Leblanc, Robert Zoël Bell, Georges Ouellet, Caroline Lamarche, Anne Devin, Michel Vallee. *Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Treatment of dyslipidemia is controversial in hemodialysis patient. KDIGO guidelines suggest continuing statin therapy for patients already on statin when starting dialysis. Non-HDL cholesterol (non-HDL C) in contrast to calculated LDL cholesterol (LDL C) can be measure in non-fasting patient but has not been validated in hemodialysis patients. LDL C is obtained by subtracting non-HDL C and triglycerides from total cholesterol and is falsely low in non-fasting patient. Non-HDL C is the difference between total cholesterol and HDL cholesterol. In high risk patients goal of treatment are LDL C ≤ 2.0 mmol/L (70 mg/dl) or non-HDL C ≤ 2.6 mmol/L (100 mg/dl).

Methods: We conducted a cross-sectional study on 360 hemodialysis patients. We analyzed clinical data and measured LDL cholesterol, non-HDL cholesterol and apolipoprotein B (apoB) just before the hemodialysis treatment. The patients dialyzed in the morning (132 patients) were asked to fast for 14 hours prior to blood sampling but this could not be validated. The lipid panel from the patients dialyzed in the afternoon or the evening was obtained without fasting.

Results: Among the 360 hemodialysis patients, 51% were on statin therapy and 45% had coronary heart disease (CHD). Correlation between apoB and non-HDL C was stronger (r=0.939, p<0.0001) than correlation between apoB and non-fasting LDL C(r=0.83, p<0.0001). Forty patients (11 %) had an undetermined or ≤ 2.0 mmol/L non-fasting LDL C combined with a non-HDL C superior to the goal of 2.6 mmol/L. Of these patients, 60% were taking statins and 45 % had CHD.

Conclusions: These results suggest that we may use non-HDL C from the non-fasting lipid profile of hemodialysis patients to adjust lipid-lowering therapy in patients already on statin therapy when starting hemodialysis.

PUB358

Ideal Screening Tools for Coronary Artery Disease in Dialysis Patients: An Angiographic Examination Min-Jee Han, Chae Rim Kim, Do Hyoung Kim, Su Hyun Kim. *Dept of Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea.*

Background: Screening for coronary artery disease in dialysis patients is important, because of high cardiovascular mortality in dialysis patients. But there were no defined consensus for screening methods, therefore we studied the clinical effect for coronary angiography (CAG) as a screening tool for coronary artery disease (CAD) in dialysis patients.

Methods: A total of 120 patients who were undergoing dialysis patients (hemodialysis, n= 113, peritoneal dialysis, n= 7) were enrolled in this study. We evaluated the prevalence of coronary artery disease, and diagnostic values of non-invasive test were measured by using coronary angiography as the gold standard, and survival rate of patients.

Results: The patientswere divided into three groups according to ischemic heart disease related symptoms and performance of CAG; Group 1 (symptoms without CAG, n= 58), Group 2 (symptoms with CAG, n=42) and Group 3 (no symptoms with CAG, n=20). Among 62 dialysis patients who underwent CAG (Group 2 and 3), prevalence of CAD was 52(83.9%) and there were no statistically different between two groups. The accuracy of non-invasive diagnostic test was measured by using CAG as the gold standard, regional wall motion abnormality on resting echocardiography showed comparatively good sensitivity (65.4%) and specificity (80%), but its sensitivity was less than clinical symptoms (69.2%). Electrocardiography and chest X-ray showed low sensitivity (40.4%). Specificity of Troponin I (≥ 0.8 ng/mL) showed highest (90%) but low sensitivity (40.4%). Cardiovascular mortality rate was significantly higher in Group 1 than in Group 2 (p=0.049) and Group 3 (p=0.045). Age, performance of CAG, troponin-I, electrocardiography abnormalities, total cholesterol showed independent predictors of cardiovascular mortality. In multivariate Cox proportional hazard analysis, performance of CAG (4.16, 1.44-11.98, p = 0.017) and troponin-I (4.78, 1.55-14.72, p = 0.006) showed significant correlated with cardiovascular deaths.

Conclusions: This report suggests that performance of CAG as a screening test for CAD in dialysis patient may further improve cardiovascular survival rate.

PUB359

Reduced Systolic Longitudinal Strain in Hemodialysis Patients with Preserved Ejection Fraction Is Independent of Symptomatic Coronary Artery Disease Diana Chiu,[1] Nik Abidin,[2] Philip A. Kalra,[1] Darren Green.[1] *[1]Manchester Univ; [2]Salford Royal Hospital, United Kingdom.*

Background: Myocardial strain is a measure of the deformation of tissue from its resting dimensions.Left ventricular (LV) strain abnormalities have been found in hemodialysis(HD) patients with preserved ejection fraction (LVEF),indicating sub-clinical systolic dysfunction.This study compares strain pattern in HD patients with LVEF>50%,with and without symptomatic coronary artery disease (CAD) to establish whether previous findings were as a result of CKD or CAD.

Methods: 2D transthoracic echocardiography was performed in 194 stable HD patients on a non-dialysis day. Strain was assessed by speckle tracking software. The LV was divided into 21 segments and strain determined in each (abnormal strain is ≥-15%). Global longitudinal strain(GLS) was the mean of peak systolic longitudinal strain from the 3 apical views. CAD was defined as previous myocardial infarction,angina or coronary revascularization. Comparison between groups with and without CAD was made with t-test for continuous data and Fisher's exact test for categorical data.

Results: Of the 194 patients,166 had LVEF>50%.Those with CAD were older and more likely to have diabetes.Despite this,there was no difference in LV mass(118 v 113g/m^2,p=0.5),or LVEF(66 v 68%,p=0.2)between groups.Patients with CAD did not have more segments with abnormal strain(12 v 11,p=0.1),nor was there a difference in GLS(-13 v -14%,p=0.1).

Table1.Demographics and results of 2D echocardiography and speckle tracking

	No CAD (n=127)	CAD (n=39)	p
Age(yrs)	59(15)	68(9)	<0.01
Sex(male)	79(62)	29(74)	0.18
Diabetes	39(31)	20(51)	0.02
LVEF(%)	67.8(9.1)	65.7(9.8)	0.24
LVMI(g/m^2)	113.3(35.3)	117.6(32.7)	0.50
GLS(%)	-14.1(3.4)	-13.0(3.8)	0.11
Abnormal segments(n)	11(4)	12(4)	0.10

Data shown as mean (standard deviation,SD)-continuous variables; n(%)-categorical variables
LVMI:left ventricular mass index

Conclusions: Despite preserved LVEF,there were more LV segments showing abnormal longitudinal strain than not.This finding was the same in both groups indicating that symptomatic CAD is not responsible for these abnormalities in HD patients.Rather they are likely to be due to other factors such as uremic cardiomyopathy.

PUB360

Time-Dependent Aggravation of Abnormal Serum Sulfatide Levels Associated with Increased Oxidative Stress in Hemodialysis Patients Yuji Kamijo, Makoto Harada, Taro Kanno, Akinori Yamaguchi, Yosuke Yamada, Mai Sugiyama, Koji Hashimoto, Makoto Higuchi. *Dept of Nephrology, Shinshu Univ School of Medicine, Matsumoto, Nagano, Japan.*

Background: Sulfatides are major glycosphingolipids of lipoproteins that are speculated to influence atherosclerosis and blood coagulation. Our previous cross-sectional study of hemodialysis patients showed that serum sulfatide levels decreased markedly with increasing duration of hemodialysis treatment, which may contribute to the development of cardiovascular disease. However, the mechanisms underlying the decrease in serum sulfatide levels in HD patients are currently unknown.

Methods: To confirm the time-dependent abnormality of serum sulfatide levels and to elucidate the underlying mechanisms, we followed 95 hemodialysis patients for 3 years and analyzed correlations between clinical factors and serum sulfatide levels. As previous experimental studies reported an association between abnormal serum sulfatide levels and oxidative stress, we also measured serum levels of an oxidative stress marker, malondialdehyde.

Results: The current study detected a time-dependent decrease in serum sulfatide levels associated with increased malondialdehyde levels, regardless of baseline levels. Multiple linear regression analysis showed a significant correlation only between the time-dependent change in serum sulfatide levels and the time-dependent change in serum malondialdehyde levels.

Conclusions: These findings suggest that abnormal serum sulfatide levels are aggravated in hemodialysis patients in a time-dependent manner, and that oxidative stress is an aggravating factor. This progressively unhealthy situation may result in the development of cardiovascular diseases. As continuation of hemodialysis treatment does not improve abnormal serum sulfatide levels or the increased oxidative stress, development of novel therapeutic strategies may be important.

PUB361

Changes in Cardiac Structure and Function after Treatment with Paricalcitol in Patients on Periodical Haemodialysis. Role of Renin-Angiotensin-Aldosterone System Inhibitors Elvira Bosch,[1] Eduardo Baamonde,[1] Carlos Culebras Caeceres,[3] Fatima Batista,[1] German Perez Suarez,[1] Gloria Anton Perez,[1] Celia Lopez,[2] Mar Lago,[2] Agustin Toledo,[2] Cesar Garcia-Canton.[2] *[1]Centro de Hemodiálisis Avericum - Hospital Univ Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain; [2]Nephrology Service, Hospital Univ Insular de Gran Canaria, Spain; [3]Cardiology Service, Hospital Univ Insular de Gran Canaria, Spain.*

Background: The aim of the study was to analyze changes in cardiac structure and function of patients with secondary hyperparathyroidism at 12 and 24 months after treatment with paricalcitol.

Methods: Observational prospective study with 50 patients on haemodialysis, who started treatment with paricalcitol. Echocardiogram was performed after 12 and 24 months of treatment. Patients with and without treatment with rennin-angiotensin-aldosterone system inhibitors (RAASI) were compared.

Results: After 12 months reductions were observed in the average diameter of the left atrium (LA 42.05 versus 39.9 mm;p=0.029) and the posterior wall of the left ventricle (PW 13.1 versus 12.3 mm; p= 0.048), as well as in the percentage of patients with concentric VH (p=0.009). After 24 months (n:31) reduction in LA diameter (40.04 versus 37.2 mm;p= 0.017), improvement in left ventricular ejection fraction (LVEF 61.7 versus 68.1 %; p= 0.008) and increase in the percentage of patients with normal LV morphology (p=0.041) were observed. **Patients without RAASI treatment:** After 12 months, reductions were observed in DDLV (51.2 versus 47.3 mm;p=0.001), LVM (289.2 versus 243.2 g;p=0.021) and LVMI (148.6 versus 126.3 g/m^2;p=0.022). After 24 month**s** only improvement in LVEF was observed (63 versus 69.2 %;p= 0.043).

Conclusions: Reduction in the LA size and improvement in the LV structure were evidenced after 12 months of treatment with paricalcitol. Such changes were more evident in the group of patients without RAASI treatment, which suggests that the use of RAASI might be masking the cardiovascular effects of paricalcitol. Some of these changes were no longer observed after 24 months of treatment. This finding could be accounted for by the reduced size of the sample.

PUB362

Isolated Diastolic Dysfunction Is an Independent Predictor of Cardiovascular Events in Incident Dialysis Patients Shin-Wook Kang, Chang-Yun Yoon, Young Su Joo, Seung Gyu Han, Seung Hyeok Han, Tae-Hyun Yoo. *Dept of Internal Medicine, College of Medicine Yonsei Univ, Seoul, Korea.*

Background: Diastolic heart failure (HF) is associated with cardiovascular (CV) morbidity and mortality in the general population as well as patients with end-stage renal disease (ESRD). The concurrence of diastolic HF and systolic dysfunction is common among ESRD patients due to recurrent volume excess and CV events. However, it is not clear whether diastolic HF per se is associated with poor CV outcome in this population. This study was aimed to elucidate the impact of isolated diastolic dysfunction with preserved systolic function on CV outcomes in incident dialysis patients.

Methods: A total of 194 incident ESRD patients, who started dialysis between July 2008 and August 2012 and had normal left ventricular (LV) systolic function, were included. The independent prognostic values of echocardiographic parameters for CV events were ascertained by multivariate Cox proportional hazard regression analysis. Kaplan-Meier curves were also constructed, and between-group survival was compared.

Results: During a mean follow-up duration of 27.2 months, CV events occurred in 57 patients (29.4%). Compared to the CV event-free group, LV mass index, the ratio of early mitral flow velocity (E) to early mitral annulus velocity (E') (E/E'), left atrial volume index (LAVI), and right ventricular systolic pressure were significantly higher in patients with CV events. In multivariate Cox proportional hazard analysis, severe diastolic dysfunction (E/E'>15) and severely enlarged LA volume (LAVI>32 mL/m^2) were independent risk factors for CV events [E/E'>15: hazard ratio (HR)=5.40, 95% confidence interval (CI)=2.73–10.70, P<0.001; LAVI>32 mL/m^2: HR=5.56, 95% CI=2.28–13.59, P<0.001]. When patients were divided into four groups according to E/E' and LAVI, Kaplan-Meier analysis revealed that patients with both E/E'>15 and LAVI>32 mL/m^2 had the worst CV outcomes (P<0.001).

Conclusions: Diastolic dysfunction even with preserved LV systolic function was associated with poor CV outcomes in incident dialysis patients.

PUB363

Echocardiographic Parameters as Cardiovascular Mortality Predictors in Chronic Hemodialysis Patients Kosaku Nitta, Ken Tsuchiya. *Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

Background: Hemodialysis (HD) patients have high rates of cardiovascular (CV) mortality. Although structural and functional echocardiographic alterations in HD patients have been the subject of several survival analysis studies, the prognostic value of these alterations is not well established. The aim of this study was to determine the prognostic value of echocardiographic parameters in chronic HD patients.

Methods: One hundred eighteen HD patients were clinically evaluated and underwent Doppler echocardiography, being followed for 45.7 ± 13.6 months. The outcome measures were CV mortality. The predictive value of echocardiographic variables was evaluated by Cox regression model and survival curves were constructed using the Kaplan-Meier method and log-rank test to compare them.

Results: CV diseases accounted for 46.4% of all deaths during the follow-up period. We found that the event-free survival rates in one and two years were 96.5% and 83.0%, respectively. Diabetes and E/e' ratio were predictors of CV outcome by multivariate analyses.

Conclusions: Diabetes and diastolic dysfunction are independent predictors of CV mortality in chronic HD patients.

PUB364

Use of Supplementary Oxygen During Haemodialysis Is Not Associated with a Reduction Dialysis Induced Myocardial Stunning Lisa E. Crowley,[1] Helen J. Jefferies,[1] Chris W. McIntyre.[2] *[1]Dept of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Faculty of Medicine and Health Sciences, Univ of Nottingham, Nottingham, United Kingdom.*

Background: Myocardial stunning (recurrent segmental ischaemic injury) is a common consequence of haemodialysis (HD) treatment. Arterial hypoxaemia is well described as a consequence of HD. We investigated whether potentially addressing myocardial oxygen supply with supplementary oxygen therapy during HD might reduce the occurrence of HD induced myocardial stunning.

Methods: 9 patients receiving conventional thrice weekly haemodialysis were recruited. All patients dialysed via an arteriovenous fistula. Patients were studied at visit one with pre and peak stress echocardiography. Following this they received 24-28% inspired oxygen via nasal cannulae on 3 consecutive dialysis sessions and then underwent further echocardiographic study (visit 2). Analysis of echo's utilized 2D speckle tracking software for measurement of left ventricular longitudinal strain. A stunned segment was defined as one undergoing a 30% reduction in longitudinal strain.

Results: Median age of subjects was 72.6yrs±9.94 with a median dialysis vintage of 39.8months±24.9. Median ultrafiltration volume at visit 1 was 1.38kg±0.73 and at visit 2 was 1.29±0.83, there were no significant differences in haemodynamic response to HD between the two visits. The mean number of left ventricular segments undergoing a 30% reduction in longitudinal strain was 2.8±1.48 at baseline compared with 3.25±3.45 after 1 week of supplementary oxygen therapy. The mean pre-dialysis global longitudinal strain (GLS/%) was 16.05±6.51 at visit 1 and 16.97±4.67 at visit 2. Post dialysis GLS after visit 2 was 13.56±5.09, lower than that seen after visit 1 (16.7±2.9).

Conclusions: The results of this small study suggest that administration of oxygen during HD is not associated with any improvements in the haemodynamic response to dialysis and does not significantly abrogate myocardial stunning.

PUB365

A Study on Intradialytic Hypertension at Four South African Haemodialysis Units Sajith Sebastian,[1] Christelle Filmalter,[2] Mogamat-Yazied Chothia.[1] *[1]Nephrology, Univ of Stellenbosch, Cape Town, Western Cape, South Africa; [2]Health Science, Central Univ of Technology, Bloemfontein, Free State, South Africa.*

Background: Intradialytic hypertension (IDH) refers to the paradoxical rise in blood pressure (BP) during chronic haemodialysis, and increases morbidity and mortality. The reported prevalence ranges from 5-15% but the prevalence in South Africa is unknown. It has been suggested that IDH may be due to subclinical fluid overload. We set out to determine the prevalence of IDH in our setting and studied its association with potential risk factors.

Methods: A multicentre, cross-sectional study was conducted at four haemodialysis units in the Western Cape, South Africa. Cases of IDH were defined as a rise ≥10 mmHg in systolic BP during dialysis in 4 out of 6 consecutive dialysis sessions. Data were collected on demographics, fluid status using bioimpedance, the haemodialysis procedure and medication.

Results: The prevalence of IDH was 28.4% (n=190). There was a trend toward 'overhydration' in the IDH group as measured by whole body bioimpedance (2.6 L (95% CI 1.7- 3.4) versus 1.8 L (95% CI 1.4-2.1); p=0.06) but no difference in mean ultrafiltration volume (2.4 L versus 2.6 L; p=0.30). Mean age in the two groups was similar (57.1 versus 55.1 years; p=0.42), as was gender (males 53.7% versus 59.5%, p=0.40), time-averaged sodium concentration (138.4 mM versus 138.3 mM; p=0.72), dialysate calcium concentration (1.34 mM versus 1.36 mM; p=0.46), weekly erythropoietin stimulating agent dose (6896 IU versus 6352IU; p=0.38) in the IDH versus control groups respectively. There was a trend to more use of antihypertensive drugs in the IDH group (2.5 drugs (95% CI 2.15-2.87) versus 2.1 (95% CI 1.82-2.3); p=0.05). More participants in the IDH group received calcium channel blocker (54 versus 36, p=0.03). There was no difference in the use of other antihypertensives.

Conclusions: The prevalence of IDH in our treatment centres is much higher than has been previously reported. Subclinical fluid overload may contribute significantly to the development of IDH in our setting. The use of whole body bioimpedence has allowed us to identify patients who may benefit from additional ultrafiltration and potentially treat IDH.

PUB366

The Impact of Red Cell Distribution Width on Mortality in Chronic Hemodialyis Patients Myung Jin Choi,[1] Jiwon Ryu,[1] Jwa-Kyung Kim,[1] Youngki Lee,[1] Ja-Ryong Koo,[1] Jung-Woo Noh,[1] Yeo Jin Bang,[2] Miji Jeong.[2] *[1]Dept of Internal Medicine, College of Medicine, Hallym Univ and Hallym Kidney Research Institute, Chuncheon, Republic of Korea; [2]Hemodialysis Center, Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.*

Background: Red cell distribution width (RDW), a measure of the erythrocyte variabiltiy and heterogeneity, is a strong predictor of adverse outcomes in patients with cardiovascular disease. However, no studies have investigated the impact of RDW on cardiovascular complication and mortality in chronic hemodialysis (HD) patients.

Methods: A total of 177 HD patients (age 57.8 ± 12.0 years, male 48.0 %, diabetes 54.8 %, mean dialysis duration 48.4 ± 51.1 months) were enrolled. After baseline evaluation, patients were divided into two groups according to median RDW level. All patients were prospectively monitored for the development of coronary artery disease, cerebrovascular disease and death.

Results: The median RDW was 14.35 % (range 7.86 to 17.30). Patients with higher MPV levels (n=89) had lower levels of anemia, albumin, total cholesterol, triglyceride, LDL cholesterol and HbA1c. During a follow-up period of mean 25 months, 68 composite events (33 deaths, 25 coronary artery disease, 10 cerebral artery disease) occurred. The Kaplan-Meier curve showed significant difference between two groups in the cumulative events of all-cause mortality (11.36 % versus 25.84 %; log-rank test, p=0.006) and cardiovascular mortality (3.41 % versus 14.61 %; log-rank test, p=0.006). In multivariate Cox analysis, RDW was an independent risk factor for all-cause mortality (hazard ratio (HR), 1.499; 95% confidence interval (CI), 1.035 to 2.173; p=0.032) and cardiovascular mortality (HR, 1.857; 95% CI, 1.198 to 2.880; p=0.006). There were no significant differences between the two groups in coronary artery disease and cerebral artery disease.

Conclusions: Higher RDW level was significantly associated with increased all-cause and cardiovascular mortality. RDW may be an independent predictor of death and poor prognosis in chronic hemodialysis patients.

PUB367

Clinical Significance of Progressive Rise in Red Blood Cell Distribution Width in Incident Dialysis Patients Hye Eun Yoon, Bum Soon Choi, Eun Nim Kim, Yong-Soo Kim. *Internal Medicine, The Catholic Univ of Korea, College of Medicine, Seoul, Republic of Korea.*

Background: Red cell distribution width (RDW) represents the variabililty of sizes of circulating erythrocytes. RDW is a robust marker of adverse clinical outcomes in patients with cardiovascular diseases. However the clinical significance of rise in RDW is undetermined in incident dialysis patients.

Methods: Three hundred and thirty seven incident dialysis patients were included. Temporal changes in RDW during 12 months after the start of dialysis were assessed by calculating the coefficient by linear regression. Patients were divided in two groups; RDW-not-increased group included those with negative coefficient values (n = 184), and RDW-increased group included those with positive coefficient values (n = 153). We investigated whether increase in RDW was predictive for cardiovascular events (CVE) and deaths.

Results: The RDW-increased group showed significantly older age and lower total iron binding capacity at baseline compared with the RDW-not-increased group. During a median follow-up for 2.6 years (range, 0.3 – 7.7 years), 66 non-fatal CVE (19.6%) and 82 deaths (24.3%) occurred. The RDW-increased group showed significantly lower event-free survival rate for non-fatal CVE and deaths compared with the RDW-not-increased group (P = 0.009). In multivariate analysis, increase in RDW was an independent predictor for CVE and deaths (hazard ratio, 1.46; *P* = 0.038).

Conclusions: Progressive rise in RDW independently predicted adverse outcomes in incident dialysis patients. Assessing the change in RDW after starting dialysis may be helpful to identify high risk patients for CVE or death.

PUB368

Incident Elderly versus Young: Dialyze in the Same Way? Fatih Kircelli,[1] Ozgur Akin Oto,[2] Murvet Yilmaz,[3] Ercan Ok,[4] Kutay Gunestepe,[1] Cengiz Dogan,[1] Ali Basci,[4] Mehmet S. Sever.[2] *[1]Fresenius Medical Care; [2]Istanbul Univ; [3]Bakirkoy R&E Hospital; [4]Nephrology, Ege Univ.*

Background: The number of incident elderly hemodialysis patients is increasing. Tailor-made prescriptions may be needed in these cases considering varying demographic, clinical and laboratory features.

Methods: Data of 3934 incident patients retrieved from EuCliD-Turkey were used to compare dialytic features of elderly (>75 years) with middle-aged (45-75 years) and young (<45 years) patients.

Results: Incident elderly patients were more diabetic, had lower blood pressure levels, IDWG, processed blood volume, and blood pump rate, but higher Kt/V. All these features were present during the course of 3 years. In the elderly cases, serum creatinine, albumin and phosphorus levels were lower, while hospitalization and mortality rates were higher (3 years mortality: 48 % versus 89%)

Table 1. Demographical, clinical and laboratory data of the incident patients.

Parameters	***>75 years n=613 Elderly***	*<45 years n=592 Young*	P
Age (years)	**80,7±4,6**	34,4±7,3	<0,001
Gender (male,%)	**53,0**	60,3	0,047
Dialysis duration (months)	**0,5±0,8**	0,4±0,8	0,030
Diabetes (%)	**26,6**	12,8	<0,001
AV fistula (%)	**42**	67	<0,001
PBV (liters)	**64±13**	70±11	<0,001
taPBV (ml/min)	**68±12**	75±12	<0,001
BFR (ml/min)	**271±53**	297±43	<0,001
taBFR (ml/min)	**286±49**	311±44	<0,001
KtV	**1,27±0,33**	1,25±0,33	<0,001
taKtV	**1,38±0,30**	1,36±0,27	<0,001
SBP (mmHg)	**126±16**	133±17	<0,001
taSBP (mmHg)	**125±15**	131±17	<0,001
Serum albumin (g/dl)	**3,5±0,5**	3,7±0,5	<0,001
Serum phosphate (mg/dl)	**4,2±1,5**	5,2±1,6	<0,001
Hemoglobin (g/dl)	**10,0±1,4**	9,7±1,7	0,002

ta: time-averaged, PBV: Processed blood volüme, BFR: Effective Blood Flow Rate, SBP: Systolic Blood Pressure. Incident patient is defined as: age>18, on hemodialysis≤3 months

Conclusions: Various clinical and laboratory features differ significantly between elderly and young dialysis patients. Higher mortality and morbidity rates in the elderly can be improved by focusing on correctable factors independent of the age; hence individualized dialysis prescription is strictly needed in these cases.

Relationship Between Thyroid Function and Arterial Stiffness in Hemodialysis Patients Kota Kakeshita, Fumihiro Tomoda, Tsutomu Koike, Hidenori Yamazaki, Hayato Fujioka, Hiroshi Inoue. *Second Dept of Internal Medicine, Univ of Toyama, Toyama, Japan.*

Background: In hemodialysis patients, the decrease in thyroid hormones is frequently observed in spite of normal levels of thyroid stimulating hormone (TSH). This study was designed to explore the association of thyroid dysfunction with vascular structural alterations in hemodialysis patients.

Methods: In 45 hemodialysis patients (67±10 years, male/female= 30/15), cardio-ankle vascular index (CAVI) was automatically measured and calculated by VaSera VS-1000 (Fukuda Denshi, Tokyo, Japan) as an arterial stiffness index. Biochemical parameters and plasma levels of free thyroxine (FT4), free triiodothyronine (FT3) and TSH were also measured.

Results: FT3 and FT4 were lower than the lower limit of normal range (2.3 pg/mL and 0.8 ng/mL in FT3 and FT4, respectively) in 43 patients (96 %) and 7 patients (16 %) patients, respectively. In contrast, TSH was within normal range in all the patients. FT3 and ratio of FT3 to FT4 (i.e., index for the conversion from FT4 to FT3) correlated negatively with CAVI (r= -0.33 and -0.28, respectively; p< 0.05 of each), although FT4 and TSH did not associate with CAVI. Additionally, age, pH and serum b2-microglobulin also correlated with CAVI (r= 0.34, -0.312 and 0.274, respectively; p< 0.05 of each), although blood pressure, pulse rate and parameters for lipid, glucose, calcium, phosphate and parathyroid hormone did not associate with CAVI. Multiple regression analysis revealed that ratio of FT3 to FT4 as well as age and pH were independently associated with CAVI (r^2= 0.561).

Conclusions: In hemodialysis patients, thyroid dysfunction, especially the impairment of conversion from T4 to T3 might contribute to the aggravation of arterial stiffness in addition to aging and acidosis.

PUB371

Comparison of Arterial Stiffness and Aortic Systolic Pressure Measured in Static Conditions by the MOBIL-O-GRAPH and SPHYGMOCOR Devices in Hemodialysis Patients Pantelis Sarafidis,[1] Antonis Karpetas,[2] Panagiotis I. Georgianos,[2] Thanasis Bikos,[2] Pantelis Vakianis,[3] Maria Tersi,[3] Vassilios Liakopoulos,[2] Pantelis Zebekakis,[2] Anastasios Lasaridis,[2] Athanase Protogerou.[4] *[1]Nephrology Dept, Hippokration Hospital, Thessaloniki, Greece; [2]Div of Nephrology, 1st Dept of Medicine, AHEPA Hospital, Thessaloniki, Greece; [3]Therapeutiki Dialysis Unit, Greece; [4]Hypertension Unit and Cardiovascular Research Laboratory, "Laiko" Hospital, Athens, Greece.*

Background: A new oscillometric brachial cuff-based device (Mobil-O-Graph, IEM, Germany) assesses non-invasively aortic systolic blood pressure (aSBP), augmentation index (AIx) and pulse wave velocity (PWV) in ambulatory conditions. The aim of this study was to investigate the agreement of the Mobil-O-Graph with the currently most widely applied tonometric device (Sphygmocor, ArtCor, Australia) in hemodialysis patients.

Methods: In 73 hemodialysis patients, aSBP, heart rate-adjusted AIx (AIx(75)) and PWV were measured with both devices (order: Sphygmocor then Mobil-O-Graph) after 10 min of rest in the supine position. BP for calibration of the Sphygmocor waveform was obtained with a mercury sphygmomanometer.

Results: aSBP and AIx(75) measured with Sphygmocor did not differ from measurements obtained with Mobil-O-Graph (aSBP: 136.3±19.6 versus 133.5±19.3 mmHg, P=0.068; AIx(75): 28.4±9.3 versus 30.0±11.8%, P=0.229, for Sphygmocor versus Mobil-O-Graph). Sphygmocor-derived PWV was higher than PWV measured with Mobil-O-Graph (10.3±3.4 versus 9.5±2.1 m/sec, P<0.01). This marginally insignificant difference for aSBP is explained by the difference in peripheral SBP (146.9±20.4 versus 145.2±19.9 mmHg, P=0.274, for Sphygmocor versus Mobil-O-Graph). All 3 hemodynamic parameters obtained with Sphygmocor showed significant associations with measurements taken with Mobil-O-Graph (r=0.770, P<0.001 for aSBP, r=0.400, P<0.001 for AIx(75) and r=0.739, P<0.001 for PWV). The Bland-Altman Plots for all parameters showed acceptable agreement between the 2 devices.

Conclusions: In hemodialysis patients, aSBP and PWV were slightly underestimated by the Mobil-O-Graph compared to Sphygmocor device. However, acceptable agreement between devices was evident for aSBP, AIx(75) and PWV.

Pulse Wave Velocity in Haemodialysis Patients Is Associated with Survival and Comorbidity Ana Rita Mateus Martins,[1] Maria Gabriela Teixeira,[1] Inês Filipa Moreira,[1] Patricia Quadros Branco,[2] Teresa Adragao,[2] Andre L. Weigert.[1] *[1]Davita Portugal, Davita, Leiria, Portugal; [2]Nephrology Dept, Hospital Santa Cruz, Lisbon, Portugal.*

Background: Chronic kidney disease (CKD) is a risk factor for cardiovascular (CV) mortality. Haemodialysis (HD) patients (pts) have a high risk of death. Arterial stiffness (AS) has been recognized as a strong and independent predictor for CV events in CKD. Our aim was to evaluate risk factors of CV risk in prevalent HD pts.

Methods: Observational prospective study in 149 prevalent portuguese HD pts. We obtained baseline data regarding demographic, blood biochemistry, comorbidities, ankle-brachial index (ABI), pulse wave velocity (PWV), central buckberg sub-endocardial viability ratio (SEVR) and nutritional parameters. PWV and SEVR assessments were performed at baseline, before the second or the third dialysis session of the week.

Results: In our cohort, 93 pts were male, mean age was 67 years, 39% had diabetes (DM), average time on dialysis was 54 months. 9.3% of the patients had previous history of renal transplantation and comorbidity charlson score was on average 4.44±2,3. The follow up period time was about 10 months. During that period, 6 pts died of CV events. Patients with history of renal transplantation had lower pwv (10.79±4.136 VS 15.6±7.138; p=0.001). Multivariate Cox analysis revealed that a higher value of PWV (HR 1.186; IC(95%): 1.03-1.364; p=0.017) and a lower value of albumin (HR 0.22; IC(95%): 0.065-0.752; p=0.016) were significant risk factors for death, in a model adjusted for age and DM. In a linear regression, Charlson comorbidity score was closely related to a higher value of PWV (B=0.768; IC:0.255-1.282; p=0.004). In multivariate analysis (linear regression), there was a significant association between age (B=0.148; IC: 0.065-0.23; p=0.001), DM (B=2.903; IC: 0.559-5.247; p=0.016) and lower albumin (B=1.87; IC: 0.020-3.76; 0=0.05) with PWV, even adjusted for time on dialysis.

Conclusions: Our findings suggested that PWV value was an independent predictor of survival and comorbidity in our cohort of Portuguese HD pts.

Measurement of the Sympathetic Nerve Activity Index (LF/HF) in Diabetic and Non-Diabetic Dialysis Patients Fumiko Fukuuchi,[1] Ken Tsuchiya.[2] *[1]Nephrology, Komagome Kyouritsu Clinic, Bunkyou-ku, Tokyo, Japan; [2]Medicine IV, Tokyo Women's Medical Univ, Shinjyuku-ku, Tokyo, Japan.*

Background: Autonomic nervous system dysfunction is very common in dialysis patients. The symptoms of autonomic nervous system dysfunction are remarkably severe especially in dialysis patients with diabetes. Autonomic nervous system dysfunction is concerned with intradialysis hypotension and induced congestive heart failure. The aim of this study is to reveal the differences of sympathetic nerve activation between diabetic groups and non-diabetic groups during hemodialysis.

Methods: Holter electrocardiography power spectrum analysis carried out 24 hour chronometries from the beginning of dialysis. The ratio of low frequency band (LF; sympathetic modulation of heart rate) and high frequency band (HF; vagal modulation of heart rate), LF/HF is considered as the indices of sympathetic activation. We compared the LF/HF of these two groups.

Results: The 24 dialysis patients (eleven diabetics, thirteen non-diabetics) are included in this study. 44 Holter electrocardiography results were analyzed. LF/HF was compared between diabetic hemodialysis and non-diabetic hemodialysis patients from the beginning to 1 hr after hemodialysis treatment. In non-diabetic groups, LF/HF was increased during hemodialysis treatment. In diabetic groups, LF/HF ratio was decreased for 3 hours from the beginning of hemodialysis. Interdialytic weight gain is more in diabetic groups than non-diabetic groups. Although, LF/HF was significantly lower in diabetic groups in 1 hour, 2 hours and 3 hours after starting hemodialysis. Diastolic blood pressure was also significantly lower in diabetic groups in 3 hours and 4 hours after starting hemodialysis. Systolic blood pressure in non-diabetic groups was inversely correlated significantly with LF/HF in 2 hours and 3 hours after starting hemodialysis without intradialytic hypotension.

Conclusions: In diabetic dialysis patients, the sympathetic nerve activity assessed by LF/HF is distinctly disturbed, that is likely to result in intradialytic refractory hypotension.

Mortality following Cardiac Valve Replacement in Patients with End Stage Renal Disease Yanilda M. Nunez Germosen, Maria Coco. *Medicine, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: Valvular calcifications are common in patients (PTS) with ESRD leading to cardiac surgery. PTs on chronic dialysis who undergo valvular surgery have a high morbidity and mortality. The purpose of this study is to identify risk factors associated with the high mortality in these PTS.

Methods: We conducted an electronic chart review of ESRD PTS who underwent cardiac valve replacement at Montefiore Medical Center between 1999 to 2009, comparing cohorts pre and post 2005, corresponding to the introduction of cinacalcet and lanthanum. We evaluated median survival times post surgery, biochemical parameters of mineral metabolism, demographics, BMI, BSA, Left Ventricular Ejection Fraction, vintage dialysis time, access type, valve used, diabetes, endocarditis. Multivariate models were constructed to determine predictors of survival.

Results: 99 PTS (56M, 43F) age 58.7± 13 yrs had valve replacement. They were on dialysis for 3.1±.89yrs; 41 tunneled catheters, 38 AVF, 13 AVG, 5 peritoneal dialysis, 2 unknown. P was lower post 2005 (4.8±1.5 versus 5.5±2.2, p=.046). CxP was lower post 2005 (42±15 versus 53±25, p=.022). The entire cohort survived a median of 639 days. Median survival pre versus post 2005 was 427 versus 726 days (p=0.016). PTH, Ca, P, Ca X P, access, age and BSA individually impacted survival. Multivariate adjusted models showed that only Ca x P affected survival. When compared pre and post 2005: Ca, P, Ca x P, BSA and endocarditis impacted individually, but in the adjusted model, only P predicted survival pre-2005. Post 2005, PTH, access, type of valve and age were significant in the unadjusted survival model. Post-2005 PTS had been on dialysis for a longer period compared with pre-2005 (3.6 yrs±0.47 versus 2.1±0.6 p=.001).

Conclusions: Mineral metabolism in ESRD has improved since 2005 with new and aggressive treatment targeting P and PTH. PTS who had valvular surgery after 2005 had been on dialysis for a longer period suggesting that better control of mineral metabolism

may have delayed the progression of calcification. In addition, post-operative survival was improved. However, further study is needed to evaluate other factors contributing to the high mortality.

Factors Involved in Coronary Artery Calcification in Maintenance Hemodialysis Patients Yoshiko Nishizawa,[1,2] Sonoo Mizuiri,[2] Kyoka Ono,[2] Mariko Asai,[2] Kazuomi Yamashita,[2] Kenichiro Shigemoto,[2] Kohji Usui,[3] Noriaki Yorioka,[4] Yasuhiko Tomino.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [3]Nephrology, Ichiyokai Clinic, Hiroshima, Japan; [4]Nephrology, General Incorporated association Hiroshima Kidney Organization, Hiroshima, Japan.*

Background: Cardiovascular diseases related to coronary artery calcification are common causes of morbidity and mortality in maintenance hemodialysis (MHD) patients. In addition to the well-known traditional risk factors, uremia-specific factors, medications appear to affect coronary artery calcification. The objective of this study was to evaluate coronary artery calcification score (CACS) in MHD patients, and to identify potentially involved factors.

Methods: The study included 207 patients (58 females, 149 males), aged 64±14 years, who were on MHD treatment for 94±88 months (mean±SD). We assessed sex, age, dialysis vintage, presence of diabetes mellitus (DM), smoking history, presence of ≥100 ml urine volume/day, normalized protein catabolic rate (nPCR), geriatric nutritional risk index (GNRI), administration of active vitamin D_3, cinacalcet and phosphate binders, antihypertensive agents, and circulation parameters including creatinine, albumin, corrected calcium and phosphate in sera. CACS was assessed using Agatston Score by multi-detector CT (MDCT).

Results: Coronary artery calcifications were observed in 192 MHD patients (92.8%), and CACS ≥400 Hounsfield units was recognized in 62.8%. In univariate analysis, age, dialysis vintage and presence of DM, serum creatinine, serum albumin and administration of active vitamin D_3 were significant independent factors for CACS ($p<0.05$). In multivariate analysis, CACS showed direct associations with age ($p<0.001$), dialysis vintage ($p<0.001$) and presence of DM ($p<0.005$), and an inverse association only with active vitamin D_3 administration ($p<0.001$).

Conclusions: In conclusion, age, dialysis vintage and presence of DM were risk factors, and the administration of active vitamin D_3 was a modifiable protective factor for coronary artery calcification in MHD patients.

Comparison of Metal versus Tissue Valve Replacements in End-Stage Renal Disease Suzanne H. Forbes, Luxme Nadarajah, Andrea Cove-Smith, Neil Ashman, Mark Blunden. *Nephrology and Transplantation, Royal London Hospital, London, United Kingdom.*

Background: Little evidence guides the choice of valve replacement in end-stage renal disease (ESRD) patients; meta-analyses suggest no survival difference between bio- and mechanical prostheses. The use of metal valves necessitates anticoagulation, usually with warfarin. It is increasingly recognised that haemodialysis (HD) patients have significant increased bleeding risk, and that warfarin should be avoided. We examined outcomes in ESRD patients with both bio- and mechanical valve replacements.

Methods: We retrospectively studied patients known to our services who had a valve replacement, excluding those with insufficient follow up data or without stage 5 CKD. We gathered demographics from the time of replacement and data on anticoagulation. We noted outcomes including major bleeding, endocarditis, tissue valve redo and mortality.

Results: We included 82 patients, equating to 419 patient years. Median age at replacement was 58. 43 had metal valves, 39 tissue. All metal valves were anticoagulated with warfarin. 5 patients with tissue valves also took warfarin. 63% of patients with a metal valve and 59% of tissue valves were on HD or peritoneal dialysis at the time of operation. There were 44 major bleeding events (2 fatal) in 24 patients with metal valves versus 9 in tissue; a bleed rate of 19.6 per 100 patient years versus 4.6 (p=0.004). Rates of endocarditis were higher in metal valves (23% versus 10%,p=0.05). Median time before death was 5.7yrs in metal valves and 3.6 in tissue. 3 patients with metal valves had calciphylaxis (2 fatal). 3 patients with tissue valves required redo operations (1 paediatric valve, 2 due to endocarditis).

Conclusions: The usual indication for metal valves is in younger patients for whom tissue valve lifespan must be considered. Poor 5 year survival in ESRD makes this less relevant. The necessity of future procedures (vascular access, transplantation, biopsy) in a population at increased risk of major bleeding makes anticoagulation hazardous. We demonstrate increased risk of major bleeding, endocarditis and calciphylaxis with metal valves in ESRD with no valve-survival advantage and suggest metal valves be avoided in this population.

PUB377

Correlation of Serum Visfatin Levels with Cardiovascular Disease and Serum Biochemical Parameters in Hemodialysis Patients Nimet Aktas,[1] Abdulmecit Yildiz,[2] Cuma Bülent Gül,[3] Osman Z. Sahin.[4] *[1]Nephrology, Bilecik State Hospital, Bilecik, Turkey; [2]Dept of Nephrology, Uludag Univ Medical School, Bursa, Turkey; [3]Dept of Nephrology, Sevket Yilmaz Research and Training Hospital, Turkey; [4]Dept of Nephrology, Recep Tayyip Erdogan Univ Medical School, Turkey.*

Background: Cardiovascular (CV) diseases constitute a major cause of mortality in chronic kidney disease. We evaluated the role of visfatin; an adipokine, on end-stage renal disease(ESRD), investigated its relation with CV diseases and risk factors.

Methods: There'retwo control groups included participants without diabetes mellitus: healthy control group HC (n=40) and CC (n=28), included patients with normal renal functions, had coronary artery disease. There're two study groups includedhemodialysis patients without diabetes mellitus: HD (n=30), who had no coronary artery disease history and HDC (n=32), who had established coronary artery disease. Biochemical parameters and visfatin of serumwere done in all patients.

Results: The average level of serum visfatin was 26,52 ng/ml (9,10-47,18) in HC group, 33,68 ng/ml (13,25-55,3) in CC group, 35,96 ng/ml (11,62-60,61) in HD group, 35,74 ng/ml (9,21-61,64) in HDC group. Whereas there was statisticaly significant difference between HC and other groups in case of serum visfatin levels ($p<0,005$), no significant difference was found between other groups. In correlation analysis serum visfatin levels were correlated with triglyceride in HC group, with systolic blood pressure, urea, creatinine in CC and with uric acid in HD group. In HDC group no correlation was found with any parameter. Serum visfatin are compared between groups. The level of visfatin were 30,51 ng/ml (9,1-55,3) in control group and 35,745 ng/ml (9,21-61,64) in study group, this's statistically significant ($p =0,014$) (Table). In correlation analysis in control group serum visfatin level correlated with urea, creatinine, uric acid, total cholesterol, triglyseride and parathormone. In study group it was correlated with serum insülin, HOMA-IR, uric acid levels.

Conclusions: Visfatin has effects on CV disease however this effect is less in ESRD.

PUB378

Echocardiographic Abnormalities Associated with Cardiac Death in a Cohort of Dialysis Patients Mauro Castellano, Pablo U. Massari, Javier De Arteaga, Walther Douthat. *Servicio de Nefrología., Hospital Privado Centro Médico, Córdoba, Argentina.*

Background: There is a strong association between end-stage renal disease (ESRD) with cardiovascular (CV) events and death. Echocardiographic studies in these patients have shown a high prevalence of pathological findings.

Methods: We conducted a prospective study to assess CV changes by echocardiography and establish its influence on the survival in a single-center dialysis population. We included 70 patients, age 18 or higher, both incident and prevalent at November 1, 2009.

Results: Mean age was 58.0 ± 14.9 years, male (62.0%). Main causes of ESRD were diabetes and nephroangioesclerosis, 28.2 and 23.5% respectively. 81.7% were on hemodialysis, with an average time from the beginning of therapy of 41.6 months. The follow-up time was 36 months. Just 7.0% of patients had preserved ventricular geometry. 60% of patients with impaired ventricular geometry showed concentric remodeling, 29.8% concentric hypertrophy and 3.5% eccentric hypertrophy. 27.6% showed ventricular systolic dysfunction and 47.6% diastolic dysfunction. During follow-up, 27.5% were transplanted, 34.8% continued on dialysis and 37.7% died. The main cause of death was CV (42.3%). Patients who remained alive had a higher ejection fraction marginally significantly to the deceased ones, especially from CV causes (56.4 ± 9.8 versus 51.4 ± 14.8%, P=0.22). Patients who died from CV causes had a higher proportion of wall motion disorders than the living patients (50.0 versus 16.2%, P=0.10). They also had higher prevalence of mitral and aortic deficiency that living patients (70.0 versus 45.9%, P=0.44 and 30.0 versus 24.3%, p=0.39 respectively).There was statistical differences in the survival curves (Kaplan-Meier analysis) and increased mortality in patients with disorders in ventricular wall motion than those who did not (50.0 versus 81.1%; Logrank p=0.01). In univariate analysis (Cox model) the presence of wall motion disorders represented a 52% increase in the risk of death (p=0.11).

Conclusions: We found a high prevalence of echocardiographic abnormalities, predominating changes in ventricular geometry. The deceased patients showed a tendency to higher wall motion being a factor that influenced survival.

PUB379

Determinants of Metabolic Acidosis in Maintenance Hemodialysis Patients Hironori Nakamura,[1] Anayama Mariko,[1] Yasushi Makino,[1] Makoto Higuchi,[2] Masaki Nagasawa.[1] *[1]Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan; [2]Dept of Internal Medicine, National Hospital Organization, Matsumoto Hospital, Matsumoto, Japan.*

Background: Metabolic acidosis is associated with poor nutritional status and survival in hemodialysis (HD) patients. The K/DOQI clinical practice guidelines recommend that serum bicarbonate level should be maintained at 22 mEq/L as the standard level for HD patients. However, factors involved in metabolic acidosis are not fully clarified.

Methods: The aim of this study was to evaluate the association between predialysis bicarbonate level, clinical parameters, and phosphate binder types. We enrolled 159 consecutive HD patients (at least 1-year follow-up after HD initiation) in this cross-sectional study. Clinical parameters included age, HD vintage, HD time, body weight
